13

14 Abstract

15 With 59 Recent species, Bursidae, known as « frog shells », are a small but widely distributed
16 group of tropical and subtropical gastropods that are most diverse in the Indo-West Pacific.
17 The present study is aimed at reconstructing phylogenetic relationships of bursid gastropods
18 based on extensive and representative taxon sampling. Five genetic markers (cytochrome c
19 oxidase subunit I (*coxI*), 16s and 12s rRNA mitochondrial genes, 28s rRNA and Histone H3
20 nuclear gene) were sequenced for over 30 species in every known genus but *Crossata*.
21 Furthermore, we sequenced the complete mt-genome of 9 species (10 specimens) (*Aspa*
22 *marginata*, *Marsupina bufo*, *Korrigania quirihorai*, *Korrigania fijiensis*, *Tutufa rubeta*, *Bursa*
23 *lamarckii*, *Lampasopsis rhodostoma* (twice), *Bufonaria perelegans* and *Bursa* aff.
24 *tuberosissima*). Our analysis recovered Bursidae as a monophyletic group, whereas the genus
25 *Bursa* was found to be polyphyletic. The genera *Talisman* and *Dulcerana* are resurrected and
26 the genera *Alanbeuella* gen. nov. and *Korrigania* gen. nov. are described. Dating analysis
27 using 21 extinct taxa for node and simplified tip calibrations was performed, showing a
28 diversification of the group in two phases. Diversification seems to be linked to tectonic
29 events leading to biodiversity relocation from the western Tethys toward the Indo-Pacific.

30

31 Key words: Bursidae, *Bursa*, marine molluscs, time-tree, fossil calibration, phylogeny

32

33 **1. Introduction**

34 Bursidae Thiele, 1925 (frog shells) are a moderately diverse tonnoidean family with 59
35 currently recognized extant species (WoRMS, 2020). Twenty extinct species were previously
36 recognized but this number was downsized recently to eleven (Sanders *et al.*, 2019). Recent
37 bursids have a tropical and subtropical distribution with the southernmost records in eastern
38 South Africa (Sanders *et al.*, 2017), Northern New Zealand (Spencer *et al.*, 2016) and the
39 Walters shoal (<https://expeditions.mnhn.fr/campaign/waltersshoal>). The northernmost records
40 (*Bursa scrobilator* (Linnaeus, 1758)) are from Nice, southern France and Savona,
41 northwestern Italy [we consider the specimen from northern Finistère, Britany, France
42 attributed by Delongueville & Scaillet (2000) to *Bufonaria rana* (Linnaeus, 1758) to be
43 dubious]. They are intertidal to subtidal organisms most often associated with hard substrates
44 such as rocks, coral or sponges, where they can be abundant. Very little is known about bursid
45 diet; Houbrick & Fretter (1969) described it for three species (*Lampasopsis cruentata* (G. B.
46 Sowerby II, 1835), *Lampasopsis rhodostoma* (G. B. Sowerby II, 1835) & *Bursa granularis*
47 (Röding, 1798)); all of them prey on annelids by removing them from their tubes or crevices
48 and swallowing them. Kohn (1983) figured a specimen of *Bursa bufonia* (Gmelin, 1791)
49 using its muscular foot and its radula to grip a starfish and saw through its armored skin,
50 much in the same fashion as species belonging to the genus *Charonia* Gistel, 1848 (Bose *et*
51 *al.*, 2017).

52 In Southeast Asia, frog shells are consumed as food, resulting in a human health issue since
53 they host bacteria producing tetrodotoxin (Noguchi *et al.*, 1984; Magarlamov *et al.*, 2017).
54 Shells of *Bufonaria rana* (Linnaeus, 1758) are used in traditional Chinese medicine to cure
55 ulcers and furuncle carbuncles (Ahmad *et al.*, 2018). Bursids also have had cultural
56 importance to mankind since at least the Middle Palaeolithic (300,000 to 50,000 BP); Peresani
57 *et al.* (2013) showed that Neanderthals used a fossil shell belonging to the genus *Aspa* H.

58 Adams & A. Adams, 1853 as a pendant. The most culturally significant use of Bursidae is
59 reported from western Fiji where shells from *Tutufa* Jousseaume, 1881 (called
60 *davuisogasoga*) are considered sacred and are used as ceremony trumpets (Gatty, 2009) or
61 worn as earlobe stretcher during battle (*Sau mocemoce*, Fiji Museum, 2017). In the last few
62 centuries, trumpets made of *Tutufa* shells have been sold throughout the Pacific instead of the
63 more traditional and much rarer (and pricy) Triton (*Charonia tritonis* (Linnaeus, 1758)).

64 Bursidae are readily recognizable by their shell showing a well-defined posterior exhalant
65 siphon (anal notch) at the top of the outer lip and by their thick, coarsely sculptured
66 ornamentation displaying knobs, warts, tubercles and nodules, hence their vernacular name:
67 frog shells. Very variable in size, the smallest species, *Lampasopsis lucaensis* (Parth, 1991),
68 never exceeds 23 mm in height whereas *Tutufa bardeyi* (Jousseaume, 1881), with a height up
69 to 450 mm and a width up to 300 mm, is one of the largest and most capacious of all
70 gastropod shells (Beu, 1998). Most bursids range between 40 and 50 mm in height. The
71 radula is characterized by a basal interlocking process on the central tooth (Beu, 1998), and by
72 a flap on the outer posterior edge of each lateral tooth that overlaps the tooth in the preceding
73 row (Barkalova *et al.*, 2016).

74 As inferred from their protoconch, similar to all other tonnoideans, they are supposed to have
75 a long to extremely long larval stage granting for some of them trans-oceanic dispersal
76 capabilities. However, Sanders *et al.* (2017) showed that such capabilities were greatly
77 overestimated for one of the most widespread species of Bursidae: *Bursa granularis*. Once
78 considered to be a single species with a worldwide distribution, it in fact includes at least four
79 species restricted to the Indian, the Pacific and the western Atlantic Oceans, respectively, plus
80 one restricted to southernmost Western Australia, as confirmed by an integrative taxonomy
81 approach combining molecular and morphological characters. This result thus suggests that
82 the species diversity of the family may be underestimated.

83 Further morphological characteristics are a spiral ornamentation of the convex part of the
84 whorl composed of six to eight primary cords (*sensu* Merle, 2005 and Sanders *et al.*, 2017)
85 that can be lost during the ontogeny. Secondary and tertiary ones can appear later on and
86 sometimes grow to such importance that they can be confused with primary cords (e.g.,
87 *Dulcerana granularis* (Röding, 1798)). Such characters, sometimes difficult to observe for
88 shallow water species, whose shells are often colonized and strongly encrusted by coralline
89 algae (especially in the genera *Bursa* Röding, 1798, *Lampasopsis* Jousseaume, 1881 and
90 *Tutufa*), can be also difficult to interpret. Consequently, the systematics of the Bursidae,
91 largely based on the morphological work carried out by Beu (1981, 1987, 1998) and
92 Cossignani (1994), remains confusing.

93 Until recently, the most widely accepted classification of Bursidae recognized seven genera:
94 *Aspa* Adams & A. Adams, 1853, *Bufonaria* Schumacher, 1817, *Bursa* Röding, 1798, *Bursina*
95 Oyama, 1964, *Crossata* Jousseaume, 1881, *Marsupina* Dall, 1904 and *Tutufa* Jousseaume,
96 1881. As happened for many other gastropod taxa in the last decade, molecular phylogenies
97 challenged this shell-based classification. Although based on a limited number of species,
98 Castelin *et al.* (2012) and Strong *et al.* (2018) demonstrated that the genera *Bursa* and *Bursina*
99 are polyphyletic. Hence, Strong *et al.* (2018) resurrected two previously synonymized genera,
100 *Lampasopsis* and *Tritonoranella* Oyama, 1964. This suggests that an extended dataset may
101 reveal other discrepancies and calls for a new classification for the group.

102 The main goal of this study is to propose a phylogeny of the Bursidae using several genetic
103 markers, including full mitogenomic coding regions (plus non-coding 12s and 16s) and
104 nuclear genes for better resolution than previous studies. We added several species compared
105 to the works of Castelin *et al.* (2012) and Strong *et al.* (2018) (from 17 and 21, respectively, to
106 33), focusing on the type species of the available genus names, in order to convert the
107 molecular phylogeny into a new genus-level classification of the frog shells. Furthermore, the

108 fossil record of the Bursidae is rather good. A recent review (Sanders *et al.*, 2019) showed
109 that, in addition to the 11 extinct species, 26 extant ones have an exceptionally long fossil
110 record (reaching the Miocene for some), making the Bursidae a good empirical model for
111 testing two calibration strategies (node dating and simplified tip dating).

112

113 **2. Material and methods**

114 *2.1 Sampling*

115 The material for this study was collected from various localities during a series of shallow-
116 water and deep-sea expeditions, mainly organized by the MNHN (Muséum national
117 d'Histoire naturelle, Paris), in Vanuatu (SANTO 2006), the Philippines (PANGLAO 2004,
118 PANGLAO 2005), French Guiana (GUYANE 2014), Guadeloupe (KARBENTHOS 2012,
119 KARBENTHOS 2015), Marquesas Islands (PAKAIHI I TE MOANA), Western Australia
120 (WESTERN AUSTRALIA 2011), New Caledonia (CONCALIS, EBISCO, EXBODI,
121 NORFOLK 1, NORFOLK 2, TERRASSES), French Polynesia (Tuhaa Pae 2013),
122 Mozambique (INHACA 2011, MAINBAZA), Madagascar (ATIMO VATAE, MIRIKY),
123 Salomon Islands (SALOMON 2), Papua New Guinea (PAPUA NUIGINI), Taiwan (Zhong
124 Sha 2015), Viet Nam (NT-2014), Mauritania (MIWA), Azores, Panama and California.
125 MNHN specimens collected before 2012 were anaesthetized with an isotonic solution of
126 MgCl₂ and fixed in 96% ethanol. Specimens collected after 2012 were processed with a
127 microwave oven (Galindo *et al.*, 2014); the living molluscs in small volumes of sea water
128 were exposed to microwaves for c. 30 s. Bodies were immediately removed from shells and
129 dropped into 96% ethanol. Non-MNHN material was preserved in 90% ethanol; we do not
130 know how they were originally fixed. The analyzed material included 432 specimens; 385
131 deposited in the MNHN, one in the Natural History Museum of Santa Barbara (SBMNH),
132 four in the Zoology department of the University of Bergen (ZMB), 38 in the Florida natural

133 History Museum (UF) and four in the Severtsov Institute of Ecology and Evolution, Moscow.
134 Furthermore, sequences from five species (*Bufo nana* (Broderip, & Sowerby, 1829),
135 *Galeodea echinophora* (Linnaeus, 1758), *Cymatium parthenopeum* (Salis Marschlin, 1793),
136 *Cymatium cingulatum* (Lamarck, 1822) and *Tonna galea* (Linnaeus, 1758)) were mined from
137 GenBank. Sequences from four of these taxa (*G. echinophora*, *C. parthenopeum*, *C.*
138 *cingulatum* and *T. galea*) were used as outgroups. The specimens and their corresponding
139 sequences were registered in the Barcode of Life Data System and GenBank (Supp. Tab. 1).
140 Sampling was selected to be as taxonomically extensive as possible, covering all the currently
141 recognized genera. Particular effort was put into adding type species in order to provide a
142 sound systematic revision of the group. All specimens with sequences obtained by either
143 Sanger sequencing (single gene fragments) or Ion Torrent sequencing (mt-genomes) are listed
144 in Supp. Tab. 1.

145
146 *2.2 DNA extraction, PCR amplification and Sanger sequencing*
147 DNA was extracted using the EpMotion 5075 robot (Eppendorf), following the
148 manufacturers' recommendations. Fragments of five genes were analyzed: (i) the cytochrome
149 c oxidase subunit I (*cox1*) using primers LCO1490/HCO2198 (Folmer *et al.*, 1994), (ii)
150 mitochondrially encoded 12s rRNA (12s) using primers 12sA/12sB (Palumbi, 1996), (iii)
151 mitochondrially encoded 16s rRNA (16s) using primers 16SH/16LC (Palumbi, 1996), (iv) the
152 nuclear 28S rRNA gene using primers C1 and D2 (Jovelin & Justine 2001) and the nuclear
153 Histone H3 gene using primers H3F/H3R (Colgan *et al.*, 2000). PCR reactions were
154 performed in volumes of 20 µl, containing 3 ng DNA, 1× reaction buffer, 2.5mM MgCl₂,
155 0.26 mM dNTP, 0.3 mM of each primer, 5% DMSO and 1.5 units of Qbiogene Q-Bio Taq.
156 The amplification consisted of an initial denaturation step at 94°C for 5 min (3 min for H3),
157 followed by 40 cycles of denaturation at 94°C for 35 s (20 s for H3), annealing at 47°C for

158 *cox1*, 62°C for 12s, 54°C for 16s, 52°C for 28s and 58°C for H3 during 35 s (20 s for H3)
159 followed by extension at 72°C for 1 min (30 s for H3). The final extension was at 72°C for 5
160 min. PCR products were purified and Sanger sequenced in both directions by the Eurofins
161 sequencing facility.

162

163 *2.3 Primer design for long range PCR*

164 The Myseq shotgun sequencing of a specimen of *Lampasopsis rhodostoma* (G.B. Sowerby II,
165 1835) (MNHN-IM-2013-11042) was subcontracted to Genome Quebec, using the Illumina
166 Genomic DNA Sample Preparation protocol for libraries preparation. The mitogenome of this
167 specimen was assembled over the closest tonnoidean mitogenome available in the literature:
168 *Galeodea echinophora* (Linnaeus, 1758) (GenBank accession number: NC_028003.1, Osca *et*
169 *al.*, 2015) using the Map-to-reference tool of Geneious 9.1.7 (<http://www.geneious.com>,
170 Kearse *et al.*, 2012) set on medium sensitivity (allowing 15% of gaps per read and 30% of
171 mismatches). These two mitogenomes were then aligned using MAFFT (Katoh *et al.*, 2002)
172 with the only other tonnoidean mitogenome available in the literature at the time of the study,
173 *Cymatium parthenopeum* (Salis Marschlins, 1793) (GenBank accession number: NC_013247,
174 Cunha *et al.*, 2009). Conserved regions (identified by eye) were analyzed using the primer
175 design option of Geneious for melting temperature calculation (Breslauer *et al.*, 1986).
176 Following the recommendations of Hinsinger *et al.* (2015), we selected primers with little or
177 no self- or heterodimer, and closely matching annealing temperatures with primer melting
178 temperatures selected between 50 and 65°C. We also used universal *cox1* primers. Primers are
179 provided in Supplementary Table 2. Only 10 over the 13 primers where used to amplify the
180 complete mitogenomes; they were chosen in order to minimize the number of fragments
181 needed for reconstructing a mitogenome. When two primers were neighboring, they were
182 pooled in the mix to minimize the number of PCRs and maximize the probability of

183 amplification in case of mutation within the primers (they are noted “bis” in the first column
184 of Supp. Table 2).

185

186 *2.4 Long range PCRs for complete mitogenome amplification and sequencing.*

187 In order to complete the mitogenome amplification, we amplified four overlapping fragments
188 (Fig. 1). Long range PCR were used because it allows the amplification of much longer
189 fragments than Sanger PCR. We followed a modified protocol of Hinsinger *et al.* (2015):
190 PCR reactions were performed in 18 µl volume including 5X LongAmp Taq Reaction Buffer,
191 0.4 ng/µl Bovine Serum Albumin (BSA), 3.5% DMSO, 300 nM of each primer, 300 µM of
192 dNTPs, and 1 unit of LongAmp Taq polymerase. After an initial denaturation of 30 s at 94°C,
193 the DNA was amplified through 60 cycles of 20 s at 94°C, 30 s at 55°C, and 15 min at 65°C,
194 with a terminal elongation for 15 min at 65°C.

195

196 The PCRs were visualized on ethidium bromide stained agarose gel, and the amounts for
197 pooling were estimated from the intensity of the bands (Timmermans *et al.*, 2010), taking into
198 account PCR size and using one of our own PCRs as intensity standard across gels. Libraries
199 for genome sequencing approach were generated using NEBNext® Fast DNA Fragmentation
200 & Library Prep Set for Ion TorrentTM (E6285L, New England Biolabs), loaded onto Ion
201 316V2 chips. The sequencing was performed at the *Service de Systématique Moléculaire*
202 (UMS 2700, 2AD, MNHN, Paris).

203

204 *2.5 Genome assembly*

205 Short-read DNA sequences from Ion Torrent were assembled into a single sequence
206 corresponding to a complete mt genome using the Map to reference tool of Geneious (using
207 the *Lampasopsis rhodostoma* MNHN-IM-2013-11042 reconstructed mt genome as reference)

208 set on custom sensitivity (Min map quality: 30, allowing 10% gap per read and 20%
209 mismatch per read). The 13 mt protein-coding genes were annotated by identifying their open
210 reading frames and by comparing them with other reported tonnoidean mt genomes. The
211 transfer RNA (tRNA) and the ribosomal RNA (rRNA) were annotated by comparing them
212 with other reported tonnoidean mt genomes and assumed to extend to the boundaries of
213 adjacent genes (Boore *et al.*, 2005).

214

215 2.6 Sequence alignment

216 Sequences were aligned for each gene independently using MAFFT (Katoh *et al.*, 2002). The
217 accuracy of automatic alignments was controlled using Gblocks 0.91b for poor quality
218 positions (Castresana 2002) on the LIRM online server
219 (http://phylogeny.lirmm.fr/phylo_cgi/). No indels were detected in the protein-coding genes.

220

221 2.7 Data sets

222 The first dataset corresponds to all available *cox1* sequences. The second dataset includes the
223 *cox1*, 12s, 16s, H3 and 28S concatenated sequences of one specimen of each of the 33 species
224 previously recognized morphologically and confirmed as clades with the *cox1* dataset. In
225 order to minimize the number of missing data, in several cases, sequences from conspecific
226 specimens were concatenated (Supp. Table 3), but only if their *cox1* sequences had a pairwise
227 uncorrected p distances less than 2% (thus suggesting conspecificity). For the same reason,
228 outgroup sequences downloaded from GenBank were concatenated when they belonged to the
229 same family (Strong *et al.*, 2018) (the correspondence is shown in Supp. Table 1). The third
230 dataset includes the concatenated analysis of the 13 protein-coding genes and the two rRNAs
231 from the mitochondria, using nucleotide sequences. The fourth dataset is a concatenation of
232 the second and third datasets (partial *cox1*, 12s and 16s, where replaced by complete genes in

233 the taxa for which we sequenced the mt-genome), resulting in a dataset with a similar set of
234 genes compared to the dataset 3 (only the two nuclear genes from dataset 2 were added), but
235 with a higher number of samples.

236

237 *2.8 Phylogenetic analyses*

238 Maximum likelihood (ML) trees were estimated using IQ-TREE V 1.6.12 (Trifinopoulos *et*
239 *al.*, 2016) from 1,000 independent searches, each starting from distinct random trees.
240 Robustness of the nodes was assessed using the thorough bootstrapping algorithm
241 (Felsenstein, 1985) with 1,000 iterations and using the ultrafast bootstrap approximation
242 (Hoang *et al.*, 2017). IQ-TREE analyses were performed on the IQ-TREE web server
243 (<http://iqtree.cibiv.univie.ac.at/>). Bayesian inferences (BI) were performed by running two
244 parallel analyses in MrBayes 3.2.2 (Ronquist *et al.*, 2012). For *cox1* analyses, each run
245 consisted of 8 Markov chains and 10,000,000 generations, three swaps at each generation, a
246 sampling frequency of one tree each 1,000 generations, and the chain temperature set at 0.02;
247 for datasets 2 to 4 the number of generations was increased (30,000,000 for dataset 2 and 3,
248 and 70,000,000 for dataset 4). Convergence of each analysis was evaluated using TRACER
249 1.4.1 (Rambaut *et al.*, 2014) to check that all effective sample size values exceeded 200.
250 Consensus trees were calculated after omitting the first 25% of the trees as burn-in. Analyses
251 were performed on the Cipres Science Gateway, using MrBayes 3.2.2 on XSEDE. In all
252 analyses (ML and BI), genes were separated into unlinked partitions; additionally, all protein-
253 coding genes were separated into three partitions, one for each codon position. The
254 substitution model was set to GTR + I + G for both ML and BI analyses following Abadi *et*
255 *al.* (2019).

256

257 *2.9 Calibration strategy and molecular dating*

258 Dating was performed by running two parallel analyses in MrBayes 3.2.2 (Ronquist *et al.*,
259 2012), with prior probability distribution on branch lengths set on a birth-death model, with
260 an independent gamma rate (igr) relaxed clock model (variance distribution of the prior set on
261 exponential 10). Each run consisted of eight Markov chains and 100,000,000 generations,
262 three swaps at each generation, a sampling frequency of one tree each 1,000 generations and
263 the chain temperature set at 0.02. Two dating analyses were conducted; one solely using node
264 dating and one combining tip and node dating.

265 Most node calibrations were done using a truncated log normal distribution as it places the
266 highest probability on ages somewhat older than the fossil, diversification being necessarily
267 older than the observed fossil record. We used a uniform distribution to calibrate the node
268 Bursidae. Boundaries of the distribution were determined using the occurrence of the oldest
269 Bursidae of the extinct genus *Olssonia* Sanders, Merle & Puillandre, 2019 for the lower
270 boundary and the oldest fossil of the genus *Aquitanobursa* M. T. Sanders, Merle & Puillandre,
271 2019 for the upper boundary, as Sanders *et al.* (2019) suggested that crown Bursidae may be
272 bracketed by these two fossils.

273 Bursidae, *Bursa*, *Bufonaria*, *Lampasopsis*, *Tritonoranella*, *Marsupina*, *Dulcerana*, *Korrigania*
274 gen. nov. and *Bursina* were the only clades constrained.

275 For the simplified tip dating analysis we considered the sequence of extant specimens to be of
276 the same age as those of fossil specimens belonging to the same species (Tab. 1). Normally,
277 tip dating requires integrating morphological data into the analysis (for both extinct and recent
278 species) in addition to the molecular data. However, in such analyses, the fossil record
279 typically concerns extinct taxa for which no molecular sequences are available (e.g., Pyron
280 2011, Vinther *et al.*, 2017). In the present case, we have an abundant fossil record of extant
281 taxa that appears to belong to the same branches (tips or species) as the sequenced taxa.
282 Furthermore, for our dataset that includes closely related taxa (five genera are represented by

283 four to five species each), shell characters are generally too poorly informative to fully
284 resolve the phylogeny. We have thus tested this new, simplified tip dating method to see if it
285 gives results coherent with those of node dating.

286 All tip calibrations were set to follow a uniform distribution of the prior as it is the only
287 distribution that allows the implementation of a wide stratigraphic range. Information
288 regarding the fossils used in calibration, the parameters of the calibration prior distribution
289 and references for fossil identifications and stratigraphic attributions are reported in Tab. 1.

290

291 *2.10 Transforming a phylogeny into a genus-level classification.*

292 Following the guidelines of Puillandre *et al.* (2014), genus names were given only to well-
293 supported clades. Then, genus names were applied based on the position of their type species
294 in the tree. If the type species of a nominal genus had not been sequenced, application of the
295 name was determined by reference to the morphologically most similar species included in
296 the molecular analysis. If more than one name was applicable for a clade, the valid name was
297 determined by the rule of priority.

298 Providing an extended classification of the Bursidae including the attribution of all currently
299 accepted species to the new genera based on a reevaluation of the shell morphology goes far
300 beyond the scope of this paper and will be treated in an upcoming article.

301

302 **3. Results**

303

304 *3.1 Mitochondrial genome organization*

305

306 The complete mt genomes of *Tutufa rubeta*, *Marsupina bufo*, *Lampasopsis rhodostoma* (two
307 specimens), and the partial mt genome of *Bufonaria perelegans*, *Aspa marginata*, *Bursa* cf.

308 *tuberosissima*, *Korrigania quirihorai* and *Korrigania fijiensis* were sequenced and assembled
309 (see Table 2 for genome length and sequencing coverage). Like most animal mt genomes
310 (Boore & Brown, 1994), they encode for 13 protein-coding genes, 22 tRNA, and two rRNA
311 genes (Fig. 1) The gene order of the newly sequenced mt genomes is identical to the gene
312 arrangement of other reported tonnoidean mt genomes (Osca *et al.*, 2015).

313

314 3.2 Phylogenetic analyses

315

316 Dataset 1 yielded poorly resolved phylogenies that did not present any evidence of conflict
317 with the other datasets in the topologies (minor conflicts are always unsupported). This
318 dataset will not be discussed further but the ML tree is accessible in Supplementary Fig. 1.
319 Datasets 2, 3 and 4 produced compatible topologies, the only difference being that the clade
320 *Aspa* + *Alanbeuella* gen. nov. of dataset 2 (Supp. Fig. 2) does not branch as sister to most of
321 the other Bursidae but with the clade C, containing *Bursina*, *Bufonaria*, *Korrigania* gen. nov.
322 and *Tritonoranella*, with very low support (Fig. 2; Supp. Figs. 2 and 3). Of all the datasets,
323 dataset 4 (mitogenomes + 28S + H3) produced the phylogeny with the highest support and is
324 the one further discussed below.

325 As shown by Castelin *et al.* (2012) and Strong *et al.* (2018), the monophyly of the Bursidae is
326 well supported (posterior probabilities PP = 1, ultrafast bootstrap UFBP=100, bootstrap BS =
327 100) (Fig. 2).

328 The ML and BI analyses showed some minor differences within *Tutufa* and regarding the
329 relationship between *Aspa* and *Alanbeuella corrugata*; these differences are shown in Fig. 2.
330 In the BI analysis the first dichotomy divides two poorly supported clades, an Atlantic clade
331 (not found in ML) containing *Aspa marginata* and *Alanbeuella corrugata*, and a second clade
332 that contains the rest of the Bursidae. The early branching of *Aspa* and *Alanbeuella* gen. nov.

333 is consistent with the fact that they are the only extant genera with, for each of them, a Late
334 Paleogene record (Sanders *et al.*, 2019). Nine supported major clades can be recognized
335 within the main bursid group (highlighted in Fig. 2). These clades, in addition with three other
336 single species lineages, are each attributed to a distinct genus (see classification for name
337 attribution). Relationships between genera have various levels of support, ranging from highly
338 supported for clade A (PP = 0.99, UFBS= 99.7 BS = 86), containing *Tutufa*, *Marsupina* and
339 *Lampasopsis* and Clade C minus *Tritonoranella* (PP = 1, UFBS= 98.5 BS = 96), to
340 moderately supported for clade B containing *Bursa*, *Talismann* and *Dulcerana* (Fig. 2).

341 Compared with earlier works (Castelin *et al.*, 2012 and Strong *et al.*, 2018), the main
342 difference lies in the phylogenetic position of *Tutufa*; in both previous works, it branches as a
343 sister group of all the other bursids, but with the increased sampling, in particular in the
344 *Lampasopsis* clade, and with the addition of *Marsupina*, *Aspa* and *Alanbeuella corrugata*, and
345 more genes sequenced, it is well embedded within the Bursidae with good support (PP = 1,
346 UFBS= 97.4 BS = 88), as sister group to *Marsupina*. The deep sea (200 to 1000 m deep)
347 genus *Tritonoranella* was closely related to *Lampasopsis* (with low support) in previous
348 studies; it is now sister group to the clade containing *Korrigania* gen. nov., *Bufonaria* and
349 *Bursina* (still with low support, PP = 0.82, UFBS= 84.2 BS = 86). All the species belonging
350 to these clades are commonly found in deep water (to the exception of some species of
351 *Bufonaria*), unlike *Lampasopsis* that never occurs below 100 m deep. The species
352 *Lampasopsis thomae* (d'Orbigny, 1847) and *L. rhodostoma* were still recently accepted as
353 synonyms; Strong *et al.* (2018) suggested the resurrection of the name *L. thomae*, and our
354 work supports their suggestion; furthermore, they are not even sister species.
355

356 *3.3 Dating analyses*

357 The two dating datasets recover rather similar divergence times (Supp. Fig. 4) except for the
358 clade *Aspa* + *Alanbeuella* gen. nov., which is four million years older (34.07 My, Fig. 3A) in
359 the tip+node dating dataset. However, this difference is not statistically significant because
360 the credibility intervals overlap broadly.

361 All the nodes but those used for calibration had credibility intervals broader than 2 Ma. The
362 Bursidae found their origin during the Late Campanian (72.4 Ma, Late Cretaceous). Frog shell
363 genera appeared between 25 and 30 Mya with a diversification starting between 12 and 21
364 Mya for non-monospecific genera.

365

366 **4. classification**

367 *4.1 Name attribution*

368 Clades containing type species are readily nameable: *Aspa* (type species: *Ranella laevigata*
369 Lamarck, 1822 = *Buccinum marginatum* Gmelin, 1791), *Tritonoranella* (type species: *Triton*
370 *ranelloides* Reeve, 1844), *Lampasopsis* (type species: *Ranella rhodostoma* G. B. Sowerby II,
371 1835), *Marsupina* (type species: *Buffo spadiceus* Montfort, 1810 = *Murex bufo* Bruguière,
372 1792), *Tutufa* (type species: *Murex rana bubo* Linnaeus, 1758), *Dulcerana* (type species:
373 *Tritonium granulare* Röding, 1798) and *Bursa* (type species: *Bursa monitata* Röding, 1798 =
374 *Murex bufonius* Gmelin, 1791).

375 We retain the original spelling *Lampasopsis* instead of *Lampadopsis* used by Strong *et al.*
376 (2019). *Lampadopsis* was an unjustified emendation of *Lampasopsis* made by Fischer (1884)
377 and is not of prevailing usage (P. Bouchet pers. com.), therefore the ICZN Article 33.3.1 does
378 not apply.

379 The type species of *Bufonaria* and *Bursina*, respectively *Bufonaria spinosa* Schumacher, 1817
380 (a junior synonym of *Bufonaria echinata* (Link, 1807)) and *Ranella nobilis* Reeve, 1844, were
381 not included in this study. *Bufonaria perelegans* Beu, 1987 is morphologically extremely

382 similar to *Bufonaria echinata*; the only noticeable difference is that *Bufonaria echinata* has
383 much longer spines on its sutural, first and third primary cords. *Bursina nobilis* and *B.*
384 *ignobilis* (Beu, 1987) can only be differentiated by their size when they are adult, *Bursina*
385 *nobilis* being slightly larger and taller. Consequently, the well supported clades containing
386 *Bufonaria perelegans* and *Bursina nobilis* are attributed to the genera *Bufonaria* and *Bursina*,
387 respectively.

388 We still consider *Crossata* (not included in the sampling) to be a valid genus under the current
389 delimitation (Powell & Berschauer, 2017). “*Bursa*” *verrucosa* (G. B. Sowerby I, 1825) and
390 “*Bursa*” *condita* (Gmelin, 1791) are two morphologically distinct species that we were unable
391 to obtain for this phylogenetic study, and they are not readily attributable solely based on their
392 morphology to any newly delimited genus; fortunately, they are type species of *Annaperenna*
393 and *Colubrellina* respectively. These two monospecific genera are provisionally considered
394 valid, pending their inclusion in a molecular phylogeny.

395 The only two remaining species in our phylogeny that must be attributed to a new genus are
396 the Atlantic and Pacific species “*Bursa*” *corrugata* and the Mediterranean Sea and Eastern
397 Atlantic Ocean “*Bursa*” *scrobilator*. A possible genus name for *A. corrugata* may be
398 *Talisman*, a name based on the type species *Talisman parfaiti* Folin, 1884. Warén & Bouchet
399 (1990) considered this genus to be a *nomen dubium* based on a juvenile of either “*Bursa*”
400 *scrobilator*, *Aspa marginata* or “*Bursa*” *corrugata*; they restricted the possible attribution of
401 *Ta. parfaiti* to these three species because they are the only ones occurring in the Atlantic. *Ta.*
402 *parfaiti* is known by a single juvenile specimen (held in the MNHN) composed of a bursid-
403 like protoconch and a single shell whorl. Crocetta *et al.*, (2020) reanalyzed the type specimen
404 and concluded that based on the strongly reticulate sculpture of protoconch II, *Talisman*
405 *parfaiti* was likely based on a larval shell of “*Bursa*” *scrobilator*. *Bufonariella* Thiele, 1929
406 (type species *Murex scrobilator* Linnaeus, 1758) is another available name for “*Bursa*”

407 *scrobilator* but *Talisman* has priority over it. To our knowledge there is no other available
408 name for “*B*”. *corrugata*, and a new genus name is given for this genus: *Alanbeuella* gen.
409 nov.

410 The only other clade that we consider to be of generic level without a previously published
411 name is the well supported one containing “*Bursa*” *awatii*, “*Bursina*” *fijiensis*, “*Bursa*”
412 *fosteri*, and “*Bursa*” *quirihorai*; we erect a new name for it: *Korrigania* gen. nov.

413

414 4.2 *Systematics*

415

416 Phylum Mollusca Cuvier, 1795

417 Class Gastropoda Cuvier, 1795

418 Order Neogastropoda (following the opinion of Osca *et al.*, 2015)

419 Superfamily Tonoidea Suter, 1913 (1825)

420 Family Bursidae Thiele, 1925

421

422 Genus *Alanbeuella* Sanders, Merle, Laurin, Bonillo & Puillandre gen. nov.

423 Zoobank: zoobank.org:act:99B4D509-7B27-40FA-A53D-BEB3ADA14E7E

424 **Type species.** *Biplex corrugata* Perry, 1811

425 **Included species.** *Alanbeuella corrugata* (Perry, 1811) n. comb., Recent; *Alanbeuella*
426 *victrix* (Dall, 1916) n. comb., Late Oligocene, Georgia, USA.

427 **Etymology.** Dedicated to the malacologist and paleontologist Alan G. Beu for his remarkable
428 contribution to the taxonomy of the Bursidae.

429 **Diagnosis.** Relatively lightly built shell, varices aligned (can be slightly displaced in the last
430 whorl), six primary cords (P) on the convex part of the whorl, P2 and P4 totally atrophied in
431 varical and intervarical position, P6 reduced in intervarical and atrophied in varical only, large

432 nodules on varical P1 and P3, disappearing entirely on the last whorl of large specimens.

433 Varical P1 is split into two cords, first whorl lost in nearly every specimen, strong projection
434 of the outer lip, and second row of denticles (ID, D1-D6) on the outer lip. Ovate operculum,
435 subanterior nucleus.

436

437 Genus *Korrigania*, Sanders, Merle, Laurin, Bonillo & Puillandre gen. nov.

438 Zoobank: zoobank.org:act:73224CBE-CD87-4EC0-A6B8-612966A5608D

439 **Type species.** *Ranella fijiensis* Watson, 1881

440 **Included species.** (only extant taxa), *Korrigania awatii* (Ray, 1949) n. comb., *Korrigania*
441 *fijiensis* (Watson, 1881) n. comb., *Korrigania fosteri* (Beu, 1987) n. comb., *Korrigania*
442 *quirihorai* (Beu, 1987) n. comb.

443 **Etymology.** Based on the Brittany (France) elusive dwarf-like spirit Korrigan.

444 Diagnosis: Fusiform, very light built shell (extremely light in *K. awatii*), seven primary cords
445 (P1-P7) on the convex part of the whorl, P2 and P4 atrophied, P6 and P7 reduced, varices
446 displaced but less than in *Tutufa* or *Tritonoranella*. Ovate operculum, subanterior nucleus.

447 Comparison: resembles *Tritonoranella* but lacks black stripes on the columella.

448

449 **5. Discussion**

450 *5.1. Using molecular trees to reinterpret shell characters*

451 While morphological data played a pioneering role in malacology, in recent times it was
452 supplanted by molecular data due to decreasing cost of generating molecular data and because
453 morphology-based phylogenies of molluscs are often poorly resolved, in particular when
454 considering shell characters alone. Yet morphological data remain tremendously important
455 (Giribet, 2015) and mollusc taxonomy remains largely dependent on shell characters, in
456 particular for non-academics (Bouchet *et al.*, 2016) that have no access to sequencing

457 facilities. Hence, re-interpreting morphological characters in the light of molecular
458 phylogenies is crucial in order to provide operational classifications.

459 A detailed review of bursid morphology would be beyond the scope of this paper and we
460 focus here on the recently resurrected and newly described genera. Until recently nearly half
461 of the bursid species belonged to the genus *Bursa*; they are now allocated to seven genera
462 (plus two extinct genera discussed in Sanders *et al.*, 2019).

463 Species belonging to *Bursa sensu stricto* are now relatively easy to identify, with a white,
464 thick, plump and a nodulous shell with a strongly curved anterior siphonal canal, similar to
465 *Lampasopsis* but with a very long and tubular posterior siphonal canal. Species of *Dulcerana*
466 and *Talisman* are also rather similar with their brownish fusiform shells but can be easily
467 distinguished by their varices that are aligned in *Dulcerana* (one varix every 180° of the
468 whorl) and unaligned in *Talisman* (one varix every 200° or so of the whorl). Specimens of
469 *Allanbeuella* are also similar to *Dulcerana* and *Talisman* in shape, size and color but they
470 have two rows of denticles on the outer lip while there is only one in other Bursidae. Species
471 of *Tritonoranella* and *Korrigania* gen. nov. are more difficult to distinguish, as they both have
472 white and elongated thin shells, but the black stripes on the columella are characteristics of
473 *Tritonoranella* species. *Annaperenna* specimens also have black stripes but large black warts
474 on their otherwise white shell make them easily recognizable.

475

476 5.2 Drawbacks of the Node+tip calibration approach, and potential alternatives

477 The trees obtained with the two calibration approaches are rather similar, but the “node+tip”
478 tree presents two major drawbacks: First, our method assumes that the molecular sequences
479 have not changed significantly since the time represented by the fossil used to date each tip.
480 However, these ages represent a very small proportion of tree depth, so the impact of this
481 problem should be minor. Second, even though every species represented in the tree are

482 extant species, the resulting tree is not ultrametric. This is due to the fact that, even if the
483 fossils were considered to belong to an extant species, during the analysis they are considered
484 as possibly extinct because Mr Bayes 3.2 cannot accommodate stratigraphic ranges, per se, as
485 prior. However, the fact that the set of nodal ages yielded by our simplified tip dating analysis
486 overlap broadly those of the node-dated analyses (Supp. Fig. 4) suggests that this method
487 performs well, at least on this dataset.

488 Another option to use an even greater proportion of the data on the bursid fossil record would
489 be to estimate diversification rates and divergence times under the Fossilized Birth–Death
490 Process (Heath *et al.*, 2016; Stadler *et al.*, 2018; Didier & Laurin, 2020; Luo *et al.*, 2020). In
491 any case, the main caveat for the use of all those methods is our ability to reconstruct a sound
492 morpho-anatomical phylogeny of our group.

493

494 5.3 Origin of the Bursidae

495 The very early diversification of the Bursidae remains obscure due to the fact that no
496 undisputable bursid fossil has ever been found in strata older than those in which specimens
497 of the Eocene Peruvian genus *Olssonia* were found (Beu, 1988; Sanders *et al.*, 2019).

498 Our dataset gives us a late Cretaceous to early Paleogene origin of the Bursidae. Even though
499 *Alanbeuella* gen. nov. and *Aspa* are among the geologically oldest genera known in Bursidae
500 with fossils as old as the Aquitanian (Early Miocene) (Sanders *et al.*, 2019), time trees show
501 an earlier origin of both genera during the Early Oligocene. Three hypotheses can be proposed
502 to explain why *Alanbeuella* gen. nov. and *Aspa* fossil are not found in Oligocene deposits. (1)
503 Considering the low support of clade A + B + C (Fig. 2), our topology may be wrong; (2)
504 Early Oligocene *Aspa* and *Alanbeuella* gen. nov. occur in the Aquitaine Basin where deposits
505 of that period are poorly preserved. This may prevent the discovery of early forms of those
506 genera. (3) The evolutionary rates of this part of the tree is apparently different from the rest

507 the Bursidae tree (*Aspa* shows quite a longer branch compared to its sister group - Fig. 2). It is
508 then possible that the clock model used in the analysis artificially gave an older diversification
509 time. Such artefacts have been consistently shown in other groups (Schwartz & Maresca,
510 2006). Pending new fossil discoveries, this problem could be addressed by increasing the
511 number of molecular characters for *Alanbeuella corrugata*, the only extant species of its
512 genus, or by using a Fossilized Birth–Death Process, which does not necessarily require to
513 estimate molecular rates of evolution (e.g., Didier and Laurin, 2020).

514 Molecular dating suggests that the crown Bursidae diversifies during the Bartonian (Middle
515 Eocene) (Fig. 3); this is consistent with the fact that the Thanetian (Late Paleocene) extinct
516 species “*Bursa*” *saudersi* Adegoke, 1977 from West Africa (Nigeria) bears numerous
517 characters resembling those of bursids (the varices closely spaced and nearly aligned up the
518 whorls, the sculpture of coarse nodes and the short spire place it in the Bursidae rather than in
519 the Ranellidae or the Cymatiidae). However, it lacks the distinctive anal notch of the family.
520 Even though it was removed from crown Bursidae by Sanders *et al.* (2019), it may very well
521 be an early, stem-bursid that pre-dates the acquisition of the posterior siphonal canal. The
522 surprising Paleocene/Eocene biogeographic connection between West Africa and Peru is
523 rather easy to understand because there were fewer biogeographic constraints (there was
524 no Panama isthmus at this time) and because the geologic record in these regions is poor.

525

526 *5.4 Speciation in the Bursidae*

527 The speciation event (cladogenesis) that gave birth to the clades A+B and C was probably
528 caused by bathymetric isolation. Clade C is composed of species commonly found more than
529 300 m deep, and up to 1000 m for some species of *Korrigania* gen. nov. and *Tritonoranella*.
530 On the contrary, species within A+B are rarely collected alive below 100 m deep (*Tutufa*
531 *tenuisgranosa* is the sole species to be found under 100 m but never over 220 m). *Aspa* and

532 *Alanbeuella corrugata* being shallow water species as well, deep sea colonization by the clade
533 C is then considered as an apomorphy of the clade. Speciation induced by bathymetry has
534 already been hypothesized for gastropods in the Bursidae by Castelin *et al.* (2012) and in the
535 Abyssochrysoidea by Osca *et al.* (2014).

536 Among the sampled species, two are geographically restricted to Western Atlantic and the
537 Caribbean: *Lampasopsis thomae* and *Marsupina bufo*. Separation with their sister groups,
538 respectively *Lampasopsis cruentata* from the East Indo-Pacific and *Marsupina nana* from
539 eastern Pacific, are both estimated to have occurred around 15 Mya, which corresponds to the
540 initial closure of the Panama isthmus (Montes *et al.*, 2015).

541

542 *5.5 Diversification of the Bursidae*

543 Global climatic events have been recognized to be possible biodiversity drivers
544 (Erwin, 2009). According to our results, the first diversification event of Bursidae (Bartonian)
545 is synchronous with such an event: the last supra-regionally recognized Eocene thermal event,
546 the MECO (Mid Eocene Climatic Optimum; Vandenberghe *et al.*, 2012; Fig. 3B). However,
547 this does not imply that there is a causal link, and no other pattern could be linked between
548 observed time diversification and later climatic events such as the “grande coupure” (Eocene–
549 Oligocene glaciation) or the middle Miocene disruption, casting doubt on the link between the
550 two events.

551 Most Bursidae are dependent of coral, for both hunting and nesting, and some genera
552 (*Lampasopsis* and *Bursa*) even developed camouflage strategies to look like bits of coral.
553 Those that do not rely on coral (*Aspa*, *Talisman*, *Korrigania* gen. nov. and *Alanbeuella* gen.
554 nov.) live on rocky shores or sponges, especially in the case of deep-sea organisms
555 (*Korrigania* gen. nov.). Coral reef geographical location and extension has changed
556 drastically during the Cenozoic (Renema *et al.*, 2008, Pellissier *et al.*, 2014), probably driven

557 by the tectonic activity (Leprieur *et al.*, 2016). It is quite possible that bursid diversification
558 follows this pattern. Leprieur *et al.* (2016) showed that the location of the major marine
559 biodiversity hotspot (modeled using coral diversity data) has moved across the globe during
560 the last 50 million years, transitioning from the western Tethys during the Eocene (55–33 Ma)
561 to the Arabian Peninsula and Western Indian Ocean during the Late Eocene and Oligocene
562 (37–15 Ma), and finally to the Indo-Australian Archipelago in the Miocene (15–5 Ma) (Fig.
563 3C). This movement was primarily driven by successive closure of the Tethys followed by the
564 collision of the Arabian and Indian plates with Eurasia. Bursid diversity through time seems
565 to follow the same pattern. Genera branching early in the timetree, namely *Aspa* and
566 *Alanbeuella* gen. nov., originated between the Bartonian (Middle Eocene, 41-38 Ma) and the
567 Chattian (Late Oligocene, 28-23 Ma); both genera occur in western Tethys during the Early
568 Miocene and are still living in the Atlantic. As suggested by the fossil record, the maximal
569 diversity occurred between the Early and Middle Miocene in the Eastern Atlantic, Western
570 Tethys and Paratethys (Sanders *et al.*, 2019), with the appearance of genera like *Talisman* and
571 *Tritonoranella* (a genus that only occurs in the Indo-Pacific now). The second phase of
572 diversification started during the Langhian (Middle Miocene, 16-13 Ma). Then, most bursid
573 genera diversified outside the Mediterranean Sea (ancient Western Tethys), mainly in the
574 Indo-Pacific region (*Bufonaria*, *Bursina*, *Korigania*, *Lampasopsis*, *Bursa* and *Dulcerana*) and
575 some in the Western Atlantic and Caribbean (*Marsupina*, *Crossata*). *Lampasopsis* may have
576 originally diversified in Western Atlantic, even though most of its recent diversity is in the
577 Indo-Pacific today, because the oldest fossil representatives of the group are found in the
578 Caribbean (Beu, 2010; Sanders *et al.*, 2019). The Mediterranean Sea was drained completely
579 during the Messinian (Late Miocene, 7-5 Ma), forcing out or trapping in every species of
580 Bursidae. *Talisman scrobilator* was the only one to come back.

581

582 **6 Conclusion**

583 With 56% of the currently-recognized extant species represented in the dataset, this work
584 constitutes the first large-scale revision of the Bursidae. A new classification of the frog shells
585 is proposed, including a tentative solution to the decade-long debate regarding the
586 delimitation of the family type genus, *Bursa*, leading to the resurrection of all previously
587 synonymized genus names (though two are not phylogenetically tested). The integrative
588 approach using mitogenomic data and the extensive fossil record allow us to infer the chain of
589 events leading to the extant diversity of the Bursidae. However, further work needs to be done
590 in order to provide a complete phylogeny of the Bursidae. First, shifting to the mitogenomic
591 scale has been proven to significantly improve the resolution of the trees, but to this day, we
592 have no full mitogenomic data for *Dulcerana*, *Alanbeuella* gen. nov. and *Tritonoranella*.
593 Second, taxonomic sampling should be increased, including in particular the species *Crossata*
594 *ventricosa* (Broderip, 1833), *Annaperenna verrucosa*, *Colubrellina condita* and *Bufonaria*
595 *foliata* (Broderip, 1826), respectively type species of *Crossata* Jousseaume, 1881,
596 *Annaperenna* Iredale, 1936, *Colubrellina* Fischer, 1884 and *Chasmotheca* Dall, 1904.
597 Furthermore, *Bufonaria* is among the most diverse bursid genera (nine recognized species),
598 but it is greatly under-sampled in this study. To thoroughly test the monophyly of this group,
599 several species need to be added to the tree.

600 This phylogeny of Bursidae is only a first step toward a more integrative study of the group.
601 Indeed, the complex ornamentation of the shell may allow us to reconstruct a phylogeny of
602 the group using morphological characters for both extant and extinct species. Using this
603 matrix in combination with the molecular one and a fossil occurrence database, diversification
604 analyses could be conducted using the fossilized birth death process (Didier *et al.*, 2017), and
605 paleontological dating of this clade could be performed (Didier and Laurin, 2020).

606 Finally, if generating genomic-scale molecular data is becoming easier, achieving a
607 representative sampling for molecular systematics is becoming increasingly difficult,
608 considering the multiplicity of permits required to sample the whole distribution area of the
609 targeted taxa, spanning numerous countries. The future will tell whether the Article 8a of the
610 Nagoya Protocol for the Convention of Biological Diversity (encouraging the Parties to apply
611 the protocol to “create conditions to promote and encourage research [...] through simplified
612 measures on access for non-commercial research purposes”) will reverse the trend (Bouchet *et*
613 *al.*, 2016). For the time being, compliance with regulations on ‘Access and Benefit Sharing’
614 and ‘Prior Informed Consent’ is an obstacle that hampers study of biodiversity to such an
615 extent that it may hinder conservation efforts which is contrary to the main purpose of the
616 Nagoya protocol. For instance, by unduly delaying research, entire species might vanish
617 before they are detected or recognized. The recent finding by Sanders *et al.* (2017) that *Bursa*
618 *granularis* actually includes four species illustrates this danger.

619

620 **Acknowledgments.**

621 A large part of the molecular material in this paper originates from various shore-based
622 expeditions conducted by MNHN, Pro-Natura International (PNI) and Institut de Recherche
623 pour le Développement (IRD) as part of the Our Planet Reviewed program (SANTO 2006,
624 MAINBAZA, INHACA 2011, PAPUA NIUGINI 2014); by MNHN and IRD as part of the
625 Tropical Deep-Sea Benthos program (TERRASSES); by MNHN and AAMP (Pakaihi i Te
626 Moana); and by MNHN (PANGLAO 2004, Western Australia 2011, KARUBENTHOS
627 2012). Domestic and foreign partners include the University of San Carlos, Cebu City;
628 Maritime College, Luganville; Universidade Eduardo Mondlane, Maputo; University of
629 Papua New Guinea, Port Moresby, and National Fisheries College, Kavieng; the Western
630 Australian Museum, Perth. Funders and sponsors include the Total Foundation, Prince Albert

631 II of Monaco Foundation, Stavros Niarchos Foundation, Richard Lounsbery Foundation,
632 Vinci Entrepose Contracting, Fondation EDF, the Philippines Bureau of Fisheries and Aquatic
633 Resources (BFAR), and the French Fonds Pacifique. We thank Jon Anders Kongsrud (ZMB)
634 and Daniel Geiger (SBMNH) for the loan of material from their respective institutions. All
635 expeditions operated under the regulations then in force in the countries in question and
636 satisfy the conditions set by the Nagoya Protocol for access to genetic resources. We thank
637 Barbara Buge, Julien Brisset and Gilberto Marani (MNHN) for their role in specimen
638 processing during the expeditions and their help in curating the specimens. We gratefully
639 acknowledge Philippe Bouchet for his continuing insight during this project and Agnès Dettaï
640 for technical guidance during mt-genome amplification and sequencing. Finally, we express
641 our gratitude to the two anonymous reviewers of this paper, for their insightful comments and
642 suggestions. This project was jointly supported by the Service de Systématique Moléculaire
643 (UMS 2700 CNRS-MNHN), by the LABEX BCDiv (SU, MNHN, UPMC, CNRS, IRD,
644 ANR, EPHE, Investissements d'avenir, Paris Diderot) ant the ATM Emergence (MNHN).

Tutufa		(13.5,18.5,1);	Tutufa sp.	Middle Miocene	Ena Limestone Japan	Tomida et al. 2013	Tomida et al. 2013
Aspa Marginata	uniform	(0,18);	Aspa Marginata	Middle Miocene	Po valley Italy & Paratethys	Landau et al., 2004	Landau et al., 2004

<i>Bufonaria perelegans</i>	(0,11);	<i>Bufonaria perelegans</i>	Middle Miocene (early Preangerian)	Cijarian, western Java	Sanders et al., 2019	Beu 2005
<i>Talismann scrobilator</i>	(0,14);	<i>Talismann scrobilator</i>	Langhian/ Seravalian (Middle Miocene)	Paratethys Austria and Poland	Landau et al., 2004	Baluk 1995
<i>Bursina margaritula</i>	(0,3,5);	<i>Bursina margaritula</i>	Pliocene	Tjikeusik, Java	Beu 2005	Beu, 2005
<i>Dulcerana cubaniana</i>	(0,2);	<i>Dulcerana cubaniana</i>	Pleistocene	Various formation from Panama, Cuba, Dominican republic and Barbados	Sanders et al., 2017	Beu 2010
<i>Lampasopsis thomae</i>	(0,12);	<i>Lampasopsis thomae</i>	Burdigalian (Early Miocene)	Chipola Formation, Florida, USA	this study	Beu 2010
<i>Marsupina bufo</i>	(0,7);	<i>Marsupina bufo</i>	Tortonian/Messinian (Late Miocene)	Gurabo Formation in Dominican Republic	Sanders et al., 2019	Beu 2010
<i>Marsupina nana</i>	(0,5);	<i>Marsupina nana</i>	Early Zanclean (Early Pliocene)	Charco Azul Group, Penita Formation , Quebrada La Penita, Pacific coast of Costa Rica	Beu 2010	Beu 2010
<i>Alanbeuella corrugata</i>	(0,20);	<i>Alanbeuella corrugata</i>	Burdigalian (Early Miocene)	Aquitaine basin	Landau et al., 2009	Landau et al., 2009
<i>Tritonoranella latitudo</i>	(0,2,5);	<i>Tritonoranella latitudo</i>	late Pliocene	Kendeng beds, Java	Beu 2005	Beu 2005
<i>Tritonoranella ranelloides</i>	(0,2,5);	<i>Tritonoranella ranelloides</i>	Pliocene	Cayo Agua Formation Panama	Beu 2010	Beu 2010
<i>Tutufa bubo</i>	(0,5);	<i>Tutufa bubo</i>	Late Miocene	Pendopo Oilfield, east of Talang Akar,	Beu 2005	Robba, 1996

Sumatra

Tutufa rubeta	(0,7);	Tutufa rubeta	Late Miocene	Citalahab, West Java	Beu 2005	Beu 2005
---------------	--------	---------------	--------------	-------------------------	----------	----------

Table 2. Complete and partial mt genomes sequenced and reconstructed in this study

Species	Specimen ID	Proportion assembled	Mitogenome size	Number of read assembled	Coverage				Standard dev.
					Min	Max	Mean		
<i>Tutufa rubeta</i>	IM-2013-10139	100	15397	7421	12	438	122	101	
<i>Bufo perelegans</i>	IM-2007-43034	52		2574	0	273	46	63	
<i>Aspa marginata</i>	ZMB-92447	56		3568	0	522	66	100	
<i>Marsupina bufo</i>	IM-2013-56144	100	15403	3736	9	200	51	32	
<i>Bursa aff tuberosissima</i>	IM-2007-43041	69		507	0	22	7	6	
<i>Lampasopsis rhodostoma</i>	IM-2013-11043	100	15392	6604	14	284	86	46

Figure Legends

Fig. 1. Position of the primers on the mitogenome of *Lampasopsis rhodostoma*. Blue lines represent the fragments of mtDNA amplified by the long range PCRs. Black lines represent the overlapping sections of the amplified fragments, green lines represent coding genes, red lines represent rRNA genes, clockwise green arrows represent forward primers, counterclockwise green arrows represent reverse primers, pink arrows represent tRNA.

Fig. 2. Bayesian phylogram based on a concatenated mitochondrial and nuclear gene dataset (dataset 4) analyzed in Maximum likelihood (ML) with Bayesian analysis (BA) support plotted on the ML topology. Support for nodes is given as Posterior probabilities (PP)/ ultrafast bootstraps (UFBS)/ bootstraps (BS). Figured specimens are sequenced vouchers. Black cartouche show clade found in BI but not in ML with PP written in white. Outgroup branches are not to scale. Scale bar indicates substitution/site.

Fig. 3. Bursid biodiversity evolution through time and relevant paleoenvironmental context. A. Maximum clade credibility chronogram obtained from the Bayesian analyses performed on dataset 4 with *Galeodea echinophora* and *Cymatium parthenopeum* as outgroup (*C. parthenopeum* not shown). Node values are posterior mean ages (Ma), with node bars representing their 95% highest probability density (HPD) intervals. Black * indicates calibrated nodes. Figured fossils are those used for node calibration (see Tab. 2). B. Thermal variations during the Cenozoic. The blue curve represents the benthic foraminiferal oxygen isotopic (d18O) trends through time (reproduced from Cramer *et al.*, 2009) d18O is a proxy of the temperature. Geological time scale in million years with abbreviations: Lut, Lutetian, Bar, Bartonian, Pri, Priabonian, Rup, Rupelian, Cha, Chattian, Aqui, Aquitanian, Lan, Langhian, Ser, Serravallian, Tor, Tortonian, Mes, Messinian, Zan, Zanclean, Pia, Piazencian, Pleisto,

Pleistocene. C. Hopping hotspot observed from coral simulated model for three time periods, Eocene, Miocene and Quaternary/current. Diversity values were rescaled between 0 (minimum, pink) and 1 (maximum, green). Reproduced after Leprieur *et al.* (2016).

Supp. Fig. 1: Maximum likelihood phylogram based on partial *coxI* sequences (dataset 1). Bootstrap values are indicated at the nodes. Voucher registration numbers are indicated for each terminal. See Tab. 1 for sources. Scale bar indicates number of nucleotide substitutions per site.

Supp. Fig. 2: Maximum likelihood phylogram based on a concatenated mitochondrial (*coxI*, 12s, 16s) and nuclear gene (28S, H3) dataset (dataset 2), bootstrap frequencies are indicated at the nodes. Scale bar indicates number of nucleotide substitutions per site.

Supp. Fig. 3: Maximum likelihood phylogram based on a concatenated analysis of the 13 protein-coding genes in the mitochondria (dataset 3), ultrafast bootstrap and conventional bootstrap frequencies are indicated at the nodes. Scale bar indicates number of nucleotide substitutions per site.

Supp. Fig. 4: Maximum clade credibility chronograms obtained from Bayesian analysis of the concatenated dataset, calibrated with fossils at the nodes and tips (A), and with node only (B). Time indicated in millions of years. 95% confidence intervals indicated in blue bars.
