# ON THE ENERGY TRANSFER TO HIGH FREQUENCIES IN THE DAMPED/DRIVEN NONLINEAR SCHRÖDINGER EQUATION 

GUAN HUANG AND SERGEI KUKSIN

#### Abstract

We consider a damped/driven nonlinear Schrödinger equation in $\mathbb{R}^{n}$, where $n$ is arbitrary, $$
\mathbb{E} u_{t}-\nu \Delta u+i|u|^{2} u=\sqrt{\nu} \eta(t, x), \quad \nu>0
$$ under odd periodic boundary conditions. Here $\eta(t, x)$ is a random force which is white in time and smooth in space. It is known that the Sobolev norms of solutions satisfy $\|u(t)\|_{m}^{2} \leq C \nu^{-m}$, uniformly in $t \geq 0$ and $\nu>0$. In this work we prove that for small $\nu>0$ and any initial data, with large probability the Sobolev norms $\|u(t, \cdot)\|_{m}$ with $m>2$ become large at least to the order of $\nu^{-\kappa_{n, m}}$ with $\kappa_{n, m}>0$, on time intervals of order $\mathcal{O}\left(\frac{1}{\nu}\right)$. It proves that solutions of the equation develop short space-scale of order $\nu$ to a positive degree, and rigorously establishes the (direct) cascade of energy for the equation.

## 1. Introduction

In this work we study a damped/driven nonlinear Schrödinger equation

$$
\begin{equation*}
u_{t}-\nu \Delta u+i|u|^{2} u=\sqrt{\nu} \eta(t, x), \quad x \in \mathbb{R}^{n} \tag{1.1}
\end{equation*}
$$

i.e. a CGL equation without linear dispersion, with cubic Hamiltonian nonlinearity and a random forcing. The dimension $n$ is any, $0<\nu \leq 1$ is the viscosity constant and the random force $\eta$ is white in time $t$ and regular in $x$. The equation is considered under the odd periodic boundary conditions,

$$
u\left(t, \ldots, x_{j}, \ldots\right)=u\left(t, \ldots, x_{j}+2 \pi, \ldots\right)=-u\left(t, \ldots, x_{j}+\pi, \ldots\right), \quad j=1, \ldots, n
$$

The latter implies that $u$ vanishes on the boundary of the cube of half-periods $K^{n}=[0, \pi]^{n}$,

$$
\left.u\right|_{\partial K^{n}}=0 .
$$

We denote by $\left\{\varphi_{d}(\cdot), d=\left(d_{1}, \ldots, d_{n}\right) \in \mathbb{N}^{n}\right\}$ the trigonometric basis in the space of odd periodic functions,

$$
\varphi_{d}(x)=\left(\frac{2}{\pi}\right)^{\frac{n}{2}} \sin \left(d_{1} x_{1}\right) \cdots \sin \left(d_{n} x_{n}\right)
$$

The basis is orthonormal with respect to the normalised scalar product $\langle\langle\cdot, \cdot\rangle$ in $L_{2}\left(K^{n}, \pi^{-n} d x\right)$,

$$
\begin{equation*}
\langle u, v\rangle\rangle=\int_{K^{n}}\langle u(x), v(x)\rangle \pi^{-n} d x \tag{1.2}
\end{equation*}
$$

where $\langle\cdot, \cdot\rangle$ is the real scalar product in $\mathbb{C},\langle u, v\rangle=\mathfrak{R} u \bar{v}$. It is formed by eigenfunctions of the Laplacian:

$$
(-\Delta) \varphi_{d}=|d|^{2} \varphi_{d} .
$$

The force $\eta(t, x)$ is a random field of the form

$$
\begin{equation*}
\eta(t, x)=\frac{\partial}{\partial t} \xi(t, x), \quad \xi(t, x)=\sum_{d \in \mathbb{N}^{n}} b_{d} \beta_{d}(t) \varphi_{d}(x) . \tag{1.3}
\end{equation*}
$$

Here $\beta_{d}(t)=\beta_{d}^{R}(t)+i \beta_{d}^{I}(t)$, where $\beta_{d}^{R}(t), \beta_{d}^{I}(t)$ are independent real-valued standard Brownian motions, defined on a complete probability space $(\Omega, \mathcal{F}, \mathbb{P})$ with a
filtration $\left\{\mathcal{F}_{t} ; t \geqslant 0\right\}$. The set of real numbers $\left\{b_{d}, d \in \mathbb{N}^{n}\right\}$ is assumed to form a non-zero sequence, satisfying

$$
\begin{equation*}
0<B_{m_{*}}<\infty, \quad m_{*}=\min \{m \in \mathbb{Z}: m>n / 2\} \tag{1.4}
\end{equation*}
$$

where for a real number $k$ we set

$$
B_{k}:=\sum_{d \in \mathbb{N}^{n}}|d|^{2 k}\left|b_{d}\right|^{2} \leq \infty .
$$

For $m \geq 0$ we denote by $H^{m}$ the Sobolev space of order $m$, formed by complex odd periodic functions, equipped with the homogeneous norm,

$$
\|u\|_{m}=\left\|(-\Delta)^{\frac{m}{2}} u\right\|_{0}
$$

where $\|\cdot\|_{0}$ is the $L^{2}$-norm on $K^{n},\|u\|_{0}^{2}=\left\langle\langle u, u\rangle\right.$ (see (1.2)). If we write $u \in H^{m}$ as Fourier series, $u(x)=\sum_{d \in \mathbb{N}^{n}} u_{d} \varphi_{d}(x)$, then $\|u\|_{m}^{2}=\sum_{d \in \mathbb{N}^{n}}|d|^{2 m}\left|u_{d}\right|^{2}$.

Eq. (1.1) with small $\nu$ belongs to a group of equations, describing turbulence in the CGL equations. These equations have got quite a lot of attention in physical literature as models for turbulence in various media, e.g. see [3, Chapter 5]. In particular - as a natural model for hydrodynamical turbulence since eq. (1.1) is obtained from the Navier-Stokes system by replacing the Euler term $(u \cdot \nabla) u$, which is a quadratic Hamiltonian nonlinearity, by $i|u|^{2} u$, which is a cubic Hamiltonian nonlinearity, see [13].

The global solvability of eq. (1.1) for any space dimension $n$ is established in [8, 10]. It is proved there that if

$$
\begin{equation*}
u(0, x)=u_{0}(x), \tag{1.5}
\end{equation*}
$$

where $u_{0} \in H^{m} \cap C\left(K^{n}\right), m \in \mathbb{N}$, and if $B_{m}<\infty$, then the problem (1.1), (1.5) has a unique strong solution $u(t, x)$ in $H^{m}$ which we write as $u\left(t, x ; u_{0}\right)$, or $u\left(t ; u_{0}\right)$, or $u_{\nu}\left(t ; u_{0}\right)$. Its norm satisfies

$$
\mathbb{E}\left\|u\left(t ; u_{0}\right)\right\|_{m}^{2} \leq C_{m} \nu^{-m}, \quad t \geq 0
$$

where $C_{m}$ depends on $\left\|u_{0}\right\|_{m},\left|u_{0}\right|_{\infty}$ and $B_{m}, B_{m_{*}}$. Furthermore, denoting by $C_{0}\left(K^{n}\right)$ the space of continuous complex functions on $K^{n}$, vanishing at $\partial K^{n}$, we have that the solutions $u(t, x)$ define a Markov process in $C_{0}\left(K^{n}\right)$. Moreover, if the noise $\eta(t, \cdot)$ is non-degenerate in the sense that in (1.3) all coefficients $b_{d}$ are non-zero, then this process is mixing. ${ }^{1}$

Our goal is to study the growth of higher Sobolev norms for solutions of eq. (1.1) as $\nu \rightarrow 0$ on time intervals of order $\mathcal{O}\left(\frac{1}{\nu}\right)$. The main result of this work is the following.

Theorem 1. For any real number $m>2$, in addition to (1.4), assume that $B_{m}<\infty$. Then there exists $\kappa_{n, m}>0$ such that for every fixed quadruple $\left(\delta, \kappa, \mathscr{K}, T_{0}\right)$, where

$$
\kappa \in\left(0, \kappa_{n, m}\right), \quad \delta \in\left(0, \frac{1}{8}\right), \quad \mathscr{K}, T_{0}>0
$$

there exists a $\nu_{0}>0$ with the property that if $0<\nu \leq \nu_{0}$, then for every $u_{0} \in$ $H^{m} \cap C_{0}\left(K^{n}\right)$, satisfying

$$
\begin{equation*}
\left|u_{0}\right|_{\infty} \leqslant \mathscr{K}, \quad\left\|u_{0}\right\|_{m} \leq \nu^{-\kappa m} \tag{1.6}
\end{equation*}
$$

the solution $u\left(t, x ; u_{0}\right)$ is such that
(1)

$$
\mathbb{P}\left\{\sup _{t \in\left[t_{0}, t_{0}+T_{0} \nu^{-1}\right]}\left\|u_{\nu}^{\omega}(t)\right\|_{m}>\nu^{-m \kappa}\right\} \geq 1-\delta, \quad \forall t_{0} \geq 0 .
$$

[^0](2) If $m$ is an integer, $m \geq 3$, then a possible choice of $\kappa_{n, m}$ is $\kappa_{n, m}=\frac{1}{35}$, and there exists $C \geq 1$, depending on $\kappa<\frac{1}{35}, \mathscr{K}, m, B_{m_{*}}$ and $B_{m}$, such that
\[

$$
\begin{equation*}
C^{-1} \nu^{-2 m \kappa+1} \leqslant \mathbb{E}\left(\nu \int_{t_{0}}^{t_{0}+\nu^{-1}}\left\|u_{\nu}(s)\right\|_{m}^{2} d s\right) \leqslant C \nu^{-m}, \quad \forall t_{0} \geq 0 \tag{1.7}
\end{equation*}
$$

\]

A similar result holds for the classical $C^{k}$-norms of solutions:
Proposition 2. For any integer $m \geq 2$ in addition to (1.4) assume that $B_{m}<\infty$. Then for every fixed triplet $K, \mathcal{K}, T_{0}>0$ and any $0<\kappa<1 / 16$ we have

$$
\begin{equation*}
\mathbb{P}\left\{\sup _{t \in\left[t_{0}, t_{0}+T_{0} \nu^{-1}\right]}\left|u_{\nu}^{\omega}\left(t ; u_{0}\right)\right|_{C^{m}}>K \nu^{-m \kappa}\right\} \rightarrow 1 \quad \text { as } \quad \nu \rightarrow 0 \tag{1.8}
\end{equation*}
$$

for each $t_{0} \geq 0$, if $u_{0}$ satisfies $\left|u_{0}\right|_{\infty} \leq \mathcal{K},\left|u_{0}\right|_{C^{m}} \leq \nu^{-\kappa m}$. The rate of convergence depends only on the triplet and $\kappa$.

For a proof of this result see the extended version of our work [6]. Due to (1.8), for any $m>2+n / 2$ we have

$$
\mathbb{P}\left\{\sup _{T_{0} \leq t \leq t_{0}+T_{0} \nu^{-1}}\|u(t)\|_{m} \geq K \nu^{-\left\lfloor m-\frac{n}{2}\right\rfloor \kappa}\right\} \rightarrow 1 \quad \text { as } \quad \nu \rightarrow 0
$$

for every $K>0$ and $0<\kappa<1 / 16$, where for $a \in \mathbb{R}$ we denote $\lfloor a\rfloor=\max \{n \in \mathbb{Z}: n<a\}$. This improves the first assertion of Theorem 1 for large $m$.

We have the following two corollaries from Theorem 1, valid if the Markov process defined by the equation (1.1) is mixing:

Corollary 3. Assume that $B_{m}<\infty$ for all $m$ and $b_{d} \neq 0$ for all $d$. Then eq. (1.1) is mixing and for any $\kappa<1 / 35$ and $0<\nu \leq \nu_{0}$ its unique stationary measure $\mu_{\nu}$ satisfies

$$
\begin{equation*}
C^{-1} \nu^{-2 m \kappa+1} \leq \int\|u\|_{m}^{2} \mu_{\nu}(d u) \leq C \nu^{-m}, \quad 3 \leq m \in \mathbb{N} . \tag{1.9}
\end{equation*}
$$

Here $C$ and $\nu_{0}$ are as in Theorem 1.
Corollary 4. Under the assumptions of Corollary 3, for any $u_{0} \in C^{\infty}$ we have

$$
\frac{1}{2} C^{-1} \nu^{-2 m \kappa+1} \leq \mathbb{E}\left\|u\left(s ; u_{0}\right)\right\|_{m}^{2} \leq 2 C \nu^{-m}, \quad 3 \leq m \in \mathbb{N}
$$

if $s \geq T\left(\nu, u_{0}, \kappa, B_{m}, B_{m_{*}}\right)$, where $C$ is the same as in (1.9).
Theorem 1 rigorously establishes the energy cascade to high frequencies for solutions of eq. (1.1) with small $\nu$. Indeed, if $u_{0}(x)$ and $\eta(t, x)$ are smooth functions of $x$ (or even trigonometric polynomials of $x$ ), then in view of (1.7) for $0<\nu \ll 1$ and $t \gtrsim \nu^{-1}$ a substantial part of the energy $\frac{1}{2} \sum\left|u_{d}(t)\right|^{2}$ of a solution $u\left(t, x ; u_{0}\right)$ is carried by high modes $u_{d}$ with $|d| \gg 1$. Relation (1.7) (valid for all integer $m \geq 3$ ) also means that the averaged in time space-scale $l_{x}$ of solutions for (1.1) satisfies $l_{x} \in\left[\nu^{1 / 2}, \nu^{1 / 35}\right]$, and goes to zero with $\nu$ (see $[1,9]$ ). We recall that the energy cascade to high frequencies and formation of short space-scale is the driving force of the Kolmogorov theory of turbulence, see [5].

We mention that in the work [12] the stochastic CGL equation

$$
\begin{equation*}
u_{t}-(\nu+i) \Delta u+i|u|^{2} u=\sqrt{\nu} \eta(t, x), \quad 0<\nu \leq 1 \tag{1.10}
\end{equation*}
$$

with linear dispersion and white in time random force $\eta$ as in (1.3) was considered under the odd periodic boundary conditions, and the inviscid limiting dynamics as $\nu \rightarrow 0$ was examined. However, since the limiting equation (1.10) $)_{\nu=0}$ is a regular PDE in difference with the equation (1.1) $)_{\nu=0}$, the results on the inviscid limit in [12] differ in spirit from those in our work, and we do not discuss them now.

Deterministic versions of the result of Theorem 1 for eq. (1.1) with $\eta=0$, where $\nu$ is a small non-zero complex number such that $\mathfrak{R} \nu \geq 0$ and $\mathfrak{I} \nu \leq 0$ are known,
see [9]. In particular, if $\nu$ is a positive real number and $u_{0}$ is a smooth function of order one, then for any integer $m \geq 4$ a solution $u_{\nu}\left(t, x ; u_{0}\right)$ satisfies estimates (1.7) with the averaging $\nu \mathbb{E} \int_{t}^{t+\nu^{-1}} \ldots d s$ replaced by $\nu^{1 / 3} \int_{0}^{\nu^{-1 / 3}} \ldots d s$, with the same upper bound and with the lower bound $C_{m} \nu^{-\kappa_{m} m}$, where $\kappa_{m} \rightarrow 1 / 3$ as $m \rightarrow \infty$. Moreover, it was then shown in [2] that the lower bounds remain true with $\kappa=1 / 3$, and that the estimates $\sup _{t \in\left[0,|\nu|^{-1 / 3}\right]}\|u(t)\|_{C^{m}} \geq C_{m}|\nu|^{-m / 3}, m \geq 2$, hold for smooth solutions of equation (1.1) with $\eta=0$ and any non-zero complex "viscosity" $\nu$.

The better quality of the lower bounds for solutions of the deterministic equations is due to an extra difficulty which occurs in the stochastic case: when time grows, simultaneously with increasing of high Sobolev norms of a solution, its $L_{2}$-norm may decrease, which accordingly would weaken the mechanism, responding for the energy transfer to high modes. Significant part of the proof of Theorem 1 is devoted to demonstration that the $L_{2}$-norm of a solution cannot go down without sending up the second Sobolev norm.

If $\eta=0$ and $\nu=i \delta \in i \mathbb{R}$, then (1.1) is a Hamiltonian PDE (the defocusing Schrödinger equation), and the $L_{2}$-norm is its integral of motion. If this integral is of order one, then the results of [9] (see there Appendix 3) imply that at some point of each time-interval of order $\delta^{-1 / 3}$ the $C^{m}$-norm of a corresponding solution will become $\gtrsim \delta^{-m \kappa}$ if $m \geq 2$, for any $\kappa<1 / 3$. Furthermore, if $n=2$ and $\delta=1$, then due to [4] for $m>1$ and any $M>1$ there exists a $T=T(m, M)$ and a smooth $u_{0}(x)$ such that $\left\|u_{0}\right\|_{m}<M^{-1}$ and $\left\|u\left(T ; u_{0}\right)\right\|_{m}>M$.

The paper is organized as follows. In Section 2, we recall the results from [8, 10] on solutions of the equation (1.1). Next we show in Section 3 that if the noise $\eta$ is non-degenerate, the $L^{2}$-norm of a solution of eq. (1.1) cannot stay too small on time intervals of order $\mathcal{O}\left(\frac{1}{\nu}\right)$ with high probability, unless its $H^{2}$-norm gets very large (see Lemma 12). Then in Section 4 we derive from this fact the assertion (1) of Theorem 1. We prove assertion (2) and both corollaries in Section 5.

Constants in estimates never depend on $\nu$, unless otherwise stated. For a metric space $M$ we denote by $\mathcal{B}(M)$ the Borel $\sigma$-algebra on $M$, and by $\mathcal{P}(M)$ - the space of probability Borel measures on $M$. By $\mathcal{D}(\xi)$ we denote the law of a r.v. $\xi$, and by $|\cdot|_{p}$ - the norm in $L_{p}\left(K^{n}\right)$.

## 2. Solutions and estimates

Strong solutions for the equation (1.1) are defined in the usual way:
Definition 5. Let $\left(\Omega, \mathcal{F},\left\{\mathcal{F}_{t}\right\}_{t \geqslant 0}, \mathbb{P}\right)$ be the filtered probability space as in the introduction. Let $u_{0}$ in (1.5) be a r.v., measurable in $\mathcal{F}_{0}$ and independent from the Wiener process $\xi$ (e.g., $u_{0}(x)$ may be a non-random function). Then a random process $u(t)=u\left(t ; u_{0}\right) \in C_{0}\left(K^{n}\right), t \in[0, T]$, adapted to the filtration, is called a strong solution of (1.1), (1.5), if
(1) a.s. its trajectories $u(t)$ belong to the space

$$
\mathcal{H}([0, T]):=C\left([0, T], C_{0}\left(K^{n}\right)\right) \cap L^{2}\left([0, T], H^{1}\right) ;
$$

(2) we have

$$
u(t)=u_{0}+\int_{0}^{t}\left(\nu \Delta u-i|u|^{2} u\right) d s+\sqrt{\nu} \xi(t), \quad \forall t \in[0, T], \quad \text { a.s. }
$$

where both sides are regarded as elements of $H^{-1}$.
If (1)-(2) hold for every $T<\infty$, then $u(t)$ is a strong solution for $t \in[0, \infty)$. In this case a.s. $u \in C\left([0, \infty), C_{0}\left(K^{n}\right)\right) \cap L_{l o c}^{2}\left([0, \infty), H^{1}\right)$.

Everywhere below when we talk about solutions for the problem (1.1), (1.5) we assume that the r.v. $u_{0}$ is as in the definition above.

The global well-posedness of eq. (1.1) was established in $[8,10]$ :
Theorem 6. For any $u_{0} \in C_{0}\left(K^{n}\right)$ the problem (1.1), (1.5) has a unique strong solution $u^{\omega}\left(t, x ; u_{0}\right), t \geq 0$. The family of solutions $\left\{u^{\omega}\left(t ; u_{0}\right)\right\}$ defines in the space $C_{0}\left(K^{n}\right)$ a Fellerian Markov process.

In $[8,10]$ the theorem above is proved when (1.4) is replaced by the weaker assumption $B_{*}<\infty$, where $B_{*}=\sum\left|b_{d}\right|$ (note that $B_{*} \leq C_{n} B_{m_{*}}^{1 / 2}$ ).

The transition probability for the obtained Markov process in $C_{0}\left(K^{n}\right)$ is

$$
P_{t}(u, \Gamma)=\mathbb{P}\{u(t ; u) \in \Gamma\}, \quad u \in C_{0}\left(K^{n}\right), \Gamma \in \mathscr{B}\left(C_{0}\left(K^{n}\right)\right),
$$

and the corresponding Markov semigroup in the space $\mathscr{P}\left(C_{0}\left(K^{n}\right)\right)$ of Borel measures on $C_{0}\left(K^{n}\right)$ is formed by the operators $\left\{\mathcal{B}_{t}^{*}, t \geq 0\right\}$,

$$
\mathcal{B}_{t}^{*} \mu(\Gamma)=\int_{C_{0}\left(K^{n}\right)} P_{t}(u, \Gamma) \mu(d u), \quad t \in \mathbb{R} .
$$

Then $\mathcal{B}_{t}^{*} \mu=\mathcal{D} u\left(t ; u_{0}\right)$ if $u_{0}$ is a r.v., independent from $\xi$ and such that $\mathcal{D}\left(u_{0}\right)=\mu$.
Introducing the slow time $\tau=\nu t$ and denoting $v(\tau, x)=u\left(\frac{\tau}{\nu}, x\right)$, we rewrite eq. (1.1) in the following form, more convenient for some calculations:

$$
\begin{equation*}
\frac{\partial v}{\partial \tau}-\Delta v+i \nu^{-1}|v|^{2} v=\tilde{\eta}(\tau, x) \tag{2.1}
\end{equation*}
$$

where

$$
\tilde{\eta}(\tau, x)=\frac{\partial}{\partial \tau} \tilde{\xi}(\tau, x), \quad \tilde{\xi}(\tau, x)=\sum_{d \in \mathbb{N}^{n}} b_{d} \tilde{\beta}_{d}(\tau) \varphi_{d}(x)
$$

and $\tilde{\beta}_{d}(\tau):=\nu^{1 / 2} \beta_{d}\left(\tau \nu^{-1}\right), d \in \mathbb{N}^{d}$, is another set of independent standard complex Brownian motions.

Let $\Upsilon \in C^{\infty}(\mathbb{R})$ be any smooth function such

$$
\Upsilon(r)= \begin{cases}0, & \text { for } r \leqslant \frac{1}{4} \\ r, & \text { for } r \geqslant \frac{1}{2}\end{cases}
$$

Writing $v \in \mathbb{C}$ in the polar form $v=r e^{i \Phi}$, where $r=|v|$, and recalling that $\langle\cdot, \cdot\rangle$ stands for the real scalar product in $\mathbb{C}$, we apply Itô's formula to $\Upsilon(|v|)$ and obtain that the process $\Upsilon(\tau):=\Upsilon(|v(\tau)|)$ satisfies

$$
\begin{align*}
\Upsilon(\tau)= & \Upsilon_{0}+\int_{0}^{\tau}\left[\Upsilon^{\prime}(r)\left(\nabla r-r|\nabla \Phi|^{2}\right)\right. \\
& \left.+\frac{1}{2} \sum_{d \in \mathbb{N}^{n}} b_{d}^{2}\left(\Upsilon^{\prime \prime}(r)\left\langle e^{i \Phi}, \varphi_{d}\right\rangle^{2}+\Upsilon^{\prime}(r) \frac{1}{r}\left(\left|\varphi_{d}\right|^{2}-\left\langle e^{i \Phi}, \varphi_{d}\right\rangle^{2}\right)\right)\right] d s+\mathbb{W}(\tau), \tag{2.2}
\end{align*}
$$

where $\Upsilon_{0}=\Upsilon(|v(0)|)$ and $\mathbb{W}(\tau)$ is the stochastic integral

$$
\mathbb{W}(\tau)=\sum_{d \in \mathbb{N}^{n}} \int_{0}^{\tau} \Upsilon^{\prime}(r) b_{d} \varphi_{d}\left\langle e^{i \Phi}, d \tilde{\beta}_{d}(s)\right\rangle
$$

In [10] eq. (2.1) is considered with $\nu=1$ and, following [8], the norm $|v(t)|_{\infty}$ of a solution $v$ is estimated via $\Upsilon(t)$ (since $|v| \leq \Upsilon+1 / 2)$. But the nonlinear term $i \nu^{-1}|v|^{2} v$ does not contribute to eq. (2.2), which is the same as the $\Upsilon$-equation (2.3) in [10] (and as the corresponding equation in [8, Section 3.1]). So the estimates on $|\Upsilon(t)|_{\infty}$ and the resulting estimates on $|v(t)|_{\infty}$, obtained in [10], remain true for solutions of (2.1) with any $\nu$. Thus we get the following upper bound for quadratic exponential moments of the $L_{\infty}$-norms of solutions: ${ }^{2}$

[^1]Theorem 7. For any $T>0$ there are constants $c_{*}>0$ and $C>0$, depending only on $B_{*}$ and $T$, such that for any r.v. $v_{0}^{\omega} \in C_{0}\left(K^{n}\right)$ as in Definition 5, any $\tau \geqslant 0$ and any $c \in\left(0, c_{*}\right]$, a solution $v\left(\tau ; v_{0}\right)$ of eq. (2.1) satisfies

$$
\begin{equation*}
\mathbb{E} \exp \left(c \sup _{\tau \leqslant s \leqslant \tau+T}|v(s)|_{\infty}^{2}\right) \leqslant C \mathbb{E} \exp \left(5 c\left|v_{0}\right|_{\infty}^{2}\right) \leq \infty . \tag{2.3}
\end{equation*}
$$

In [10] the result above is proved for a deterministic initial data $v_{0}$. The theorem's assertion follows by averaging the result of [10] in $v_{0}^{\omega}$.

The estimate (2.3) is crucial for derivation of further properties of solutions, including the given below upper bounds for their Sobolev norms, obtained in the work [8]. Since the scaling of the equation in [8] differs from that in (2.1) and the result there is a bit less general than in the theorem below, a sketch of the proof is given in Appendix B.

Theorem 8. Assume that $B_{m}<\infty$ for some $m \in \mathbb{N}$, and $v_{0}=v_{0}^{\nu} \in H^{m} \cap C_{0}\left(K^{n}\right)$ satisfies

$$
\left|v_{0}\right|_{\infty} \leq M, \quad\left\|v_{0}\right\|_{m} \leq M_{m} \nu^{-m}, \quad 0<\nu \leq 1 .
$$

Then

$$
\begin{equation*}
\mathbb{E}\left\|v\left(\tau ; v_{0}\right)\right\|_{m}^{2} \leqslant C_{m} \nu^{-m}, \quad \forall \tau \in[0, \infty) \tag{2.4}
\end{equation*}
$$

where $C_{M, m}$ also depends on $M, M_{m}$ and $B_{m}, B_{m_{*}}$.
Neglecting the dependence on $\nu$, we have that if $B_{m}<\infty, m \in \mathbb{N}$, and a r.v. $v_{0}^{\omega} \in H^{m} \cap C_{0}\left(K^{n}\right)$ satisfies $\mathbb{E}\left\|v_{0}\right\|_{m}^{2}<\infty$ and $\mathbb{E} \exp \left(c\left|v_{0}\right|_{\infty}^{2}\right)<\infty$ for some $c>0$, then eq. (2.1) has a solution, equal $v_{0}$ at $t=0$, such that

$$
\begin{gather*}
\mathbb{E}\left\|v\left(\tau ; v_{0}\right)\right\|_{m}^{2} \leq e^{-t} \mathbb{E}\left\|v_{0}\right\|_{m}^{2}+C, \quad \tau \geq 0,  \tag{2.5}\\
\mathbb{E} \sup _{0 \leq \tau \leq T}\left\|v\left(\tau ; v_{0}\right)\right\|_{m}^{2} \leq C^{\prime}, \tag{2.6}
\end{gather*}
$$

where $C>0$ depend on $c, \nu, \mathbb{E} \exp \left(c\left|v_{0}\right|_{\infty}^{2}\right), B_{m_{*}}$ and $B_{m}$, while $C^{\prime}$ also depends on $\mathbb{E}\left\|v_{0}\right\|_{m}^{2}<\infty$ and $T$. See Appendix B.

As it is shown in [10], the estimate (2.3) jointly with an abstract theorem from [11], imply that under a mild nondegeneracy assumption on the random force the Markov process in the space $C_{0}\left(K^{n}\right)$, constructed in Theorem 6, is mixing:

Theorem 9. For each $\nu>0$, there is an integer $N=N\left(B_{*}, \nu\right)>0$ such that if $b_{d} \neq 0$ for $|d| \leqslant N$, then the equation (1.1) is mixing. I.e. it has a unique stationary measure $\mu_{\nu} \in \mathscr{P}\left(C_{0}\left(K^{n}\right)\right)$, and for any probability measure $\lambda \in \mathscr{P}\left(C_{0}\left(K^{n}\right)\right)$ we have $\mathcal{B}_{t}^{*} \lambda \rightarrow \mu_{\nu}$ as $t \rightarrow \infty$.

Under the assumption of Theorem 8, for any $u_{0} \in H^{m}$ the law $\mathcal{D} u\left(t ; u_{0}\right)$ of a solution $u\left(t ; u_{0}\right)$ is a measure in $H^{m}$. The mixing property in Theorem 9 and (2.4) easily imply

Corollary 10. If under the assumptions of Theorem $9 B_{m}<\infty$ for some $m \in \mathbb{N}$ and $u_{0} \in H^{m}$, then $\mathcal{D}\left(u\left(t ; u_{0}\right)\right) \rightarrow \mu_{\nu}$ in $\mathcal{P}\left(H^{m}\right)$.

In view of Theorems 7,8 with $v_{0}=0$ and the established mixing, we have:
Corollary 11. Under the assumptions of Theorem 9, if $v^{s t}(\tau)$ is the stationary solution of the equation, then

$$
\mathbb{E} \exp \left(c_{*} \sup _{\tau \leqslant s \leqslant \tau+T}\left|v^{s t}(s)\right|_{\infty}^{2}\right) \leqslant \mathcal{C}
$$

where the constant $\mathcal{C}>0$ depends only on $T$ and $B_{*}$. If in addition $B_{m}<\infty$ for some $m \in \mathbb{N} \cup\{0\}$, then $\mathbb{E}\left\|v^{s t}(\tau)\right\|_{m}^{2} \leqslant C_{m} \nu^{-m}$, where $C_{m}$ depends on $B_{*}$ and $B_{m}$.

Finally we note that applying Itô's formula to $\left\|v^{s t}(\tau)\right\|_{0}^{2}$, where $v^{s t}$ is a stationary solution of (2.1), and taking the expectation we get the balance relation

$$
\begin{equation*}
\mathbb{E}\left\|v^{s t}(\tau)\right\|_{1}^{2}=B_{0} \tag{2.7}
\end{equation*}
$$

We cannot prove that $\mathbb{E}\left\|v^{s t}(\tau)\right\|_{0}^{2} \geq B^{\prime}>0$ for some $\nu$-independent constant $B^{\prime}$, and cannot bound from below the energy $\frac{1}{2} \mathbb{E}\left\|v\left(\tau ; v_{0}\right)\right\|_{0}^{2}$ of a solution $v$ by a positive $\nu$-independent quantity. Instead in next section we get a weaker conditional lower bound on the energies of solutions.

## 3. CONDITIONAL LOWER BOUND FOR THE $L^{2}$-NORM OF SOLUTIONS

In this section we prove the following result:
Lemma 12. Let $B_{2}<\infty$ and $u\left(\tau ; u_{0}\right)$, where $u_{0} \in H^{2} \cap C_{0}\left(K^{n}\right)$ is non-random, be a solution of eq. (2.1). Take any constants $\chi>0, \Gamma \geq 1, \tau_{0} \geq 0$, and define the stopping time

$$
\tau_{\Gamma}:=\inf \left\{\tau \geq \tau_{0}:\|u(\tau)\|_{2} \geqslant \Gamma\right\}
$$

(as usual, $\tau_{\Gamma}=\infty$ if the set under the inf-sign is empty). Then

$$
\begin{equation*}
\mathbb{E} \int_{\tau_{0}}^{\tau \wedge \tau_{\Gamma}} \mathbb{I}_{[0, \chi]}\left(\|u(s)\|_{0}\right) d s \leqslant 2\left(1+\tau-\tau_{0}\right) B_{0}^{-1} \chi \Gamma \tag{3.1}
\end{equation*}
$$

for any $\tau>\tau_{0}$.
Proof. We establish the result by adapting the proof from [16] (also see [11, Theorem 5.2.12]) to non-stationary solutions. The argument relies on the concept of local time for semi-martingales (see e.g. [14, Chapter VI.1] for details of the concept). By $[\cdot]_{b}$ we denote the quasinorm $[u]_{b}^{2}=\sum_{d}\left|u_{d}\right|^{2} b_{d}^{2}$.

Without loss of generality we assume $\tau_{0}=0$. Otherwise we just need to replace $u(\tau, x)$ by the process $\tilde{u}(\tau, x):=u\left(\tau+\tau_{0}, x\right)$, apply the lemma with $\tau_{0}=0$ and with $u_{0}$ replaced by the initial data $\tilde{u}_{0}^{\omega}=u^{\omega}\left(\tau_{0} ; u_{0}\right)$, and then average the estimate in the random $\tilde{u}_{0}^{\omega}$.

Let us write the solution $u\left(\tau ; u_{0}\right)$ as $u(\tau)=\sum_{d \in \mathbb{N}^{n}} u_{d}(\tau) \varphi_{d}$. For any fixed function $g \in C^{2}(\mathbb{R})$, consider the process

$$
f(\tau)=g\left(\left\|u\left(\tau \wedge \tau_{\Gamma}\right)\right\|_{0}^{2}\right)
$$

Since

$$
\left.\left.\left.\left.\partial_{u} g\left(\|u\|_{0}^{2}\right)=2 g^{\prime}\left(\|u\|_{0}^{2}\right)\langle u u, \cdot\rangle\right\rangle, \quad \partial_{u u} g\left(\|u\|_{0}^{2}\right)=4 g^{\prime \prime}\left(\|u\|_{0}^{2}\right)\langle u u, \cdot\rangle\right\rangle\langle u, \cdot\rangle\right\rangle+2 g^{\prime}\left(\|u\|_{0}^{2}\right)\langle\cdot \cdot, \cdot\rangle\right\rangle,
$$

then by Itô's formula we have

$$
\begin{equation*}
f(\tau)=f(0)+\int_{0}^{\tau \wedge \tau_{\Gamma}} A(s) d s+\sum_{d \in \mathbb{N}^{n}} b_{d} \int_{0}^{\tau \wedge \tau_{\Gamma}} 2 g^{\prime}\left(\|u(s)\|_{0}^{2}\right)\left\langle u_{d}(s), d \beta_{d}(s)\right\rangle \tag{3.2}
\end{equation*}
$$

where

$$
\begin{align*}
A(s) & =2 g^{\prime}\left(\|u\|_{0}^{2}\right)\left\langle\left.\left\langle u, \Delta u-\frac{1}{\nu} i\right| u\right|^{2} u\right\rangle+2 \sum_{d} b_{d}^{2}\left(g^{\prime \prime}\left(\|u\|_{0}^{2}\right)\left|u_{d}\right|^{2}+g^{\prime}\left(\|u\|_{0}^{2}\right)\right)  \tag{3.3}\\
& =-2 g^{\prime}\left(\|u\|_{0}^{2}\right)\|u\|_{1}^{2}+2 g^{\prime \prime}\left(\|u\|_{0}^{2}\right)[u]_{b}^{2}+2 g^{\prime}\left(\|u\|_{0}^{2}\right) B_{0}, \quad u=u(s)
\end{align*}
$$

Step 1: We firstly show that for any bounded measurable set $G \subset \mathbb{R}$, denoting by $\mathbb{I}_{G}$ its indicator function, we have the following equality

$$
\begin{align*}
2 \mathbb{E} \int_{0}^{\tau \wedge \tau_{\Gamma}} & \mathbb{I}_{G}(f(s))\left(g^{\prime}\left(\|u(s)\|_{0}^{2}\right)\right)^{2}[u(s)]_{b}^{2} d s=\int_{-\infty}^{\infty} \mathbb{I}_{G}(a)  \tag{3.4}\\
& {\left[\mathbb{E}(f(\tau)-a)_{+}-\mathbb{E}(f(0)-a)_{+}-\mathbb{E} \int_{0}^{\tau \wedge \tau_{\Gamma}} \mathbb{I}_{(a+\infty)}(f(s)) A(s) d s\right] d a . }
\end{align*}
$$

Let $L(\tau, a),(\tau, a) \in[0, \infty) \times \mathbb{R}$, be the local time for the semi martingale $f(\tau)$ (see e.g. [14, Chapter VI.1]). Since in view of (3.2) the quadratic variation of the process $f(\tau)$ is

$$
d\langle f, f\rangle_{s}=\sum_{d}\left(2 g^{\prime}\left(\|u\|_{0}^{2}\right)\left|u_{d}\right| b_{d}\right)^{2}=4\left(g^{\prime}\left(\|u\|_{0}^{2}\right)\right)^{2}[u]_{b}^{2}
$$

then for any bounded measurable set $G \subset \mathbb{R}$, we have the following equality (known as the occupation time formula, see [14, Corollary VI.1.6]),

$$
\begin{equation*}
\int_{0}^{\tau \wedge \tau_{\Gamma}} \mathbb{I}_{G}(f(s)) 4\left(g^{\prime}\left(\|u(s)\|_{0}^{2}\right)\right)^{2}[u(s)]_{b}^{2} d s=\int_{-\infty}^{\infty} \mathbb{I}_{G}(a) L(\tau, a) d a \tag{3.5}
\end{equation*}
$$

For the local time $L(\tau, a)$, due to Tanaka's formula (see [14, Theorem VI.1.2]) we have

$$
\begin{align*}
(f(\tau)-a)_{+}= & (f(0)-a)_{+} \\
& +\sum_{d \in \mathbb{N}^{n}} b_{d} \int_{0}^{\tau \wedge \tau_{\Gamma}} \mathbb{I}_{(a,+\infty)}(f(s)) 2 g^{\prime}\left(\|u(s)\|_{0}^{2}\right)\left\langle u_{d}(s), d \beta_{d}(s)\right\rangle  \tag{3.6}\\
& +\int_{0}^{\tau \wedge \tau_{\Gamma}} \mathbb{I}_{(a,+\infty)}(f(s)) A(s) d s+\frac{1}{2} L(\tau, a) .
\end{align*}
$$

Taking expectation of both sides of (3.5) and (3.6) we obtain the required equality (3.4).

Step 2: Let us choose $G=\left[\rho_{0}, \rho_{1}\right]$ with $\rho_{1}>\rho_{0}>0$, and $g(x)=g_{\rho_{0}}(x) \in C^{2}(\mathbb{R})$ such that $g^{\prime}(x) \geqslant 0, g(x)=\sqrt{x}$ for $x \geqslant \rho_{0}$ and $g(x)=0$ for $x \leqslant 0$. Then due to the factors $\mathbb{I}_{G}(f)$ and $\mathbb{I}_{G}(a)$ in (3.4), we may there replace $g(x)$ by $\sqrt{x}$, and accordingly replace $g\left(\|u\|_{0}^{2}\right), g^{\prime}\left(\|u\|_{0}^{2}\right)$ and $g^{\prime \prime}\left(\|u\|_{0}^{2}\right)$ by $\|u\|_{0}, \frac{1}{2}\|u\|_{0}^{-1}$ and $-\frac{1}{4}\|u\|_{0}^{-3}$. So the relation (3.4) takes the form

$$
\begin{aligned}
& \mathbb{E} \int_{0}^{\tau \wedge \tau_{\Gamma}} \mathbb{I}_{G}(f(s))\|u(s)\|_{0}^{-2}[u(s)]_{b}^{2}=2 \int_{\rho_{0}}^{\rho_{1}}\left[\mathbb{E}(f(\tau)-a)_{+}-\mathbb{E}(f(0)-a)_{+}\right] d a \\
& -2 \int_{\rho_{0}}^{\rho_{1}}\left\{\mathbb{E} \int_{0}^{\tau \wedge \tau_{\Gamma}} \mathbb{I}_{(a,+\infty)}(f(s))\left[\frac{2}{2\|u(s)\|_{0}}\left(B_{0}-\|u(s)\|_{1}^{2}\right)-\frac{2}{4\|u(s)\|_{0}^{3}}[u(s)]_{b}^{2}\right] d s\right\} d a .
\end{aligned}
$$

Since the l.h.s. of the above equality is non-negative, we have

$$
\begin{align*}
& \int_{\rho_{0}}^{\rho_{1}}\left[\mathbb{E} \int_{0}^{\tau \wedge \tau_{\Gamma}} \mathbb{I}_{(a,+\infty)}(f(s)) \frac{1}{\|u(s)\|_{0}^{3}}\left(B_{0}\|u(s)\|_{0}^{2}-\frac{1}{2}[u(s)]_{b}^{2}\right) d s\right] d a \\
& \leqslant \int_{\rho_{0}}^{\rho_{1}} \mathbb{E}\left[\left((f(\tau)-a)_{+}-(f(0)-a)_{+}\right)+\int_{0}^{\tau \wedge \tau_{\Gamma}} \mathbb{I}_{(a,+\infty)}(f(s)) \frac{\|u(s)\|_{1}^{2}}{\|u(s)\|_{0}} d s\right] d a . \tag{3.7}
\end{align*}
$$

Noting that

$$
B_{0}\|u\|_{0}^{2}-\frac{1}{2}[u(s)]_{b}^{2}=\sum_{d \in \mathbb{N}^{n}}\left(B_{0}-\frac{1}{2} b_{d}^{2}\right)\left|u_{d}\right|^{2} \geqslant \frac{B_{0}}{2}\|u\|_{0}^{2}
$$

that by the definition of the stopping time $\tau_{\Gamma}$

$$
(f(\tau)-a)_{+}-(f(0)-a)_{+} \leqslant \Gamma
$$

and that by interpolation,

$$
\int_{0}^{\tau \wedge \tau_{\Gamma}} \frac{\|u(s)\|_{1}^{2}}{\|u(s)\|_{0}} d s \leqslant \int_{0}^{\tau \wedge \tau_{\Gamma}}\|u(s)\|_{2} d s \leqslant\left(\tau \wedge \tau_{\Gamma}\right) \Gamma
$$

we derive from (3.7) the relation

$$
\frac{B_{0}}{2} \int_{\rho_{0}}^{\rho_{1}}\left(\mathbb{E} \int_{0}^{\tau \wedge \tau_{\Gamma}} \mathbb{I}_{(a,+\infty)}(f(s))\|u(s)\|_{0}^{-1} d s\right) d a \leq\left(\rho_{1}-\rho_{0}\right) \Gamma(1+\tau)
$$

When $\rho_{0} \rightarrow 0$, we have $g(x) \rightarrow \sqrt{x}$ and $f(\tau) \rightarrow\left\|u\left(\tau \wedge \tau_{\Gamma}\right)\right\|_{0}$. So sending $\rho_{0}$ to 0 and using Fatou's lemma we get from the last estimate that

$$
\int_{0}^{\rho_{1}} \mathbb{E} \int_{0}^{\tau \wedge \tau_{\Gamma}} \mathbb{I}_{(a, \infty)}\left(\|u(s)\|_{0}\right)\|u(s)\|_{0}^{-1} d s d a \leqslant 2 \rho_{1}(1+\tau) B_{0}^{-1} \Gamma
$$

As the l.h.s. above is not smaller than

$$
\frac{1}{\chi} \int_{0}^{\rho_{1}} \mathbb{E} \int_{0}^{\tau \wedge \tau_{\Gamma}} \mathbb{I}_{(a, \chi]}\left(\|u(s)\|_{0}\right) d s d a
$$

then

$$
\begin{equation*}
\frac{1}{\rho_{1}} \int_{0}^{\rho_{1}} \mathbb{E} \int_{0}^{\tau \wedge \tau_{\Gamma}} \mathbb{I}_{(a, \chi]}\left(\|u(s)\|_{0}\right) d s d a \leqslant 2(1+\tau) B_{0}^{-1} \Gamma \chi \tag{3.8}
\end{equation*}
$$

By the monotone convergence theorem

$$
\lim _{a \rightarrow 0} \mathbb{E} \int_{0}^{\tau \wedge \tau_{\Gamma}} \mathbb{I}_{(a, \chi]}\left(\|u(s)\|_{0}\right) d s=\mathbb{E} \int_{0}^{\tau \wedge \tau_{\Gamma}} \mathbb{I}_{(0, \chi]}\left(\|u(s)\|_{0}\right) d s
$$

so we get from (3.8) that

$$
\begin{equation*}
\mathbb{E} \int_{0}^{\tau \wedge \tau_{\Gamma}} \mathbb{I}_{(0, \chi]}\left(\|u(s)\|_{0}\right) d s \leqslant 2(1+\tau) B_{0}^{-1} \Gamma \chi \tag{3.9}
\end{equation*}
$$

Step 3: We continue to verify that

$$
\begin{equation*}
\mathbb{E} \int_{0}^{\tau \wedge \tau_{\Gamma}} \mathbb{I}_{\{0\}}\left(\|u(s)\|_{0}\right) d s=0 \tag{3.10}
\end{equation*}
$$

To do this let us fix any index $d \in \mathbb{N}^{n}$ such that $b_{d} \neq 0$. The process $u_{d}(\tau)$ is a semimartingale, $d u_{d}=v_{d} d s+b_{d} d \beta_{d}$, where $v_{d}(s)$ is the $d$-th Fourier coefficient of $\Delta u+\frac{1}{\nu} i|u|^{2} u$ for the solution $u(\tau)=\sum_{d} u_{d}(\tau) \varphi_{d}$ which we discuss. Consider the stopping time

$$
\tau_{R}=\inf \left\{s \leq \tau \wedge \tau_{\Gamma}:|u(s)|_{\infty} \geq R\right\} .
$$

Due to (2.3) and (2.6), $\mathbb{P}\left(\tau_{R}=\tau \wedge \tau_{\Gamma}\right) \rightarrow 1$ as $R \rightarrow \infty$. Let us denote $u_{d}^{R}(\tau)=$ $u_{d}\left(\tau \wedge \tau_{R}\right)$. To prove (3.10) it suffices to verify that

$$
\pi(\delta):=\mathbb{E} \int_{0}^{\tau \wedge \tau_{\tau}} \mathbb{I}_{\left\{\left|u_{d}(s)\right|<\delta\right\}} d s \rightarrow 0 \quad \text { as } \quad \delta \rightarrow 0
$$

If we replace above $u_{d}$ by $u_{d}^{R}$, then the obtained new quantity $\pi^{R}(\delta)$ differs from $\pi(\delta)$ at most by $\mathbb{P}\left(\tau_{R}<\tau \wedge \tau_{\Gamma}\right)$. The process $u_{d}^{R}$ is an Ito process with a bounded drift. So by [7, Theorem 2.2 .2 , p. 52], $\pi^{R}(\delta)$ goes to zero with $\delta$. Thus, given any $\varepsilon>0$, we firstly choose $R$ sufficiently big and then $\delta$ sufficiently small to achieve $\pi(\delta)<\varepsilon$, for a suitable $\delta(\varepsilon)>0$. So (3.10) is verified. Jointly with (3.9) this proves (3.1).

## 4. Lower bounds for Sobolev norms of solutions

In this section we work with eq. (1.1) in the original time scale $t$ and provide lower bounds for the $H^{m}$-norms of its solutions with $m>2$. This will prove the assertion (1) of Theorem 1. As always, the constants do not depend on $\nu$, unless otherwise stated.

Theorem 13. For any integer $m \geqslant 3$, if $B_{m}<\infty$ and

$$
0<\kappa<\frac{1}{35}, \quad T_{0} \geq 0, \quad T_{1}>0,
$$

then for any r.v. $u_{0}(x) \in H^{m} \cap C_{0}\left(K^{n}\right)$, satisfying

$$
\begin{equation*}
\mathbb{E}\left\|u_{0}\right\|_{m}^{2}<\infty, \quad \mathbb{E} \exp \left(c\left|u_{0}\right|_{\infty}^{2}\right) \leq C<\infty \tag{4.1}
\end{equation*}
$$

for some $c, C>0$, we have

$$
\begin{equation*}
\mathbb{P}\left\{\sup _{T_{0} \leq t \leq T_{0}+T_{1} \nu^{-1}}\left\|u\left(t ; u_{0}\right)\right\|_{m} \geq K \nu^{-m \kappa}\right\} \rightarrow 1 \quad \text { as } \quad \nu \rightarrow 0 \tag{4.2}
\end{equation*}
$$

for every $K>0$.
Proof. Consider the complement to the event in (4.2):

$$
Q^{\nu}=\left\{\sup _{T_{0} \leqslant t \leqslant T_{0}+\frac{T_{1}}{\nu}}\|u(t)\|_{m}<K \nu^{-m \kappa}\right\} .
$$

We will prove the assertion (4.2) by contradiction. Namely, we assume that there exists a $\gamma>0$ and a sequence $\nu_{j} \rightarrow 0$ such that

$$
\begin{equation*}
\mathbb{P}\left(Q^{\nu_{j}}\right) \geqslant 5 \gamma \quad \text { for } \quad j=1,2, \ldots \tag{4.3}
\end{equation*}
$$

and will derive a contradiction. Below we write $Q^{\nu_{j}}$ as $Q$ and always suppose that

$$
\nu \in\left\{\nu_{1}, \nu_{2}, \ldots\right\} .
$$

The constants in the proof may depend on $\mathcal{K}, K, \gamma, B_{m \vee m_{*}}$, but not on $\nu$.
Without lost of generality we assume that $T_{1}=1$. For any $T_{0}>0$, due to (2.5) and (2.3) the r.v. $\tilde{u}_{0}:=u\left(T_{1}\right)$ satisfies (4.1) with $c$ replaced by $c / 5$. So considering $\tilde{u}(t, x)=u\left(t+T_{0}, x\right)$ we may assume that $T_{0}=0$.

Let us denote $J_{1}=\left[0, \frac{1}{\nu}\right]$. Due to Theorem 7,

$$
\mathbb{P}\left(Q_{1}\right) \geqslant 1-\gamma, \quad Q_{1}=\left\{\sup _{t \in J_{1}}|u(t)|_{\infty} \leqslant C_{1}(\gamma)\right\},
$$

uniformly in $\nu$, for a suitable $C_{1}(\gamma)$. Then, by the definition of $Q$ and Sobolev's interpolation,

$$
\begin{equation*}
\left\|u^{\omega}(t)\right\|_{l} \leqslant C_{l, \gamma} \nu^{-l \kappa}, \quad \omega \in Q \cap Q_{1}, t \in J_{1} \tag{4.4}
\end{equation*}
$$

for $l \in[0, m]$ (and any $\nu \in\left\{\nu_{1}, \nu_{2}, \ldots\right\}$ ).
Denote $J_{2}=\left[0, \frac{1}{2 \nu}\right]$ and consider the stopping time

$$
\tau_{1}=\inf \left\{t \in J_{2}:\|u(t)\|_{2} \geqslant C_{2, \gamma} \nu^{-2 \kappa}\right\} \leq \frac{1}{2 \nu} .
$$

Then $\tau_{1}=\frac{1}{2 \nu}$ for $\omega \in Q \cap Q_{1}$. So due to (3.1) with $\Gamma=C_{2, \gamma} \nu^{-2 \kappa}$, for any $\chi>0$, we have

$$
\begin{aligned}
\mathbb{E}\left(\nu \int_{J_{2}} \mathbb{I}_{[0, \chi]}\left(\|u(s)\|_{0}\right) d s \mathbb{I}_{Q \cap Q_{1}}(\omega)\right) & =\mathbb{E}\left(\nu \int_{0}^{\frac{1}{2 \nu} \wedge \tau_{1}} \mathbb{I}_{[0, \chi]}\left(\|u(s)\|_{0}\right) d s \mathbb{I}_{Q \cap Q_{1}}(\omega)\right) \\
& \leqslant \mathbb{E}\left(\nu \int_{0}^{\frac{1}{2 \nu} \wedge \tau_{1}} \mathbb{I}_{[0, \chi]}\left(\|u(s)\|_{0}\right) d s\right) \leqslant C \nu^{-2 \kappa} \chi .
\end{aligned}
$$

Consider the event

$$
\Lambda=\left\{\omega \in Q \cap Q_{1}:\|u(s)\|_{0} \leqslant \chi, \forall s \in J_{2}\right\}
$$

Due to the above, we have,

$$
\mathbb{P}(\Lambda) \leqslant 2 \mathbb{E}\left(\nu \int_{J_{2}} \mathbb{I}_{[0, \chi]}\left(\|u(s)\|_{0}\right) d s \mathbb{I}_{Q \cap Q_{1}}(\omega)\right) \leqslant 2 C \nu^{-2 \kappa} \chi
$$

So $\mathbb{P}(\Lambda) \leqslant \gamma$ if we choose

$$
\begin{equation*}
\chi=c_{3}(\gamma) \nu^{2 \kappa}, \quad c_{3}(\gamma)=\gamma(2 C)^{-1} \tag{4.5}
\end{equation*}
$$

Let us set

$$
\begin{equation*}
Q_{2}=\left(Q \cap Q_{1}\right) \backslash \Lambda, \quad \mathbb{P}\left(Q_{2}\right) \geqslant 3 \gamma, \tag{4.6}
\end{equation*}
$$

and for $\chi$ as in (4.5), consider the stopping time

$$
\tilde{\tau}_{1}=\inf \left\{t \in J_{2}:\|u(t)\|_{0} \geqslant \chi\right\}
$$

Then $\tilde{\tau}_{1} \leqslant \frac{1}{2 \nu}$ for all $\omega \in Q_{2}$. Consider the function

$$
v(t, x):=u\left(\tilde{\tau}_{1}+t, x\right), \quad t \in\left[0, \frac{1}{2 \nu}\right] .
$$

It solves eq. (1.1) with modified Wiener processes and with initial data $v_{0}(x)=$ $u^{\omega}\left(\tilde{\tau}_{1}, x\right)$, satisfying

$$
\begin{equation*}
\left\|v_{0}^{\omega}\right\|_{0} \geq \chi=c \nu^{2 \kappa} \quad \text { if } \quad \omega \in Q_{2} \tag{4.7}
\end{equation*}
$$

Now we introduce another stopping time, in terms of $v(t, x)$ :

$$
\tau_{2}=\inf \left\{t \in\left[0, \frac{1}{2 \nu}\right]:\|v(t)\|_{m} \geqslant K \nu^{-m \kappa}\right\} \leq \frac{1}{2 \nu}
$$

For $\omega \in Q_{2}, \tau_{2}=\frac{1}{2 \nu}$ and in view of (4.4)

$$
\begin{equation*}
\left\|v^{\omega}(t)\right\|_{l} \leqslant C_{3}(\gamma) \nu^{-l \kappa}, \quad t \in\left[0, \frac{1}{2 \nu}\right], l \in[0, m], \quad \forall \omega \in Q_{2} . \tag{4.8}
\end{equation*}
$$

Step 1: Let us estimate from above the increment $\mathscr{E}(t, x)=\left|v\left(t \wedge \tau_{2}, x\right)\right|^{2}-\left|v_{0}(x)\right|^{2}$. Due to Itô's formula, we have that

$$
\begin{gathered}
\mathscr{E}(t, x)=2 \nu \int_{0}^{t \wedge \tau_{2}}\left(\langle v(s, x), \Delta v(s, x)\rangle+\sum_{d \in \mathbb{N}^{n}} b_{d}^{2} \varphi_{d}^{2}(x)\right) d s+\sqrt{\nu} M(t, x) \\
M(t, x)=\int_{0}^{t \wedge \tau_{2}} \sum_{d \in \mathbb{N}^{n}} b_{d} \varphi_{d}(x)\left\langle v(s, x), d \beta_{d}(s)\right\rangle
\end{gathered}
$$

We treat $M$ as a martingale $M(t)$ in the space $H^{1}$. Since in view of (A.3) for $0 \leq s<\tau_{2}$ we have

$$
\left\|v(s) \varphi_{d}\right\|_{1} \leq C\left(|v(s)|_{\infty}\left\|\varphi_{d}\right\|_{1}+\left.\left|v(s) \|_{1}\right| \varphi_{d}\right|_{\infty}\right) \leq C\left(\zeta d+\zeta^{(m-1) / m} \nu^{-\kappa}\right)
$$

where $\zeta=\sup _{0 \leqslant s \leqslant \frac{1}{\nu}}|u(s)|_{\infty}$ (the assertion is empty if $\tau_{2}=0$ ), then for any $0<T_{*} \leq \frac{1}{2 \nu}$

$$
\begin{equation*}
\mathbb{E}\left\|M\left(T_{*}\right)\right\|_{1}^{2} \leq \int_{0}^{T_{*}} \mathbb{E} \sum_{d} b_{d}^{2}\left\|\varphi_{d} v(s)\right\|_{1}^{2} d s \leq C T_{\star} \nu^{-2 \kappa} \tag{4.9}
\end{equation*}
$$

where we used that $B_{1}<\infty$. So by Doob's inequality

$$
\begin{equation*}
\mathbb{P}\left(\sup _{0 \leqslant s \leqslant T_{*}}\|M(s)\|_{1}^{2} \geqslant r^{2}\right) \leqslant C T_{*} r^{-2} \nu^{-2 \kappa}, \quad \forall r>0 . \tag{4.10}
\end{equation*}
$$

Let us choose

$$
T_{*}=\nu^{-b}, \quad b \in(0,1),
$$

where $b$ will be specified later. Then $1 \leq T_{*} \leq \frac{1}{2 \nu}$ if $\nu$ is sufficiently small, so due to (4.10)

$$
\mathbb{P}\left(Q_{3}\right) \geqslant 1-\gamma, \quad Q_{3}=\left\{\sup _{0 \leqslant \tau \leqslant T_{*}}\|M(\tau)\|_{1} \leqslant C_{4}(\gamma) \nu^{-\kappa} \sqrt{T_{*}}\right\},
$$

for a suitable $C_{4}(\gamma)$ (and for $\nu \ll 1$ ); thus $\mathbb{P}\left(Q_{2} \cap Q_{3}\right) \geq 2 \gamma$. Since $\|\langle v, \Delta v\rangle\|_{1} \leq$ $C|v|_{\infty}\|v\|_{3}$ by (A.2) and $\left\|\sum_{d} b_{d} \varphi_{d}\right\|_{1} \leq C$, then in view of (4.8) and the definition of $Q_{3}$,

$$
\begin{equation*}
\left\|\mathscr{E}^{\omega}(\tau)\right\|_{1} \leqslant C(\gamma)\left(\nu^{1-3 \kappa} T_{*}+\nu^{\frac{1}{2}-\kappa} T_{*}^{1 / 2}\right), \quad \forall \tau \in\left[0, T_{*}\right], \quad \forall \omega \in Q_{2} \cap Q_{3} . \tag{4.11}
\end{equation*}
$$

Step 2: For any $x \in K^{n}$, denoting $R(t)=|v(t, x)|^{2}, a(t)=\Delta v(t, x)$ and $\xi(t)=$ $\xi(t, x)$, we write the equation for $v(t):=v(t, x)$ as an Itô process:

$$
\begin{equation*}
d v(t)=(-i R v+\nu a) d t+\sqrt{\nu} d \xi(t) \tag{4.12}
\end{equation*}
$$

Setting $w(t)=e^{i \int_{0}^{t} R(s) d s} v(t)$, we observe that $w$ also is an Itô process, $w(0)=v_{0}$ and $d v=e^{-i \int_{0}^{t} R(s) d s} d w-i R v d t$. From here and (4.12),

$$
w(t)=v_{0}+\nu \int_{0}^{t} e^{i \int_{0}^{s} R\left(s^{\prime}\right) d s^{\prime}} a(s) d s+\sqrt{\nu} \int_{0}^{t} e^{i \int_{0}^{s} R\left(s^{\prime}\right) d s^{\prime}} d \xi(s) .
$$

So $v\left(t \wedge \tau_{2}\right)=v\left(t \wedge \tau_{2}, x\right)$ can be written as

$$
\begin{equation*}
v\left(t \wedge \tau_{2}, x\right)=I_{1}\left(t \wedge \tau_{2}, x\right)+I_{2}\left(t \wedge \tau_{2}, x\right)+I_{3}\left(t \wedge \tau_{2}, x\right) \tag{4.13}
\end{equation*}
$$

where

$$
\begin{array}{r}
I_{1}(t, x)=e^{-i \int_{0}^{t}|v(s, x)|^{2} d s} v_{0}, \quad I_{2}(t, x)=\nu \int_{0}^{t} e^{-i \int_{s}^{t}\left|v\left(s^{\prime}, x\right)\right|^{2} d s^{\prime}} \Delta v(s, x) d s \\
I_{3}(t, x)=\sqrt{\nu} e^{-i \int_{0}^{t}\left|v\left(s^{\prime}, x\right)\right|^{2} d s^{\prime}} \int_{0}^{t} e^{i \int_{0}^{s}\left|v\left(s^{\prime}, x\right)\right|^{2} d s^{\prime}} d \xi(s, x)
\end{array}
$$

Our next goal is to obtain a lower bound for $\left\|v\left(T_{*}\right)\right\|_{1}$ when $\omega \in Q_{2} \cap Q_{3}$, using the above decomposition (4.13).
Step 3: We first deal with the stochastic term $I_{3}(t)$. For $0 \leqslant s \leqslant s_{1} \leqslant T_{*} \wedge \tau_{2}$ we set

$$
\begin{equation*}
W\left(s, s_{1}, x\right):=\exp \left(i \int_{s}^{s_{1}}\left|v\left(s^{\prime}, x\right)\right|^{2} d s^{\prime}\right), \quad F\left(s, s_{1}, x\right):=\int_{s}^{s_{1}}\left|v\left(s^{\prime}, x\right)\right|^{2} d s^{\prime} \tag{4.14}
\end{equation*}
$$

then $W\left(s, s_{1}, x\right)=\exp \left(i F\left(s, s_{1}, x\right)\right)$. The functions $F$ and $W$ are periodic in $x$, but not odd. Speaking about them we understand $\|\cdot\|_{m}$ as the non-homogeneous Sobolev norm, so $\|F\|_{m}^{2}=\|F\|_{0}^{2}+\left\|(-\Delta)^{m / 2} F\right\|_{0}^{2}$, etc. We write $I_{3}$ as

$$
\begin{equation*}
I_{3}(t)=\sqrt{\nu} \bar{W}\left(0, t \wedge \tau_{2}, x\right) \int_{0}^{t \wedge \tau_{2}} W(0, s, x) d \xi(s, x) \tag{4.15}
\end{equation*}
$$

In view of (A.1),

$$
\begin{equation*}
\left\|\exp \left(i F\left(s, s_{1} \cdot\right)\right)\right\|_{k} \leq C_{k}\left(1+\left|F\left(s, s_{1}, \cdot\right)\right|_{\infty}\right)^{k-1}\left\|F\left(s, s_{1}, \cdot\right)\right\|_{k}, \quad k \in \mathbb{N} \tag{4.16}
\end{equation*}
$$

For any $s \in J=\left[0, T_{*} \wedge \tau_{2}\right.$ ), by (A.3) and the definition of $\tau_{2}$, we have that $v:=v(s)$ satisfies

$$
\begin{equation*}
\left\||v|^{2}\right\|_{1} \leq C|v|_{\infty}\|v\|_{1} \leq C|v|_{\infty}\|v\|_{0}^{1-1 / m}\|v\|_{m}^{1 / m} \leq C^{\prime}|v|_{\infty}^{2-1 / m} \nu^{-\kappa} \tag{4.17}
\end{equation*}
$$

(this assertion is empty if $\tau_{2}=0$ since then $J=\varnothing$ ). So for $s, s_{1} \in J$,
$\left|F\left(s, s_{1}, \cdot\right)\right|_{\infty} \leqslant\left|s_{1}-s\right| \sup _{s^{\prime} \in J}\left|v\left(s^{\prime}\right)\right|_{\infty}^{2}, \quad\left\|F\left(s, s_{1}, \cdot\right)\right\|_{k} \leq C \nu^{-\kappa k}\left|s_{1}-s\right|\left(\sup _{s^{\prime} \in J}\left|v\left(s^{\prime}\right)\right|_{\infty}\right)^{2-k / m}$ for $k \leq m$. Then, due to (4.16),

$$
\begin{equation*}
\left\|W\left(0, s \wedge \tau_{2}, \cdot\right)\right\|_{1} \leqslant C^{\prime} T_{*} \nu^{-\kappa}\left(1+\sup _{s \in J}|v(s)|_{\infty}^{2}\right) \tag{4.18}
\end{equation*}
$$

Consider the stochastic integral in (4.15),

$$
N(t, x)=\int_{0}^{t} W(0, s, x) d \xi(s, x)
$$

The process $t \mapsto W(0, t, x)$ is adapted to the filtration $\left\{\mathcal{F}_{t}\right\}$, and

$$
d W(0, t, x)=i|v(t, x)|^{2} W(0, t, x) d t .
$$

So integrating by parts (see, e.g., [14, Proposition IV.3.1]) we re-write $N$ as

$$
N(t, x)=W(0, t, x) \xi(t, x)-i \int_{0}^{t} \xi(s, x)|v(s, x)|^{2} W(0, s, x) d s
$$

and we see from (4.15) that

$$
\begin{equation*}
I_{3}(t)=\sqrt{\nu} \xi\left(t \wedge \tau_{2}, x\right)+i \sqrt{\nu} \int_{0}^{t \wedge \tau_{2}} \xi(s, x)|v(s, x)|^{2} W\left(s, t \wedge \tau_{2}, x\right) d s \tag{4.19}
\end{equation*}
$$

Due to (1.4) and since $B_{m}<\infty$, the Wiener process $\xi(t, x)$ satisfies

$$
\mathbb{E}\left\|\xi\left(T_{\star}, x\right)\right\|_{1}^{2} \leqslant C B_{1} T_{\star},
$$

and

$$
\mathbb{E} \sup _{0 \leqslant t \leqslant T_{*}}|\xi(t, \cdot)|_{\infty} \leqslant \sum_{d \in \mathbb{N}^{n}} b_{d}\left(\mathbb{E} \sup _{0 \leqslant t \leqslant T_{*}}\left|\beta_{d}(t) \varphi_{d}\right|_{\infty}\right) \leqslant C B_{*} \sqrt{T_{*}},
$$

(we recall that $B_{*}=\sum_{d \in \mathbb{N}^{n}}\left|b_{d}\right|<\infty$ ). Therefore,

$$
\mathbb{P}\left(Q_{4}\right) \geqslant 1-\gamma, \quad Q_{4}=\left\{\sup _{0 \leqslant t \leqslant T_{*}}\left(\|\xi(t)\|_{1} \vee|\xi(t)|_{\infty}\right) \leqslant C T_{*}^{1 / 2}\right\},
$$

with a suitable $C=C(\gamma)$. Let

$$
\tilde{Q}=\bigcap_{i=1}^{4} Q_{i}
$$

then $\mathbb{P}(\tilde{Q}) \geqslant \gamma$. As $\tau_{2}=T_{*}$ for $\omega \in \tilde{Q}$, then due to (4.17), (4.18), (4.19) and (A.3), for $\omega \in \tilde{Q}$ we have

$$
\begin{align*}
\sup _{0 \leqslant t \leqslant T_{*}}\left\|I_{3}^{\omega}(t)\right\|_{1} & \leq \sqrt{\nu} \sup _{0 \leqslant t \leqslant T_{*}}\left(\left\|\xi^{\omega}(t)\right\|_{1}+\int_{0}^{t}\left\|\xi^{\omega}(s)\left|v^{\omega}(s)\right|^{2} W^{\omega}(s, t)\right\|_{1} d s\right)  \tag{4.20}\\
& \leqslant C T_{*}^{5 / 2} \nu^{\frac{1}{2}-\kappa} .
\end{align*}
$$

Setp 4: We then consider the term $I_{2}=\nu \int_{0}^{t \wedge \tau_{2}} \bar{W}\left(s, t \wedge \tau_{2}, x\right) \Delta v(s, x) d s$. To bound its $H^{1}$-norm we need to estimate $\|W \Delta v\|_{1}$. Since

$$
\left\|\partial_{x}^{a} W \partial_{x}^{b} v\right\|_{0} \leqslant C\|W\|_{3}^{1 / 3}\|v\|_{3}^{2 / 3}|v|_{\infty}^{1 / 3} \quad \text { if }|a|=1,|b|=2
$$

(see [17, Proposition 3.6]), we have

$$
\|W \Delta v\|_{1} \leqslant C\left(\|v\|_{3}+\|W\|_{3}^{1 / 3}\|v\|_{3}^{2 / 3}|v|_{\infty}^{1 / 3}\right) .
$$

Then in view of (4.16) and (4.8), for $\omega \in \tilde{Q}$

$$
\|W \Delta v\|_{1} \leq C\left(\nu^{-3 \kappa}+\left(T_{*}^{3} \nu^{-3 \kappa}\right)^{1 / 3} \nu^{-2 \kappa}\right) \leq C \nu^{-3 \kappa} T_{*},
$$

and accordingly

$$
\begin{equation*}
\sup _{0 \leqslant t \leqslant T_{*}}\left\|I_{2}^{\omega}(t)\right\|_{1} \leqslant \nu \sup _{0 \leqslant t \leqslant T_{*}} \int_{0}^{t}\left\|W^{\omega}\left(s, T_{*}\right) \Delta v^{\omega}(s)\right\|_{1} d s \leqslant C \nu^{1-3 \kappa} T_{*}^{2}, \quad \forall \omega \in \tilde{Q} \tag{4.21}
\end{equation*}
$$

Step 5: Now we estimate from below the $H^{1}$-norm of the term $I_{1}^{\omega}\left(T_{\star}, x\right), \omega \in \tilde{Q}$. Writing it as $I_{1}^{\omega}\left(T_{*}, x\right)=e^{-i T_{*}\left|v_{0}(x)\right|^{2}} e^{-i \int_{0}^{T_{*}} \mathscr{E}(s, x) d s} v_{0}(x)$ wee see that

$$
\left\|I_{1}^{\omega}\left(T_{*}\right)\right\|_{1} \geqslant \| \nabla\left(\exp \left(-i T_{*}\left|v_{0}\right|^{2}\right) v_{0}\left\|_{0}-\right\| \nabla\left(\exp \left(-i \int_{0}^{T_{*}} \mathscr{E}(s) d s\right)\right) v_{0}\left\|_{0}-\right\| v_{0} \|_{1}\right.
$$

This first term on the r.h.s is

$$
T_{*}\left\|v_{0} \nabla\left(\left|v_{0}\right|^{2}\right)\right\|_{0}=T_{*} \frac{2}{3}\left\|\nabla\left|v_{0}\right|^{3}\right\|_{0} \geqslant C T_{*}\left\|\left|v_{0}\right|^{3}\right\|_{0} \geqslant C T_{*}\left\|v_{0}\right\|_{0}^{3} \geq C T_{*} \nu^{6 \kappa}, \quad C>0,
$$

where we have used the fact that $\left.u\right|_{\partial K^{n}}=0$, Poincaré's inequality and (4.7).
For $\omega \in \tilde{Q}$ and $0 \leq s \leq T_{\star}$, in view of (4.11), the second term is bounded by

$$
\left\|\left(\int_{0}^{T_{*}} \nabla \mathscr{E}(s) d s\right) v_{0}\right\|_{0} \leqslant C T_{*}\left|v_{0}\right|_{\infty} \sup _{0 \leqslant s \leqslant T_{*}}\|\mathscr{E}(s)\|_{1} \leq C T_{*}\left(\nu^{1-3 \kappa} T_{*}+\nu^{\frac{1}{2}-\kappa} T_{*}^{1 / 2}\right)
$$

Therefore, using (4.11), we get for the term $I_{1}^{\omega}\left(T_{*}\right)$ the following lower bound:

$$
\left\|I_{1}^{\omega}\left(T_{*}\right)\right\|_{1} \geqslant C\left(\nu^{6 \kappa} T_{*}-T_{*}\left(\nu^{1-3 \kappa} T_{*}+\nu^{\frac{1}{2}-\kappa} T_{*}^{1 / 2}\right)-\nu^{-\kappa}\right) .
$$

Recalling $T_{*}=\nu^{-b}$ we see that if we assume that

$$
\left\{\begin{array}{l}
6 \kappa-b<-\kappa  \tag{4.22}\\
6 \kappa-b<1-3 \kappa-2 b, \\
6 \kappa-b<1 / 2-\kappa-\frac{3}{2} b,
\end{array}\right.
$$

then for $\omega \in \tilde{Q}$,

$$
\begin{equation*}
\left\|I_{1}^{\omega}\left(T_{*}\right)\right\|_{1} \geqslant C \nu^{6 \kappa} T_{*}, \quad C>0 \tag{4.23}
\end{equation*}
$$

provided that $\nu$ is sufficiently small.
Step 6: Finally, remembering that $\tau_{2}=T_{*}$ for $\omega \in \tilde{Q}$ and combining the relations (4.20), (4.21) and (4.23) to estimate the terms of (4.13), we see that for $\omega \in \tilde{Q}$ we have

$$
\begin{equation*}
\left\|v^{\omega}\left(T_{*}\right)\right\|_{1} \geqslant\left\|I_{1}^{\omega}\left(T_{*}\right)\right\|_{1}-\left\|I_{2}^{\omega}\left(T_{*}\right)\right\|_{1}-\left\|I_{3}^{\omega}\left(\tau_{*}\right)\right\|_{1} \geqslant \frac{1}{2} C_{1} \nu^{6 \kappa-b}, \quad C_{1}>0, \tag{4.24}
\end{equation*}
$$

if we assume in addition to (4.22) that

$$
\begin{equation*}
6 \kappa-b<\frac{1}{2}-\kappa-\frac{5}{2} b \tag{4.25}
\end{equation*}
$$

and $\nu$ is small. Note that this relation implies the last two in (4.22).
Combining (4.8) and (4.24) we get that

$$
\begin{equation*}
\nu^{-b+7 \kappa} \leqslant C_{2}^{-1} \tag{4.26}
\end{equation*}
$$

for all sufficiently small $\nu$. Thus we have obtained a contradiction with the existence of the sets $Q^{\nu_{j}}$ as at the beginning of the proof if (for a chosen $\kappa$ ) we can find a $b \in(0,1)$ which meets $(4.22),(4.25)$ and

$$
-b+7 \kappa<0
$$

Noting that this is nothing but the first relation in (4.22), we see that we have obtained a contradiction if

$$
\kappa<\frac{1}{7} b, \quad \kappa<\frac{1}{14}-\frac{3}{14} b,
$$

for some $b \in(0,1)$. We see immediately that such a $b$ exists if and only if $\kappa<\frac{1}{35}$.

Amplification. If we replace the condition $m \geqslant 3$ with the weaker assumption

$$
\mathbb{R} \ni m>2,
$$

then the statement (4.2) remains true for $0<\kappa<\kappa(n, m)$ with a suitable (less explicit) constant $\kappa(n, m)>0$. In this case we obtain a contradiction with the assumption (4.3) by deriving a lower bound for $\left\|v\left(T_{*}\right)\right\|_{\alpha}$, where $\alpha=\min \{1, m-2\} \in$ $(0,1]$, using the decomposition (4.13). The proof remains almost identical except that now, firstly, we bound $\left\|I_{2}\right\|_{\alpha}(\alpha<1)$ from above using the following estimate from [15, Theorem 5, p. 206] (also see there p. 14):

$$
\|W \Delta u\|_{\alpha} \leqslant C\|u\|_{2+\alpha}\left(|W|_{\infty}+|W|_{\infty}^{1-\frac{2 \alpha}{n}}\|W\|_{2}^{\frac{2 \alpha}{n}}\right) ;
$$

and, secondly, estimate $\left\|I_{1}^{\omega}\left(T_{*}\right)\right\|_{\alpha}(\alpha<1)$ from below as

$$
\left\|I_{1}^{\omega}\left(T_{*}\right)\right\|_{\alpha} \geqslant\left\|I_{1}^{\omega}\left(T_{*}\right)\right\|_{1}^{2-\alpha}\left\|I_{2}^{\omega}\left(T_{*}\right)\right\|_{2}^{-1+\alpha}
$$

which directly follows from Sobolev's interpolation. See [6] for more details.

## 5. Lower bounds for time-averaged Sobolev norms

In this section we prove the assertion (2) of Theorem 1. We provide each space $H^{r}, r \geq 0$, with the scalar product

$$
\left\langle\langle u, v\rangle_{r}:=\left\langle\left\langle(-\Delta)^{\frac{r}{2}} u,(-\Delta)^{\frac{r}{2}} v\right\rangle,\right.\right.
$$

corresponding to the norm $\|u\|_{r}$. Let $u(t)=\sum u_{d}(t) \varphi_{d}$ be a solution of eq. (1.1). Applying Itô's formula to the functional $\|u\|_{m}^{2}$, we have for any $0 \leqslant t<t^{\prime}<\infty$ the relation

$$
\begin{align*}
\left\|u\left(t^{\prime}\right)\right\|_{m}^{2}= & \left.\|u(t)\|_{m}^{2}+\left.2 \int_{t}^{t^{\prime}}\langle u(s), \nu \Delta u(s)-i| u(s)\right|^{2} u(s)\right\rangle_{m} d s  \tag{5.1}\\
& +2 \nu B_{m}\left(t^{\prime}-t\right)+2 \sqrt{\nu} M\left(t, t^{\prime}\right),
\end{align*}
$$

where $M$ is the stochastic integral

$$
M\left(t, t^{\prime}\right):=\int_{t}^{t^{\prime}} \sum_{d \in \mathbb{N}^{n}} b_{d}|d|^{2 m}\left\langle u_{d}(s), d \beta_{d}(s)\right\rangle
$$

Let us fix a $\gamma \in\left(0, \frac{1}{8}\right)$. Due to Theorems 7 and 13 , for small enough $\nu$ there exists an event $\Omega_{1} \subset \Omega, \mathbb{P}\left(\Omega_{1}\right) \geqslant 1-\gamma / 2$, such that for all $\omega \in \Omega_{1}$ we have:
a) $\sup _{0 \leqslant t \leqslant \frac{1}{\nu}}\left|u^{\omega}(t)\right|_{\infty} \leqslant C(\gamma)$, for a suitable $C(\gamma)>0$;
b) there exist $t_{\omega} \in\left[0, \frac{1}{3 \nu}\right]$ and $t_{\omega}^{\prime} \in\left[\frac{2}{3 \nu}, \frac{1}{\nu}\right]$ satisfying

$$
\begin{equation*}
\left\|u^{\omega}\left(t_{\omega}\right)\right\|_{m},\left\|u^{\omega}\left(t_{\omega}^{\prime}\right)\right\|_{m} \geqslant \nu^{-m \kappa} . \tag{5.2}
\end{equation*}
$$

Since for the martingale $M(0, t)$ we have that

$$
\mathbb{E}\left|M\left(0, \frac{1}{\nu}\right)\right|^{2} \leqslant B_{m} \mathbb{E} \int_{0}^{\frac{1}{\nu}}\|u(s)\|_{m}^{2} d s=: X_{m}
$$

then by Doob's inequality

$$
\mathbb{P}\left(\Omega_{2}\right) \geqslant 1-\frac{\gamma}{2}, \quad \Omega_{2}=\left\{\sup _{0 \leqslant t \leqslant \frac{1}{\nu}}|M(0, t)| \leqslant c(\gamma) X_{m}^{1 / 2}\right\}
$$

Now let us set $\hat{\Omega}=\Omega_{1} \cap \Omega_{2}$. Then $\mathbb{P}(\hat{\Omega}) \geqslant 1-\gamma$ for small enough $\nu$, and for any $\omega \in \hat{\Omega}$ there are two alternatives:
i) there exists a $t_{\omega}^{0} \in\left[0, \frac{1}{3 \nu}\right]$ such that $\left\|u^{\omega}\left(t_{\omega}^{0}\right)\right\|_{m}=\frac{1}{3} \nu^{-\kappa m}$. Then from (5.1) and (5.2) in view of (A.4) we get
$\frac{8}{9} \nu^{-2 m \kappa}+2 \nu \int_{t_{\omega}^{0}}^{t_{\omega}^{\prime}}\left\|u^{\omega}(s)\right\|_{m+1}^{2} d s \leqslant C(m, \gamma) \int_{0}^{\frac{1}{\nu}}\left\|u^{\omega}(s)\right\|_{m}^{2} d s+2 B_{m}+2 \sqrt{\nu} c(\gamma) X_{m}^{1 / 2}$.
ii) There exists no $t \in\left[0, \frac{1}{3 \nu}\right]$ with $\left\|u^{\omega}(t)\right\|_{m}=\frac{1}{3} \nu^{-\kappa m}$. In this case, since $\left\|u^{\omega}(t)\right\|_{m}$ is continuous with respect to $t$, then due to (5.2) $\left\|u^{\omega}(t)\right\|_{m}>\frac{1}{3} \nu^{-m \kappa}$ for all $t \in\left[0, \frac{1}{3 \nu}\right]$. This leads to the relation

$$
\frac{1}{27} \nu^{-2 m \kappa-1} \leqslant \int_{0}^{\frac{1}{\nu}}\left\|u^{\omega}(s)\right\|_{m}^{2} d s
$$

In both cases for $\omega \in \hat{\Omega}$ we have:

$$
\frac{1}{27} \nu^{-2 m \kappa} \leqslant C^{\prime}(m, \gamma) \int_{0}^{\frac{1}{\nu}}\|u(s)\|_{m}^{2} d s+2 B_{m}+\nu c(\gamma)^{2}+X_{m}
$$

It implies that

$$
\mathbb{E} \nu \int_{0}^{\frac{1}{\nu}}\|u(\tau)\|_{m}^{2} d \tau \geqslant C \nu^{-2 m \kappa+1}
$$

(for small enough $\nu$ ), and gives the lower bound in (1.7).
The upper bound follows directly from Theorem 8.
Proof of Corollaries 3 and 4: Since $B_{k}<\infty$ for each $k$ and all coefficients $b_{d}$ are non-zero, then eq. (1.1) is mixing in the spaces $H^{m}, m \in \mathbb{N}$, see Corollary 10. As the stationary solution $v^{s t}$ satisfies Corollary 11 with any $m$, then for each $\mu \in \mathbb{N}$ and $M>0$, interpolating the norm $\|u\|_{\mu}$ via $\|u\|_{0}$ and $\|u\|_{m}$ with $m$ sufficiently large we get that the stationary measure $\mu_{\nu}$ satisfies

$$
\begin{equation*}
\int\|u\|_{\mu}^{M} \mu_{\nu}(d u)<\infty \quad \forall \mu \in \mathbb{N}, \forall M>0 \tag{5.3}
\end{equation*}
$$

Similar, in view of (2.5) and Theorem 7,

$$
\begin{equation*}
\mathbb{E}\left\|u\left(t ; u_{0}\right)\right\|_{\mu}^{M} \leq C_{\nu}\left(u_{0}\right) \quad \forall t \geq 0 \tag{5.4}
\end{equation*}
$$

for each $u_{0} \in C^{\infty}$ and every $\mu$ and $M$ as in (5.3). Now let us consider the integral in (1.7) and write it as

$$
J_{t}:=\nu \int_{t}^{t+\nu^{-1}} \mathbb{E}\|u(s)\|_{m}^{2} d s
$$

Replacing the integrand in $J_{t}$ with $\mathbb{E}\left(\left\|u_{\nu}(s)\right\|_{m} \wedge N\right)^{2}, N \geq 1$, using the convergence

$$
\begin{equation*}
\mathbb{E}\left(\left\|u\left(s ; v_{0}\right)\right\|_{m} \wedge N\right)^{2} \rightarrow \int\left(\|u\|_{m} \wedge N\right)^{2} \mu_{\nu}(d u) \quad \text { as } \quad s \rightarrow \infty \quad \forall N \tag{5.5}
\end{equation*}
$$

which follows from Corollary 10, and the estimates (5.3), (5.4) we get that

$$
\begin{equation*}
J_{t} \rightarrow \int\|u\|_{m}^{2} \mu_{\nu}(d u) \quad \text { as } \quad t \rightarrow \infty \tag{5.6}
\end{equation*}
$$

This convergence and (1.7) imply the assertion of Corollary 3.
Now the convergence (5.5) jointly with estimates (5.3), (5.4) and (1.8) imply Corollary 4.

## Appendix A. Some estimates

For any integer $l \in \mathbb{N}$ and $F \in H^{l}$ we have that

$$
\begin{equation*}
\|\exp (i F(x))\|_{l} \leq C_{l}\left(1+|F|_{\infty}\right)^{l-1}\|F\|_{l} \tag{A.1}
\end{equation*}
$$

Indeed, to verify (A.1) it suffices to check that for any non-zero multi-indices $\beta_{1}, \ldots, \beta_{l^{\prime}}$, where $1 \leq l^{\prime} \leqslant l$ and $\left|\beta_{1}\right|+\cdots+\left|\beta_{l^{\prime}}\right|=l$, we have

$$
\begin{equation*}
\left\|\partial_{x}^{\beta_{1}} F \cdots \partial_{x}^{\beta_{l^{\prime}}} F\right\|_{0} \leq C|F|_{\infty}^{l^{\prime}-1}\|F\|_{l} . \tag{A.2}
\end{equation*}
$$

But this is the assertion of Lemma 3.10 in [17]. Similarly,

$$
\begin{equation*}
\|F G\|_{r} \leqslant C_{r}\left(|F|_{\infty}\|G\|_{r}+|G|_{\infty}\|F\|_{r}\right), \quad F, G \in H^{r}, r \in \mathbb{N} \tag{A.3}
\end{equation*}
$$

see [17, Proposition 3.7] (this relation is known as Moser's estimate). Finally, since for $|\beta| \leq m$ we have $\left|\partial_{x}^{\beta} v\right|_{2 m / \beta \mid} \leq C|v|_{\infty}^{1-|\beta| / m}\|v\|_{m}^{|\beta| / m}$ (see relation (3.17) in [17]), then

$$
\begin{equation*}
\left.|\langle | v|^{2} v, v\right\rangle\left._{m}\left|\leq C_{m}\|v\|_{m}^{2}\right| v\right|_{\infty} ^{2}, \quad \left\lvert\,\left.\left\langle\left.\langle | v\right|^{2} v, v\right\rangle_{m}\left|\leq C_{m}^{\prime}\|v\|_{m+1}^{\frac{2 m}{m+1}}\right| v\right|_{\infty} ^{\frac{2 m+4}{m+1}} .\right. \tag{A.4}
\end{equation*}
$$

## Appendix B. Proof of Theorem 8

Applying Ito's formula to a solution $v(\tau)$ of eq. (2.1) we get a slow time version of the relation (5.1):

$$
\begin{equation*}
\|v(\tau)\|_{m}^{2}=\left\|v_{0}\right\|_{m}^{2}+2 \int_{0}^{\tau}\left(-\|v\|_{m+1}^{2}-\nu^{-1}\left\langle\left.\langle i| v\right|^{2} v, v\right\rangle_{m}\right) d s+2 B_{m} \tau+2 M(\tau) \tag{B.1}
\end{equation*}
$$

where $M(\tau)=\int_{0}^{\tau} \sum_{d} b_{d}|d|^{2 m}\left\langle v_{d}(s), d \beta_{d}(s)\right\rangle$. Since in view of (A.4)

$$
\left.\mathbb{E}|\langle | v|^{2} v, v\right\rangle_{m} \left\lvert\, \leq C_{m}\left(\mathbb{E}\|v\|_{m+1}^{2}\right)^{\frac{m}{m+1}} \mathbb{E}\left(|v|_{\infty}^{2 m+4}\right)^{\frac{1}{m+1}}\right.
$$

then denoting $\mathbb{E}\|v(\tau)\|_{r}^{2}=: g_{r}(\tau), r \in \mathbb{N} \cup\{0\}$, taking the expectation of (B.1), differentiating the result and using (2.3), we get that

$$
\begin{equation*}
\frac{d}{d \tau} g_{m} \leq-2 g_{m+1}+C_{m} \nu^{-1} g_{m+1}^{\frac{m}{m+1}}+2 B_{m} \leq-2 g_{m+1}\left(1-C_{m}^{\prime} \nu^{-1} g_{m}^{-\frac{1}{m}}+2 B_{m}\right) \tag{B.2}
\end{equation*}
$$

since $g_{m} \leq g_{0}^{1 /(m+1)} g_{m+1}^{m /(m+1)} \leq C_{m} g_{m+1}^{m /(m+1)}$. We see that if $g_{m} \geq\left(2 \nu^{-1} C_{m}^{\prime}\right)^{m}$, then the r.h.s. of (B.2) is

$$
\begin{equation*}
\leq-g_{m+1}+2 B_{m} \leq-C_{m}^{-1} g_{m}^{(m+1) / m}+2 B_{m} \leq-\bar{C}_{m} \nu^{-m-1}+2 B_{m} \tag{B.3}
\end{equation*}
$$

which is negative if $\nu \ll 1$. So if

$$
\begin{equation*}
g_{m}(\tau)<\left(2 \nu^{-1} C_{m}^{\prime}\right)^{m} \tag{B.4}
\end{equation*}
$$

at $\tau=0$, then (B.4) holds for all $\tau \geq 0$ and (2.4) follows. If $g_{m}(0)$ violates (B.4), then in view of (B.2) and (B.3), for $\tau \geq 0$, while (B.4) is false, we have that

$$
\frac{d}{d \tau} g_{m} \leq-C_{m} g_{m}^{(m+1) / m}+2 B_{m}
$$

which again implies (2.4).Besides, in view of (B.2),

$$
\frac{d}{d \tau} g_{m} \leq-g_{m}+C_{m}\left(\nu,\left|v_{0}\right|_{\infty}, B_{m_{*}}, B_{m}\right)
$$

This relation immediately implies (2.5).
Now let us return to eq. (B.1). Using Doob's inequality and (2.4) we find that

$$
\mathbb{E}\left(\sup _{0 \leq \tau \leq T}|M(\tau)|^{2}\right) \leq C<\infty .
$$

Next, applying (A.4) and Young's inequality we get

$$
\int_{0}^{\tau}\left(-\|v\|_{m+1}^{2}-\nu^{-1}\left\langle\left.\langle i| v\right|^{2} v, v\right\rangle_{m}\right) d s \leq C_{m} \int_{0}^{\tau}|v(s)|_{\infty}^{2 m+3} d s, \quad \forall 0 \leq \tau \leq T .
$$

Finally, using in (B.1) the last two displayed formulas jointly with (2.3) we obtain (2.6).

[^0]:    ${ }^{1}$ We note that solutions of equations (1.1) with complex $\nu$ behave differently, and solubility of those equations with large $n$ is unknown.

[^1]:    ${ }^{2}$ In [8] polynomial moments of the random variables $\left.\sup _{\tau \leqslant s \leqslant \tau+T}|v(s)|_{\infty}^{2}\right)$ are estimated, and in [10] these results are strengthened to the exponential bounds (2.3).
