BACKGROUND

Individuals with Autism Spectrum Disorder (ASD) show abilities in tasks requiring mental imagery (e.g., mental rotation task; Soulières et al., 2011). Furthermore, according to personal reports, some of them would possess a specific visual cognitive style (Grandin, 2010)

⇒ Objectives: Assess the presence of a visual cognitive style in autistic individuals and verify whether this visual cognitive style is related to the sensory atypicalities present in ASD.

METHOD

Participants

- 39 adults with ASD (age range 18 to 62, mean = 33.5, SD = 10.6)
- 104 comparison participants (age range 18 to 69, mean = 37.0, SD = 12.7)

Groups are matched on age (p = .184), education levels (p = .089) and gender (73.1 % of women in the control group, 71.8 % in the ASD group, p = .878).

Protocol

An online questionnaire containing 66 items:

- **Attention to details**: 6 items from the Autism Spectrum Quotient (AQ; Baron-Cohen et al., 2001).
- **Adolescent/Adult Sensory Profile** (AASP; Brown & Dunn, 2002): 42 items including sensory sensitivity.
- **Mental imagery quality**: 6 items concerning the colors, level of details, duration, level of abstraction, movements and manipulation of mental images.
- **Mental imagery use in daily situation**:

  - **Questionnaire**: Participants indicated whether they use images only, words only or both images and words in seven different situations: recollection, problem solving, anticipation, decision making, planning, comprehension and memorization. The visual score corresponds to the importance of use of mental images among these different situations.
  - **Two open questions**: “Describe what comes to your mind when you hear the name of a city you’ve already been to”.

RESULTS

The attention to details score and the sensory sensitivity score are significantly more important in participants with ASD than in controls (p < .005).

<table>

</tr>
</thead>
<tbody>
<tr>
<td>Duration of mental images</td>
<td>Use of mental images</td>
</tr>
</tbody>
</table>

Mental images appear to be more persistent in participants with ASD than in controls (p = .052).

The use of mental images is reported more frequently in participants with ASD than in controls (p < .001).

Qualitative analysis

A hierarchical descending classification of lexical classes was performed on the open question’s responses.

When describing their experiences:

⇒ **Control participants** tend to use the lexical field of MEMORIES: “the cities will stand out more for the encounters and experiences in these cities, so the memories and sensations more than the city itself”

⇒ **Participants with ASD** tend to use the VISUAL lexical field “An overall plan of an emblematic place (the Capitol Square), the overall architecture and the shape of the buildings. An often impersonal point of view, a bit like a postcard’s image”.

Correlations

There are correlations between the use of images, sensory sensitivity and attention to details only in participants with ASD.

Matrix of correlations between the use of images, sensory sensitivity, and attention to details in autistic and non-autistic participants.

CONCLUSION

Our results support the existence of a visual cognitive style in ASD individuals with the frequent and persistent use of mental images. This visual cognitive style is related to the sensory atypicalities present in individuals with ASD. These results question the impact of this particular cognitive style on the daily life of these individuals, especially in terms of learning and attention.
