ABSTRACT

A screening of 57 entomopathogenic microorganisms against human pathogens was subjected to mass spectrometry molecular networking-based dereplication. A particular strain of fungus, *Isaria farinosa* BSNB-1250, producing potentially both active and novel metabolites, was grown on a large-scale on potato dextrose agar (PDA) medium. Paecilosetin (1) and five new analogues (2–6) were isolated. The structures of the new compounds were elucidated using 1D and 2D NMR. The absolute configurations of compounds 1–6 were determined by Mosher ester derivatives (1), comparison of experimental and calculated ECD spectra (2–4 and 6), and single-crystal X-ray diffraction analysis (5). Compounds 1–6 were assayed against methicillin-sensitive (MSSA) and methicillin-resistant *Staphylococcus aureus* (MRSA), *Escherichia coli, Candida albicans, Trichophyton rubrum* and the MRC-5 cell line. Compounds 1 and 5 exhibited strong antibacterial activity against MSSA and MRSA with MIC values of $1-2 \mu g/mL$.

The development of novel antimicrobial agents is urgently needed as drug-resistant pathogenic microorganisms become a major public health problem.¹ Natural products are a historical source of valuable antimicrobials and still offer significant potential for the discovery of novel antibacterial and antifungal therapies.² Microbes largely contribute to the chemodiversity of natural products owing to their diversity and ubiquitous occurrence.^{3,4,5} In addition, they have the advantage of being a renewable source, as they can be cultured in the laboratory and scaled up as required. Entomopathogenic microorganisms, the natural enemies of insects, are known to provide bioactive metabolites implicated in complex defense mechanisms.⁶ Since they must control the defensive barriers of their host and other microorganisms that colonize insects, they produce many compounds, including antibiotics and antifungals. However, time-consuming purifications and rediscovery of known compounds are a recurring problem. Mass spectrometry-based molecular networking approaches can be used to overcome these difficulties, allowing the targeting of specific metabolites through the tandem mass spectrometry datasets organization they confer.^{7–11}

Fifty-seven bacterial and fungal isolates from living infected insect cuticle have been screened against several human pathogenic microorganisms. In parallel, the collection was analyzed by high-resolution tandem mass spectrometry profiling (HRMS/MS), and the combined data were organized into molecular networks (MNs). As a result, an *Isaria farinosa* BSNB-1250 ethyl acetate (EtOAc) extract exhibited interesting antimicrobial activities and potentially new metabolites. The strain was thus selected for further investigations. Fungi belonging to the genus *Isaria* are known to infect insects belonging to the orders Homoptera, Lepidoptera and Coleoptera.¹² They have been the source of a wide array of metabolites of different chemical classes and diverse biological activities. Among them, antimicrobial compounds such as

3

hydroxypyridinone and tetramic acid derivatives,^{13,14} cytotoxic cycloaspeptides C, F and G,¹⁵ and the antioxidant pseudodipeptide hanasanagin have been reported from diverse *Isaria* spp.¹⁶

Large-scale cultivation on potato dextrose agar (PDA) medium, fractionation, and molecular networking attached to biological activities allowed six decanoyl tetramic acids to be isolated. To optimize metabolite production and/or increase chemical diversity, diverse culture conditions were tested.^{17–19} Indeed, it has been established that microbial chemical diversity is often largely underestimated under standard culture conditions.^{20–22} Small changes in culture conditions or cocultivation with other microbial species may activate cryptic biosynthetic pathways.^{23–25} Therefore, to analyze substantial subsequent production of the metabolites identified, the fungal strain was cultivated on seven different culture media.

RESULTS AND DISCUSSION

As shown in the previous study of Touré *et al.*,¹⁰ 57 microorganisms isolated from diverse insect cuticles were cultivated on a small-scale (10 Petri dishes) on PDA medium. Extracts were obtained by maceration in EtOAc, and screened for activity against methicillin-sensitive and methicillin-resistant *Staphylococcus aureus* (MSSA and MRSA), *Candida albicans*, and *Trichophyton rubrum*. The extracts were also analyzed by ultrahigh-performance liquid chromatography-high-resolution mass spectrometry (UHPLC-HRMS/MS) using the data-dependent acquisition mode.

MZmine^{8,26} was used to process the data and MetGem⁹ to calculate and visualize a single molecular network (Figure 1 and Supporting Information S1). A molecular network with 9007 nodes was obtained. Each nodes is represented by pie charts showing relative quantification of the ions, based on the respective areas of the corresponding extracted ion chromatograph (XIC). Activity against human pathogens can then be mapped on this molecular network.²⁷ Each strain with a minimal inhibitory concentration equal or better than 64 μ g/mL is represented with a single color, while the other strains are colored in gray.

The *Isaria farinosa* strain showed both interesting MIC values (32–64 μ g/mL) and unique clusters in the molecular network. One particular cluster showed MS² spectra libraries matches as analogues of decanoyl tetramic acids (Figure 1). According to their *m/z* value, the three nodes of this cluster at *m/z* 374.233 correspond to paecilosetin, first isolated by Lang *et al.*¹⁴ It was then assumed that several new analogues of paecilosetin could be isolated from this fungus.

Figure 1. (A) Global molecular network with detection of bioactive clusters by mapping MRSA activity. Only ions from strains with significant antimicrobial activity (MIC <64 μ g/mL) are highlighted with color tags; gray tags are used for non-active strains. (B) Decanoyl tetramic acid cluster. One of the ions circled in purple may correspond to the protonated ion of paecilosetin.

Based on these results, isolation of putative tetramic acid derivatives was undertaken from a large-scale culture of *I. farinosa* on PDA medium, leading to paecilosetin A (1) and five new paecilosetin analogues (2–6).

Compound 1 was isolated as a yellow solid. A molecular formula of C₂₂H₃₁NO₄ was determined based on HRESIMS analysis. MS analysis and evaluation of NMR data suggested that compound 1 was paecilosetin (Table 2), previously isolated from *Paecilomyces farinosus* (syn. I. farinosa)¹² found on an infected insect larva in New Zealand.¹⁴ ¹H-¹H NOE correlations confirmed that the relative configuration of the decaline subunit was identical to equisetin and trichosetin (Figure 2 and Figure 3)^{28–32} and indicated a $(2S^*, 3R^*, 6S^*, 8R^*, 11R^*)$ relative configuration. The specific negative optical rotation data were also similar to the ones given in the literature.¹⁴ As described previously for this class of compounds, the two negative Cotton effects at 239 and 284 nm for compound 1 suggest an S-configuration at C-5' (Supporting Information S3).²⁸⁻³² Consequently, it was assumed that compound **1** had a 2*S*.5'*S* configuration. The configuration in C-6' cannot be determined by ECD and has never been described before. (S)- and (R)-MTPA esters of compound 1 were therefore synthetized (respectively 1a and 1b, Figure 4 and Supporting Information S15 to S18). The chemical shift differences between hydrogens H-5' (+0.49) and H-7' (-0.04) in **1a** and **1b** allowed the relative configuration of C-6' to be assigned as S for compound 1^{33} Consequently, this compound was assigned as 2S,3R,6S,8R,11R,5'S,6'S and was named paecilosetin A.

Figure 2. Key ¹H-¹H COSY (bold bonds) and ¹H-¹³C (plain arrow) correlations of 1–6.

Figure 3. Key NOESY correlations of compounds 1–6 decaline moiety.

Figure 4. Chemical shift differences between the (S)-MTPA and (R)-MTPA esters of 1, 3 and 4.

Compound 2 was isolated as a yellow solid and showed the same molecular formula as 1. In comparison with 1, ¹H NMR data of compound 2 showed differences at H-5' (at 3.78 ppm) instead of 3.69 for 1) and H-7' (1.18 ppm instead of 1.32 for 1). The ¹³C NMR data showed significant shift differences for C-6' and C-7' (Table 2). The 2D NMR spectra (COSY, HMBC, NOESY) were also very similar (Supporting Information S26 to S28). ¹H-¹H NOE correlations confirmed that the relative configuration was identical in the decaline moiety. For example, correlations H-8/H-10, H10-H6, H-6/H-12 and H12-H3 indicated that these protons are on the same face of the decaline (Figure 3). Altogether, these data suggested that 1 and 2 are diastereoisomers in C-5' and/or C-6'. The absolute configuration of 2 was determined by the comparison of CD spectrum with that from 1, suggesting an S-configuration at C-2 and C-5' similar to in 1 (Supporting Information S3 and S20) and by comparison with literature data (see S32 and S33). Consequently, it has been assumed that the absolute configuration should be R in C-6'. Hence, compound 2 was assigned as 2S,3R,6S,8R,11R,5'S,6'R. This compound was named 6'-epi-paecilosetin A. When comparing H-7' and C-7' chemical shifts of compounds 1 and 2 with the paecilosetin described by Lang *et al.*,¹⁴ it can be deduced that paecilosetin A corresponds to their description.

Compounds **3** and **4**, isolated as yellow solids, exhibited a protonated molecular ion peak at respectively m/z 390.2292 [M+H]⁺ and m/z 390.2280 [M+H]⁺ (calculated for C₂₂H₃₂NO₅, 390.2280) corresponding to eight indices of hydrogen deficiency. Except for the methyl in C-16, the ¹H and ¹³C NMR data (Table 2) of **3** and **4** were similar to those of **1** and **2**. ¹H-¹H COSY correlations between H-8 and H-16, and a ¹H-¹³C HMBC correlation of H-16 with C-7, combined with the integration of H-16 corresponding to two hydrogens and their chemical shift (3.48 ppm (**3**) and 3.49 (**4**) for H-16, 68.5 ppm for C-16 (**3** and **4**), demonstrated that C-16 was

hydroxylated. Eventually, the relative and absolute configurations of **3** were found to be the same as in **1** by comparison of 1D and 2D NMRs, and CD data (Table 2 and Supporting Information S35 to S43), including 6'(*S*) configuration (by comparison of ¹H and ¹³C chemical shifts on positions C-5' and C-7').

Therefore, the designation 2S, 3R, 6S, 8R, 11R, 5'S, 6'S was proposed for compound **3**, which was named paecilosetin B. In the same way, comparison of 1D and 2D NMRs and CD data of compounds **2** and **4** confirmed their identical relative and absolute configurations (Table 2 and Supporting Information S49 to S57). Compounds **3** and **4** are thus 6'-epimers as with **1** and **2**. From these observations, compound **4** was identified as 6'-*epi*-paecilosetin B, and the 2S, 3R, 6S, 8R, 11R, 5'S, 6'R absolute configuration was assigned. More evidence is given by analysis of the Mosher esters of compounds **3** and **4**. In **3**, a negative chemical shift between *S*-MTPA and *R*-MTPA esters on H-6' indicated a 6'S configuration, while a positive chemical shift between *S*-MTPA and *R*-MTPA esters of **4** spoke out for a 6'R configuration.

Compound **5**, colorless needles, showed a protonated molecular ion peak at m/z 356.2234 $[M+H]^+$ (calculated for C₂₂H₃₀NO₃, 356.2226) indicating nine indices of hydrogen deficiency. The ¹H and ¹³C NMR data (Table 2) of **5** were similar to those of **1** and **2** for the decalin moiety. Regarding the tetramic acid moiety, two main differences between compound 5 and the latter can be identified. The first is the presence of a C5'-C6' olefin moiety, confirmed by the low-field shifts of C-5' (δ_C 132.6 ppm) and CH-6' (δ_H/δ_C 5.88/110.2 ppm) (Supporting Information S66 to S73). A *Z* configuration for this olefin is supported by a NOE correlation between H-1' and H-7'. The second concerns NMR chemical shift differences for the tetramic moiety, which can be explained by the planar conjugated system (Table 2). The relative and absolute configurations of the decalin moiety of **5** and **6** were found to be identical to those of **1** on the basis of 2D NOESY spectrum and ECD data analysis (Supporting Information S65 and S72). They were confirmed by X-ray diffraction analysis (Figure 5 and Supporting Information S85). Thus, the absolute configuration of compound **5**, named paecilosetin C, was assigned as 2*S*, 3*R*, 6*S*, 8*R*, 11*R*.

Figure 5. ORTEP view of the X-ray structure of compound 5.

The elemental composition of compound **6**, a pale pink solid, was determined to be $C_{22}H_{29}NO_4$ (nine indices of hydrogen deficiency) by HRESIMS analysis. ¹H and ¹³C NMR spectroscopic data of compound **6** were similar to those of compound **5**, with the presence of a CH₂OH group at C-8 in **6** instead of a methyl group (Table 2). Corroborating correlations can be observed between H-8 and H-16 on the ¹H-¹H COSY experiment and between H-16 and C-7 on the ¹H-¹³C HMBC. Analysis of ECD and 2D NMR spectroscopic data established the same relative and absolute configurations as compound **5** (Supporting Information S75 to S83). Thus, the absolute configuration of compound **6**, paecilosetin D, was assigned as 2*S*, 3*R*, 6*S*, 8*R*, 11*R*.

Compounds 1, 2 and 5 showed potent antimicrobial activities against human pathogens MSSA and MRSA with MIC values of 1–16 μ g/mL, and weak cytotoxic activities against MRC-5

(Table 1). Since compounds **3**, **4** and **6** exhibited no or weak antimicrobial activities, it can be deduced that the presence of a hydroxy group at C-16 has a detrimental effect on the activity against these strains.

Table 2. NMR Spectroscopic Data of 1-6 (CDCl₃)^{*a*}

^{a1}H NMR data recorded at 500 MHz, ¹³C NMR data recorded at 125 MHz, "m" means multiplet or overlapped with other signals, nd: not determined. ^bδ_C determined by 2D experiments. Nd : not determined

A metabolomic profiling and a differential analysis of *I. farinosa* extracts produced with different culture conditions was also conducted (S86). Biological activities of each extracts obtained were consistent with the distribution of the metabolites observed in the previous molecular network (Supporting Information S87). Extract obtained from malt medium culture displayed the strongest MIC values against MRSA (8 μ g/mL), *C. albicans* (16 μ g/mL) and *T. rubrum* (32 μ g/mL) after 15 days of culture. Thus, to maximize antimicrobial metabolites production, malt medium should be used for further cultivation of the *Isaria farinosa* strain (S88-S89).

EXPERIMENTAL SECTION

General Experimental Procedures. Optical rotations were measured on an Anton Paar MCP 300 polarimeter (Anton Paar Graz, Austria) in a 100 mm long, $350-\mu$ L cell, at 20 °C, with MeOH used as the solvent. UV spectra were recorded on a Varian Cary 100 UV-vis spectrophotometer and measured in a 1 cm quartz cell at 20 °C. ECD spectra were acquired at 20 °C on a JASCO J-810 spectropolarimeter. NMR spectra were recorded on a Bruker 500 MHz spectrometer (Bruker, Rheinstetten, Germany). The chemical shifts (δ) are reported as ppm based on the TMS (tetramethylsilane) signal, and coupling constants (J) are in hertz.

High Resolution ESITOFMS measurements were performed using a Waters Acquity UHPLC system (Waters, Manchester, England) with a column bypass coupled to a Waters Micromass LCT (Low Chromatography Time-of-flight) Premier time-of-flight mass spectrometer equipped with an electrospray interface (ESI).

Flash chromatography was performed on a Grace Reveleris system with dual UV and ELSD (Evaporative Light Scattering Detector) and equipped with a 120 g or 4 g C_{18} column. The flow rate was 50 or 80 mL/min for the 120 g column and 18 mL/min for the 4 g column, and the effluents were monitored at 210 and 270 nm.

Analytical and preparative HPLC work was conducted using a Gilson system equipped with a 322 pump device, a GX-271 fraction collector, a 171 diode array detector, and a prepELSII electrospray nebulizer detector. The columns used for these experiments included: a Phenomenex Luna C_{18} 5 µm 4.6 × 250 mm analytical column and a Phenomenex Luna C_{18} 5 µm 21.2 × 250 mm preparative one (Phenomenex, Le Pecq, France). The flow rate was set to 1 or 21 mL/min, respectively, using a gradient of H₂O mixed with an increasing proportion of acetonitrile. Both solvents were modified with 0.1% formic acid. All solvents were HPLC grade, purchased from Sigma-Aldrich (Saint-Quentin-Fallavier, France).

Fungus Material. The fungal strain was isolated by Christian Lechat (ASCOFRANCE) from an unidentified insect larva found under the bark of a dead *Carpinus betulus*, in France, Deux-Sèvres, Villiers-en-Bois, June 16, 2010 and identified as *Isaria farinosa*. The strain BSNB-1250 was saved in triplicate at -80 °C in H₂O-glycerol (50:50). A sample was submitted for amplification of the nuclear ribosomal internal transcribed spacer region ITS1 that allowed for identification by comparison to the NCBI database. The sequence was registered in the NCBI GenBank database with the accession number MF950892 and the strain was also conserved in the CIRM under number BRFM 1607.

Large-Scale Cultivation on PDA, Extraction and Isolation. The fungal strain was cultivated on PDA (potato dextrose agar) in 390 14-cm Petri dishes at 28 °C for 15 days. The culture medium containing the mycelium was cut into small pieces and macerated with ethyl acetate (EtOAc) for 24 h. The organic solvent was evaporated to dryness under reduced pressure to yield 4.36 g of an oily brown-red crude extract.

It was then fractionated by reverse flash chromatography on a C_{18} column with a 5-minstep gradient of water mixed with an increasing proportion of acetonitrile (v/v, 95:5, 80:20, 60:40, 45:55, 30:70, 15:85, 0:1, flow rate 80 mL/min) to generate 3 fractions, F1 to F3, according to their UV and DEDL profiles. Another step gradient of acetonitrile - methylene chloride (v/v, 1:1 to 0:1, flow rate 80 mL/min) was conducted to generate 2 additional fractions, F4 and F5. Purification of 1.86 g of F3 by reverse flash chromatography on a C₁₈ column with a gradient of water - acetonitrile (v/v, 1:1 during 4 min, 1:1 to 35:65 during 8 min, 35:65 to 0:1 in 2 min, flow rate 50 mL/min) yielded 15 fractions, F3-1 to F3-15. Another step gradient of acetonitrile - methylene chloride (v/v, 1:1 to 0:1, flow rate 50 mL/min) was conducted to generate an additional fraction, F3-16.

Fractions F3-2 and F3-10 were two pure compounds: respectively compound **2** (87.6 mg, $t_R = 20.0 \text{ min}$) and compound **3** (58.9 mg, $t_R = 7.4 \text{ min}$). F3-4 (43.3 mg) was subjected to preparative HPLC (Luna C₁₈, mobile phase H₂O + 0.1% FA/CH₃CN + 0.1% FA, isocratic elution 55:45 during 12 min, flow rate 21 mL/min) leading to compound **4** (22.8 mg, $t_R = 9.8 \text{ min}$). F3-6 (87.7 mg) was subjected to preparative HPLC (Luna C₁₈, mobile phase H₂O + 0.1% FA/CH₃CN + 0.1% FA, isocratic elution 45:55 during 12 min, then a linear gradient 45:55 to 0:1 over 12 min, flow rate 21 mL/min) leading to 6 fractions, F3-6A to F3-6F. F3-6A (67.7 mg) was subjected to preparative HPLC (Luna C₁₈, mobile phase H₂O + 0.1% FA/CH₃CN + 0.1% FA, isocratic elution 1:1 during 25 min, flow rate 21 mL/min) leading to compound **6** (9.2 mg, $t_R = 21 \text{ min}$). F3-8 (143.1 mg) was subjected to reverse flash chromatography on a C₁₈ column with a gradient of water - acetonitrile (*v*/*v*, 4:6 to 2:8 in 20 min, then 0:1, flow rate 18 mL/min) leading to compound **1** (61 mg, $t_R = 3.2 \text{ min}$). Dissolution of F3-14 (107.4 mg) in methanol precipitated compound **5** that was isolated by filtration (25.0 mg).

Paecilosetin A (1): yellow solid; $[\alpha]^{20}_{D}$ – 528 (*c* 0.1, MeOH); CD (MeOH) λ_{max} ($\Delta \varepsilon$) 239 (-0.8), 251 (-0.3), 284 (-11.3), 317 (+7.56); UV (MeOH) λ_{max} (log ε) 250 (0.57), 287 (0.72); ¹H

and ¹³C NMR data, see Table 2 and S5 to S10; HRESITOFMS m/z 374.2334 [M+H]⁺ (calcd for C₂₂H₃₂NO₄, 374.2331, err. 0.80 ppm).

6'-epi-Paecilosetin B (**2**): yellow solid; $[\alpha]^{20}_{D}$ – 304 (*c* 0.1, MeOH); CD (MeOH) λ_{max} (Δε) 245 (-2.6), 286 (-11.9), 316 (+5.6); UV (MeOH) λ_{max} (log ε) 249 (0.64), 285 (0.81); ¹H and ¹³C NMR data, see Table 2 and S18 to S23; HRESITOFMS *m/z* 374.2327 [M+H]⁺ (calcd for C₂₂H₃₂NO₄, 374.2331, err. -1.06 ppm).

Paecilosetin B (**3**): yellow solid; $[\alpha]^{20}{}_{D}$ – 569 (*c* 0.1, MeOH); CD (MeOH) λ_{max} ($\Delta \varepsilon$) 239 (-0.3), 251 (-4.0), 284 (-15.1), 318 (+3.4); UV (MeOH) λ_{max} (log ε) 251 (0.65), 286 (0.87); ¹H and ¹³C NMR data, see Table 2 and S27 to S32; HRESITOFMS *m/z* 390.2292 [M+H]⁺ (calcd for C₂₂H₃₂NO₅, 390.2280, err. 3.07 ppm).

6'-epi-Paecilosetin B (4): yellow solid; $[\alpha]^{20}{}_{D}$ – 290 (c 0.1, MeOH); CD (MeOH) λ_{max} (Δε) 246 (-2.2), 286 (-9.4), 315 (+4.7); UV (MeOH) λ_{max} (log ε) 249 (0.77), 285 (0.91); ¹H and ¹³C NMR data, see Table 2 and S36 to S41; HRESITOFMS *m/z* 390.2280 [M+H]⁺ (calcd for C₂₂H₃₂NO₅, 390.2280, err. 0.00 ppm).

Paecilosetin C (**5**): colorless needle (CH₂Cl₂); $[\alpha]^{20}{}_{D}$ – 363 (*c* 0.1, MeOH); CD (MeOH) λ_{max} (Δε) 242 (-5.8), 269 (-13.2), 295 (-3.8), 305 (-4.39), 338 (+3.2); UV (MeOH) λ_{max} (log ε) 274 (0.89); ¹H and ¹³C NMR data, see Table 2 and S45 to S51; HRESITOFMS *m/z* 356.2234 [M+H]⁺ (calcd for C₂₂H₃₀NO₃, 356.2226, err. 2.24 ppm).

Paecilosetin D (**6**): pale pink solid; $[\alpha]^{20}{}_{D}$ – 320 (*c* 0.1, MeOH); CD (MeOH) λ_{max} ($\Delta \varepsilon$) 241 (-4.3), 271 (-10.8), 299 (-3.2), 337 (+2.4); UV (MeOH) λ_{max} (log ε) 275 (0.81); ¹H and ¹³C NMR data, see Table 2 and S55 to S61; HRESITOFMS *m/z* 372.2169 [M+H]⁺ (calcd for C₂₂H₃₀NO₄, 372.2175, err. 1.61 ppm).

OSMAC Cultures and Extraction. *I. farinosa* was cultivated under several culture conditions: PDA, Czapek, malt extract, PDA with yeast extract (3 and 10 g/L), and PDA with NaCl (3 and 10 g/L) on 10 Petri dishes (diameter 10 cm) for 15 days. The fungus on the culture media was macerated with 250 mL EtOAc for 24 h on a shaking platform, then filtered and washed twice with H₂O. Solvent evaporation yielded: 18.4 mg extract on PDA medium, 5.3 mg on Czapek medium, 32.3 mg on malt extract, 34.2 mg on PDA with 3 g/L yeast, 28.4 mg on PDA medium with 10 g/L yeast, 28.2 mg on PDA medium with 3 g/L NaCl, and 36.1 mg on PDA medium with 10 g/L NaCl. Sterile culture media were also extracted in the same conditions for subtraction of culture media peaks in the metabolomic analysis.

Mosher Ester Analysis of 1, **3** and **4**. In an NMR sample tube (3 mm diameter) 1 mg of dimethylaminopyridine (DMAP) was added to 1.0 mg (8.2 μ mol) of compound **1**, **3** or **4**. Nine microliters of pyridine- d_5 and 600 μ L of CDCl₃ were added to this mixture. Then, 13.5 μ L of (*R*)-MTPA chloride (72 μ mol) was added. The resultant reaction mixture was stirred at RT for 120 min to produce (*S*)-MTPA esters **1a**, **3a** and **4a**. The identical procedure was carried out to obtain the (*R*)-MTPA ester **1b**, **3b** and **4b** from (*S*)-MTPA chloride.

Antimicrobial Assays. The ATCC strains were purchased from the Institut Pasteur and a clinical isolate was provided by Phillipe Loiseau (University Paris-Saclay, Châtenay-Malabry, France). The strains used in this study were: *Candida albicans* ATCC10231, *Escherichia coli* ATCC25922, *Staphylococcus aureus* ATCC29213, methicillin-resistant *Staphylococcus aureus* ATCC33591 and *Trichophyton rubrum* SNB-TR1. Extracts, fractions and pure compounds were tested according to the reference protocol of the European Committee on Antimicrobial Susceptibility Testing (EUCAST, http://www.eucast.org, 11 April 2016)³⁴. The standard microdilution test as described by the Clinical and Laboratory Standards Institute guidelines (M7, M27 and M38)^{35–37} was used to determine minimal inhibition concentrations

(MIC) against dermatophyte fungi, bacteria, and yeasts. Crude extracts and pure compounds were tested at concentrations ranging from 256 to $0.5 \,\mu$ g/mL. The microplates were incubated at 35 °C. MIC values were obtained after 24 h for bacteria, 48 h for yeasts and 5 days for other fungi. The MIC values reported refer to the lowest concentration preventing visible growth in the wells. All assays were conducted in duplicate.

Cell Culture and Proliferation Assay. The MRC-5 cell line derived from normal lung tissue was obtained from the American Type Culture Collection (Rockville, MD, USA) and it was cultured according to the supplier's instructions. Human MRC-5 cells were grown in DMEM supplemented with 10% fetal calf serum (FCS) and 1% glutamine. ell line was maintained at 37 °C in a humidified atmosphere containing 5% CO₂. Cell viability was determined by a luminescent assay according to the manufacturer's instructions (Promega, Madison, WI, USA). For IC₅₀ determination, the cells were seeded in 96-well plates (3×10^3) cells/well) containing 100 µL of growth medium. After 24 h of culture, the cells were treated with the tested compounds at 10 different final concentrations. Each concentration was obtained from serial dilutions in culture medium starting from the stock solution. Control cells were treated with the vehicle. Experiments were performed in triplicate. After 72 h of incubation, 100 µL of CellTiter Glo Reagent was added for 15 min before recording the luminescence with a spectrophotometric plate reader PolarStar Omega (BMG LabTech). The dose-response curves were plotted with Graph Prism software and the IC₅₀ values were calculated from the polynomial curves (four or five-parameter logistic equations) using the Graph Prism software.

Data Dependent LC ESI HRMS² Analysis for Global Network. Chromatographic separation was performed using a Waters Acquity UHPLC system interfaced to a Q-Exactive Focus mass spectrometer (Thermo Scientific, Bremen, Germany), using a heated electrospray ionization (HESI-II) source. Thermo Scientific Xcalibur 3.1 software was used for instrument

control and data analysis. The LC conditions were as follows: column, Waters BEH (Ethylene Bridget Hybrid) C_{18} 50 × 2.1 mm, 1.7 μ m; mobile phase, (A) water with 0.1% formic acid; (B) acetonitrile with 0.1% formic acid; flow rate, 600 μ L/min; injection volume, 1 μ L; gradient, linear gradient of 2-100% B over 6 min and isocratic at 100% B for 0.6 min. An Acquity UPLC photodiode array detector was used to acquire the PDA spectra, which were collected in the 210-450 nm range. In the positive ion mode, the di-isooctyl phthalate $C_{24}H_{38}O_4 [M+H]^+$ ion (*m/z* 391.28429) was used as the internal lock mass. The optimized HESI-II parameters were as follows: source voltage, 4.0 kV (pos); sheath gas flow rate (N₂), 55 units; auxiliary gas flow rate, 15 units; spare gas flow rate, 3.0; capillary temperature, 275.00 °C (pos), S-Lens RF Level, 45. The mass analyzer was calibrated using a mixture of caffeine, methionine-arginine-phenylalanine-alanine-acetate (MRFA), sodium dodecyl sulfate, sodium taurocholate, and Ultramark 1621 in an acetonitrile/methanol/water solution containing 1% acid formic acid by direct injection. The data-dependent MS/MS events were performed on the three most intense ions detected in the full MS scans (Top 3 experiment). The MS/MS isolation window width was 1 Da, and the stepped normalized collision energy (NCE) was set to 15, 30 and 45 units. In the data-dependent MS/MS experiments, full scans were acquired at a resolution of 35,000 FWHM (at m/z 200) and MS/MS scans were acquired at 17,500 FWHM, both with an automatically determined maximum injection time of 50 ms. After being acquired in a MS/MS scan, the parent ions were placed on the dynamic exclusion list for 2.0 s. AGC target: 1E6 (for full MS), 5E4 (for MS2) and 1E4 (minimum target).

Data Dependent LC ESI HRMS² Analysis for the OSMAC Network. Metabolome profiling was conducted with a Thermo UHPLC-HRMS system. Analyse of each extract (1.0 μ L injected, 2 μ g on the column) was performed in electrospray positive ionization mode in the 133.4-2000 Da range in centroid mode. The mass detector was an Orbitrap MS/MS FT Q-Exactive focus mass spectrometer. The analysis was conducted in FullMS data dependent

 MS^2 mode. In FullMS, the resolution was set to 70,000 and the AGC target was 3.10^6 . In MS^2 , the resolution was 17,500, AGC target 10^5 , isolation window 0.4 Da, normalized collision energy 30, with 20 s dynamic exclusion. The UHPLC column was a Phenomenex Luna Omega polar C_{18} 150 × 2.1 nm, 1.6 μ m. The column temperature was set to 42°C, and the flow rate was 0.5 mL/min. The solvent system was a mixture of water with increasing proportions of acetonitrile, both solvents modified with 0.1% formic acid.

MZmine 2 Data Preprocessing Parameters for Global Network. Raw files were converted into mzXML (mass spectrometry data format) files using the MSConvert software. Then, mzXML files were processed using MZmine 2.38.^{8,26} Mass detection was carried out with a centroid mass detector with the noise level set to 1.0E7 for the MS1 level and 1.0E4 for the MS2 level set to all. The ADAP (Automated Data Analysis Pipeline) chromatogram builder³⁸ was achieved using a minimum group size of scans of 4, a minimum group intensity threshold of 3000, a minimum highest intensity of 3000 and a m/z tolerance of 0.002 or 10.0 ppm. The wavelets (ADAP) algorithm was used for the chromatogram deconvolution with the following settings: S/N threshold of 5, an intensity window SN, a minimum feature height of 3000, a coefficient area threshold of 20, a peak duration range between 0 and 1 and an RT wavelet range between 0 and 0.02. Chromatograms were deisotoped using the isotopic peaks grouper algorithm with an m/z tolerance of 0.004 (15 ppm), RT tolerance of 0.2 (absolute), maximum charge of 3 and the representative isotope used was the most intense. Peak alignment was performed using the join aligner method: m/z tolerance of 0.003 or 10 ppm, weight for m/z of 1.00, RT tolerance of 0.3 min, weight for RT of 1.00. The peak list was gap filled with the peak finder method multithreaded with intensity tolerance of 30.00, m/ztolerance of 0.003 (10 ppm) and 0.20 for RT tolerance.

MZmine 2 Data Preprocessing Parameters for the OSMAC Network. Raw files were converted into mzXML (mass spectrometry data format) files using the MSConvert software.

20

Then, mzXML files were processed using MZmine 2.38.^{8,26} Mass detection was carried out with a centroid mass detector with the noise level set to 1.8E7 for the MS1 level and 1.0E4 for MS2 level set to all. The ADAP (Automated Data Analysis Pipeline) chromatogram builder³⁸ was achieved using a minimum group size of scans of 4, a minimum group intensity threshold of 2.6E7, a minimum highest intensity of 2.6E7 and a *m/z* tolerance of 0.005 or 20.0 ppm. The wavelets (ADAP) algorithm was used for the chromatogram deconvolution with the following settings: S/N threshold of 10, an intensity window SN, a minimum feature height of 2.6E7, a coefficient area threshold of 20, a peak duration range between 0 and 1 and an RT wavelet range between 0 and 0.02. Chromatograms were deisotoped using the isotopic peaks grouper algorithm with an *m/z* tolerance of 0.004 (15 ppm), RT tolerance of 0.2 (absolute), maximum charge of 3 and the representative isotope used was the most intense. Peak alignment was performed using the join aligner method: *m/z* tolerance of 0.003 or 10 ppm, weight for *m/z* of 1.00, RT tolerance of 0.3 min, weight for RT of 1.00.

Global and OSMAC Molecular Network Analysis. After preprocessing the UHPLC-HRMS/MS data with MZmine 2.38, the output .mgf file was processed with the MetGem software version 1.2.2 RC3⁹ to give a network containing nodes distributed in clusters. Networks were generated using the following parameters: m/z tolerance set to 0.01, Minimum Matched Peaks set to 4, topK set to 10, Minimal Cosine score Value of 0.65 and Max. Connected Component Size of 400. Then, the associated CSV file was loaded. For the mapping process, the relative quantification of each ion was represented by pie chartdiagrams for which the proportions were based on the respective areas of the corresponding extracted ion chromatograph areas (XIC). Then, the analogues of the spectra in the network were searched in the available spectral libraries. The library spectra were filtered in the same manner as the input data. All of the matches between the network spectra and library spectra were required to have a score above 0.6 and at least 4 matched peaks. The m/z tolerance for

21

the analogues search was set to 100. T-SNE visualization was generated using the following parameters: at least 1 cosine score above 0.60; number of iterations: 1000; perplexity: 6; learning rate: 200; early exaggeration: 12; using Barnes-hut approximation with an angle of 0.5.

X-ray structure determination of compound 5. Crystals suitable for single-crystal X-ray analysis were obtained from MeOH solution evaporation at 5 °C. X-ray crystallographic data were collected on a Rigaku Rapid II (IP area detector system) diffractometer equipped with a rotating anode mm007 HF generator and Osmic mirrors (Cu Kα radiation, $\lambda = 1.54187$ Å) using ω -scans. Samples were irradiated at a low temperature in a continuous LN₂ stream at 235 K. Crystallographic data for compound 5: C₂₂H₂₉NO₃, M = 355.46, 0.35 × 0.075 × 0.03 mm, orthorhombic, P212121, a = 13.5830(5) Å, b = 15.4136(5) Å, c = 19.6284(14) Å, V = 4109.5(4) Å3, Z = 8, Dcalc = 1.149 g/cm³, µ(CuKα) = 0.600 mm-1, T = 235.15 K, 21525 reflections measured (13.036° ≤ 2Θ ≤ 140.024°), 7402 unique (Rint = 0.0409, Rsigma = 0.0995) which were used in all calculations. The final R1 was 0.0480 (I > 2σ(I)) and wR2 was 0.1131 (all data). S = 1.040, Flack parameter = -0.07(10). Crystallographic data for this structure have been deposited in the Cambridge Crystallographic Data Centre database (deposition number CCDC 1985120). Copies of the data can be obtained free of charge from the CCDC at www.cedc.cam.ac.uk.

Author Contributions

The manuscript was written through contributions of all authors. All authors have given approval to the final version of the manuscript. These authors contributed equally.

Notes

The authors declare no competing financial interest.

ACKNOWLEDGMENTS

This work was supported by an "Investissement d'Avenir" grant managed by Agence Nationale de la Recherche (CEBA, ref. ANR-10-LABX-25-01). We are grateful to Jean-François Gallard from ICSN for his help in carrying out the NMR experiment and Marine Bourceau for her help on the fractionation. The authors are very grateful to Christian Lechat for the transfer of the biological material from the CIRM collection voucher conserved under the number BRFM 1607.
