1	ABSTRACT: In the course of investigations on peptaibol chemodiversity from marine-derived
2	Trichoderma spp., five new 15-residue peptaibols named pentadecaibins I-V (1-5) were isolated
3	from the solid culture of the strain Trichoderma sp. MMS1255 belonging to the T. harzianum
4	species complex. Phylogenetic analyses allowed precise positioning of the strain close to
5	T. lentiforme lineage inside the Harzianum clade. Peptaibol sequences were elucidated on the basis
6	of their MS/MS fragmentation and extensive 2D-NMR experiments. Amino acid configurations
7	were determined by Marfey's analyses. The pentadecaibins are based on the sequences Ac-Aib1-
8	Gly2-Ala3-Leu4-Aib/Iva5-Gln6-Aib/Iva7-Val/Leu8-Aib9-Ala10-Aib11-Aib12-Aib13-Gln14-
9	Pheol15. Characteristic of the pentadecaibin sequences is the lack of the Aib-Pro motif commonly
10	present in peptaibols produced by Trichoderma spp. Genome sequencing of Trichoderma sp.
11	MMS1255 allowed the detection of a 15-module NRPS-encoding gene closely associated with
12	pentadecaibin biosynthesis. Pentadecaibins were assessed for their potential antiproliferative and
13	antimicrobial activities.

Page 3 of 35

Numerous fungi belonging to the genus *Trichoderma* are known to produce bioactive linear nonribosomal peptides (NRP) named peptaibols. Peptaibols are characterized by molecular masses ranging from 500 to 2 000 Da containing 5-20 amino-acid (AA) residues, an N-acetyl terminus and a C-terminal AA reduced into the corresponding amino-alcohol.¹⁻⁴ Peptaibol biosynthesis by non ribosomal peptide synthetases (NRPS)⁵⁻⁷ allows incorporation of non-proteinogenic AA into the chain such as α -aminoisobutyric acid (Aib) or isovaline (Iva).² In *Trichoderma* spp., peptaibols are produced as complex microheterogeneous mixtures and can be classified into five main families (11-, 14-, 18-, 19- and 20-residue peptaibols) according to their AA chain length. Peptaibols represent the most important subgroup of the peptaibiotics group and numerous sequences have already been published and listed in the Comprehensive Peptaibiotics Database.^{8,9}

Peptaibols have been studied for their potential biological activities particularly as alternative sources for antibiotic research or as new therapeutic agents.^{10,11} Indeed, they have been shown to exhibit a wide range of biological activities including antibacterial activity against Gram-positive bacteria¹²⁻¹⁵ and dormant mycobacteria,^{16,17} antifungal activity,^{14,18,19} antiviral activity -particularly against infection caused by the tobacco mosaic virus,²⁰⁻²² and antiparasitic activity against amoebae (Dictvostelium sp.)²³ and protozoa (Plasmodium falciparum).²⁴ They have been also studied for their activities against fungal plant pathogens.²⁵⁻²⁸ Peptaibols are known to act by forming pores or voltage-dependent ion channels in cell membranes increasing membrane permeability.23,29

In a continuation of our investigations into peptaibol chemodiversity of French marine-derived *Trichoderma*,³⁰⁻³³ we focused in this study on the peptaibol production of the strain *Trichoderma* sp. MMS1255. Phylogenetic analysis was performed to determine the precise taxonomic position

of the peptaibol-producing strain within the Trichoderma genus and more specifically in the T. harzianum species complex. Peptaibols isolated contained 15 AA and were characterized by the lack of the widespread Aib-Pro motif. Their sequences were determined by MS analysis and their complete structures were established by NMR spectroscopy. Marfey analysis and circular dichroism were used for the determination of the AA configurations. The genome sequencing of the peptaibol-producing strain revealed the presence of a new gene encoding a 15 module-NRPS. The organization of modules and domains in this gene has never been described before and may be involved in the biosynthesis of the isolated peptaibols. Cytotoxicity and antimicrobial activities were shown for these new compounds.

RESULTS AND DISCUSSION

Morphological and Phylogenetic Analyses of Trichoderma sp. MMS1255. The Dextrose Casein Agar (DCA) culture of strain MMS1255 was observed as successive concentric greenish to whitish zones on the agar surface plate. Microscopically, typically highly branched conidiophores were observed producing clustered phialides arising near 90° with respect to the others members (Figure S1). The taxonomic identification was performed by DNA Barcoding (Table S1, Figure S2). Preliminary molecular identification based on the internal transcribed spacer regions of the nuclear ribosomal RNA gene cluster (ITS1 and ITS2) led to the Trichoderma harzianum species complex. However, ITS is not sufficiently polymorphic to distinguish species in the T. harzianum complex.³⁴ thus we used the translation elongation factor $1-\alpha$ (*tef1*) and RNA polymerase II subunit 2 (*rpb2*) gene markers. This analysis localized the strain *Trichoderma* sp. MMS1255 among the Trichoderma Harzianum Clade (Figure S6).³⁵ For a deeper identification inside this infrageneric group, we performed a combined analysis of the marker genes *tef1* and calmodulin (*cal*). This resulted in the identification of the strain MMS1255 close to the T. lentiforme lineage and to two isolates previously described as T. harzianum JBNZ24 and JBNZ111 (Figure 1).³⁶ Considering the Genealogical Concordance Phylogenetic Species Recognition (GCPSR) concept.³⁷ further phenotyping characterizations are needed to clarify Trichoderma sp. MMS1255, T. harzianum JBNZ24 and JBNZ111 phylogenetic localization within or outside the borders of *T. lentiforme*.

Figure 1. Phylogram of the best maximum likelihood tree (log likelihood: -4619.24) of *tef1* and *cal*, which includes
 only species in the *T. harzianum* complex. Values at nodes represent ML bootstrap (MLBP)/MP bootstrap (MPBP).
 The tree is drawn to scale, with branch lengths measured in the number of substitutions per site. The analysis involved
 fo nucleotide sequences. There were a total of 734 positions in the final dataset. Evolutionary analyses were conducted
 in MEGA7.³⁸

Isolation and Structure Elucidation of Pentadecaibins (1–5). A peptaibol-enriched fraction extracted from a solid culture (DCA) of Trichoderma sp. MMS1255 was analyzed by MS and revealed the presence of an unusual MS profile with $[M + Na]^+$ ions ranging from m/z 1466 to 1521 (Figure S3). Whereas ions ranging from m/z 1466 to m/z 1493 were supposed to correspond to 14-residue peptaibols produced by *Trichoderma* strains, 5,26,39,40 ions m/z 1493 and m/z 1521 did not match any known peptaibols. Herein, we report the discovery, structure elucidation and biological activities of five 15-residue peptaibols (1-5) isolated from the marine-derived strain Trichoderma sp. MMS1255.

9 Chart 1

11 Compound **1** was obtained as a white powder. The molecular formula was determined to be 12 $C_{68}H_{113}N_{17}O_{18}$ on the basis of HRESIMS (*m/z* 750.9132 [M + 2Na]²⁺). The amino acid sequence 13 of **1** was determined on the basis of ESIMS² analyses by identifying fragment ions of the series a_n, 14 b_n , y_{nP} generated in positive ionization (P refers to positive-ion mode) and y_{nN} generated in negative

ionization (N for negative-ion mode) (Figure 2, Table S2). Fragmentation of the sodium adduct $[M + Na]^+$ produced a series of fragment ions a_5/b_5 to a_{14}/b_{14} providing successive losses of Gln⁶, Aib⁷, Vxx⁸, Aib⁹, Ala¹⁰, Aib¹¹, Aib¹², Aib¹³, Gln¹⁴ and the *C*-terminal Pheol¹⁵ (phenylalaninol; Vxx = Val or Iva). In order to complete the sequence, $ESI-MS^2$ fragmentation of the deprotonated molecule $[M - H]^-$ yielded diagnostic fragment ions y_{4N} to y_{14N} . Hence, the *N*-terminal part of the sequence was assigned as Ac-Aib¹-Gly²-Ala³-Lxx⁴-Aib⁵-Gln⁶-Aib⁷-Vxx⁸-Aib⁹-Ala¹⁰-Aib¹¹ (Lxx = Leu or Ile). Fragment ions y_{7P} to y_{14P} assigned in positive mode supported the N-terminal sequence deduced from the y_{nN} ions series. Based on the above mass spectrometry analysis, the sequence of 1 was proposed to be Ac-Aib¹-Gly²-Ala³-Lxx⁴-Aib⁵-Gln⁶-Aib⁷-Vxx⁸-Aib⁹-Ala¹⁰-Aib¹¹-Aib¹²-Aib¹³-Gln¹⁴-Pheol¹⁵.

The sequence determined from mass spectral fragmentations was thus verified by 1D and 2D-NMR correlations allowing in addition the assignment of the isomeric residues Val/Iva and Leu/Ile (Figure 3, Table 1).

Figure 3. NMR key correlations of pentadecaibin I (1) (COSY/TOCSY, HMBC and NOESY).

The ¹H NMR spectrum of compound **1** exhibited in the range 6.7-9 ppm, 17 exchangeable signals characteristic of amide protons among which 11 singlets corresponding to seven Aib residues, two side-chain NH₂ protons of the two Gln, one broad singlet characterising one Gly, five doublets (for Ala, Leu, two Gln and Val) and two multiplets (for Ala and Pheol). In addition, the aromatic protons of the mono-substituted phenyl ring of the Pheol were characterized by multiplets at δ_H 7.13, 7.18 and 7.27. Between δ_H 1.48 and 1.37 ppm were depicted 14 methyl singlets assigned to seven Aib residues.

¹H-¹H correlations from COSY and TOCSY spectra allowed to define seven spin systems corresponding to Gly, two Ala, Leu, Val and two Gln as represented in bold in Figure 3. An additional moiety was pointed out by ¹H-¹H correlations between a hydroxy group at $\delta_{\rm H}$ 4.53, the methylene group at δ_H 3.37 (δ_C 63.2) and the methine at δ_H 3.89 (δ_C 52.4), which itself was linked to the NH at $\delta_{\rm H}$ 7.13 and the methylene at $\delta_{\rm H}$ 2.89/2.57 ($\delta_{\rm C}$ 36.7). ¹H-¹³C HMBC correlations allowed this methylene carbon to be linked to the protons of the phenyl ring, resulting in the characterization of a Pheol residue (Table 1). The ɛ-amide protons of the two Gln were assigned from their HMBC correlations with the corresponding γ -carbon and their syn or anti-disposition

1	from their NOE correlations with the respective γ -protons of the lateral chain (Figure S15). The
2	carbonyl at δ_{C} 171.0 was assigned to the <i>N</i> -terminal acetyl because its HMBC correlation with the
3	methyl at δ_H 1.93 and the NH of an Aib at δ_H 8.74, thus assigned to Aib ¹ . The carbonyl of this Aib ¹
4	at δ_c 176.1 was correlated not only to the NH of Aib ¹ , but also to the α, α' -protons of Gly ² . The
5	CO of Gly ² at $\delta_{\rm C}$ 171.8 gave cross-peaks with these α, α' -protons and the NH at $\delta_{\rm H}$ 8.00 (d, $J =$
6	6.3) assigned to Ala ³ . Continuing this series of NH_{i+1} to CO_i correlations thus observed from Ac-
7	Aib ¹ to Pheol ¹⁵ , the following completed sequence of 1 was finally confirmed as Ac-Aib ¹ -Gly ² -
8	Ala ³ -Leu ⁴ -Aib ⁵ -Gln ⁶ -Aib ⁷ -Val ⁸ -Aib ⁹ -Ala ¹⁰ -Aib ¹¹ -Aib ¹² -Aib ¹³ -Gln ¹⁴ -Pheol ¹⁵ and was named
9	pentadecaibin I (1). The sequences of the other isolated peptaibols were identified and
10	characterized in the same way.

 Compound 2 was obtained as a white powder. The molecular formula was determined to be $C_{69}H_{115}N_{17}O_{18}$ on the basis of HRESIMS (m/z 757.9172 [M + 2Na]²⁺) indicating the presence of an additional methylene group between 1 and 2. This was confirmed by positive and negative mass fragmentations (Figures S4-S5, Table S2), suggesting the presence of Ile/Leu in position 8 instead of Val⁸ for 1. Detailed analyses of 1D and 2D NMR spectroscopic data were consistent with mass fragmentation analyses and both residues were identified as leucine from COSY and TOCSY data (Table S3). HMBC correlations confirmed the second Leu residue in position 8. Indeed, ¹H-¹³C correlations were observed between the CO group of the Aib⁷ at $\delta_{\rm C}$ 176.3 was correlated to the NH at $\delta_{\rm H}$ 7.89 of the Leu⁸ and the CO group of this Leu at $\delta_{\rm C}$ 174.0 was correlated to the methine H α at $\delta_{\rm H}$ 3.90 ($\delta_{\rm C}$ 54.8) and to the NH at $\delta_{\rm H}$ 8.03 of the Aib⁹ (Figure S27). Therefore, the structure of compound 2 was established as Ac-Aib¹-Gly²-Ala³-Leu⁴-Aib⁵-Gln⁶-Aib⁷-Leu⁸-Aib⁹-Ala¹⁰-Aib¹¹-Aib¹²-Aib¹³-Gln¹⁴-Pheol¹⁵ and named pentadecaibin II.

Compound 3 was obtained as a white powder and exhibited the same molecular formula $(C_{69}H_{115}N_{17}O_{18})$ as compound 2. On the basis of mass fragmentation analyses, compound 3 only differed from 1 by the presence of a Val/Iva instead of an Aib in position 7 (Figures S6-S7, Table S2). Mass spectrometry sequencing was confirmed by NMR investigations (Table S4) and the TOCSY spectrum showed characteristic signals of one Iva and one Val isomeric residues. The CO group of Gln⁶ at δ_C 173.1 was correlated to the NH of Iva⁷ at δ_H 7.76 and the CO of Iva⁷ at δ_C 176.6 to the NH of Val⁸ at $\delta_{\rm H}$ 7.74 (Figure S36). Thus Aib⁷ in compound **1** was changed into Iva⁷ in **3**. Compound 3 was identified as Ac-Aib¹-Gly²-Ala³-Leu⁴-Aib⁵-Gln⁶-Iva⁷-Val⁸-Aib⁹-Ala¹⁰-Aib¹¹-Aib¹²-Aib¹³-Gln¹⁴-Pheol¹⁵ and consequently named pentadecaibin III.

Compound 4 was obtained as a white powder. On the basis of HRESIMS studies, the molecular formula $C_{70}H_{117}N_{17}O_{18}$ was deduced from the Na⁺-adduct ion $[M + 2Na]^{2+}$ at *m/z* 764.9263. Mass

fragmentation analyses (Figures S8-S9) demonstrated that peptide **4** only differs from **3** by the replacement of the Val residue by a Ile/Leu in position 8 (Table S2). Detailed NMR analyses were consistent with mass fragmentation sequencing and revealed that compound **4** only differed from **3** by the presence of two Leu residues instead of one, the presence of an Iva and the absence of Val (Table S5). The CO of Gln⁶ at δ_{C} 173.2 was correlated to the NH of the Iva⁷ at δ_{H} 7.78, the CO of which at δ_{C} 176.8 was correlated to the NH at δ_{H} 7.85 of the second Leu, which was thus located at position 8 (Figure S45). Therefore, compound 4 was determined as Ac-Aib¹-Gly²-Ala³-Leu⁴-Aib⁵-Gln⁶-Iva⁷-Leu⁸-Aib⁹-Ala¹⁰-Aib¹¹-Aib¹²-Aib¹³-Gln¹⁴-Pheol¹⁵ and named pentadecaibin IV.

Compound 5 was obtained as a white powder. HRESIMS analyses of the $[M + 2Na]^{2+}$ at m/z 764.9180 confirmed that compound 5 exhibits the same molecular formula (C₇₀H₁₁₇N₁₇O₁₈) as compound 4. Based on mass fragmentation sequencing, three Val or Iva residues were assigned in position 5, 7 and 8 (Figures S10-S11, Table S2). NMR investigations confirmed the mass fragmentation and revealed that 5 was characterised by the presence of two Iva and one Val (Table S6, Figure S54). The CO of Leu⁴ at $\delta_{\rm C}$ 173.5 was correlated to the NH at $\delta_{\rm H}$ 8.10 of one of the Iva (Iva⁵). The CO of this Iva at $\delta_{\rm C}$ 176.6 gave a cross-peak in the HMBC spectrum with the NH of Gln⁶ at δ_H 7.80. As the CO of Gln⁶ at δ_C 173.1 was correlated to the NH at δ_H 7.75 of the second Iva (Iva⁷) and the CO of which at $\delta_{\rm C}$ 176.6 was correlated to the NH at $\delta_{\rm H}$ 7.80 of a Val (Val⁸), compound 5 only differed from compound 4 by the replacement of an Aib by an Iva in position 5. Therefore, compound 5 was determined as Ac-Aib1-Gly2-Ala3-Leu4-Iva5-Gln6-Iva7-Val8-Aib9-Ala¹⁰-Aib¹¹-Aib¹²-Aib¹³-Gln¹⁴-Pheol¹⁵ and named pentadecaibin V.

1	The solution conformation of pentadecaibins in DMSO- d_6 was tentatively examined by NMR,
2	based on the observed ${}^{3}J_{\rm NH,\alpha H}$ coupling constants and the inter-residue NOE connectivities. The
3	${}^{3}J_{\rm NH,\alpha H}$ coupling constants values mainly lower than 7 Hz agreed with a helical structure. The inter-
4	residue NOE patterns observed for the five pentadecaibins (1-5) on their NOESY spectra were
5	similar, and strong NOE correlations $d_{NN(i, i+1)}$ and $d_{\alpha N(i, i+1)}$ were observed, in agreement with the
6	proposed sequences (Figure 3, Figures S15, S23, S27, S32, S36, S41, S45, S50 and S54). A helical
7	structure was also obvious from the series of NOESY correlations between contiguous residues
8	such as strong $d_{NN(i, i+1)}$, $d_{NN(i, i+2)}$ and $d_{NN(i, i+3)}$. The prevalence of a helix stabilised by $4 \rightarrow 1$ intra-
9	molecular hydrogen bonds (3 ₁₀ -helix type) over an α -helix which is stabilised by 5 \rightarrow 1 intra-
10	molecular hydrogen bonds arose from the absence of $d_{NN(i, i+4)}$ and the stronger peaks of $d_{NN(i, i+2)}$
11	as compared to $d_{NN(i, i+3)}$. As similar conformational results were observed for all the five peptaibols,
12	it was concluded that the substitutions Aib \rightarrow Iva (positions 5 and 7) and Val \rightarrow Leu (position 8)
13	which were responsible for the microheterogeneity of the pentadecaibins were without significant
14	influence on their secondary structure.

In addition, on the basis of ECD spectra analyses (Figures S19, S28, S37, S46 and S55), the occurrence of two negative maxima at 210 and 225 nm and a positive maximum near 200 nm confirmed the right-handed helical conformation of the pentadecaibins.⁴¹ In this case, for Iva residues of pentadecaibins III (3), IV (4) and V (5), the large $\Delta \delta_{\rm H}$ values of ¹H chemical shift differences between the diastereotopic β -methylene protons (> 0.28 ppm) and the chemical shifts of γ -methyl protons and β -methylene carbons confirmed the presence of D-configured Iva (Table $2).^{42,43}$

ACS Paragon Plus Environment

$\delta_{\mathrm{H}} \gamma$ -CH ₃	0.76	0.76	0.76	0.75
$\delta_{\rm C} \beta$ -CH ₂	25.0	24.9	25.0	25.0

Moreover, the absolute configurations of the constituent chiral AA of pentadecaibins I–V (1–5) were determined after acid hydrolysis and subsequent derivatization of the amino acids with Marfey's reagent (L-FDAA)⁴⁴ (Figures S56-S60). Comparison of the L-DAA derivatives of 1-5 with appropriate L- and D- standard AA L-DAA derivatives by reversed-phase LC indicated the presence of L-configured AA for Ala, Val, Leu, Glu (resulting from Gln hydrolysis during Marfey's analysis) and Pheol. Marfey's analyses confirmed the presence of D-configured Iva for compounds **3–5**. Consequently, all chiral AA present in pentadecaibins I–V possess the L-configuration except for the Iva residues (D-configuration).

This is the first report of the description of 15-residue peptaibols within the genus *Trichoderma*. These peptaibols are characterized by the lack of the highly conserved Aib-Pro motif which is generally characteristic for peptaibols produced by *Trichoderma* spp. Ampullosporins, chalciporins and tylopeptins, 15-residue peptaibols produced by *Sepedonium* species, are also characterized by the absence of the Aib-Pro motif.⁴⁵⁻⁴⁹ However, these peptaibols exhibit sequence patterns which remain different from pentadecaibins.

Interestingly, no 18-residue peptaibols could be detected in *Trichoderma* sp. MMS1255 strain extracts, whereas *Trichoderma* species belonging to the *T. harzianum* complex are known to produce these peptaibol series.^{5,7} Comparison of new 15- and already known 18-residue patterns produced by various *T. harzianum* strains showed a complete sequence similarity with an absence

of a 3 AA sequence (Aib¹²-Pro¹³-Leu¹⁴) (Figure S61). *Trichoderma* sp. MMS1255 genome sequencing was performed in order to identify the putative NRPS gene encoding the pentadecaibins.

Genome Sequencing and NRPS Gene Analysis. The genome was sequenced with the PacBio technology. We obtained 228 contigs and the genome assembly size was estimated at 38.7 Mbp which is coherent with the size of the other fungi within the *Trichoderma harzianum* complex.⁵⁰ All sequences were submitted to the AntiSMASH software pipeline.⁵¹ Interestingly, only one NRPS gene encoding 15-module protein was identified in the genome, estimated to 53.5 kbp (Figure 4).

12 indicated by numbers I-XV.
13 The presence of ketoacyl synthase and acyltransferase domain genes before the first module gene
14 was consistent with the typical *N*-terminal acetylation of peptaibols. The latest domain in the gene
15 corresponds to a thioesterase domain or reductase domain. This domain catalyzes the reduction of
16 the acyl thioester into its primary alcohol *via* the aldehyde intermediate,⁵² which is in agreement
17 with the typical *C*-terminal amino-alcohol of peptaibols. This NRPS-encoding gene analysis was
18 completed by the prediction of incorporated AA based on the 10 AA signature sequences in the

1 adenylation domains of NRPS modules based on both NRPS/PKS Substrate predictor and by

2 NRPSPredictor2 SVM (Table 7).^{53,54}

Table 3. Prediction of Incorporated AA in Pentadecaibins Based on the Signature Sequences in 15-module NRPS Adenylation Domains

Amino acid position in pentadecaibins	Signature sequence in NRPS module ^{<i>a</i>}	Amino acids predicted by NRPS/PKS substrate predictor/NRPSPredictor2 SVM (Small clusters prediction) ^b	Amino acids detected in pentadecaibins
0	PKS-AT	Methylmalonyl-CoA	Ac
1	DLGYLAGVFK	Iva/Val,Leu,Ile,Abu,Iva	Aib
2	DLGiiCaVmK	Gly,Ala,Val,Leu,Ile,Abu,Iva/NP	Gly
3	DVGFVAGVLK	Ala/Gly,Ala	Ala
4	DMGFLGGVaK	Val/Val,Leu,Ile,Abu,Iva	Leu
5	DLGivCGVyK	NP/Val,Leu,Ile,Abu,Iva	Aib/Iva
6	DGGMVGGNYK	Gln/Glu,Gln	Gln
7	DAawIVGVvK	Val,Leu,Ile,Abu,Iva/ Val,Leu,Ile,Abu,Iva	Aib/Iva
8	DAFILGgViK	Ala/Val,Leu,Ile,Abu,Iva	Val/Leu
9	DLGYLAGCFK	Iva/Val,Leu,Ile,Abu,Iva	Aib
10	DVGYvAAVYK	Ser/Ser	Ala
11	DLMyFagVAK	Gly,Ala,Val,Leu,Ile,Abu,Iva/NP	Aib
12	DLGFLAGVFK	Iva/Val,Leu,Ile,Abu,Iva	Aib
13	DLGILAGLFK	Iva/Val,Leu,Ile,Abu,Iva	Aib
14	DGGMVGGNYK	Gln /Glu,Gln	Gln
1.5	DoFV1AGicK	NP/Pheol Trpol	Pheol

All signatures in the adenylation domains were consistent with the AA sequences of pentadecaibins I-V. Based on these results, it can be assumed that pentadecaibins are synthetized by a 15-module NRPS. This is the first detection of a 15-module peptaibol synthetase gene within the *Trichoderma* spp. Contrary to other investigated *Trichoderma* strains within the *T. harzianum* complex, MMS1255 is the only one producing 15-residue peptaibols associated with a 15-module peptaibol synthetase.

Biological Activities of Pentadecaibins. Biological activities of pentadecaibins I-V (1–5) were assessed against cancer cells (KB), Gram-positive (*Staphylococcus aureus*) and negative (*Escherichia coli*) bacteria and human-pathogenic yeast (*Candida albicans*) (Table 4).

Table 4. Biological Activities of Pentadecaibins I-V (1–5)

6 The Cytotoxic activities of the pentadecaibins were consistent with previous reports of cell 7 growth inhibitory activity of 11- and 20-residue peptaibols from a marine-derived T. *longibrachiatum* strain.^{30,32} Pentadecaibins III-V (3-5) incorporating a D-Iva⁷ residue instead of 8 9 Aib⁷ exhibited higher growth inhibitory activity against KB cells than pentadecaibins I–II (1–2). 10 Interestingly, similar observations were obtained with trichodermides A-E assessed on SW620 11 human colorectal carcinoma cells.⁵⁷ Pentadecaibins did not exhibit noticeable growth inhibition 12 against Gram-negative E. coli or yeast C. albicans. However, moderate antibacterial activity 13 against S. aureus was observed for pentadecaibins I (1), III (3) and V (5) with MIC values of 25 14 μ g/mL, being in agreement with previous observations in the literature for antimicrobial activity.30,56 15

In conclusion, in this study we have identified a new series of 15-residue peptaibols named pentadecaibins I–IV (1–5). They are produced by a marine-derived strain belonging to the *Harzianum* Clade. The phylogenetic position of *Trichoderma* sp. MMS1255 within the

Trichoderma genus was studied using sequence alignment of combined genes of representatives Trichoderma strains. No precise identification can be proposed, but the phylogenetic analysis clearly demonstrates the relation of Trichoderma sp. MMS1255 to the T. lentiforme lineage. The pentadecaibins discovered differ between them by AA exchange in positions 5 (Aib/Iva), 7 (Aib/Iva) and 8 (Val/Leu). They are all characterized by the lack of the Aib-Pro motif widespread in peptaibols produced by Trichoderma spp. Genome sequencing allowed the identification for the first time within Trichoderma spp. of a 15-module peptaibol synthetase encoding gene closely related to pentadecaibin biosynthesis, according to the prediction of the incorporated AA. The pentadecaibins exhibit moderate cytotoxicity on KB cells and antibacterial activity against S. aureus.

EXPERIMENTAL SI	ECTION
-----------------	--------

General Experimental Procedures. The specific rotation was measured with a Perkin Elmer model 341 polarimeter at 589 nm. UV spectra were obtained from a Shimadzu 1605 UV/visible spectrophotometer, at room temperature over a wavelength range of 200–400 (peptaibols 0.1 mM, MeOH). ECD experiments were carried out using a Jasco J-810 CD spectropolarimeter. Spectra were recorded at room temperature over a wavelength range of 195–260 nm using a 0.2 cm path length cuvette (peptaibols 0.1 mM, MeOH). Measurements were performed using a step scan scanning mode with data acquisition interval of 0.1 nm, bandwidth of 2 nm and accumulation of 5. ECD sample spectra are shown after subtracting the baseline, smoothing and data normalization. IR spectra were recorded on a Shimadzu IR Affinity FTIR spectrometer fitted with an ATR MiRacle 10. One- and two-dimensional NMR spectra were performed on a Bruker Avance III HD 600 MHz spectrometer operating at 600.193 MHz and using a triple resonance TCI cryoprobe. equipped with shielded gradients z. NMR spectra were recorded in DMSO- d_6 solution and were processed using the Bruker TOPSPIN 3.2 software. Chemical shifts are expressed in δ (ppm) and are referenced to the residual non-deuterated solvent signals (for DMSO-*d6* $\delta_{\rm H}$ 2.49 and $\delta_{\rm C}$ 39.5). For the HMBC experiments the delay (1/2J) was 70 ms and for the NOESY experiments the mixing time was 500 ms. Mass analyses were carried out using a LCOTM electrospray ionization ion-trap mass spectrometer instrument (ESI-IT/MS, Thermo Fischer Scientific) in positive and negative mode with capillary temperature of 160°C, capillary voltage of 3.44 V (positive mode) or -9.81 V (negative mode), spray voltage of 4.51 kV, and sheath gas (N₂) flow rate of 19.50 AU. Compounds were infused as methanolic solutions (0.5 µg/mL) directly into the ESI probe with a 500-µL micrometrically automated syringe (Hamilton) at a flow rate of 3 µL/min. All spectra were acquired and analyzed by LCQ Xcalibur software (Thermo Fischer Scientific). Total current ion mass

1 spectra (Fullscan mode) were acquired in the range m/z 150 to 2000. Charge state and isotopic 2 distribution were analyzed by a narrow-scan range mode (Zoomscan mode). MS fragmentation 3 was performed by positive and negative ionizations under the same experimental conditions described above for regular MS analysis *via* infusion of methanolic solutions (0.5 µg/mL). The 4 5 sodium adduct ions $[M + Na]^+$ and the deprotonated molecules $[M - H]^-$ were selected as precursor ions for MS². Peptaibols were sequenced by assignation of the diagnostic fragment ions of the 6 series a_n / b_n and y_{nP} produced in positive-ion mode and y_{nN} produced in negative-ion mode. 7 8 HRESIMS analyses were conducted using an electrospray ionization ion-trap time-of-flight 9 multistage mass spectrometer (IT-TOFMS, Shimadzu). Organic solvents used for extraction and 10 purification of compounds were purchased form Carlo Erba SDS and distilled prior to use. Water 11 was purified to HPLC-grade quality with a Millipore-QRG ultrapure water system (Millipore). MS 12 analyses were performed using LCMS-grade MeOH (Biosolve). Semi-preparative HPLC 13 purifications and AA Marfey's analysis were carried out on Agilent 1200 HPLC instrument 14 connected to corresponding quaternary pump, fraction collector, DAD detector and Chemstation 15 software. All D- and L- amino acids, Gly and Aib were purchased from Sigma-Aldrich, except D-16 and L-Iva, purchased from Thermo Fisher Scientific. Acetonitrile (CH₃CN) and trifluoroactetic 17 acid (TFA) used for AA Marfey's analysis were purchased from Carlo Erba and Sigma-Adrich, 18 respectively.

19 Isolation, Fungal Strain Identification and Phylogenetic Analysis. The fungal strain was 20 isolated from marine sediment collected in a shellfish-farming area from the estuary of the river 21 Loire at Port-du-Bec, France. The isolated strain is deposited in the laboratory fungal collection 22 (MMS-Marine Fungal Collection, University of Nantes) under the reference number MMS1255 as 23 well as in the TU Wien Collection of Industrially Important Microorganisms under the reference

1	TUCIM 5509. Strain MMS1255 was identified as belonging to the genus Trichoderma on the basis
2	of macroscopic and microscopic morphological features (Figure S1). The identification was
3	completed at the molecular level by amplification and sequencing of internal transcribed spacers
4	(ITS) and DNA partial sequences of the fourth large intron of translation elongation factor 1- α
5	(tef1); RNA polymerase II subunit 2 (rpb2) and calmodulin (cal). Sequences were deposited in
6	GenBank under accession numbers JQ653081.1, KU758964.1, MN450663.1 and MN428075.1,
7	respectively. Briefly, mycelium for DNA extraction was grown on potato dextrose agar (PDA) and
8	harvested after seven days. Genomic DNA was extracted according to the microwave mini-prep
9	procedure described by Goodwin and Lee $(1993)^{58}$ using 100 µL lysis buffer (50 mM Tris-HCl pH
10	7.5, 50 mM EDTA, 3% SDS, 1% 2-mercaptoethanol). The final DNA pellet was supplemented
11	into 100 μ L TE buffer (10 mM Tris-HCl pH 8.0, 0.1 mM EDTA) and stored at –20°C until used.
12	Gene sequences were obtained by polymerase chain reaction (PCR) amplification (GoTaq® G2
13	Hot Start Polymerase, Promega Corporation) and sequenced using Eurofins Genomics facility.
14	DNA partial sequences of <i>cal</i> , ITS, <i>rpb2</i> and <i>tef1</i> were amplified using the following primers:
15	CAL-228F/CAL-737R, ⁵⁹ ITS1/ITS4, ⁶⁰ fRPB2-5f/fRPB2-7cr ⁶¹ and EF1-728f ⁵⁹ /TEF1LLErev, ⁶²
16	respectively. ITS sequence (JQ653081) allowed to assign MMS1255 strain to <i>Trichoderma</i> genus.
17	A first phylogenetic analysis aiming to affiliate MMS1255 strain to the Trichoderma subclades
18	defined by Jaklitsch and Voglmayr ³⁵ was performed using 112 Trichoderma spp. combined
19	sequences of tef1 and rpb2 (Table S1). For the Trichoderma subclade affiliation tree,
20	Protocrea farinosa sequences were used as outgroup taxa. A second analysis was performed to
21	determine MMS1255 strain lineages inside the Trichoderma Harzianum clade or to the
22	<i>T. harzianum</i> complex defined by Jaklitsch and Voglmayr ³⁵ and Chaverri <i>et al.</i> , ³⁴ respectively.
23	According to Chaverri et al., ³⁴ T. catoptron is one of the more distant species from the

1	T. harzianum complex, thus the T. catoptron strain GJS 02-76 sequences were used to root
2	phylogenetic trees. For the Trichoderma sp. MMS1255 lineage affiliation to the T. harzianum
3	complex, the combined sequences <i>tef1</i> and <i>ca1</i> gene of 76 representative strains were used (Table
4	S1). As described by Jaklitsch and Voglmayr, ³⁵ all alignments were produced with the server
5	version of MAFFT (www.ebi.ac.uk/Tools/mafft), with a gap open penalty of 1.0 and a gap
6	extension penalty in the range of 0.05 to 0.1, with a tree building number = 100 and maxiterate =
7	100. The resulting alignments were checked and refined using BioEdit version v. 7.0.5.3.63
8	Maximum likelihood (ML) analysis was performed with MEGA 7.0.26. The general time-
9	reversible model (GTR) ⁶⁴ with gamma-distributed substitution rates, additionally assuming a
10	proportion of invariant sites (GTR+I+G) was selected according to the Akaike information
11	criterion (AIC). Initial tree(s) for the heuristic search were obtained automatically by applying
12	Neighbor-Join and BioNJ algorithms to a matrix of pairwise distances estimated using the
13	Maximum Composite Likelihood (MCL) approach, and then selecting the topology with superior
14	log likelihood value. Maximum likelihood bootstrap proportions (MLBP) were computed with
15	1000 replicates. Maximum parsimony (MP) trees were obtained by MEGA 7.0.26 using 1000
16	replicates of heuristic search with random addition of sequences and tree bisection-reconnection
17	(TBR) as the branch-swapping algorithm. All characters were weighted equally. Maximum
18	parsimony bootstrap proportions (MPBP) were calculated from 1000 replicates, each with 10
19	replicates of random addition of taxa. Trees were visualized with MEGA 7.0.26 with MLBP and
20	MPBP above 50% as shown at the nodes.

Analytical Cultivation and Peptaibol Profiling by ESI-IT-MS. For peptaibol chemical profiling, *Trichoderma* sp. MMS1255 was inoculated onto a Petri dish (10-cm diameter) containing 20 mL of marine DCA medium (dextrose 40 g/L, enzymatic digest of casein 10 g/L, agar 15 g/L,

Difco, VWR, synthetic sea salt 36 g/L, Reef Crystals, Aquarium Systems). Culture was incubated for 7 days at 27 °C. After incubation, culture was harvested and mycelia and conidia were scraped from the agar surface. The harvested biomass was extracted by CH₂Cl₂/MeOH 1:2 then 2:1 (v/v, 30 mL each) for 30 min at room temperature. The combined extracts were filtered, washed with distilled H₂O (10 mL) and evaporated to dryness to provide an organic extract. The extract was fractionated by vacuum liquid chromatography (VLC) on Chromabond adsorbant (OH) 2 Diol (10 \times 50 mm, 60 Å, 45 µm, Macherey-Nagel) with CH₂Cl₂/EtOH mixtures (98:2 to 85:15, v/v). The peptaibol-enriched fraction eluting with CH₂Cl₂/EtOH 90:10 (v/v) was subjected to ESI-MS analysis in infusion mode.

Preparative Cultivation, Extraction and Purification of Compounds 1-5. Strain MMS1255 was inoculated onto 35 Petri dishes (20-cm diameter) containing 125 mL of marine DCA medium. Cultures were incubated in natural light for 11 days at 27 °C prior to harvesting for biomass extraction, as previously mentioned (see above). After incubation, the harvested biomass was extracted by CH₂Cl₂/MeOH 1:2 then 2:1 (v/v, 1200 mL each) for 2 h at room temperature. The combined extracts were filtered, washed with distilled H₂O (600 mL) and evaporated to dryness to provide an extract (2.8 g). The extract was partitioned in aliquots of 276 mg and fractionated by repetitive VLC, with CH₂Cl₂/EtOH mixtures (98:2, 95:5, 92:8, 90:10 and 85:15, v/v). Peptide-containing fractions (CH₂Cl₂/EtOH 95:5 to 85:15, v/v) were combined to obtain the fraction 2 (940 mg) and subjected to a liquid chromatography on an open silica gel column (Chromagel, 200×20 mm, 60 Å, 35-70 µm, SDS), with CH₂Cl₂/MeOH mixtures (100:0 to 80:20, v/v). Fifteen-residue peptaibols were mainly eluted in the 2-9 and 2-10 CH₂Cl₂/MeOH mixtures (85:15, v/v). Chromatographic separation of the fraction 2-10 (433 mg) by repetitive reversed-phase preparative HPLC (Luna RP18 column, 250×10 mm, 100 Å, 5 µm, Phenomenex) yielded five compounds

13	<i>Pentadecaibin III</i> (3): white powder, $[\alpha]^{20}_{D} - 15.1$ (<i>c</i> 1.0, MeOH); UV (MeOH) λ_{max} (log ε) 204
14	nm (3.42) nm; IR v_{max} 3304, 2935, 1649, 1531, 1456, 1384, 1363, 1290, 1219, 1174, 1043 cm ⁻¹ ;
15	¹ H and ¹³ C NMR Data, Table S4; ESIMS m/z 757.9 [M + 2Na] ²⁺ , m/z 1492.8 [M + Na] ⁺ . HRESIMS
16	m/z 757.9174 [M + 2Na] ²⁺ (calcd for $\frac{1}{2}C_{69}H_{115}N_{17}O_{18}Na_2$, 757.9195, Δ 2.77 ppm).
17	<i>Pentadecaibin IV</i> (4): white powder, $[\alpha]^{20}_{D} - 17.9$ (<i>c</i> 1.0, MeOH); UV (MeOH) λ_{max} (log ε) 204
18	nm (3.42) nm; IR v_{max} 3304, 2937, 1649, 1531, 1456, 1384, 1361, 1290, 1220, 1176, 1045 cm ⁻¹ ;
19	¹ H and ¹³ C NMR Data, Table S5; ESIMS m/z 764.9 [M + 2Na] ²⁺ , m/z 1506.8 [M + Na] ⁺ . HRESIMS
20	m/z 764.9263 [M + 2Na] ²⁺ (calcd for $\frac{1}{2}$ C ₇₀ H ₁₁₇ N ₁₇ O ₁₈ Na ₂ , 764.9273, Δ 1.31 ppm).
21	<i>Pentadecaibin V</i> (5): white powder, $[\alpha]^{20}_{D}$ – 10.2 (<i>c</i> 0.28, MeOH); UV (MeOH) λ_{max} (log ε) 204
22	nm (3.46) nm; IR v_{max} 3305, 2933, 1647, 1531, 1455, 1384, 1360, 1288, 1219, 1172, 1043 cm ⁻¹ ;

¹H and ¹³C NMR Data, Table S6; ESIMS *m/z* 764.9 [M + 2Na]²⁺, *m/z* 1506.8 [M + Na]⁺. HRESIMS
 m/z 764.9249 [M + 2Na]²⁺ (calcd for ¹/₂ C₇₀H₁₁₇N₁₇O₁₈Na₂, 764.9273, Δ 3.14 ppm).

Marfey's Derivatization. Compounds 1–5 (0.5 mg) and 500 μ L of 6 M HCl were heated for 24 h at 110 °C in 4 mL sealed tubes (Supelco Analytical; Sigma-Aldrich). Hydrolyzed solutions of peptaibols were evaporated to dryness under a stream of nitrogen and solubilized with 100 µL of H₂O prior their derivatization with the FDAA Marfey's reagent (Thermo Fisher Scientific). Ten microliters of each aqueous solution of hydrolyzed peptaibol were transferred in insert for 1 mL HPLC vial and completed by 4 μ L of 1 M sodium bicarbonate and 20 μ L of Marfey's reagent (1%) in acetone). The resulting mixture was sealed and then heated at 40 °C during 2 h. After cooling, samples were neutralized with 4 µL of 1 M HCl and diluted 1:3 with MeOH. The same treatment was performed for the Marfey's derivatization of standard AA (Gly, Aib, D- and L- standards of Glu, Ala, Val, Iva, Leu and Pheol). Aliquots (10 µL) of hydrolyzed peptaibols and standard AA were analyzed by HPLC-UV on a reversed-phase analytical column (Inertsil ODS-3 RP18, $250 \times$ 4.6 mm, 5 µm, Interchim). The elution was insured at a constant flow rate of 0.5 mL/min using CH₃CN / 0.05% TFA in H₂O as mobile phase. The gradient started at 20% CH₃CN ramping up to 50% over 20 min and was then held for 15 min. Detection was performed at 430 nm. All data were acquired by HP ChemStation for LC.

Genome Sequencing and 15-Module NRPS-encoding Gene Analysis. *Trichoderma* sp. MMS1255 was cultivated in the dark at 25°C on PDA medium (potato 4 g/L, dextrose 20 g/L, agar 15 g/L, Difco Laboratories). Spore suspensions were produced and concentrations were adjusted to 10⁷ to 10⁸ spores/mL prior to storage at -80 °C until use. Genomic DNA was extracted from fresh mycelium, following the CTAB method proposed by the Joint Genome Institute with an optional step using Qiagen genome-tips.⁶⁵ Genome was sequenced with PacBio technology. Sequences were quality checked with FastQC.⁶⁶ The genome was assembled using canu.⁶⁷ Secondary metabolism associated genes (polyketide synthase -PKS-, non ribosomal peptide synthetase -NRPS-, terpene synthase -TPS-, dimethylallyl tryptophan synthase -DMATS-) and genes potentially involved in adaptation to the environment were searched in each species. Gene cluster associated with secondary metabolites were searched with FungiSMASH.⁵¹

Cytotoxicity Assays. KB cells (human oral epidermoid carcinoma ATCC CCL 17, American Type Culture Collection.) were cultivated in RPMI (Roswell Park Memorial Institute medium) supplemented with 5% (v/v) fetal calf serum, 1% (v/v) glutamine 200 mM and 1% (v/v) streptomycin (10 mg/mL) / penicillin (1000 U) (all Sigma-Aldrich,). Cells were cultivated in plastic flasks (Falcon; Becton Dickinson Labware,) at 37 °C in a 5% CO₂ enriched atmosphere. After an incubation period of 48 h, trypsinized cells were suspended as a 2×10^5 cells/mL suspension and 50 µL were put in each well of 96-well microplates (Nunclon Delta Surface: Thermo Fisher Scientific). After an incubation of 48h, 50 µL of peptaibol samples were added to the initial 50-µL cell suspension. Peptaibol samples were tested in well as a final 5% (v/v) methanolic solution in supplemented RPMI with concentrations ranging from 0.6 to 25 μ g/mL. A final 5% (v/v) methanolic solution in supplemented RPMI was used as solvent control. Synthetic alamethicin⁵⁵ was used as positive control. After 76 h of incubation, the cell viability was evaluated by the colorimetric 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT, Sigma-Aldrich) bioassay. 68,69

Antimicrobial Assays. The *C. albicans* clinical isolate was obtained from the Angers University Hospital (Angers, France), *E. coli* (CIP54.8T) and *S. aureus* (CIP53.156) strains are part of the Pasteur Institute Collection. Precultures were inoculated with loop-fulls of cells from agar plates

and incubated 20 h at the appropriate temperature 30 °C (for *C. albicans*) or 37 °C (for bacterial strains) on a rotator in 5 mL YDP medium (veast dextrose peptone) (for C. albicans) or LB medium (Lysogeny Broth) (for bacterial strains). Overnight precultures were then harvested by centrifugation, washed in sterile H₂O and inoculated to an optical density (OD) 0.5 in fresh YPD or LB media. The microplate wells were filled with calibrated suspensions and peptaibols to be tested at the desired concentration (ranging from 1 to 100 μ g/mL in 1% MeOH, 300 μ L/well) and microbial growth was automatically recorded at 600 nm using a multiplate spectrophotometer (Spectrostar nano; BMG Labtech). The plates were subjected to permanent shaking at 200 rpm and OD measurements were taken every 10 min during a 24 h period. For each condition, the area under the growth curve representative of the lag phase and the maximal growth rate was calculated as previously described.⁷⁰ A percentage of growth inhibition was calculated for each independent experiment (100-((AUCtreated/AUCc)×100 where AUCtreated is the Area Under the growth Curve after exposure to the selected peptaibol or antibiotic, and AUCc is the area under the growth curve of a untreated culture). All data presented herein was obtained from two independent biological repetitions and each repetition included three technical replicates. Amphotericin B (100% inhibition of C. albicans at 30 µg/mL in 1% MeOH) and gentamycin (100% inhibition of *E. coli* and *S. aureus* at 40 µg/mL in 1% MeOH) were used as positive controls.

5 ACKNOWLEDGEMENTS

6 This work was supported by a Ph.D grant for A.I.V.B. from the French Ministry of Higher 7 Education and Research. The authors acknowledge the French Ministry of Agriculture and Food 8 for the research program NABUCO (Ecophyto 2 plan). The 600 MHz NMR spectrometer used in 9 this study was funded jointly by the Région Ile-de-France, the Museum national d'Histoire 10 naturelle (Paris, France) and by CNRS (France). Dr. A. Blond is gratefully acknowledged for 11 recording the NMR spectra. Authors also thank Dr. M. Chollet-Krueler (COrint, University of 12 Rennes) for specific rotation measurements, A. Tonnerre (IICIMed, University of Nantes) for IR 13 spectroscopy and Prof. F. Fleury (IMPACT platform, Biogenouest, University of Nantes) for ECD 14 experiments. Are gratefully acknowledged Dr. Y. Fichou (ESC Bretagne Brest) for the PacBio 15 sequencing, Dr. A. Lebreton and Dr. E. Corre (Roscoff Marine Station, Sorbonne University) for 16 their help in the genome assemble and Prof. N. Inguimbert (CRIOBE, University of Perpignan Via 17 Domitia) for providing synthetic alamethicin F50/5.
