# Hemicryptophanes with Improved Fluorescent Properties for the Selective Recognition of Acetylcholine over Choline

Augustin Long, Elise Antonetti, Alberto Insuasty, Sandra Pinet, Isabelle Gosse, Vincent Robert, Jean-Pierre Dutasta, and Alexandre Martinez\*

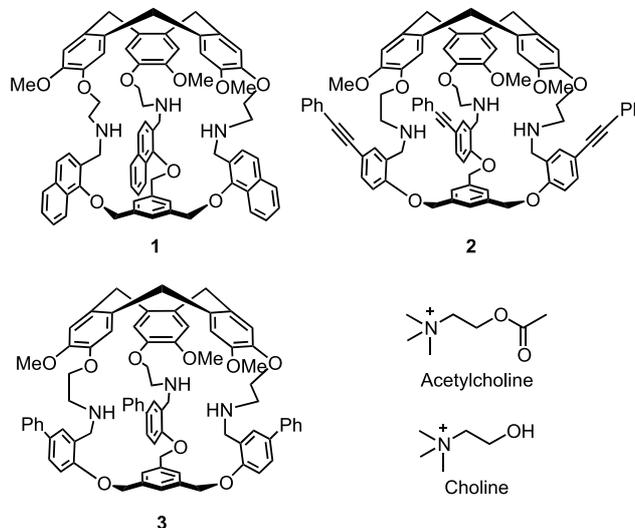

- ✓ Red-shifted emission
- ✓ Improved quantum yield
- ✓ Acetylcholine/choline selectivity
- ✓ High binding constant ( $>10^4$ )

**ABSTRACT:** The synthesis of two new fluorescent hemicryptophanes is reported. They were found to be efficient and selective receptors for acetylcholine over choline. When compared to other hemicryptophane hosts previously reported for the selective recognition of acetylcholine, they display improved fluorescent properties: their maximum emission wavelengths are red-shifted and the quantum yields are higher. NMR titration experiments and density functional theory (DFT) calculations support the results obtained from fluorescence spectroscopy and give insights into the interactions involved in the host/guest complexes and into the selectivity for acetylcholine over choline.

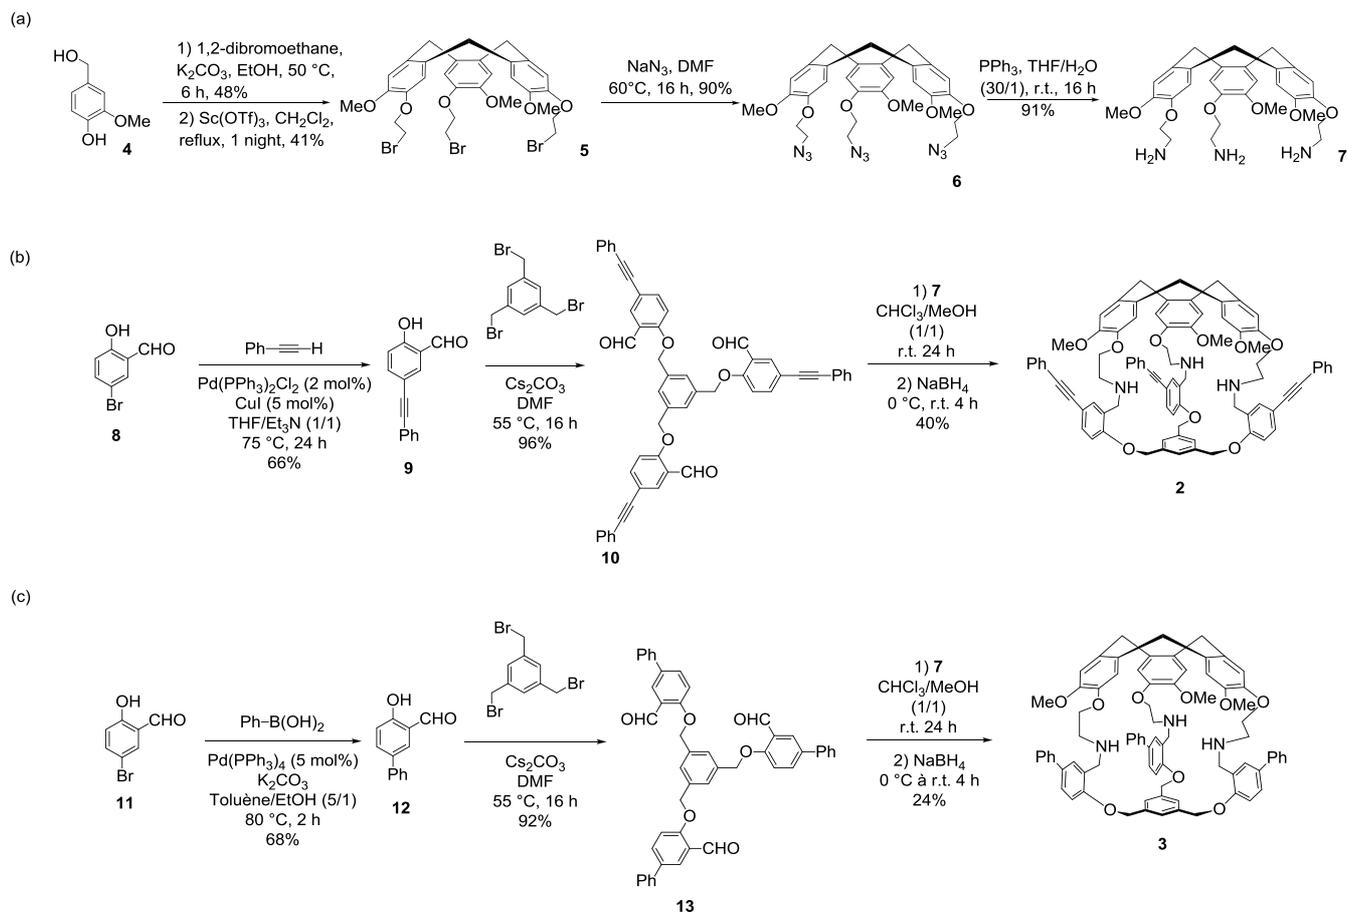

## INTRODUCTION

Acetylcholine (ACh) is a neurotransmitter that plays a crucial role in both peripheral and central nervous systems. For instance, ACh is involved in learning and memory processes or the transmission and regulation of the nervous impulse in the synaptic key.<sup>1–4</sup> Therefore, the development of synthetic receptors for ACh has aroused considerable interest.<sup>5–13</sup> In particular, fluorescent supramolecular probes have been designed to detect ACh, as they allow for high sensitivity, technical simplicity, and fast response time and are thus convenient for optical imaging and analytical sensing.<sup>14,15</sup> Although several fluorescent host compounds able to detect ACh have been reported,<sup>16–21</sup> only few display ACh/choline (Ch) selectivity in favor of ACh.<sup>22–30</sup> Recently, we reported the synthesis of the fluorescent hemicryptophane **1**, which is able to recognize ACh with a selectivity  $K_{\text{ACh}}/K_{\text{Ch}}$  of 4.1 (Figure 1).<sup>31,32</sup> However, this host suffers from modest fluorescent properties due to the naphthalene units included in the linkers of the cage compound, which lead to a modest quantum yield (1.8%) and a wavelength emission at 326 nm. We thus decided to add additional conjugated units to improve the fluorescent properties of the host without altering the size and shape of the cavity, aiming at preserving a good selectivity for ACh over Ch. Herein, we report on the synthesis of the new hemicryptophanes **2** and **3** bearing fluorescent linkers (Figure 1). The fluorescent properties have been improved when compared to our previously reported cage **1**, while the ACh/Ch selectivity is retained.

**Figure 1.** Structures of the hemicryptophane hosts (**1–3**) and the guests used in this study.

## Scheme 1. Synthesis of the Key Intermediate 7 (a) and of Hemicryptophanes 2 (b) and 3 (c)

## RESULTS AND DISCUSSION

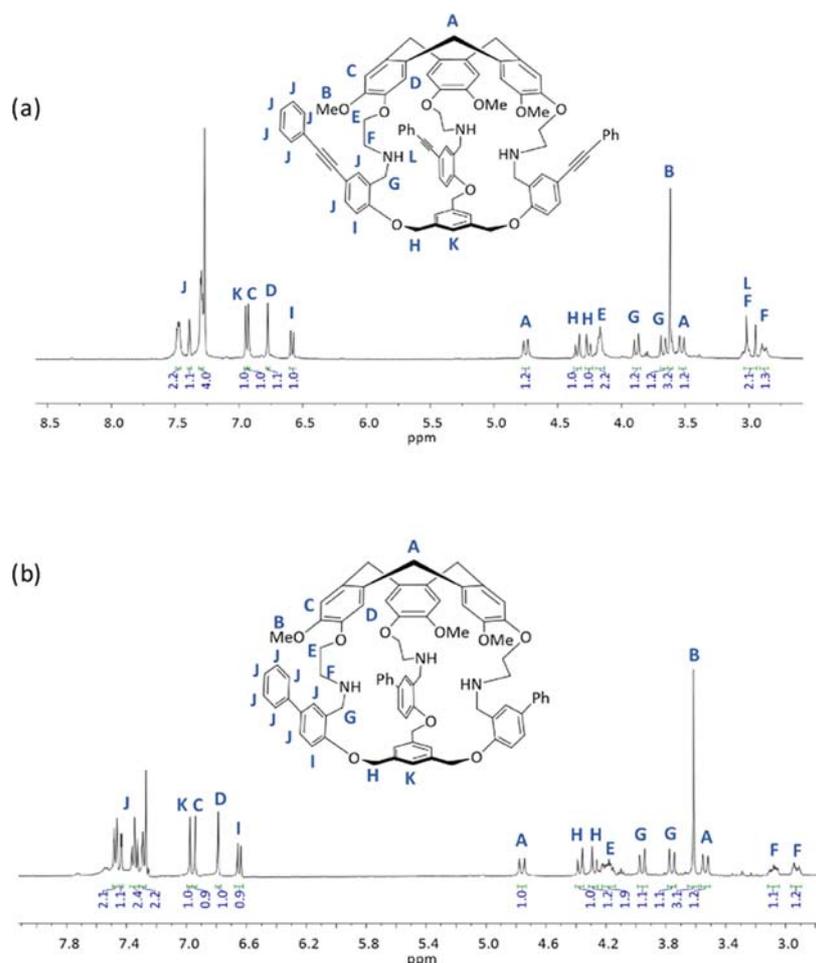

Fluorescent hemicryptophanes **2** and **3** have been obtained following the synthetic pathways shown in [Scheme 1](#). First, the tris(ethanamine)-cyclotriveratrylene derivative **7** (CTV-NH<sub>2</sub>) is synthesized according to our previously reported four-step procedure: the reaction of vanillyl alcohol with dibromoethane in EtOH followed by the triple Friedel–Crafts reaction in MeCN with Sc(OTf)<sub>3</sub> as a catalyst affords CTV-Br **5** in 20% yield.<sup>33</sup> The three bromine atoms are then substituted by azide functions, and a subsequent Staudinger's reaction gives CTV-NH<sub>2</sub> **7** with 15% overall yield.<sup>34</sup> This key intermediate **7** was used for the synthesis of cages **2** and **3**. Second, 5-bromo-2-hydroxybenzaldehyde reacts under classical Sonogashira coupling conditions or Suzuki coupling conditions to afford **9** and **12** in 66 and 68% yields, respectively. Then, nucleophilic substitutions of the phenol unit of **9** and **12** on 1,3,5-tribromomethyl-benzene, using Cs<sub>2</sub>CO<sub>3</sub> as a base, give the C<sub>3</sub>-symmetrical trialdehydes **10** and **13** in 96 and 92% yields, respectively. Finally, reductive aminations between CTV-NH<sub>2</sub> **7** and trialdehydes **10** and **13** afford cages **2** and **3** in 40 and 24% yields, respectively.

<sup>1</sup>H NMR spectra ([Figure 2](#)) show that both cages **2** and **3** exhibit the C<sub>3</sub>-symmetry usually observed for hemicryptophane hosts in solution. Both present characteristic signals of cages including a CTV moiety: two doublets for the Ar-CH<sub>2</sub> methylene bridges (**A**) at around 4.8 and 3.5 ppm, the two singlets at around 6.95 and 6.8 ppm for the aromatic protons (**C**, **D**), and a singlet near 3.6 ppm for the methoxy groups (**B**). The aromatic protons (**K**) and the diastereotopic aliphatic

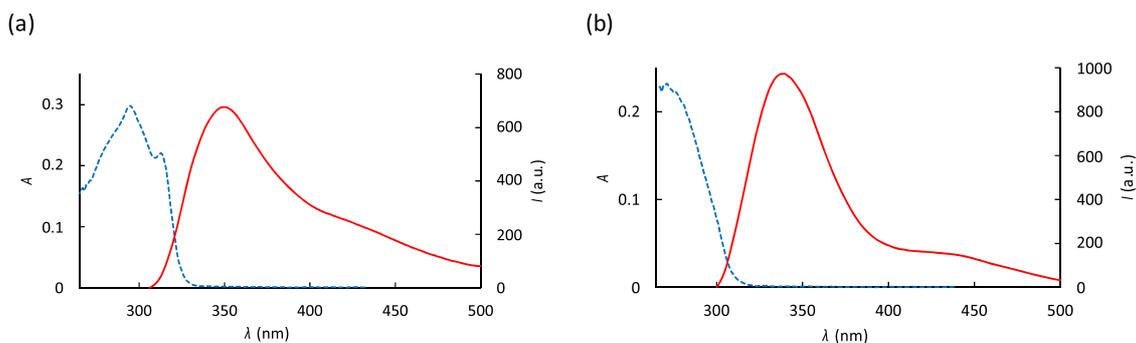

protons (**H**) of the lower part appear as a singlet at 7.0 ppm and an AB quartet at around 4.3 ppm, respectively. The diastereotopic protons **G** of the linkers give two AB doublets near 3.7 and 3.9 ppm, whereas the protons **F** and **E** give a slightly more complicated pattern at around 3.0 and 4.2 ppm, respectively. The aromatic protons **J** of the linkers are also observed as multiplets between 7.2 and 7.6 ppm, while the doublet at around 6.6 ppm is characteristic of the aromatic proton **I**.

The absorption and emission properties of compounds **2** and **3** in dimethyl sulfoxide (DMSO) containing 2% of water are shown in [Figure 3](#). The maximum emission wavelengths of **2** and **3** are in both cases red-shifted compared to that of host **1**: from 326 nm ( $\epsilon = 2.0 \times 10^4 \text{ M}^{-1} \text{ cm}^{-1}$ ) for host **1** to 352 nm ( $\epsilon = 9.4 \times 10^4 \text{ M}^{-1} \text{ cm}^{-1}$ ) and 334 nm ( $\epsilon = 5.1 \times 10^4 \text{ M}^{-1} \text{ cm}^{-1}$ ) for hosts **2** and **3**, respectively ([Table 1](#)). The fluorescent quantum yields  $\Phi$  are also improved when compared to that of host **1**: from 1.8% for cage **1** to 5.4 and 7.5% for hosts **2** and **3**, respectively ([Table 1](#)).<sup>34</sup>

We then studied the recognition of ACh and Ch by these two new hosts **2** and **3**. Additions of a solution of ACh or Ch in DMSO + 2% H<sub>2</sub>O to hosts **2** and **3** induce changes in fluorescence emission of the cages ([Figure 4](#) for ACh and [Figures S24 and S25](#) for Ch). However, the fluorescence response of these compounds strongly differs upon addition of the neurotransmitter guests. Cage **3** shows the same behavior as that reported for cage **1**: an increase of the fluorescence intensity is observed, whereas cage **2** displays a decrease of the fluorescence intensity upon progressive addition of guest

**Figure 2.** <sup>1</sup>H NMR spectra (400 MHz, CDCl<sub>3</sub>, 298 K) of hemicryptophanes 2 (a) and 3 (b).

**Figure 3.** Absorption spectra (in blue) and emission spectra (in red,  $\lambda_{\text{exc}} = 290$  nm): (a) hemicryptophane 2 (3.2  $\mu\text{M}$ ) and (b) hemicryptophane 3 (4.7  $\mu\text{M}$ ) in solution in DMSO + 2% H<sub>2</sub>O at 298 K.

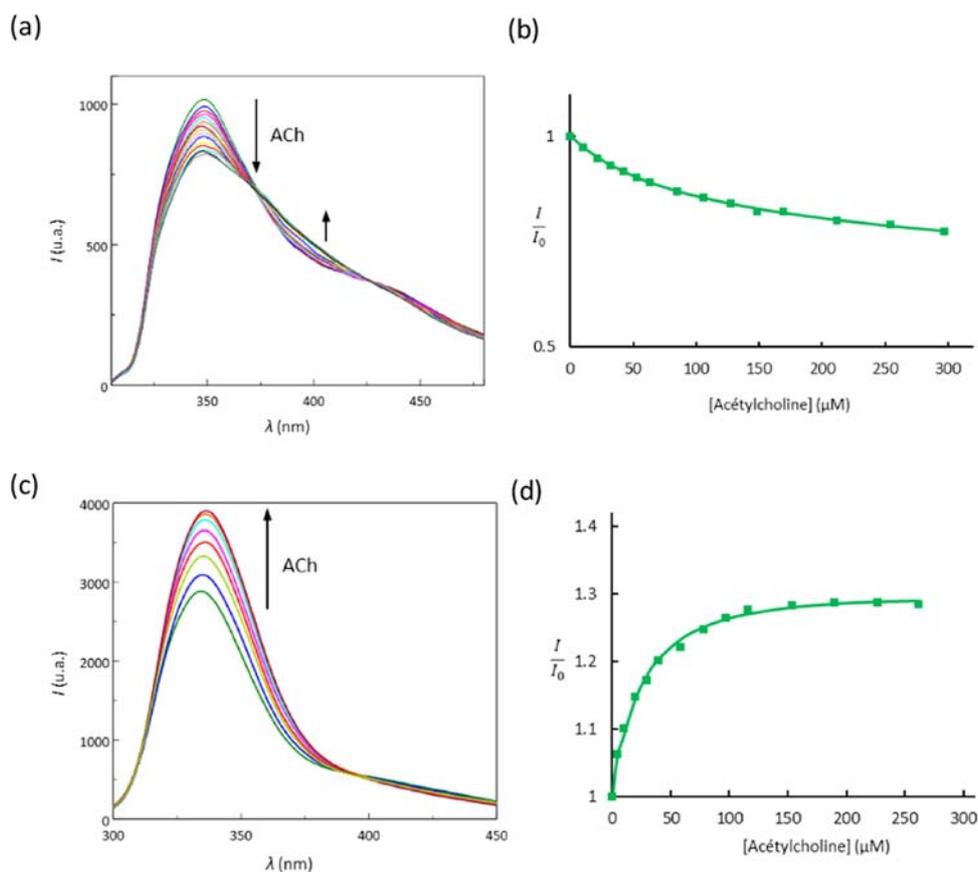

**Table 1. Spectroscopic Data of Cages 1, 2, and 3 in DMSO with 2% of Water at 298 K**

host	$\lambda_{\text{abs}}^{\text{max}}$ (nm)	$\epsilon$ (L mol <sup>-1</sup> cm <sup>-1</sup> )	$\lambda_{\text{em}}^{\text{max}}$ (nm)	$\Delta\lambda$ (nm)	$\phi_f$ (%)
1	288	$2.0 \times 10^4$	326	38	1.8
2	294	$9.4 \times 10^4$	352	58	5.4
3	274	$5.1 \times 10^4$	334	60	7.5

solutions. The expected higher rigidity of cage 2 might account for this opposite behavior. Both hosts 2 and 3 exhibit binding constants for ACh and Ch in the same range of magnitude compared to those of cage 1 (typically in the range of  $10^4$  M<sup>-1</sup>; see Table 2), highlighting that the introduction of fluorescent

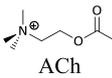

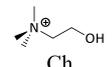

units in the linkers only slightly affects the binding properties of the host, probably because the size and shape of the cavity are similar in all cases. The ACh/Ch selectivity is also retained, with  $K_{\text{ACh}}/K_{\text{Ch}}$  ratios of 2.8 and 4.4 for hosts 2 and 3, respectively.

<sup>1</sup>H NMR titration experiments were also performed to give an insight into these recognition processes. To a solution of hosts 2 or 3 in a CDCl<sub>3</sub>/MeOH mixture (95/5) was added a concentrated solution of ACh or Ch in the same solvent mixture. Changes in the chemical shifts of both, the cages and the guests, were observed (Figures S30–S37), which is in agreement with the expected fast host–guest exchange on the

**Figure 4.** Fluorescent emission spectra at 298 K ( $\lambda_{\text{exc}} = 290$  nm) in DMSO + 2% H<sub>2</sub>O of a solution of (a) hemicryptophane 2 (5.0  $\mu\text{M}$ ) and (c) hemicryptophane 3 (5.0  $\mu\text{M}$ ) upon progressive additions of a solution of ACh (5.0 mM, counterion Cl<sup>-</sup>). Evolution of the relative fluorescence intensity as a function of the concentration of added ACh: (b) at 348 nm for host 2 and (d) at 338 nm for host 3. Curves were fitted with the Bindfit program (lines).<sup>35</sup>

Substrate	Host	$K_a$ ( $\text{L}\cdot\text{mol}^{-1}$ ) <sup>a</sup>	$K_{\text{ACh}}/K_{\text{Ch}}$
 ACh	1	$2.4 \times 10^4 \pm 2.0\%$	-
	2	$1.2 \times 10^4 \pm 2.1\%$	-
	3	$4.4 \times 10^4 \pm 4.4\%$	-
 Ch	1	$5.9 \times 10^3 \pm 2.3\%$	4.1
	2	$4.3 \times 10^3 \pm 2.2\%$	2.8
	3	$1.0 \times 10^4 \pm 4.8\%$	4.4

<sup>a</sup> $K_a$  was determined by fitting fluorescence titration curves (DMSO + 2% H<sub>2</sub>O, 298 K) with the Bindfit program.

NMR time scale that is usually observed with hemicryptophane hosts. One can see that, by increasing the ACh or Ch concentrations, both their (CH<sub>3</sub>)<sub>3</sub>N and CH<sub>2</sub> protons are downfield shifted. At the beginning of the titration experiment, the ACh or Ch guest is mostly encapsulated in the host and undergoes the shielding effect of the aromatic rings of hosts 2 and 3, leading to the upfield chemical shifts observed for N(CH<sub>3</sub>)<sub>3</sub> and CH<sub>2</sub> protons compared to that of the free guests in solution. The successive additions of the ACh or Ch guest increase the percent of the free guests and result in shifting of an average chemical shift toward that of the free guest, which

explains the downfield shift observed for the protons' guest during the titration experiments. This is consistent with the encapsulation of the guests in the heart of the cavities. For both hosts 2 and 3, the protons A, H, and J exhibit well-defined and sharp signals and no overlapping with the signals of other protons occurs during the titration experiments. Therefore, the variations of their chemical shifts against the guest/host ratio were plotted and the resulting titration curves were fitted with the Bindfit program, giving binding constants for ACh of  $4.7 \times 10^3$  and  $6.2 \times 10^3$  L mol<sup>-1</sup> and for Ch of  $6.49 \times 10^2$  and  $2.9 \times 10^2$  L mol<sup>-1</sup> for host 2 and 3, respectively.<sup>35</sup> The difference in the solvent as well as the change in the counterions used for NMR and fluorescent titration experiments could account for the difference of the binding constants measured by these two methods. Moreover, the changes in the chemical shifts during the NMR titration experiments are rather small, inducing higher errors in the determination of the  $K_a$  values. However, these NMR titration experiments nicely support the fluorescence ones, highlighting the remarkable ACh/Ch selectivity of this class of fluorescent hosts.

Then, density functional theory (DFT) calculations were performed to understand the interactions involved in these recognition processes. The optimized structures (Figure 5) show a partial encapsulation of ACh in receptors 2 and 3. The ammonium unit is located below the CTV moiety, in agreement with the NMR titration experiments where shielding of the (CH<sub>3</sub>)<sub>3</sub>N protons was observed in the presence of the cages. The ammonium unit interacts with

**Figure 5.** DFT-optimized structures of the encapsulated acetylcholine guest within the cavity of the fluorescent hemicryptophanes **2** (a) and **3** (b).

both the aromatics of the CTV and that of the south part by CH- $\pi$  interactions (C-H...C<sub>ar</sub> distances between 2.35 and 2.62 Å). Furthermore, hydrogen bonding between (i) the oxygen of the C=O carbonyl of ACh and the Ar-CH<sub>2</sub> and N-H protons of the receptors and (ii) the CH<sub>2</sub> and C(O)-CH<sub>3</sub> protons of ACh and the oxygen atoms of the CTV unit can be observed (distances between 2.2 and 2.5 Å). Thus, these DFT calculations give insight into the origin of the ACh/Ch selectivity: as Ch lacks the key ester function, these interactions described above are not possible with this guest, leading to a decrease of its affinity for the cavity of the hemicryptophanes, when compared to ACh.

## CONCLUSIONS

In summary, the synthesis of two new hemicryptophane cages **2** and **3** with improved fluorescent properties, when compared to previously reported host **1**, has been described. These cages turn out to be efficient receptors for neurotransmitter ACh displaying a marked selectivity for ACh over Ch. Whereas cage **3** behaves as a turn-on receptor of ACh, a decrease of fluorescence is observed when ACh is added to hemicryptophane **2**. Insights into the structure of the host/guest complexes have been obtained from NMR titration experiments and DFT calculations. Studies for longer-wavelength fluorescence detection and detection in water, using hemicryptophanes, are underway.

## EXPERIMENTAL SECTION

**General.** Commercial-grade solvents and starting material were used without additional purification. Chromatography and thin-layer chromatography (TLC) were performed with Merck 60 A (0.040–0.063 mm) silica gel and Merck silica gel 60 F<sub>254</sub> plates, respectively. A Büchi Melting Point B-545 apparatus was used for the determination of the melting points. A Bruker Alpha Platinum ATR spectrometer allowed for the recording of the IR spectra. <sup>1</sup>H NMR and <sup>13</sup>C NMR

were performed at 298 K on either a Bruker Avance III HD 400 MHz or a Bruker Avance III HD 300 MHz spectrometer. The protonated residual solvent signal was used as a reference for reporting the <sup>1</sup>H NMR and <sup>13</sup>C NMR chemical shifts  $\delta$ . High-resolution mass spectrometry (HRMS) was performed on a SYNAPT G2 HDMS (Waters) mass spectrometer with API and spectra obtained with time-of-flight (TOF) analysis using two internal standards. UV spectra were recorded on an Agilent Cary 60 UV-vis spectrophotometer and fluorescence spectra on a Jasco FP-8600 spectrofluorometer. CTV-Br derivative **5**, CTV-NH<sub>2</sub> **7**, and hemicryptophane **1** were synthesized according to the previously reported procedure.<sup>32–34</sup>

**Synthesis of Compound 9.** 5-Bromo-2-hydroxy-benzaldehyde **8** (1.61 g, 8.00 mmol), CuI (79 mg, 0.41 mmol), and Pd(PPh<sub>3</sub>)<sub>2</sub>Cl<sub>2</sub> (282 mg, 0.19 mmol) were added in a 100 mL round-bottom flask under an argon atmosphere. A 1/1 mixture of tetrahydrofuran (THF) and Et<sub>3</sub>N (35 mL) was added. Ethynylbenzene (1.75 mL, 15.9 mmol) was added, and the mixture was stirred under argon at 75 °C (oil bath) during 24 h. The mixture was cooled to r.t. and diluted with Et<sub>2</sub>O (50 mL) and water (50 mL). The aqueous layer was acidified with 2 M HCl solution (40 mL). The layers were separated, and the aqueous phase was extracted with Et<sub>2</sub>O (50 mL). Organic layers were combined, washed with brine (60 mL), dried over MgSO<sub>4</sub>, filtered, and concentrated under vacuum. The crude was purified by silica gel column chromatography with a gradient of petroleum ether and EtOAc (from 19/1 to 17/3) as eluent to afford **9** as a white powder (1.18 g, 66%). *R*<sub>f</sub> = 0.33 (PE/EtOAc: 95/5); <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>, 298 K)  $\delta$  11.14 (s, 1H), 9.92 (s, 1H), 7.79 (d, *J* = 2.0 Hz, 1H), 7.70 (dd, *J* = 8.6, 2.0 Hz, 1H), 7.57–7.52 (m, 2H), 7.41–7.36 (m, 3H), 7.02 (d, *J* = 8.6 Hz, 1H); <sup>13</sup>C{<sup>1</sup>H} NMR (100 MHz, CDCl<sub>3</sub>, 298 K)  $\delta$  196.1, 161.4, 139.8, 136.9, 131.5, 128.4, 122.9, 120.5, 118.1, 115.3, 88.9, 87.5; IR  $\nu$  = 3054, 2924, 2856, 1656, 1594, 1494, 1142, 1123 cm<sup>-1</sup>; HRMS (ESI-TOF) *m/z*: [M - H]<sup>-</sup> calcd for C<sub>15</sub>H<sub>9</sub>O<sub>2</sub> 221.0608; found 221.0608; mp = 82–83 °C.

**Synthesis of Compound 10.** In a 100 mL round-bottom flask were dissolved 1,3,5-tris(bromomethyl)benzene **11** (201 mg, 0.563 mmol) and compound **9** (418 mg, 1.88 mmol) in DMF (30 mL). Cs<sub>2</sub>CO<sub>3</sub> (770 mg, 2.36 mmol) was added, and the mixture was stirred at 55 °C (oil bath) for 16 h. The mixture was diluted with EtOAc (100 mL), washed with a 10% NaOH solution (4 × 50 mL) and brine (2 × 40 mL), and dried over MgSO<sub>4</sub>. The solvent was removed under reduced pressure to give **10** as a slightly orange solid (422 mg, 96%). *R*<sub>f</sub> = 0.13 (PE/CH<sub>2</sub>Cl<sub>2</sub>: 20/80); <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>, 298 K)  $\delta$  10.52 (s, 1H), 8.05 (d, *J* = 2.2 Hz, 1H), 7.71 (dd, *J* = 8.6, 2.2 Hz, 1H), 7.56–7.50 (m, 3H), 7.36–7.33 (m, 3H), 7.05 (d, *J* = 8.7 Hz, 1H), 5.30 (s, 2H); <sup>13</sup>C{<sup>1</sup>H} NMR (100 MHz, CDCl<sub>3</sub>, 298 K)  $\delta$  188.6, 160.1, 138.6, 137.3, 132.4, 131.6, 128.4, 125.9, 125.2, 123.0, 116.8, 113.2, 89.5, 87.7, 70.2; IR  $\nu$  = 2922, 2854, 1682, 1592, 1496, 1268, 1220 cm<sup>-1</sup>; HRMS (ESI-TOF) *m/z*: [M + NH<sub>4</sub>]<sup>+</sup> calcd for C<sub>54</sub>H<sub>40</sub>NO<sub>6</sub> 798.2850; found 798.2855; mp = 87–88 °C.

**Synthesis of Compound 12.** In a 100 mL round-bottom flask, 5-bromo-2-hydroxybenzaldehyde **8** (1.01 g, 5.02 mmol) was dissolved in toluene (25 mL) and EtOH (5 mL) under an argon atmosphere. Phenylboronic acid (1.25 g, 10.2 mmol), K<sub>2</sub>CO<sub>3</sub> (1.75 g, 12.5 mmol), and Pd(PPh<sub>3</sub>)<sub>4</sub> (302 mg, 0.26 mmol) were added successively under stirring. The reaction mixture was heated at 80 °C (oil bath) for 2 h. Solvents were removed under reduced pressure, and the reaction mixture was extracted with EtOAc (2 × 30 mL) and washed with a 1 M HCl solution (2 × 30 mL). Organic layers were combined, washed, and dried over MgSO<sub>4</sub>, and the solvent was removed. The crude was purified by silica gel column chromatography with petroleum ether and EtOAc (98/2) as eluent to afford **12** as a yellow powder (582 mg, 68%). *R*<sub>f</sub> = 0.41 (PE/EtOAc: 95/5); <sup>1</sup>H NMR (300 MHz, CDCl<sub>3</sub>, 298 K)  $\delta$  11.00 (s, 1H), 9.98 (s, 1H), 7.80–7.75 (m, 2H), 7.59–7.53 (m, 2H), 7.49–7.42 (m, 2H), 7.40–7.33 (m, 1H), 7.08 (d, *J* = 8.7 Hz, 1H); <sup>13</sup>C{<sup>1</sup>H} NMR (75 MHz, CDCl<sub>3</sub>, 298 K)  $\delta$  196.6, 161.0, 139.4, 135.7, 133.4, 131.9, 129.0, 128.8, 127.4, 126.8, 126.6, 120.8, 118.2; IR  $\nu$  = 3070, 2932, 2876, 1660, 1591, 1491 cm<sup>-1</sup>; HRMS (ESI-TOF) *m/z*: [M - H]<sup>-</sup> calcd for C<sub>13</sub>H<sub>9</sub>O<sub>2</sub> 197.0908; found 197.0907; mp = 93–94 °C.

**Synthesis of Compound 13.** Compounds **12** (274 mg, 1.38 mmol) and 1,3,5-tris(bromomethyl)benzene **11** (153 mg, 0.43 mmol) were dissolved in DMF (40 mL).  $\text{Cs}_2\text{CO}_3$  (612 mg, 1.88 mmol) was added, and the mixture was stirred at 55 °C (oil bath) for 16 h. The solid obtained was filtered on a frit and washed with cold ethanol and cold water to yield **13** as a slightly yellow powder (287 mg, 92%).  $R_f = 0.16$  (PE/ $\text{CH}_2\text{Cl}_2$ : 20/80);  $^1\text{H NMR}$  (300 MHz,  $\text{CDCl}_3$ , 298 K)  $\delta$  10.60 (s, 1H), 8.11 (d,  $J = 2.5$  Hz, 1H), 7.78 (dd,  $J = 8.6, 2.5$  Hz, 1H), 7.59–7.54 (m, 3H), 7.46–7.32 (m, 3H), 7.12 (d,  $J = 8.7$  Hz, 1H), 5.33 (s, 2H);  $^{13}\text{C}\{^1\text{H}\}$  NMR (75 MHz,  $\text{CDCl}_3$ , 298 K)  $\delta$  189.4, 160.0, 139.3, 137.6, 134.5, 134.3, 128.9, 127.4, 127.2, 126.7, 125.8, 125.4, 113.5, 70.3; IR  $\nu = 2932, 2857, 1688, 1595, 1491, 1260$   $\text{cm}^{-1}$ ; HRMS (ESI-TOF)  $m/z$ :  $[\text{M} + \text{NH}_4]^+$  calcd for  $\text{C}_{48}\text{H}_{40}\text{NO}_6$  726.2850; found 726.2852; mp = 114–116 °C.

**Synthesis of Hemicyptophane 2.** In a 500 mL round-bottom flask was dissolved CTV **7** (128 mg, 0.238 mmol) in a 1/1 mixture of  $\text{CHCl}_3/\text{MeOH}$  (120 mL). In the same mixture of solvent (100 mL), a solution of **10** (169 mg, 0.216 mmol) was added dropwise under stirring at r.t., and the reaction mixture was stirred at r.t. for 24 h. It was cooled to 0 °C, and  $\text{NaBH}_4$  (290 mg, 7.67 mmol) was added portionwise. The mixture was stirred at r.t. for 4 h, and solvents were evaporated. The crude residue was dissolved in  $\text{CHCl}_3$  (50 mL) and washed with a 10% NaOH solution (50 mL). The aqueous phase was extracted with  $\text{CHCl}_3$  (50 mL), and combined organic layers were washed with a 10% NaOH solution ( $3 \times 40$  mL), dried over  $\text{MgSO}_4$ , and filtered. The organic solvent was removed under reduced pressure to afford a yellowish solid purified by silica gel column chromatography with  $\text{CHCl}_3/\text{MeOH}/\text{Et}_3\text{N}$  as an eluent (gradient from 97/1/2 to 93/6/2). Hemicyptophane **2** was obtained as a white solid (110 mg, 40%).  $R_f = 0.27$  ( $\text{CHCl}_3/\text{MeOH}/\text{Et}_3\text{N}$ : 95/3/2);  $\lambda_{\text{max}} = 284$  nm (DMSO + 2%  $\text{H}_2\text{O}$ ,  $\epsilon = 94\,000$   $\text{L mol}^{-1} \text{cm}^{-1}$ );  $^1\text{H NMR}$  (400 MHz,  $\text{CDCl}_3$ , 298 K)  $\delta$  7.49–7.46 (m, 2H), 7.40–7.37 (m, 1H), 7.31–7.28 (m, 4H), 6.95 (s, 1H), 6.93 (s, 1H), 6.78 (s, 1H), 6.58 (d,  $J = 8.5$  Hz, 1H), 4.75 (d,  $J = 13.6$  Hz, 1H), 4.35 (d,  $J = 11.9$  Hz, 1H), 4.26 (d,  $J = 12.0$  Hz, 1H), 4.20–4.13 (m, 2H), 3.88 (d,  $J = 13.5$  Hz, 1H), 3.67 (d,  $J = 13.5$  Hz, 1H), 3.62 (s, 3H), 3.53 (d,  $J = 13.9$  Hz, 1H), 3.05–2.94 (m, 2H), 2.92–2.85 (m, 1H);  $^{13}\text{C}\{^1\text{H}\}$  NMR (100 MHz,  $\text{CDCl}_3$ , 298 K)  $\delta$  156.47, 148.60, 146.87, 137.02, 133.52, 132.94, 131.88, 131.46, 128.27, 127.88, 126.97, 123.57, 116.39, 115.28, 113.47, 111.87, 89.28, 88.18, 69.17, 69.09, 55.84, 49.11, 47.78, 36.41; IR  $\nu = 3332, 2924, 1606, 1507, 1260, 1240, 1142$   $\text{cm}^{-1}$ ; HRMS (ESI-TOF)  $m/z$ :  $[\text{M} + 2\text{H}]^{2+}$  calcd for  $\text{C}_{84}\text{H}_{77}\text{N}_3\text{O}_9$  635.7824; found 635.7819; mp = 169–171 °C.

**Synthesis of Hemicyptophane 3.** In a 250 mL round-bottom flask was added CTV **7** (99 mg, 0.184 mmol) dissolved in a 1/1 mixture of  $\text{CHCl}_3/\text{MeOH}$  (120 mL). In the same mixture of solvent (120 mL), a solution of **13** (117 mg, 0.166 mmol) was added dropwise under stirring at r.t., and the reaction mixture was stirred at r.t. overnight.  $\text{NaBH}_4$  (240 mg, 6.35 mmol) was added portionwise at 0 °C, and the mixture was stirred at r.t. during 4 h. Solvents were evaporated; the crude residue was dissolved in  $\text{CHCl}_3$  (30 mL) and washed with a 10% NaOH solution (30 mL). Aqueous phase was extracted twice with  $\text{CHCl}_3$  ( $2 \times 30$  mL), and combined organic layers were washed with a 10% NaOH solution ( $3 \times 25$  mL) and dried over  $\text{MgSO}_4$ . Organic solvent was removed under reduced pressure to afford a white solid purified by silica gel column chromatography ( $\text{CHCl}_3/\text{MeOH}/\text{Et}_3\text{N}$ , gradient from 97/1/2 to 90/8/2). Hemicyptophane **3** was obtained as a white solid (48 mg, 24%).  $R_f = 0.31$  ( $\text{CHCl}_3/\text{MeOH}/\text{Et}_3\text{N}$ : 95/3/2);  $\lambda_{\text{max}} = 274$  nm (DMSO + 2%  $\text{H}_2\text{O}$ ,  $\epsilon = 51\,000$   $\text{L mol}^{-1} \text{cm}^{-1}$ );  $^1\text{H NMR}$  (400 MHz,  $\text{CDCl}_3$ , 298 K)  $\delta$  7.50–7.43 (m, 3H), 7.39–7.33 (m, 2H), 7.33–7.28 (m, 2H), 6.97 (s, 1H), 6.95 (s, 1H), 6.79 (s, 1H), 6.65 (d,  $J = 8.5$  Hz, 1H), 4.76 (d,  $J = 13.7$  Hz, 1H), 4.36 (d,  $J = 12.1$  Hz, 1H), 4.30–4.14 (m, 3H), 3.97 (d,  $J = 13.3$  Hz, 1H), 3.78 (d,  $J = 13.2$  Hz, 1H), 3.62 (s, 3H), 3.54 (d,  $J = 13.6$  Hz, 1H), 3.14–3.05 (m, 1H), 2.98–2.90 (m, 1H), 2.20 (s, 1H);  $^{13}\text{C}\{^1\text{H}\}$  NMR (100 MHz,  $\text{CDCl}_3$ , 298 K)  $\delta$  155.93, 148.67, 146.87, 140.59, 137.28, 133.50, 133.02, 131.87, 128.97, 128.69, 126.89, 126.73, 126.65, 126.59, 116.54, 113.46, 112.21, 69.11, 69.03, 55.83, 49.51, 47.90, 36.44; IR  $\nu = 3348, 2912, 1613, 1511, 1413, 1248, 1206, 1108$   $\text{cm}^{-1}$ ; HRMS (ESI-TOF)  $m/z$ :

$[\text{M} + 2\text{H}]^{2+}$  calcd for  $\text{C}_{78}\text{H}_{77}\text{N}_3\text{O}_9$  599.7824; found 599.7823; mp = 187–189 °C.

**Photophysical Studies.** The absorption spectrum of a solution in DMSO + 2%  $\text{H}_2\text{O}$  of each hemicyptophane was recorded between 265 and 500 nm using a quartz cuvette (1 cm  $\times$  1 cm  $\times$  4.5 cm).

The emission spectrum was recorded between 300 and 550 nm. Emission spectra of four solutions of each hemicyptophane in DMSO containing 2%  $\text{H}_2\text{O}$ , with absorbance lower than 0.1, were recorded, and the average quantum yield was calculated with quinine bisulfate in  $\text{H}_2\text{SO}_4$  (0.5 M). All of these solutions afforded the same results. Spectra were recorded on a Jasco FP-8600 spectrofluorometer equipped with a JASCO Peltier cell holder ETC-815 to maintain the temperature at  $25.0 \pm 0.2$  °C.

**Fluorescence Titrations.** A solution of each hemicyptophane (2.5 mL, 5.0  $\mu\text{M}$ ) in DMSO + 2%  $\text{H}_2\text{O}$  was taken into the quartz cuvette, and then certain equivalents of a concentrated guest solution (5.0 mM) in the same solvents were added stepwise with a microsyringe. The final volume of the solution was almost unchanged (2.5 mL) since very small volume of guest solution was added. The solution was mixed and incubated for 30 s before irradiation at 290 nm at 25 °C. The corresponding emission values during titration were then recorded.

**NMR Titrations.** A solution of hemicyptophane host **2** or **3** ( $1.0 \times 10^{-3}$  M in  $\text{CDCl}_3/\text{CD}_3\text{OD}$  95/5, 500  $\mu\text{L}$ ) was titrated in NMR tubes with aliquots of a concentrated solution ( $5.0 \times 10^{-3}$  M in the same solvent) of picrate salts of neurotransmitters. The shifts  $\Delta\delta$  of the host's proton signals at 7.61 and 7.55 ppm were measured after each addition and plotted as a function of the substrate/receptor ratio ( $[\text{S}]/[\text{R}]$ ). Association constant  $K_a$  was obtained by nonlinear least-squares fitting of these plots using the Bindfit program from Thordarson's group.<sup>35</sup>

**Computational Method.** To access geometrical information upon the host–guest species, full geometry optimizations were performed using restricted density functional theory (DFT) calculations. A combination of the BP86 functional and an all-electron 6-31G\* basis set including polarization functions has been proven to be very satisfactory for similar issues.<sup>36</sup> However, we checked using the hybrid B3LYP functional that our results do not suffer from the arbitrariness of the exchange–correlation functional. All calculations were performed using the Gaussian 03 suite of program.<sup>37</sup>
