### I. INTRODUCTION

This supplementary document provides additional results for our main paper “The Effect of Temporal Sub-sampling on the Accuracy of Volumetric Video Quality Assessment”. As mentioned in the main paper, to evaluate the effect of temporal sub-sampling on volumetric video quality assessment accuracy, the Pearson correlation coefficient (PCC) and root-mean squared error (RMSE) were used for prediction accuracy and Spearman rank-ordered correlation coefficient (SROCC) was used for prediction monotonicity as recommended in [1]. Due to the page limitations, only PCC could be reported in the main paper.

In this supplementary document, we provide the SROCC and RMSE results that could not be reported in the main paper. The results for different pooling methods and different temporal sub-sampling rates are shown in Tables I-IV. Furthermore, we report our findings on the combined analysis for temporal sub-sampling and temporal pooling.

### II. ANALYSIS OF TEMPORAL SUB-SAMPLING RATE

Table I and Table II report the SROCC and RMSE values, respectively, computed between different objective quality metrics scores and the DMOS values for each of the different sub-sampling rates. Similar to the PCC scores reported in the main paper, the SROCC and RMSE results show that the set of p2point-RMS, Color-Y, and SSIM metrics are found best performing metrics for point-based geometry, point-base color, and image quality metrics.

### III. ANALYSIS OF TEMPORAL POOLING METHODS

Table III and Table IV report the SROCC and RMSE values, respectively, computed between different objective quality metrics scores and the DMOS values for each of the different pooling methods. These results are given for the original frame-rate of the volumetric videos, i.e., 30 fps. Similarly, the SROCC and RMSE values follow the same pattern as PCC reported in the main paper.

TABLE III

The results presented in Tables I-IV show that even though there are small changes in the numerical values, the best performing objective quality metrics do not change. In the next section, we report on the combined analyses of temporal sub-sampling and temporal pooling.

#### IV. COMBINED ANALYSIS OF TEMPORAL SUB-SAMPLING RATE AND TEMPORAL POOLING

In addition to the separate analyses of temporal sub-sampling of the volumetric video frames and of temporal pooling methods, here we analyze the effect of these two factors combined on volumetric video objective quality assessment. Fig. 1 presents the SROCC values for the combined analysis. Each row shows a different metric. Metric order is the same as rows of Tables I-IV. Each column shows a different com-

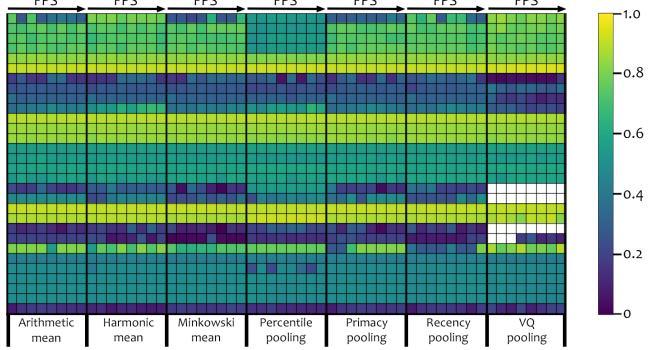

Fig. 1. The effect of both temporal sub-sampling rate and temporal pooling on the performance of the metric in terms of SROCC.

bination of temporal sub-sampling rate and temporal pooling in the following order:  $\{P_i(j)\}$ , where  $j$  is the temporal sub-sampling rate for  $j \in \{1, 2, 3, 5, 6, 10, 15, 30\}$ , and  $P_i$  is the  $i^{th}$  pooling method for  $i \in \{\text{Mean}_{\text{arith}}, \text{Mean}_{\text{harm}}, \text{Mean}_{\text{Mink}}, \text{Pool}_{\text{perc}}, \text{Pool}_{\text{prim}}, \text{Pool}_{\text{reco}}, \text{Pool}_{\text{VQ}}\}$ . That is, the order of temporal pooling methods is the same as columns of Tables I-IV.

The Fig. 1 shows that there are no patterns that emerge from the combined analysis. Although some pooling methods helps to obtain better correlation results for some metrics, we don't observe a categorical preference among pooling methods. Similarly, effect of temporal sub-sampling rate on the pooling methods is rather arbitrary. Increasing sub-sampling rate does not necessarily increase the metric accuracy for a given pooling method.
