## STATEMENT OF TRANSLATIONAL RELEVANCE

Taxane-based therapies are currently used for the clinical treatment of prostate cancer, but treatment usually fails after time as resistance emerges requiring new therapeutic strategies to overcome taxane-resistance and improve outcomes for men with prostate cancer.

Our study reveals the critical role played by FKBP7, a still uncharacterized chaperon protein as a novel mediator of taxane resistance in prostate cancer. The finding that FKBP7 interacts and regulates the level of the translation initiation factor eIF4G will allow targeting FKBP7 or the eIF4G-containing eIF4F complex, as a novel therapeutic strategy in chemoresistant prostate cancer.

## ABSTRACT

**PURPOSE:** Targeted therapies that use the signaling pathways involved in prostate cancer are required to overcome chemoresistance and improve treatment outcomes for men. Molecular chaperones play a key role in the regulation of protein homeostasis and are potential targets for overcoming chemoresistance.

**EXPERIMENTAL DESIGN:** We established four chemoresistant prostate cancer cell lines and used image-based high-content siRNA functional screening, based on gene-expression signature, to explore mechanisms of chemoresistance and identify new potential targets with potential roles in taxane resistance. The functional role of a new target was assessed by *in vitro* and *in vivo* silencing, and mass spectrometry analysis was used to identify its downstream effectors.

**RESULTS:** We identified FKBP7, a prolyl-peptidyl isomerase overexpressed in docetaxel-resistant and in cabazitaxel-resistant prostate cancer cells. This is the first study to characterize the function of human FKBP7 and explore its role in cancer. We discovered that FKBP7 was upregulated in human prostate cancers and its expression correlated with the recurrence observed in patients receiving docetaxel. *FKBP7* silencing showed that FKBP7 is required to maintain the growth of chemoresistant cell lines and chemoresistant tumors in mice. Mass spectrometry analysis revealed that FKBP7 interacts with eIF4G, a component of the eIF4F translation initiation complex, to mediate the survival of chemoresistant cells. Using small molecule inhibitors of eIF4A, the RNA helicase component of eIF4F, we were able to kill docetaxel and cabazitaxel-resistant cells.

**CONCLUSION:** Targeting FKBP7 or the eIF4G-containing eIF4F translation initiation complex could be novel therapeutic strategies to eradicate taxane-resistant prostate cancer cells.

## 1 INTRODUCTION

2 Molecular chaperones are upregulated and associated with resistance to treatment in castration-  
3 resistant prostate cancer (CRPC) (1,2), an advanced form of prostate cancer that develops when the  
4 disease progresses after initial treatment with surgery and/or medical castration using androgen  
5 deprivation therapy (ADT). Docetaxel and cabazitaxel are two taxane chemotherapies that are  
6 approved for treatment of metastatic CRPC (3). Recent studies have reported benefits when  
7 docetaxel was combined with ADT during the hormone-sensitive stage of the disease (3,4).  
8 Unfortunately, approximately 50% of patients do not respond to docetaxel. Taxane resistance  
9 mechanisms include decreased cellular drug accumulation due to membrane-bound efflux protein  
10 overexpression, tubulin isotope overexpression, and defects in apoptosis (5,6). Many of these  
11 pathways involve molecular chaperones, but strategies for targeting them have encountered only  
12 limited efficacy. New therapeutic strategies are needed to overcome taxane-resistance and improve  
13 outcomes for men with prostate cancer.

14 Several molecular chaperones, including heat-shock proteins Hsp27 and Hsp90, clusterin (CLU) and  
15 FKBP506-binding proteins (FKBPs), are involved in protein folding, cellular signaling, apoptosis and  
16 transcription, and are potential targets for cancer treatment (7,8). FKBP12 (*FKBP1A*) was the first  
17 enzyme shown to bind FK506, a natural immunosuppressant, and rapamycin, a macrolide indicated  
18 in organ rejection prophylaxis after renal transplantation (9). FKBP12-rapamycin complex associates  
19 with the major downstream Akt mammalian target of rapamycin mTOR-kinase (mammalian target of  
20 rapamycin kinase) and has immunosuppressive and antiproliferative properties. Larger FKBPs, such  
21 as FKBP52 (*FKBP4*) and FKBP51 (*FKBP5*), have also been shown to form rapamycin-induced ternary  
22 complexes that inhibit mTOR-kinase activity. FKBP51 and FKBP52 regulate the microtubule-  
23 associated protein, tau, and thus affect microtubule stability (10). FKBP7, a molecular chaperone  
24 cloned from mouse heart (11), is located in the endoplasmic reticulum and has been shown to

25 suppress the ATPase activity of mouse ER chaperone HSPA5/GRP78/Bip by its prolyl-peptidyl  
26 isomerase activity (11,12).

27 Here, we established four chemoresistant prostate cancer cell lines to explore mechanisms of taxane  
28 resistance, and investigated the FKBP7 signaling pathway and its potential role in taxane resistance in  
29 human prostate cancer patients.

## 30 **METHODS**

### 31 **Cell lines**

32 Parental and taxane-resistant IGR-CaP1, PC3, LNCaP and 22RV1 human PCa cell lines were  
33 maintained in RPMI1640 medium with 10% fetal bovine serum. Pooled taxane-resistant populations  
34 were obtained by exposing cells to docetaxel (Sanofi-Aventis) or cabazitaxel (Selleckchem) in a dose-  
35 escalation manner as described for IGR-CaP1 (13). Resistant cell lines were treated monthly with the  
36 maximum dose of docetaxel or cabazitaxel to maintain the resistant phenotype. Other cell lines are  
37 detailed in Supplementary Information.

### 38 **Microarray**

39 Gene expression was profiled using a 4×44K human whole genome (G4112F) expression array  
40 (Agilent Technologies) with dual-color dye-swap competitive hybridization. Total RNA from untreated  
41 parental IGR-CaP1 cells was the RNA reference. Total RNA from IGR-CaP1 cells resistant to 5, 12, 25  
42 50, 100 and 200nM of docetaxel were used as samples (two replicates/sample). Image (Feature  
43 Extraction software: Agilent Technologies) and gene expression (Bioconductor) analyses was  
44 performed.

45 For resistant cell lines, Log<sub>10</sub> ratios were computed against the relevant sensitive cell line. To select  
46 relevant genes we combined three strategies. Genes permanently over/under-expressed in all  
47 resistant cell lines were tested using multiple t-tests with bootstrap resampling-based analysis

48 (10,000 samples with replacement). Resulting  $p$ -values were adjusted using the Benjamini-Hochberg  
49 correction method (14) (adjusted  $p$ -values  $\leq 0.05$  considered as significant). Genes with monotonic  
50 increasing/decreasing expression over increasing doses were tested using 5-parameter logistic  
51 regression (14). The decision rule combined an absolute fold change of  $\geq 2$  between the upper and  
52 lower asymptotes, and an adjusted  $p$ -value  $\leq 1e-3$ , representing correlation quality between the  
53 fitted and observed values. Supplementary, potentially informative genes were selected using an  
54 information criterion method with reversed principal component analysis (probes considered as  
55 observations). An information criterion per gene was computed to quantify its ability to separate  
56 samples and 998 genes potentially implicated in docetaxel resistance were identified (593  
57 upregulated and 407 down-regulated). Image-based high-content siRNA screening, data analysis and  
58 hit calling are detailed in Supplementary information.

#### 59 **Tissue microarray staining and analysis**

60 Prostate tissue samples used for the tissue microarray (TMA) were obtained from the Vancouver  
61 Prostate Centre Tissue Bank. This study followed the ethical guidelines stated in the Declaration of  
62 Helsinki, specimens were obtained from patients with their informed written consent form following  
63 a protocol approved by the Institutional Review Board of the University of British Columbia (UBC).  
64 The H&E slides were reviewed and the desired areas were identified.

65 Eight TMAs were constructed (Beecher Instruments) by punching duplicate 1mm cores per sample.  
66 All specimens ( $n=381$ ) were obtained through radical prostatectomy, except CRPC samples obtained  
67 via transurethral resection of the prostate.

68 Two TMAs were constructed from 90 patients who had received docetaxel after radical  
69 prostatectomy. Analysis was performed on 69 selected cancer patients with good core integrity.  
70 Immunostaining was performed using an automatized technique (Biotin-Streptavidin system and  
71 solvent-resistant DAB Map kit) with a Discover XT™ autostainer (Ventana Medical System). Slides  
72 were digitized with the SL801 autoloader and Leica SCN400 scanning system (Leica Microsystems;  
73  $\times 20$  magnification). Clearly positive/negative and mixed positive/negative cores were identified.

74 FKBP7 staining was analyzed (0: no staining; 1: faint or focal stain; 2 and 3: convincingly intense stain  
75 in most cells).

#### 76 **SiRNA transfection**

77 Cell transfection was performed for siRNA sequences (see Supplementary Information). Cells were  
78 plated in 96-well plates with 20nM siRNA for reverse transfection. Transfection efficiency was  
79 checked by western-blot.

#### 80 **Western blot**

81 Immunoblots were prepared using whole cell lysate with RIPA buffer, protease inhibitors (Roche) and  
82 phosphatase inhibitors (Sigma-Aldrich), then analyzed using an enhanced chemoluminescence-based  
83 detection kit (Pierce). See Supplementary Information for Antibody sources.

#### 84 **ShRNA knockdown in docetaxel-resistant (Dtx-R) mouse model**

85 Animal experiments were approved by the local ethics committee (CEEA IRCIV/IGR no. 1226.01,  
86 registered with the French Ministry of Research) and performed in compliance with EU Directive  
87 63/2010. IGR Animal Resources holds a Department of Health and Human Services Animal Welfare  
88 Insurance (no. A5660-01) and complies with the Guide for the Care and Use of Laboratory Animals.

89 The Dtx-R mouse model (Supplementary Fig. S4A) was established in nude mice (see Supplementary  
90 Information). Two shRNAs targeting FKBP7 (shFK-1 and shFK-2) were engineered and packaged using  
91 the GIPZ lentivirus delivery system (see Supplementary information for details). Two  $10^6$  IGR-Rvivo  
92 cells transduced with sh-ctrl, shFK-1 or shFK-2 (in 100 $\mu$ l PBS with 50% Matrigel) were injected  
93 subcutaneously in NOD Scid gamma mice purchased from the IGR Animal Resources. Tumor growth  
94 was monitored for 50-70 days. When tumors reached an average volume of 450-500mm<sup>3</sup>, mice were  
95 injected intraperitoneally, three times with docetaxel at 30mg/kg or vehicle, once every 3 weeks.

#### 96 **Mass spectrometry analysis**

97 IGR-CaP1-Dtx-R and RPE-1 cells were grown in 4 T150 flasks and harvested at ~80% confluency. Cells  
98 were lysed and ~10mg proteins were extracted twice for 30 minutes in buffer (120mM NaCl, 20mM

99 Hepes, 1mM EDTA, 5% glycerol, 0.5% NP40 and protease inhibitor). Pooled supernatants were  
100 incubated overnight with 6 $\mu$ g of either control IgG or FKBP7 antibodies, and 50 $\mu$ l of magnetic beads  
101 (Dynabeads<sup>®</sup> Protein A, Thermo Fisher Scientific). After 4 washes, protein complexes were eluted  
102 twice in LDS buffer (Thermo Fisher Scientific) and loaded onto 10% Bis-Tris protein gel. After 5 min of  
103 migration, the band containing the proteins was excised and processed [standard protocol (15)].  
104 Peptide mixtures were analyzed on EASY 1000nLC + Q-EXACTIVE (Thermo Fisher Scientific), using an  
105 EASY-Spray nanocolumn (ES800 15cm 75 $\mu$ m), 300 nl/min flow and 2h gradient of acetonitrile + 0.1%  
106 formic acid (5% starting and 35% final acetonitrile concentrations). Mass resolution for the full scan  
107 was set at 70,000 at 400 m/z. The 10 most intense precursor ions from a survey scan were selected  
108 for MS/MS fragmentation using high-energy collision dissociation fragmentation with 27%  
109 normalized collision energy (detected at mass resolution 17,500 at 400 m/z). Dynamic exclusion was  
110 set for 30 seconds with a 10 ppm mass window. Each sample was analyzed in triplicate. The acquired  
111 data were analyzed with Proteome Discoverer software using a Mascot search engine (Proteome ID  
112 UP000005640; 20253 sequences). MS/MS spectra were searched with a precursor mass tolerance  
113 of 10 ppm and fragment mass tolerance of 0.05 Da. Trypsin was specified as protease with a  
114 maximum of two missed cleavages allowed. The minimum peptide length was specified as 6 amino  
115 acids. Data were searched against a decoy database, and the false discovery rate was set at 1% of the  
116 peptide level. FKBP7 interactors were selected when proteins (compared to IgG control) were only  
117 identified in the FKBP7 immunoprecipitation or were enriched at least 3-fold in the specific  
118 immunoprecipitation. Specific protein interactors were processed [Ingenuity Pathway Analysis<sup>®</sup>  
119 (IPA)].

## 120 **SILAC (stable isotope labeling by amino acids in cell culture) analysis**

121 IGR-CaP1-Dtx-R or RPE-1 cells were adapted, respectively, to RPMI or DMEM:F12 SILAC media  
122 containing either 12C6, 14N4 L-Arginine-HCl + 12C6 L-Lysine-2HCl (light media) or 13C6, 15N4 L-  
123 Arginine-HCl + 13C6 L-Lysine-2HCl (heavy media) (Thermo Fisher Scientific) for a minimum of 5 cell  
124 doublings. Cells grown in heavy media were transfected with control siNT and cells cultured in light

125 media were transfected with si-FKBP7-2. Equal amounts of cells were mixed and lysed in LDS sample  
126 buffer and reducing agent (Thermo Fisher Scientific). Samples were loaded onto NuPage 10% Bis-Tris  
127 protein gel and proteins were allowed to enter the gel (with application of 150 Volts) for only 5  
128 minutes, then the protein-containing band was excised and processed [standard protocol (16)].  
129 Analysis of the obtained peptide mixtures was performed as described above, except the H/L ratio  
130 per peptide, which was calculated by the quantitation node. The average light to heavy ratio was  
131 calculated per identified protein and the lists of proteins in IGR-CaP1-Dtx-R and RPE-1 were  
132 processed through IPA.

### 133 **Proximity ligation assay**

134 FKBP7-eIF4G and eIF4E-eIF4G interactions were detected by *in situ* proximity ligation assay (PLA)  
135 (Duolink, Sigma-Aldrich). Cells were fixed with paraformaldehyde, permeabilized and the PLA  
136 protocol was performed (Olink Bioscience). After blocking, primary antibodies were incubated for 1h  
137 at 37°C. PLA<sup>®</sup> probe secondary antibodies were incubated for 1h at 37°C. After ligation and DNA  
138 amplification, amplicons were detected using far red fluorescence, nuclei were stained with DAPI and  
139 slides were mounted with Olink Mounting Medium. Images were acquired with a Virtual Slides  
140 VS120-SL microscope [Olympus, Tokyo, Japan; magnification 20X, air objective (0.75 NA), 10-ms  
141 exposure for the DAPI channel and 300-ms exposure for the Cy5 channel; 1pixel=0.32µm] and the  
142 number of PLA signals/cell was counted using Image Analysis toolbox in Matlab (2011a).

### 143 **Statistical Analysis**

144 For the TMA, FKBP7 staining was analyzed with the Chi-square test and the recurrence % was  
145 calculated with a Fisher test. Kaplan–Meier curve statistical significance *p*-values were calculated  
146 using the Cox proportional hazard model. Cell proliferation curves and tumor growth curves were  
147 analyzed by a two-way ANOVA with Bonferroni post-tests. The significance of the mRNA coding level  
148 for eIF4G when FKBP is silenced was set with a Student *t*-test. The significance of eIF4G-FKBP7 and  
149 eIF4E-eIF4G interactions was tested with the linear model or Wilcoxon rank test.

150

151

152 **Accession number**

153 Microarray experiments were submitted to the Array Express data base (EBI, UK)

154 ([www.ebi.ac.uk/arrayexpress/](http://www.ebi.ac.uk/arrayexpress/)), accession number E-MTAB-4869. MS data were deposited in PRIDE

155 ([www.ebi.ac.uk/pride/](http://www.ebi.ac.uk/pride/)).

156

## 157 RESULTS

### 158 **FKBP7 is upregulated during the progression of chemoresistant CRPC**

159 To decipher the mechanisms of taxane resistance in prostate cancer, we developed a series of 4  
160 isogenic parental, docetaxel-resistant (Dtx-R), and cabazitaxel-resistant (Cbx-R) cell lines  
161 representative of the different types of epithelial prostate cancer cells (Supplementary Fig. S1). By  
162 comparing the gene expression profiles of parental and Dtx-R cells (13,17), we generated a signature  
163 of 998 highly differentially-expressed genes potentially correlating with chemoresistance  
164 (Supplementary Table S1A-B). Following image-based high-content screening in which the 593  
165 upregulated genes were independently targeted with 4 siRNAs, we identified 34 genes required for  
166 cell survival of IGR-CaP1-Dtx-R cells, for which at least 2 siRNAs showed robust Z-scores >2 for G0  
167 cell-cycle arrest phenotype modification and cell proliferation (Supplementary Table S2A-B). We  
168 focused on chaperone proteins responsive to stress. In particular, as already reported (18,19), the ER  
169 chaperone protein HSPA5 (GRP78/BiP) was sorted as a candidate involved in chemoresistance in our  
170 model. Considering that HSPA5 has been shown to interact with FKBP7 chaperone in a mouse model  
171 (12), we focused on the potential role of the uncharacterized FKBP7 human protein, one of the hits  
172 during screening, in the mechanism of taxane resistance in prostate cancer.

173 FKBP7 protein levels were higher in the four parental prostate cancer cell lines compared to RWPE-1  
174 non-cancerous prostate cells (Fig. 1A), and in all Dtx-R and Cbx-R cells compared to their respective  
175 parental cells, with an 8 fold-change in taxane-resistant IGR-CaP1 cells. Increased FKBP7 protein  
176 levels were related to gene expression upregulation, as we found more FKBP7 mRNA in the taxane-  
177 resistant cells than in parental cells (Supplementary Fig. S2A). An increase in FKBP7 expression was  
178 an early response of cells observed after 48h-72h of treatment with microtubule-targeting agents  
179 such as taxanes and nocodazole (Fig. 1B and Supplementary Fig. S2B). In contrast, FKBP7 was not  
180 overexpressed in enzalutamide-resistant 49F and 42D cells generated from an *in vivo* LNCaP model  
181 (20,21) compared to the enzalutamide-sensitive V16D cells (Fig. 1C).

182 To investigate the physiological relevance of FKBP7 expression in prostate cancer, we determined  
183 FKBP7 expression by immunohistochemistry using tissue microarrays containing 381 prostate cancer  
184 and benign tissues obtained from radical prostatectomy or transurethral resection (Supplementary  
185 Table S3). Consistent with observations in non-cancerous RWPE-1 cells *versus* CaP cell lines in Fig1A,  
186 higher FKBP7 expression was seen in prostate cancers than in benign tissues (Fig. 1D). Quantification  
187 of staining intensities showed that FKBP7 levels were significantly higher in prostate cancers than in  
188 benign tissues (Fig. 1D).

189 We evaluated FKBP7 expression using TMAs comprising a subset of 69 prostate cancers from patients  
190 who had received docetaxel as neoadjuvant therapy. High FKBP7 levels correlated significantly with  
191 recurrence % in patients (post-surgical prostate cancer recurrence, metastasis or death); 79% of  
192 patients with high FKBP7 levels developed recurrence compared to 42% of patients with low FKBP7  
193 (Fig. 1E). High levels of FKBP7 were significantly associated with a shorter time to recurrence in  
194 patients ( $p=0.004$ ; hazard ratio for low FKBP7: 0.3846) (Fig. 1F). Levels of FKBP7 during progression to  
195 lethal prostate cancer did not correspond to gene mutations in published data from whole exome  
196 sequencing in docetaxel-treated CRPC patients (22). These results show strong correlations between  
197 FKBP7 levels and resistance to cytotoxic treatment in prostate cancer.

#### 198 **SiRNA-mediated FKBP7 knock-down blocks chemoresistant cell growth and increases apoptosis in** 199 **taxane-treated resistant cells**

200 To determine whether FKBP7 could be a therapeutic target in chemoresistant prostate cancer, we  
201 used 2 siRNA sequences targeting FKBP7 to knock-down FKBP7 expression in chemoresistant cells. A  
202 statistically significant decrease in chemoresistant cell growth was observed after FKBP7 silencing  
203 (Fig. 2A). Except for 22RV1 cells, a similar effect was observed in the parental cells (Supplementary  
204 Fig. S3A). FKBP7 silencing induced slight apoptosis of chemoresistant cells, and PARP cleavage was  
205 further increased after treatment with docetaxel and cabazitaxel (Fig. 2B). This chemosensitization  
206 effect was not observed by measuring cell growth over the same time-course (Supplementary Fig.  
207 S3B). Conversely, FKBP7 overexpression is not sufficient to render prostate cancer cells more

208 resistant to taxanes as shown in parental IGR-CaP1 and 22R1 cells transduced with lentivirus  
209 expressing FKBP7 (Supplementary Fig. S3C). These results show that FKBP7 is not a primary event of  
210 the acquisition of the resistant state but show the importance of FKBP7 signaling in maintaining the  
211 chemoresistance state.

### 212 **FKBP7 silencing reduces tumor growth in docetaxel-resistant mice**

213 The IGR-CaP1 cell line was used to generate a chemoresistant mCRPC mouse model. Various clones  
214 of IGR-CaP1 resistant to docetaxel were injected subcutaneously into nude mice. The 25nM-resistant  
215 emerging tumor was maintained *in vivo* for 5 successive passages to increase the tumorigenicity  
216 (Supplementary Fig. S4A). These IGR-CaP1-Rvivo tumors did not respond to 3 successive injections of  
217 30mg/kg docetaxel, therefore constituting a new Dtx-R mouse model, whereas the parental IGR-  
218 CaP1 mouse model responded to docetaxel (Fig. 3A). A new IGR-CaP1-Rvivo cell line generated from  
219 the IGR-CaP1-Rvivo tumors showed chemoresistant characteristics (with  $IC_{50}=207nM$  towards  
220 docetaxel) (Fig. 3B). In addition, and in agreement with results obtained *in vitro* and in human  
221 samples, the resistant IGR-CaP1-Rvivo cell line showed high levels of FKBP7 (Fig. 3B). Thus, to check  
222 whether FKBP7 could be a therapeutic target in Dtx-R mice, we established two IGR-CaP1-Rvivo cell  
223 lines in which FKBP7 was stably silenced with two different shRNAs. A substantial reduction of FKBP7  
224 level was achieved in cells that were stably expressing shRNAs targeting FKBP7 (shFK-a and shFK-b),  
225 compared to control shRNA-expressing cells (Fig. 3C). ShRNA-transduced cell lines were subsequently  
226 injected subcutaneously in immunodeficient mice. In the absence of docetaxel, significantly reduced  
227 tumor growth was observed after FKBP7 depletion (68% and 47% inhibition of tumor growth in shFK-  
228 a- and -b-transduced cells, respectively), *versus* control shRNA-transduced cell line (Fig. 3C). This  
229 effect was more pronounced in the xenograft from the shFK-a cells showing a high reduction of  
230 FKBP7 to a level similar to that observed in the parental sensitive cells, suggesting that FKBP7  
231 sustains the growth of chemoresistant tumors. Treatment of mice with docetaxel when tumors  
232 reached 450-500mm<sup>3</sup> strongly abrogated the growth of shFK-a-transduced tumors, while it slightly  
233 decreased the growth of control shRNA-transduced tumors (Fig. 3C). Consistently, *in vitro*

234 proliferation data showed that shFK-a-transduced cells are more sensitive to higher dose of taxanes  
235 (Supplementary Fig. S4B). Thus these results demonstrate that *in vitro* and *in vivo* FKBP7 silencing  
236 inhibits cell proliferation and sensitizes chemoresistant cells to taxanes, and that FKBP7 can be a  
237 relevant therapeutic target to overcome chemoresistance in prostate cancer.

#### 238 **FKBP7 silencing does not affect cell growth in non-tumorous cells**

239 We determined the levels of FKBP7 in non-cancerous human cell lines of different origins  
240 (fibroblastic, myoblastic, epithelial and endothelial cells). These non-cancerous cells showed a high  
241 level of FKBP7, which was similar (in RPE-1) or even higher than that observed in IGR-CaP1-Dtx-R cells  
242 (Supplementary Fig. S5A), but in contrast to the results obtained in chemoresistant cells, we  
243 observed no effect of FKBP7 inhibition on cell growth or viability (Supplementary Fig. S5B),  
244 suggesting that FKBP7 could have different functions in cancerous and non-cancerous cells.

#### 245 **FKBP7 interacts with eukaryotic translation initiation factors to regulate protein translation**

246 To identify molecular pathways in which FKBP7 functions in non-cancerous and chemoresistant cells,  
247 we performed qualitative and quantitative mass spectrometry analyses. The protein interactome of  
248 FKBP7 was identified by immunoprecipitating endogenous FKBP7 with two antibodies in non-  
249 cancerous RPE-1 and Dtx-R IGR-CaP1 cell lines (Supplementary Table S4A-B). Protein network  
250 analysis through IPA indicated that in both cell lines, FKBP7 protein interactors were mainly  
251 distributed in the same three intracellular pathways associated with protein translation. Specifically,  
252 eIF2, eIF4 and mTOR signaling were the most represented pathways in the signatures (Fig. 4A), and  
253 many eukaryotic translation initiation factors were represented. To elucidate the molecular  
254 mechanisms by which FKBP7 depletion exerts its cytotoxic effects in chemoresistant cells only, we  
255 used SILAC in FKBP7-silenced RPE-1 and IGR-CaP1-Dtx-R cells and in cells transfected with control  
256 siRNA, and we obtained lists of 910 and 1223 differentially expressed proteins in RPE-1 and in IGR-  
257 CaP1-Dtx-R cells, respectively (Supplementary Table S5A-B). Consistently with previous results, IPA  
258 analysis showed that the major pathways affected by FKBP7-silencing were the same three pathways  
259 implicated in protein translation control; based on calculated Z-score, these pathways were

260 downregulated in IGR-CaP1-Dtx-R cells, but mainly upregulated in non-cancerous RPE-1 cells (Fig. 4B-  
261 C). All three individual components of the eIF4F cap-dependent mRNA translation complex (eIF4E,  
262 eIF4A and eIF4G) were identified as protein partners of FKBP7 in resistant and RPE-1 cells. Co-  
263 immunoprecipitation experiments confirmed the interaction of FKBP7 with eIF4G (Fig. 4D and  
264 Supplementary Fig. S6A), but interaction of FKBP7 with eIF4A was not detectable (Supplementary Fig.  
265 S6A).

#### 266 **FKBP7 regulates the level of eIF4F complexes**

267 eIF4F is an interesting target, known to be involved in resistance mechanisms to many cancer  
268 therapies (23–26). We focused on eIF4G, the most downregulated eukaryotic translation factor in  
269 IGR-CaP1-Dtx-R cells, but not in RPE-1 cells. FKBP7-silencing led to decreased eIF4G in IGR-CaP1-Dtx-  
270 R cells, but to increased eIF4G in corresponding non-cancerous RPE-1 cells (Fig. 5A). The level of  
271 eIF4G was also lower in other chemoresistant cellular models (Fig. 5B) and in parental cells  
272 (Supplementary Fig. S6B). In contrast, protein levels of eIF4A and eIF4E remained unchanged after  
273 FKBP7 silencing (Fig. 5A).

274 To understand how FKBP7 silencing decreased eIF4G level, we analyzed the effect of FKBP7 depletion  
275 on eIF4G gene expression. Efficient FKBP7 silencing did not affect eIF4G mRNA levels in FKBP7-  
276 silenced chemoresistant IGR-CaP1 and 22RV1 cells (Supplementary Fig. S6C), so our results showed  
277 that while eIF4G is still transcribed, its protein level decreases when FKBP7 is silenced, thus leading  
278 to the hypothesis that FKBP7 regulates eIF4G expression at mRNA translation or protein stability  
279 levels. Treatment with the translation inhibitor cycloheximide combined with FKBP7 silencing  
280 showed that although the steady-state level of eIF4G was decreased upon FKBP7 silencing, the  
281 amount of eIF4G in control cells decreased over time whereas it was stable in FKBP7-depleted cells  
282 supporting the hypothesis that FKBP7 regulates eIF4G expression at the protein level (Fig. 5C).  
283 However, we cannot exclude the possibility of an increase in eIF4G mRNA translation to compensate  
284 the protein loss observed when FKBP7 was silenced. We therefore investigated the ability of FKBP7

285 to interact with eIF4G by performing PLA, allowing the interaction to be quantitatively visualized as  
286 fluorescent dots. Our results revealed an interaction between FKBP7 and eIF4G in Dtx-R-IGR-CaP1  
287 and Dtx-R-22RV1 cells (Fig. 5E). This interaction was largely affected in FKBP7- and eIF4G-depleted  
288 cells, as shown by the lower numbers of dots/cell (43% and 80% reduction in IGR-CaP1-Dtx-R cells,  
289 93% and 86% in 22RV1-Dtx-R cells, for FKBP7- and eIF4G-silencing respectively) (Fig. 5E); the silencing  
290 of eIF4G was very efficient (Fig. 5D) and the specificity of the FKBP7-eIF4G interaction was validated  
291 (Supplementary Fig. S6D).

292 As FKBP7 interacts with eIF4G and modulates eIF4G protein levels, we investigated effects of FKBP7  
293 on eIF4F complex formation using PLA. Docetaxel treatment led to decreased formation of the eIF4E-  
294 eIF4G complex in Dtx-sensitive IGR-CaP1 cells (Fig. 5F). Strikingly, but consistently with other studies  
295 showing that eIF4E-eIF4G formation determines the sensitivity to anti-cancer targeted therapies (24),  
296 this effect was not observed in the IGR-CaP1-Dtx-resistant cell line (Fig. 5F). By affecting the level of  
297 eIF4G, siRNA-mediated FKBP7 depletion induced decreased eIF4E-eIF4G complex formation in  
298 resistant cells after docetaxel treatment (Fig. 5F). Thus, the reduction of FKBP7 and subsequent  
299 decrease in eIF4G level altered the global translation level (Supplementary Fig. S6B), and mimicking  
300 this reduction of eIF4G level with eIF4G knock-down equally decreased eIF4F assembly and eIF4G  
301 level (Supplementary Fig. S6E). Therefore FKBP7, which is up-regulated in chemoresistant cells, could  
302 increase eIF4F complex activity by directly upregulating eIF4G protein levels, leading to hyper-  
303 activation of cap-dependent translation and subsequent cell survival after taxane treatment. FKBP7  
304 stabilized eIF4F complex formation after taxane treatment and thus could be a novel eIF4F regulator.

### 305 **Targeting chemoresistant prostate cancer cells with small molecule inhibitors of eIF4A**

306 As FKBP7 regulates eIF4F complex formation, we first target eIF4F using eIF4G-targeted siRNA before  
307 docetaxel treatment on two chemoresistant cell lines (with different androgen-receptor expression).  
308 eIF4G silencing provoked a marked cytotoxic effect 5 days after transfection. When combined with  
309 docetaxel, chemosensitization was further observed in Dtx-R 22RV1 cells ( $IC_{50}=62nM$  with siNT and  
310  $IC_{50}=23nM$  with si4G) (Fig. 6A). We next tested three small eIF4F inhibitors (silvestrol, FL3, FL23)

311 which are reported to target eIF4F complex by inhibiting helicase eIF4A (24,27–29). Silvestrol induced  
312 a cytotoxic effect in the A375 melanoma cell line (24), but showed no effect on IGR-CaP1-Dtx-R cells  
313 (Fig. 6B), maybe because silvestrol is a Pgp drug efflux pump substrate (30) which is highly expressed  
314 in IGR-CaP1-Dtx-R cells (Supplementary Fig. S7A). In contrast, Docetaxel-resistant IGR-CaP1 and  
315 22RV1 cells were sensitive to low doses of FL3 ( $IC_{50}$ =19nM and 14nM, respectively) and FL23  
316 ( $IC_{50}$ =17nM and 7nM, respectively) (Fig. 6C). Parental cells were sensitive to the same order of  
317 flavagline concentrations. FL3 and FL23 translation inhibitors both target eIF4A, but are not Pgp  
318 substrates (31). Their  $IC_{50}$  values were lower than those observed in melanoma A375 cells ( $IC_{50}$ =35  
319 and 25nM, respectively) (Supplementary Fig. S7C). Results showed that FL3 and FL23 were able to kill  
320 parental and chemoresistant cells, but no synergy was observed when they were used in  
321 combination with docetaxel in resistant cells (Supplementary Fig. S7B-C). We confirmed their  
322 cytotoxic effect on parental, Dtx-R and Cbx-R cell lines, as shown by the induction of PARP cleavage  
323 (Fig. 6D). FL3 and FL23 did not lead to apoptosis of RPE-1 cells (Fig. 6D), thus reinforcing the interest  
324 of targeting eIF4A in prostate cancer.

## 325 DISCUSSION

326 Resistance to chemotherapy represents a major challenge (32,33). Understanding chemoresistance  
327 mechanisms and identifying biomarkers is crucial for developing new therapeutic strategies and  
328 overcoming drug resistance. In this study, we made the unprecedented observation that FKBP7 is an  
329 important determinant of prostate cancer cell response to taxanes. The acquisition of taxane  
330 resistance after long term-treatment of prostate cancer cells with docetaxel or cabazitaxel correlates  
331 with increased FKBP7 levels. Identification of the FKBP7 signaling network allowed us to link the  
332 participation of FKBP7 in chemoresistance to the initiation step of protein translation (eIF4F  
333 translation initiation complex). Using eIF4A inhibitors at nanomolar concentrations may help to  
334 circumvent docetaxel and cabazitaxel resistance in two prostate cancer chemoresistant cell lines.

335 Several FKBP proteins have been shown to participate in cancer progression and chemoresistance  
336 (7). FKBP5 regulates steroid receptor activation and prostate cancer progression (34). Its expression  
337 levels correlate with tumor-cell sensitivity to chemotherapeutic agents (35), and it negatively  
338 regulates Akt kinase, thus increasing chemosensitivity (36). FKBP5 is also involved in resistance to  
339 anthracycline in malignant melanoma (37) and in taxol resistance in ovarian cancer cells (38). FKBP5  
340 overexpressed after cells had been treated with microtubule-targeting agents, but this was not  
341 observed with DNA-damaging agents such as cisplatin (38). This specificity to microtubule-targeting  
342 agents may be related to the regulatory role of FKBP5 on the cytoskeletal proteins observed for  
343 FKBP4 and FKBP5 (10). Other FKBP5s such as FKBP1 are known to have therapeutic and biomarker  
344 potential in cancer (39). The implication of endoplasmic reticulum FKBP5s in carcinogenesis has been  
345 reported for FKBP10 (40–42) and FKBP14 (43,44).

346 Our study revealed the functional role of FKBP7 chaperone in docetaxel and cabazitaxel resistance in  
347 prostate cancer, which is observed in AR-positive and AR-negative cells, and is independent of  
348 ABCB1/MDR1 drug efflux pump expression. Our clinical data showed that high FKBP7 expression is  
349 more frequent in tumors *versus* normal tissues, and correlates with a lower time-to-recurrence in  
350 patients receiving taxane neoadjuvant chemotherapy. High levels of FKBP7 correlate with a bad  
351 prognosis, which suggests that FKBP7 expression could be a relevant marker of taxane-resistance.  
352 Pre-clinical evidence in a docetaxel-resistant mouse model confirmed that FKBP7 expression  
353 sustained taxane-resistant prostate cancer cell growth. Therefore, our results implicate a previously  
354 uncharacterized member of the peptidyl-prolyl isomerase (PPIase) family in the mechanism of  
355 resistance to microtubule-targeting agents.

356 Although high expression of FKBP7 is observed both in non-cancerous and chemoresistant cells,  
357 FKBP7 silencing triggers cell death in taxane-resistant tumor cells only, suggesting that the survival of  
358 resistant cells may be attributed to a novel function of FKBP7. The comparison of resistant and non-  
359 cancerous cells in a large proteomic approach allowed us to identify eukaryotic translational  
360 initiation factor and mTOR pathways as the main FKBP7 regulation networks. These pathways are

361 deregulated in resistant tumor cells *versus* normal cells. We also identified the eIF4G component of  
362 the eukaryotic initiation factor eIF4F as a major downstream target of FKBP7 and showed that  
363 FKBP7-eIF4G interaction controls the eIF4G protein level. Translation initiation is a highly regulated  
364 biological process hijacked by tumor cells to increase the protein synthesis rate for specific genes and  
365 promote cell survival. EIF4G is a large scaffolding protein that binds eIF4A helicase and eIF4E cap-  
366 binding protein to form the heterotrimeric eIF4F complex for mRNA translation. Evidence showed  
367 that increased eIF4F activity contributes to the malignant transformation process via increased  
368 translation of a limited set of pro-oncogenic mRNA transcripts (45). As described for the *cis-trans*  
369 prolyl isomerase Pin1 (46), the regulation of eIF4G level in resistant cells may be attributed to the  
370 PPlase activity of FKBP7 which may act as a dynamic switch allowing the maintenance of eIF4G in an  
371 activated but unstable conformation. This acceleration of isomerization may account for high eIF4G  
372 level in resistant cells. When FKBP7 is decreased by RNAi silencing, eIF4G is expressed at a low level  
373 but the protein seems to be more stable. This increased stability, which might be part of a feed-back  
374 loop to overcome the decreased level of eIF4G, may be achieved by a basal chaperone activity of  
375 FKBP7. Thus, our data suggest that chemoresistant cell survival may be attributed to over-stimulation  
376 of eIF4F, one of the downstream effectors of the Akt-mTOR pathway, mediated by FKBP7  
377 overexpression (Supplementary Fig. S7D).

378 We showed that FKBP7 plays an important role in survival networks protecting cancer cells against  
379 therapeutic agents, so FKBP7 could be an interesting target in prostate cancer. No structural analysis  
380 of the full-length FKBP7 protein is currently available for the design of inhibitory molecules, and  
381 although screening strategies have been developed to discover new drugs inhibiting FKBP activity,  
382 designing isoform specific inhibitors is still challenging (47). Thus, we will now aim our research  
383 towards the design of small molecule ligands with FKBP7 specificity. Discovery of the FKBP7-eIF4G  
384 interaction led us to assess the efficacy of inhibitors directly targeting the eIF4F complex. We believe  
385 that targeting translation machinery is a promising strategy for minimizing acquired resistance (45).

386 We tested silvestrol, an eIF4A inhibitor that is known to provide therapeutic benefits in prostate  
387 cancer xenografts (28). Unfortunately, silvestrol showed no obvious efficacy towards docetaxel-  
388 resistant IGR-CaP1 cell proliferation, which could be attributed to high expression of ABCB/MDR1 in  
389 this model. In contrast, flavaglines FL3 and FL23, which also target eIF4A, are highly cytotoxic in  
390 docetaxel-resistant models. These synthetic compounds (48,49) are known to overcome multidrug  
391 resistance *in vitro* (31) and alleviate resistance to vemurafemib in melanoma (24).

392 Our findings open a new avenue in the field of chemoresistance, and our study reveals the critical  
393 role played by chaperone FKBP7 in acquired taxane-resistance in prostate cancer and its potential for  
394 development as a predictor of chemoresistance. By targeting FKBP7 or the eIF4F complex, we also  
395 found novel therapeutic strategies that would help to manage taxane-resistant prostate cancer.

396

## 397 **ACKNOWLEDGMENTS**

398 We gratefully thank A. Lescure and S. Tessier, who are Biophenics staff, the platform of preclinical  
399 evaluation AMMICA, the bioinformatic Core Facility, the Development in Pathology Group (UMR981),  
400 and S. Shen (UMR981). We thank and pay tribute to Vasily Ogryzko (UMR8126), who gave us  
401 precious help with proteomics but passed away before this publication. RWPE-1 was a kind gift from  
402 G. Mouchiroud (University Claude Bernard, Lyon), HK-2 was provided by S. Gad-Lapiteau (UMR1186,  
403 Villejuif), and HUVEC was provided by S. Rodrigues-Ferreira (UMR981, Villejuif). We also thanks  
404 Joanna Moore, ELS (Citoxlab France), for assistance in the preparation of the manuscript. MGa was  
405 supported by the Idex Paris-Saclay fellowship and the Association pour la Recherche sur les tumeurs  
406 de la Prostate (ARTP). NJ-PM, MB and NEK were supported by the PARRAINAGE CHERCHEUR charity  
407 program of Gustave Roussy.

408 This work was supported by grants from: INSERM, the Université Paris-Sud11, the grant PAIR  
409 PROSTATE program n°2010-1-PRO-03 from the INCA, the ARC Foundation, the Ligue contre le cancer,  
410 the ECOS-Sud A10S03 program, AMGEN, the Paris Alliance of Cancer Research Institutes program,  
411 “Investissements d’Avenir” an initiative of the French Government implemented by ANR under  
412 reference ANR-11-PHUC-002, Taxe d’apprentissage Gustave Roussy P21NNGE for genomic and  
413 2014MG for proteomic analyses, and Terry Fox New Frontiers Program Project Grant TFF116129.

414

## 415 **AUTHOR CONTRIBUTIONS**

416 MGa, N J-PM, MB, CG, NEK, VO, NAN, LF, EDN, SL, and ALP performed the experiments and analyzed  
417 data; FC performed bioinformatics analysis; JC, FP, MG, YL, SV, LD and KF provided expertise and  
418 feedback; MG and LD provided useful reagents; AC and KF secured funding for the project, MGa and  
419 AC wrote the manuscript; AC conceived and supervised the project.

## FIGURE LEGENDS

### Figure 1

FKBP7 is upregulated during the progression of chemoresistant CRPC. **A**, Immunoblot of FKBP7 protein expression in RWPE-1 non-cancerous prostate cells, parental (S) IGR-CaP1, PC3, LNCaP and 22RV1, docetaxel-resistant cells (Dtx-R) and cabazitaxel-resistant cells (Cbx-R) (loading control: actin. FKBP7). Protein level was quantified with Image Lab software. FKBP7 in resistant cells is expressed relative to parental cell line. \*indicates non-specific band. **B**, Immunoblot showing FKBP7 protein level in various parental cells after treatment with 10nM Docetaxel or Cabazitaxel for 24h, 48h, 72h and 120h. Actin or Hsc70 are the loading controls. **C**, Immunoblot showing FKBP7 protein level in parental (S) or docetaxel-resistant (R) LNCaP cells in comparison with LNCaP-derived models that are responsive (V16D) or resistant (49F and 42D) to enzalutamide. Hsc70 was the loading control. **D-Left**, Representative immunohistochemistry images of FKBP7 staining in prostate tissues. Scale bars: 200 $\mu$ m (top). **D-Right**, Quantification of FKBP7 protein level in benign prostate tissue and tumor. Chi-square test  $p=0.0001$ . FKBP7 low corresponds to scores 0 and 1; FKBP7 high corresponds to scores 2 and 3.  $n=808$ . **E**, Correlation of FKBP7 expression intensity with recurrence % in 69 patients treated with docetaxel. Fisher's exact test  $p=0.0059$ . Events are defined as any recurrence, metastasis or post-surgery death from prostate cancer (baseline: date of surgery). **F**, Kaplan-Meier plot representing recurrence-free survival (RFS) associated with FKBP7 staining in TMA from 69 patients who received docetaxel as neoadjuvant therapy. The association between time-to-recurrence (months) and FKBP7-staining status (high or low), where events are defined as PSA recurrence, metastasis or death from prostate cancer, was calculated with Cox proportional hazard model: Hazard ratio 0.3846 (95% confidence interval: 0.195 to 0.7586);  $p=0.004$  (log rank test).

### Figure 2.

SiRNA-mediated knock-down of FKBP7 blocks chemoresistant cell growth and increases apoptosis in resistant cells treated with taxane. **A**, Immunoblot shows FKBP7 knockdown efficiency 48h after

transfection with different siRNA sequences targeting FKBP7 (circles) or siNT (■) (control siRNA) (loading control: actin). Cell viability was determined daily (WST1 assay) after transfection with siRNA. Data are presented as mean  $\pm$ SD. Data were normalized to control condition without siRNA. \*\* $p < 0.01$ ; \*\*\* $p < 0.0005$ ; \*\*\*\* $p < 0.0001$  as determined by two-way ANOVA with Bonferroni posttests. Experiments were performed with docetaxel- or cabazitaxel-resistant cells. **B**, Immunoblots showing cleaved (Cl.) PARP protein (89KDa) in docetaxel- or cabazitaxel-resistant cells after 96h of transfection with siNT, siFK-1 or siFK-2, alone or combined with docetaxel (Dtx) or cabazitaxel (Cbx) treatment for 72h. Chemoresistant cells were treated at their respective maximum resistance dose (Supplementary Fig. S1) (loading control: HSC70)

### Figure 3.

FKBP7 silencing reduces tumor growth in a docetaxel-resistant mouse model. **A**, Growth curves of tumors from IGR-CaP1 and IGR-CaP1-Rvivo subcutaneous xenografts after treatment with vehicle (5% glucose solution, ○) or docetaxel (30mg/kg I.P., ●). Data represent the mean  $\pm$ SD. Mice/group:  $n=5$ . Arrows indicate the times of docetaxel injections. \*\*\* $p < 0.001$  (two-way ANOVA with Bonferroni posttests). **B-Left**, Proliferation assay. Determination of docetaxel treatment  $IC_{50}$  in parental IGR-CaP1 (○) and IGR-CaP-Rvivo (●) cells. Data are presented as mean  $\pm$ SD. Cell viability is relative to control treatment. **B-Right**, Immunoblot of FKBP7 in IGR-CaP1 (S) and IGR-CaP1-Rvivo cells (loading control: actin). **C**, Immunoblot shows FKBP7 knockdown efficiency after the transduction of IGR-CaP1-Rvivo cells with lentivirus expressing two shRNAs targeting FKBP7 *versus* control shRNA, compared to the parental IGR-CaP1 cells (S). A quantification of FKBP7/actin was performed (Image Lab software). **C-Left**, Average tumor volume  $\pm$ SEM obtained from xenografts of IGR-CaP1-Rvivo transduced with control shRNA (○) ( $n=6$ ) or FKBP7-directed shRNAs (● and grey circles) ( $n=7$ /group) before treatment. **C-Right**, When tumors reached 450-500mm<sup>3</sup>, mice received vehicle or docetaxel. The tumor volume ratio between mice receiving docetaxel and mice receiving vehicle (on days 0 and 21) is presented (shCtrl:  $n=6$ /group; shFKBP7s:  $n=7$ /group).

**Figure 4.**

FKBP7 interacts with eukaryotic translation initiation factors **A**, Ingenuity pathway analysis showing the canonical pathways identified with the specific protein partners of FKBP7 in IGR-CaP1-Dtx-R and RPE-1 from global proteomic IP. **B**, Major three pathways deregulated in cells transfected with an siRNA targeting FKBP7 (siFK-2), identified with IPA analysis from SILAC data. Each pathway is associated with a p-value and a Z-score for IGR-CaP1-Dtx-R and RPE-1. **C**, Network showing the protein members of the eIF2, eIF4 and mTOR pathways deregulated by FKBP7 knockdown in IGR-CaP1-Dtx-R and RPE-1 cells. The color represents the fold change of protein expression between siFKBP7 and siNT. **D-Left**, endogenous FKBP7 was immunoprecipitated with the anti-FKBP7 antibody (or IgG as control) in docetaxel-resistant IGR-CaP1 and PC3 cells. Immunoblot showing the eIF4G co-immunoprecipitated protein. Input controls (20%) are shown. **D-Right**, eIF4G was immunoprecipitated with the anti-eIF4G antibody (or IgG as control) in docetaxel-resistant IGR-CaP1 and PC3 cells. Immunoblot showing the FKBP7 co-immunoprecipitated protein. Input controls (20%) are shown.

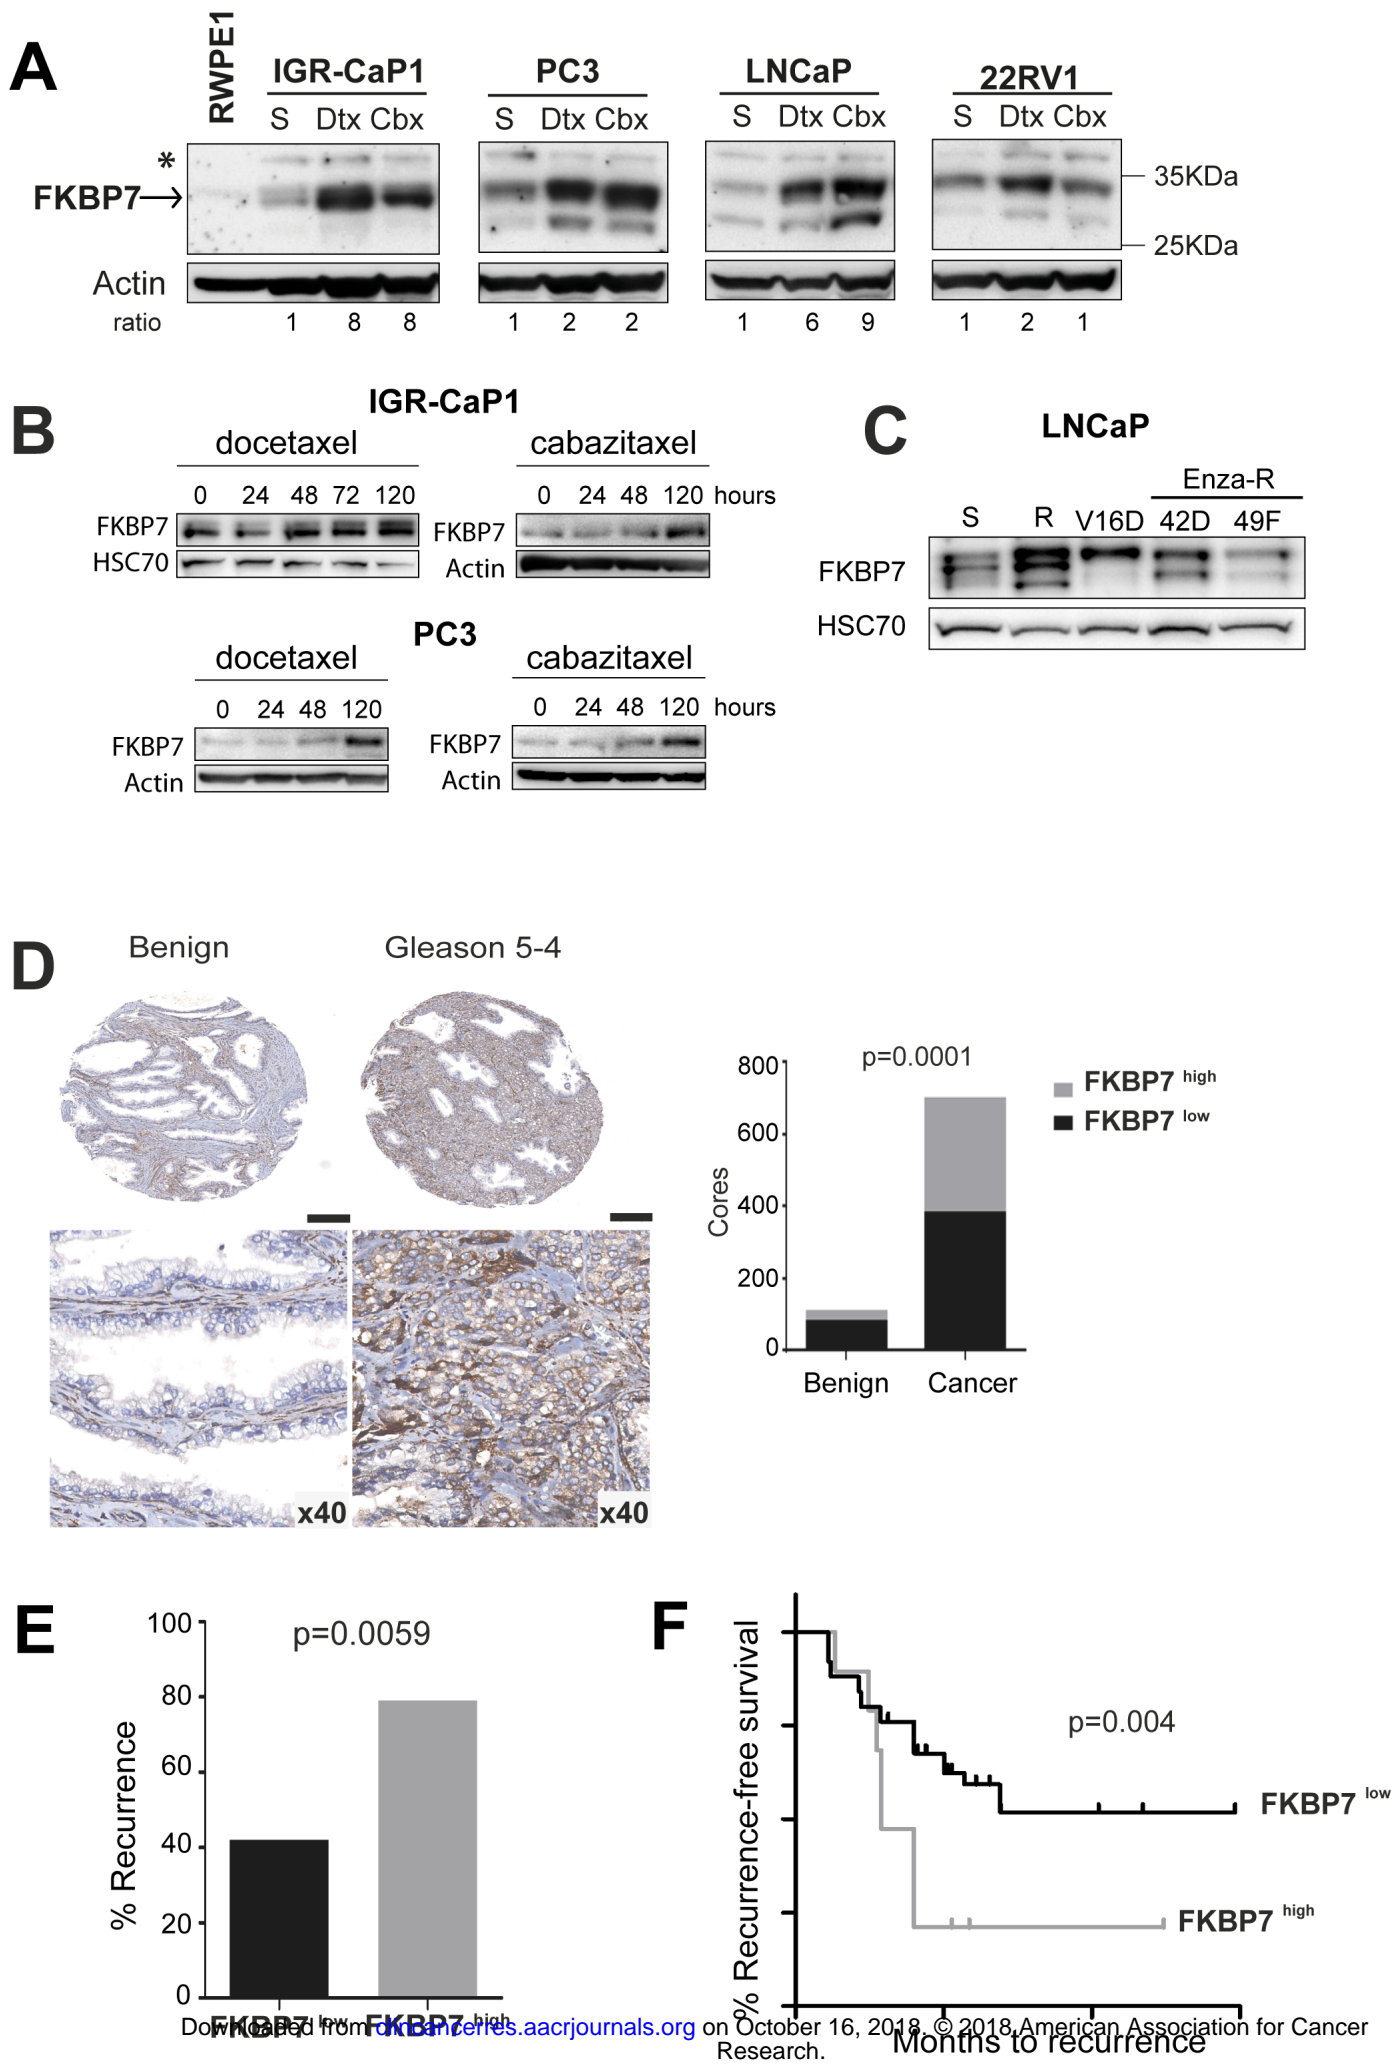

**Figure 5.**

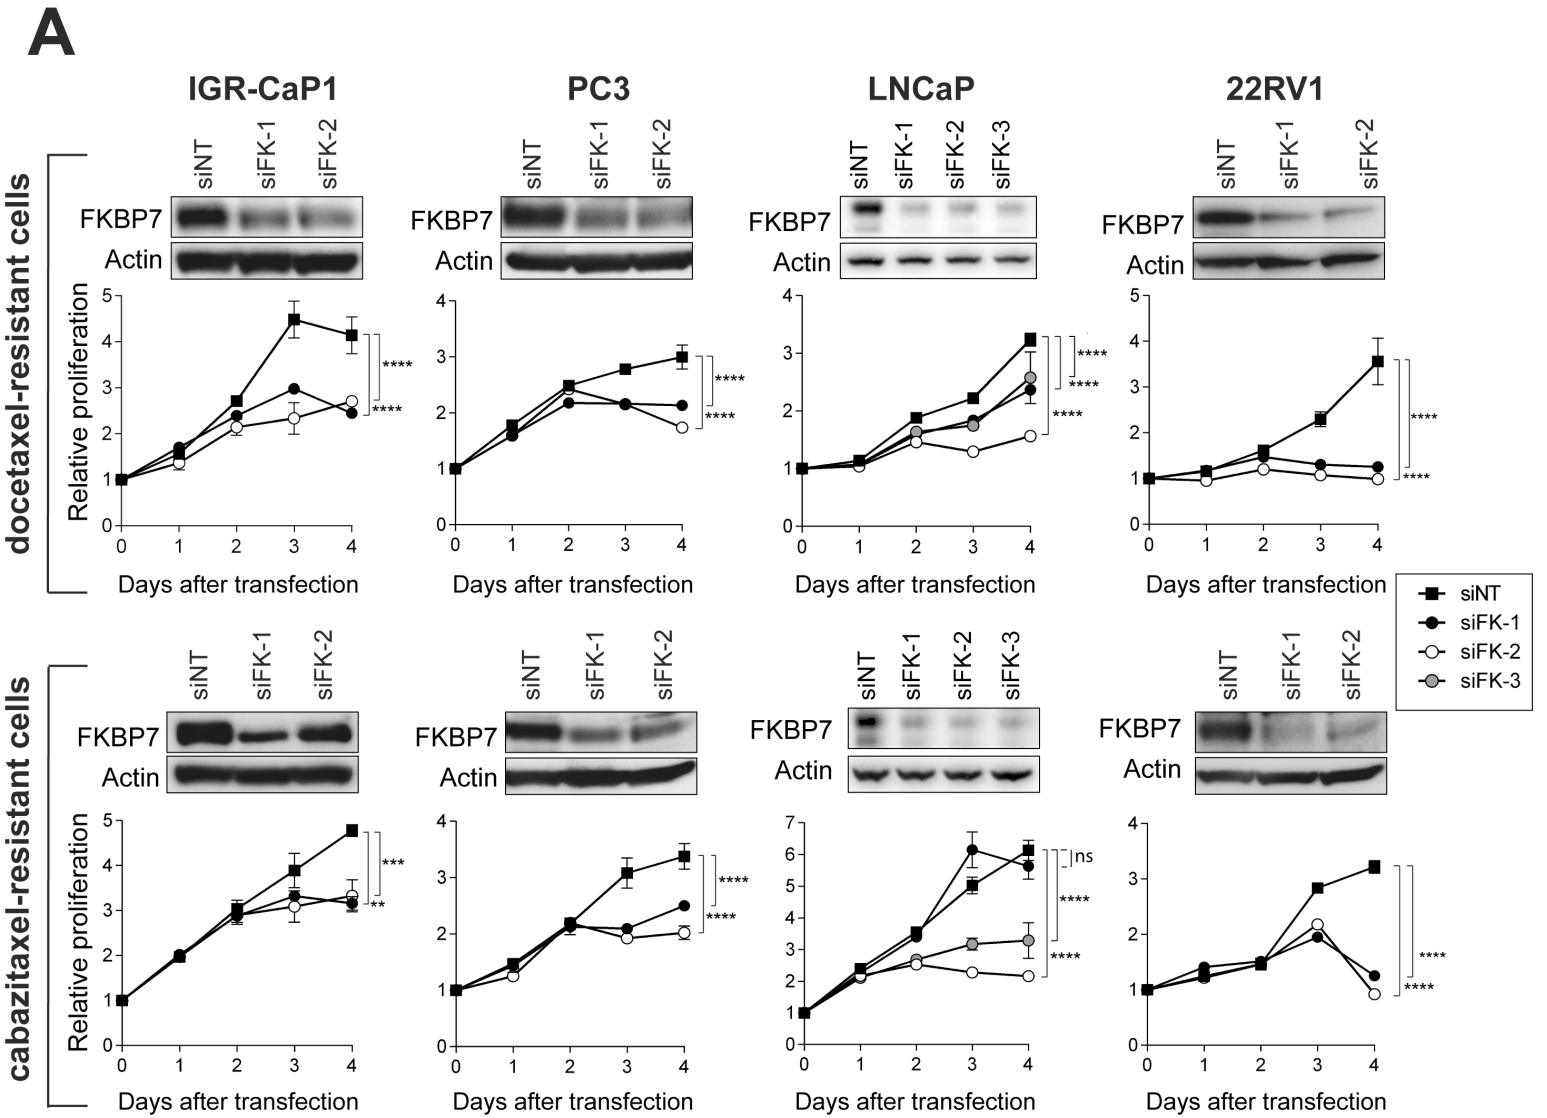

FKBP7 regulates the formation of eIF4F translation initiation complex **A**, Immunoblots showing eIF4G, eIF4A and eIF4E expression in IGR-CaP1-Dtx-R and RPE-1 cells transfected with siRNA control (siNT) or with siFK-1 or siFK-2 (siRNAs targeting FKBP7) (loading controls: HSC70 and actin). **B**, Immunoblots showing eIF4G expression in docetaxel-resistant (Dtx-R) 22RV1 and LNCaP and cabazitaxel-resistant (Cbx-R) IGR-CaP1 and LNCaP cells transfected with siNT, siFK-1 or siFK-2 (loading control: HSC70). The eIF4G/HSC70 ratio was calculated with Image Lab software. **C**, Dtx-R 22RV1 cells transfected with siRNA control (siNT) or with siFK-2 for 48h were treated with 10 $\mu$ m/ml Cycloheximide at the indicated time point. Whole cell extract was collected serially and eIF4G and FKBP7 were detected by immunoblot (loading control: actin). Quantified EIF4G level was plotted. **D**, Immunoblots showing eIF4G knockdown efficiency 48h after transfection with either siRNA targeting eIF4G (siEIF4G) or siRNA control (siNT) in Dtx-R IGR-CaP1 and 22RV1 cells. HSC70 is the loading control. **E**, FKBP7-eIF4G

interaction detected by PLA in IGR-CaP1-Dtx-R and 22RV1-Dtx-R cells. Cells were either untreated or transfected with siNT, siRNA targeting FKBP7 (siFK-2) or siRNA targeting eIF4G (siEIF4G). Scale bars: 20 $\mu$ m. Interactions: red dots, nuclei: blue dots. Interaction dots were quantified ( $n \geq 100$  cells) and analyzed (general linear model, \*\*\* $p < 0.001$ ). **F-Left**, eIF4E-eIF4G interaction detected by PLA in parental and Dtx-R IGR-CaP1 cells. Cells were either untreated or treated with 5nM of docetaxel for 24h. **F-Right**, eIF4E-eIF4G interactions were detected on Dtx-R IGR-CaP1 cells transfected with siNT, siFK-1 or siFK-2, alone or combined with 5nM of docetaxel for 24h. Scale bars: 20 $\mu$ m. Interactions: red dots, nuclei: blue dots. Interaction dots were quantified ( $n \geq 100$  cells) and analyzed (general linear model or Wilcoxon rank test, \*\*  $p < 0.01$ ; \*\*\*  $p < 0.001$ ).

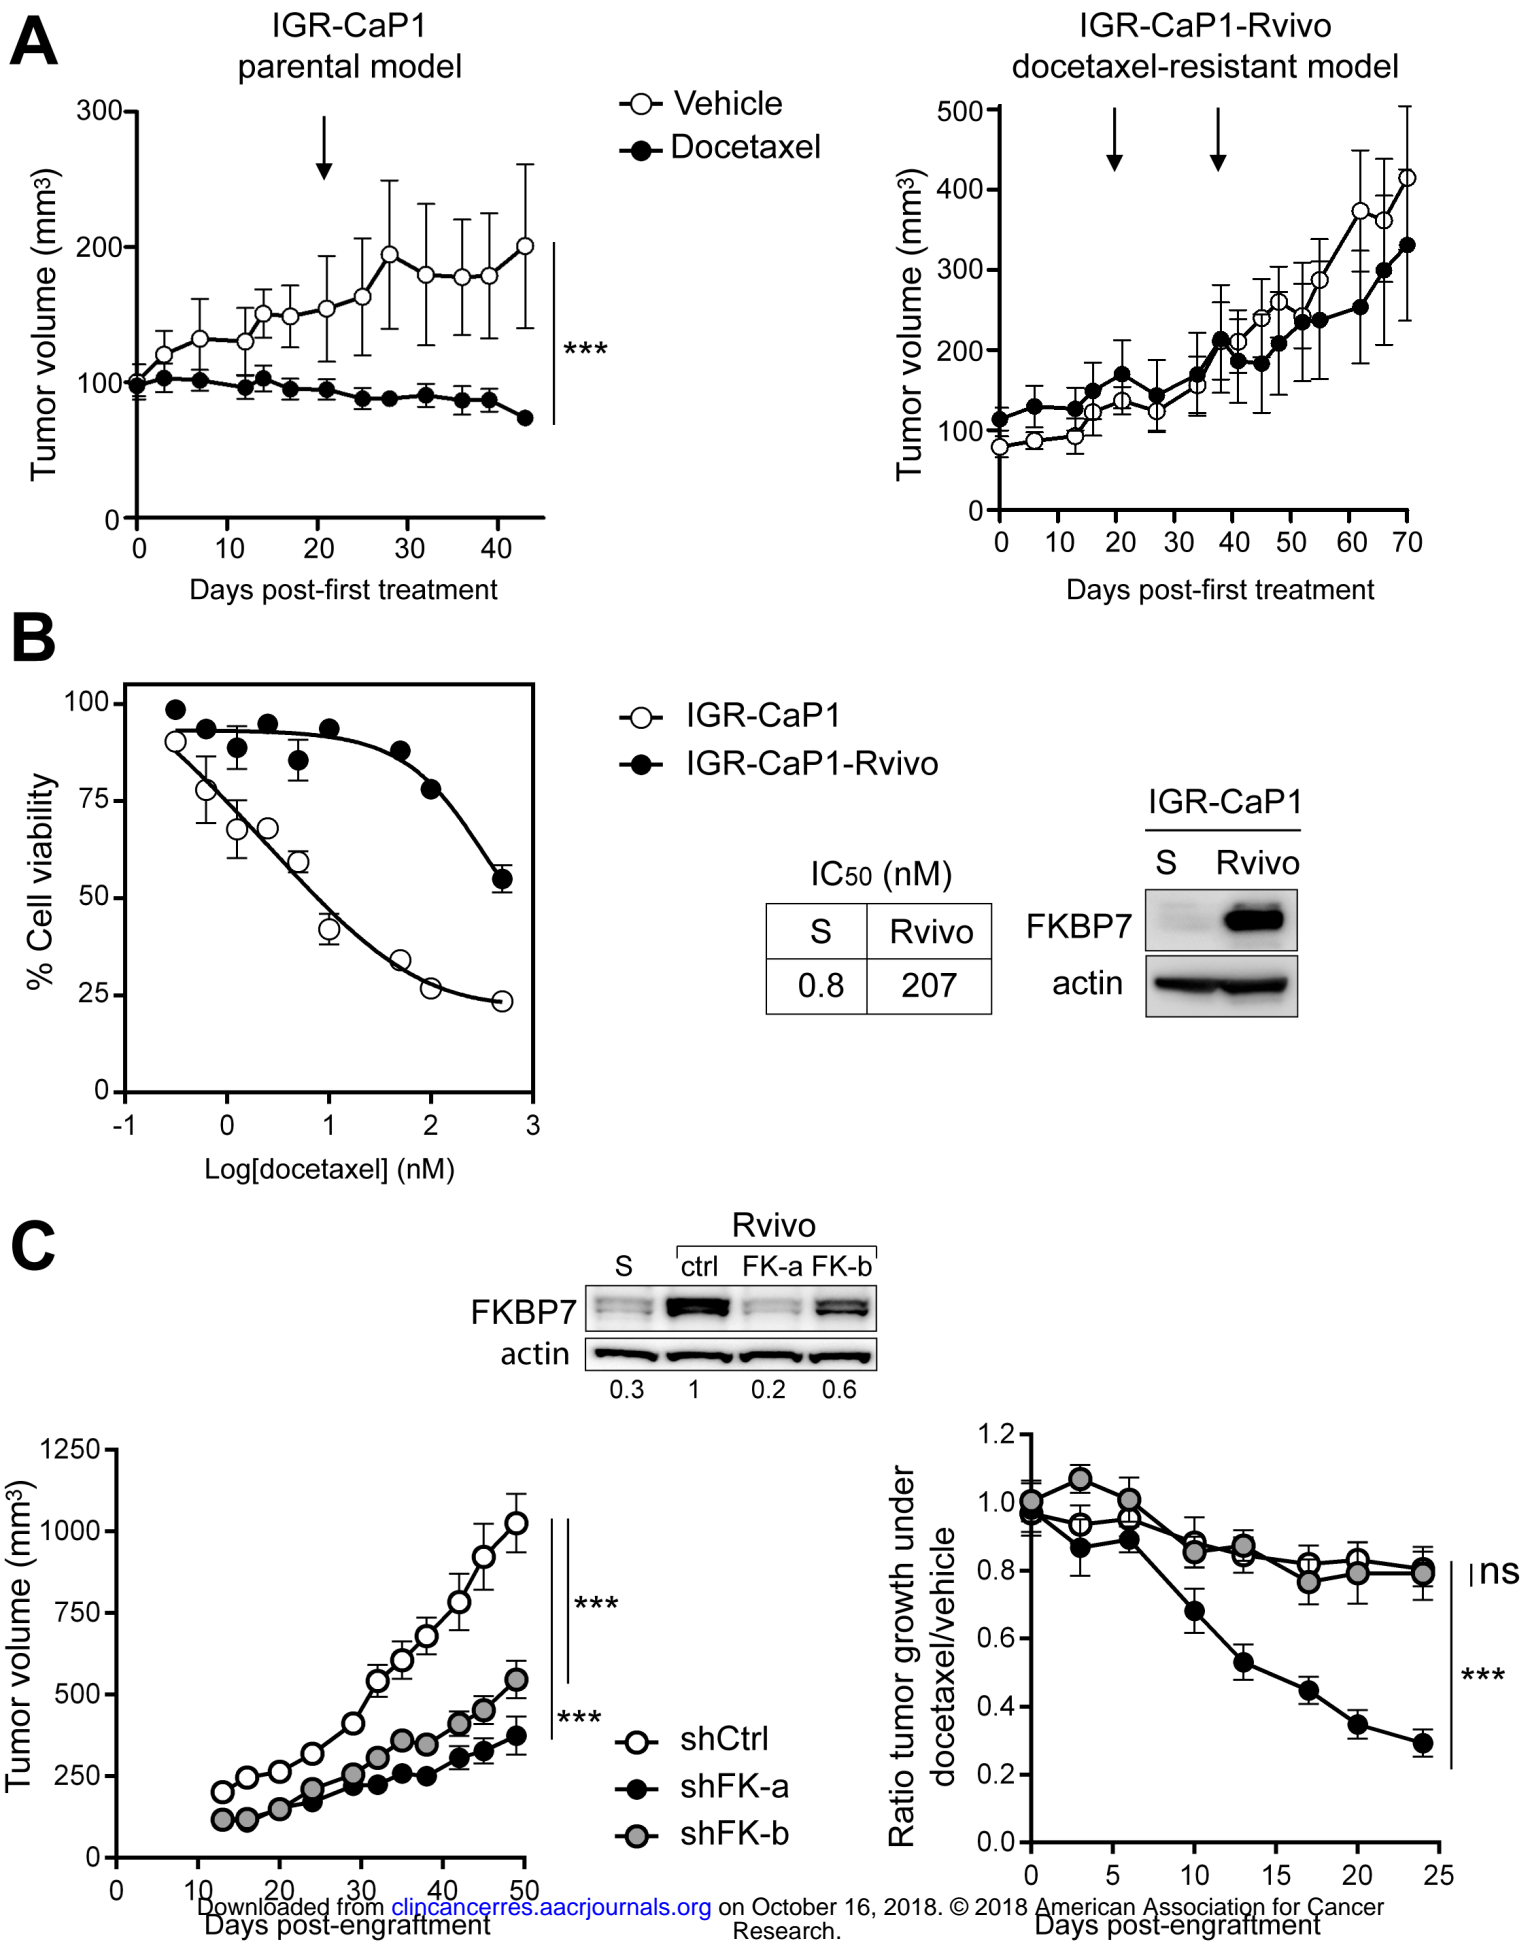

### Figure 6.

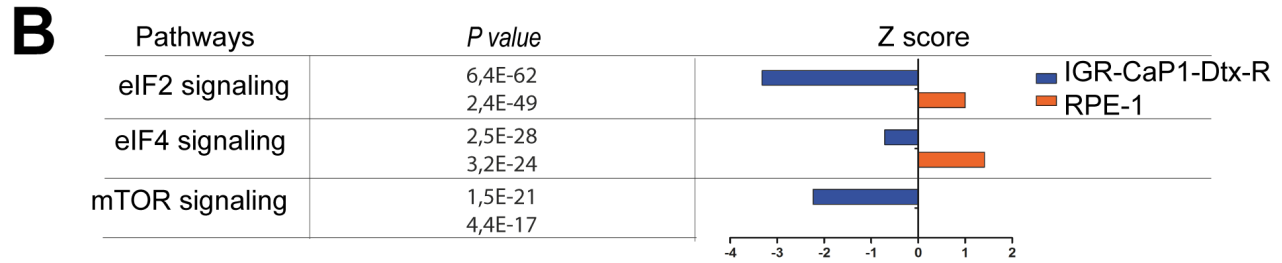

Targeting eIF4F in chemoresistant prostate cancer cells with siRNA or with small molecule inhibitors of eIF4A. **A**, Proliferation assay. Cell viability of Dtx-resistant IGR-CaP1 and 22RV1 cells after 48h transfection with siRNA targeting eIF4G (4G) or control siRNA (siNT) and a further treatment with increasing doses of docetaxel for 72h. Data are presented as mean  $\pm$ SD. **B**, Cell viability (vs control treatment) of IGR-CaP1-Dtx-R (●) and melanoma A375 cells (○) after 48h of treatment with silvestrol. Data are presented as mean  $\pm$ SD. **C**, Cell viability (vs control treatment) of docetaxel-resistant (Dtx-R, ●) and parental (○) IGR-CaP1 and 22RV1 cells after 48h of treatment with either flavagline 3 (FL3, left panel) or flavagline 23 (FL23, right panel). Data are presented as mean  $\pm$ SD. **D**, Immunoblots of cleaved (Cl.) PARP protein (89KDa) in parental, docetaxel- and cabazitaxel-resistant IGR-CaP1 and 22RV1 cells and in RPE-1 cells, either untreated (ctrl), treated for 72h with 10nM docetaxel (Dtx) or 5nM cabazitaxel (Cbx), or treated for 48h with 150nM flavagline FL3 or FL23 (loading control: HSC70).
