HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Tongue motor control: deriving articulator trajectories and muscle activation patterns from an optimization principle

INTRODUCTION

Key features of sensorimotor systems:

- Multisensory integration
- Use of internal models to predict the sensory outcomes of actions
- Comparison of the sensory input with the internal prediction to optimally update the internal estimate of the system

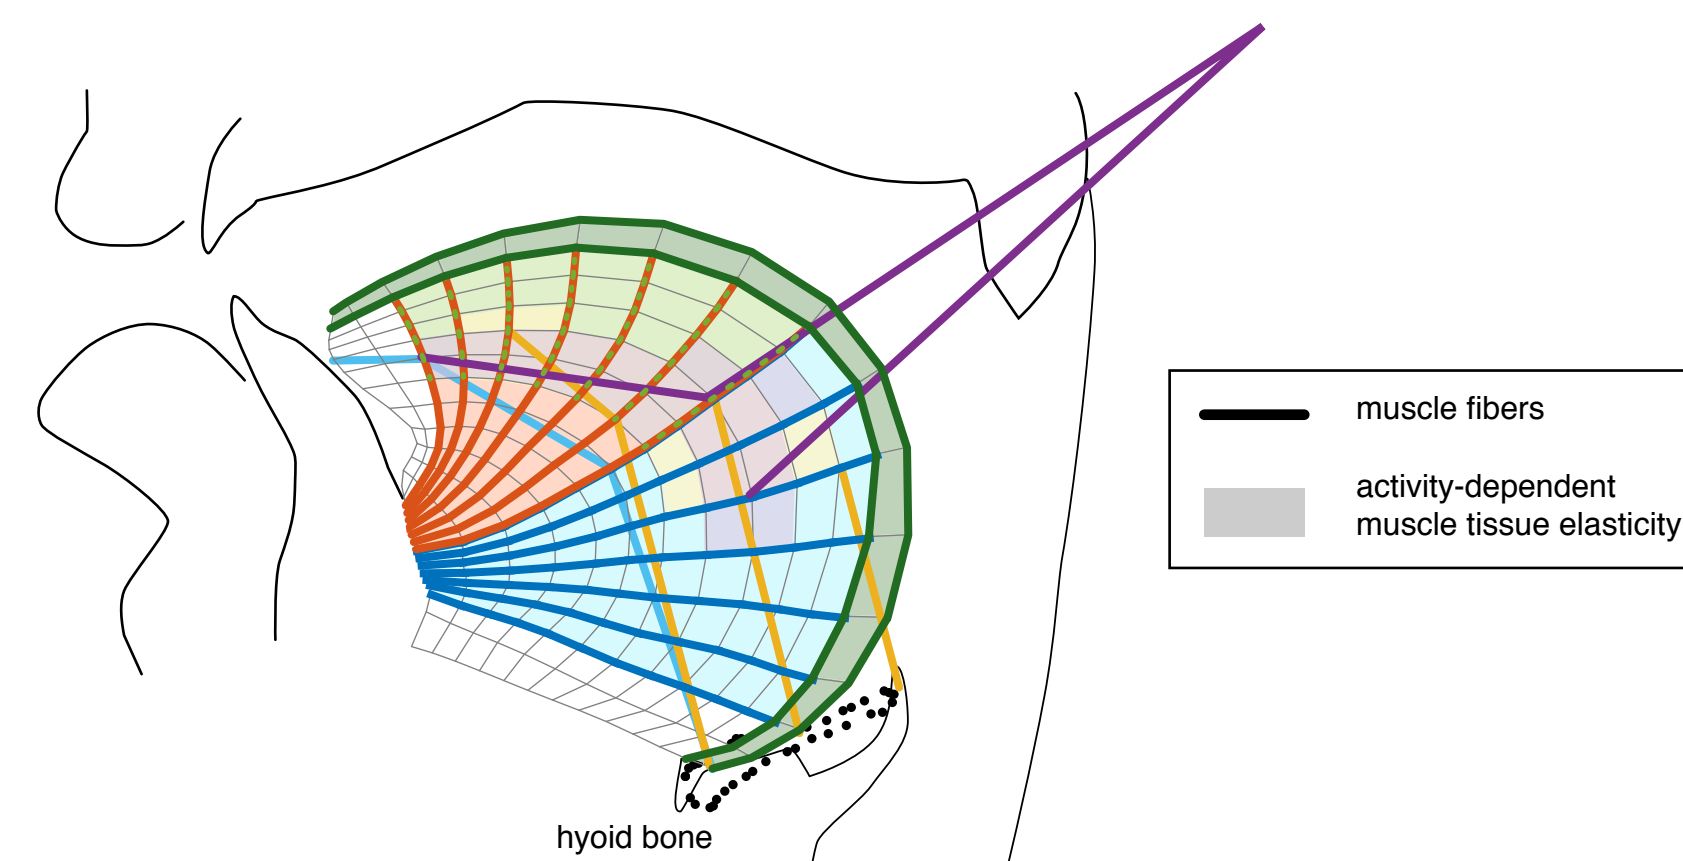

Speech production

- Coordination task: lips, jaw, tongue
- Resistance to external disturbances (inertial forces, objects in mouth, distorted audio feedback...)
- Can optimal feedback control theory illuminate the control of tongue movements during speech (tongue kinematics, coarticulation, use of feedback...)?

METHODS

Tongue biomechanics:

- Finite element (FE) model of tongue deformation (sagittal 2D model)
- Seven muscles modelled: anterior genioglossus, posterior genioglossus, hyoglossus, styloglossus, verticalis, inferior longitudinalis, superior longitudinalis [1]
- Hill-type muscle model
- Activity-dependent tissue elasticity, small deformation approximation
- Fixed tongue floor
- Contacts with palate, velum and pharyngeal wall modeled as elastic interaction (wall: high stiffness)
- System continuous-time ODE solved with robust Runge-Kutta integration

Vocal tract, from tongue shape to acoustics:

- For a given external tongue contour, a fixed jaw position, and a fixed lip aperture, we deduce the shape of the complete vocal tract using anatomical reference data (MRI, [2])
- We then compute the resonances of the vocal tract with an harmonic model following [3] after discretization of the tract in 44 tubes of identical length, and keep the first three formants.

Exploring the control of contacts:

- One degree of freedom corresponding to principal component
- Tube model with auditory, proprioceptive and tactile feedback
- Muscular redundancy, inertia, elasticity towards neutral
- Intuition for more complex models, while convergence easier

Optimal control model:

Plant:

- Continuous time dynamics $\dot{s} = F(s(t), u(t) + \epsilon_u(t))$ over fixed time T
- Proprioceptive feedback p modeled as 4D projection on principal axes of position and velocity, 3D acoustic feedback a (formant values)
- Acoustic F1-F2 goal
- Variability study:
 - linear reduced plant model identified over ~ 50,000 FEM simulations
 - only motor noise: additive (SD σ_A) and multiplicative (SD σ_M) Gaussian white noise on motor command
 - Internal state estimate via extended Kalman filtering

Optimization:

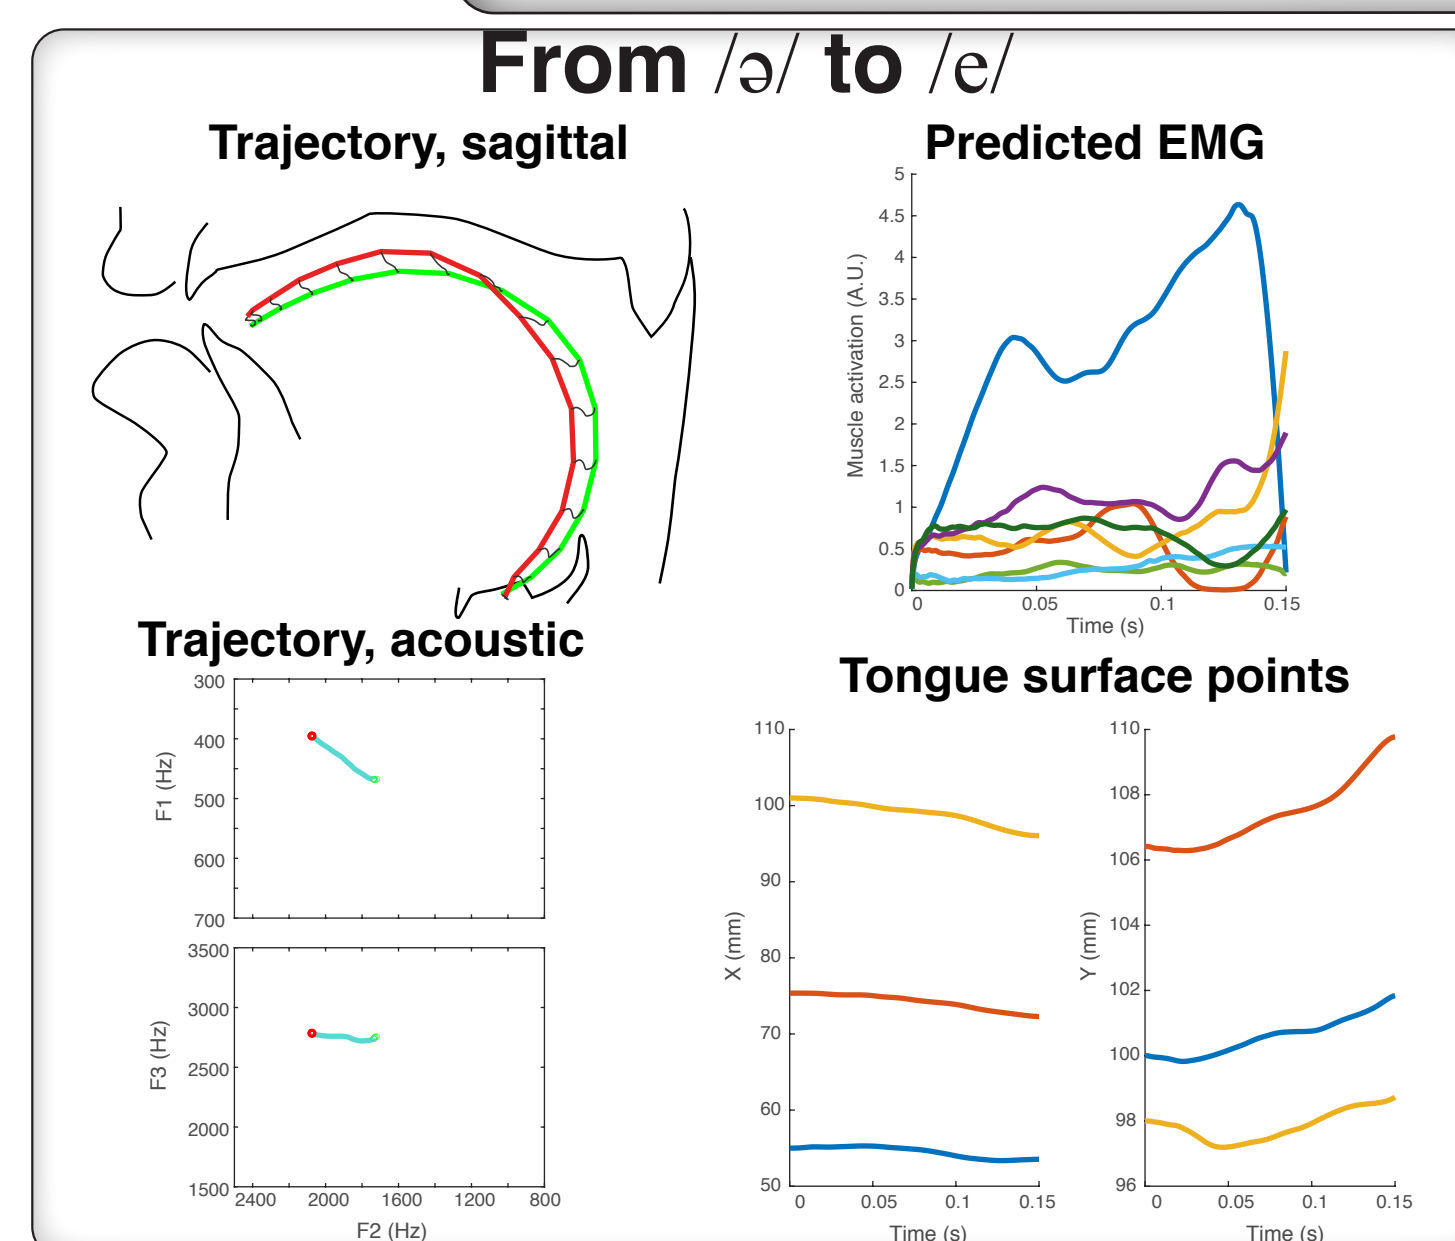

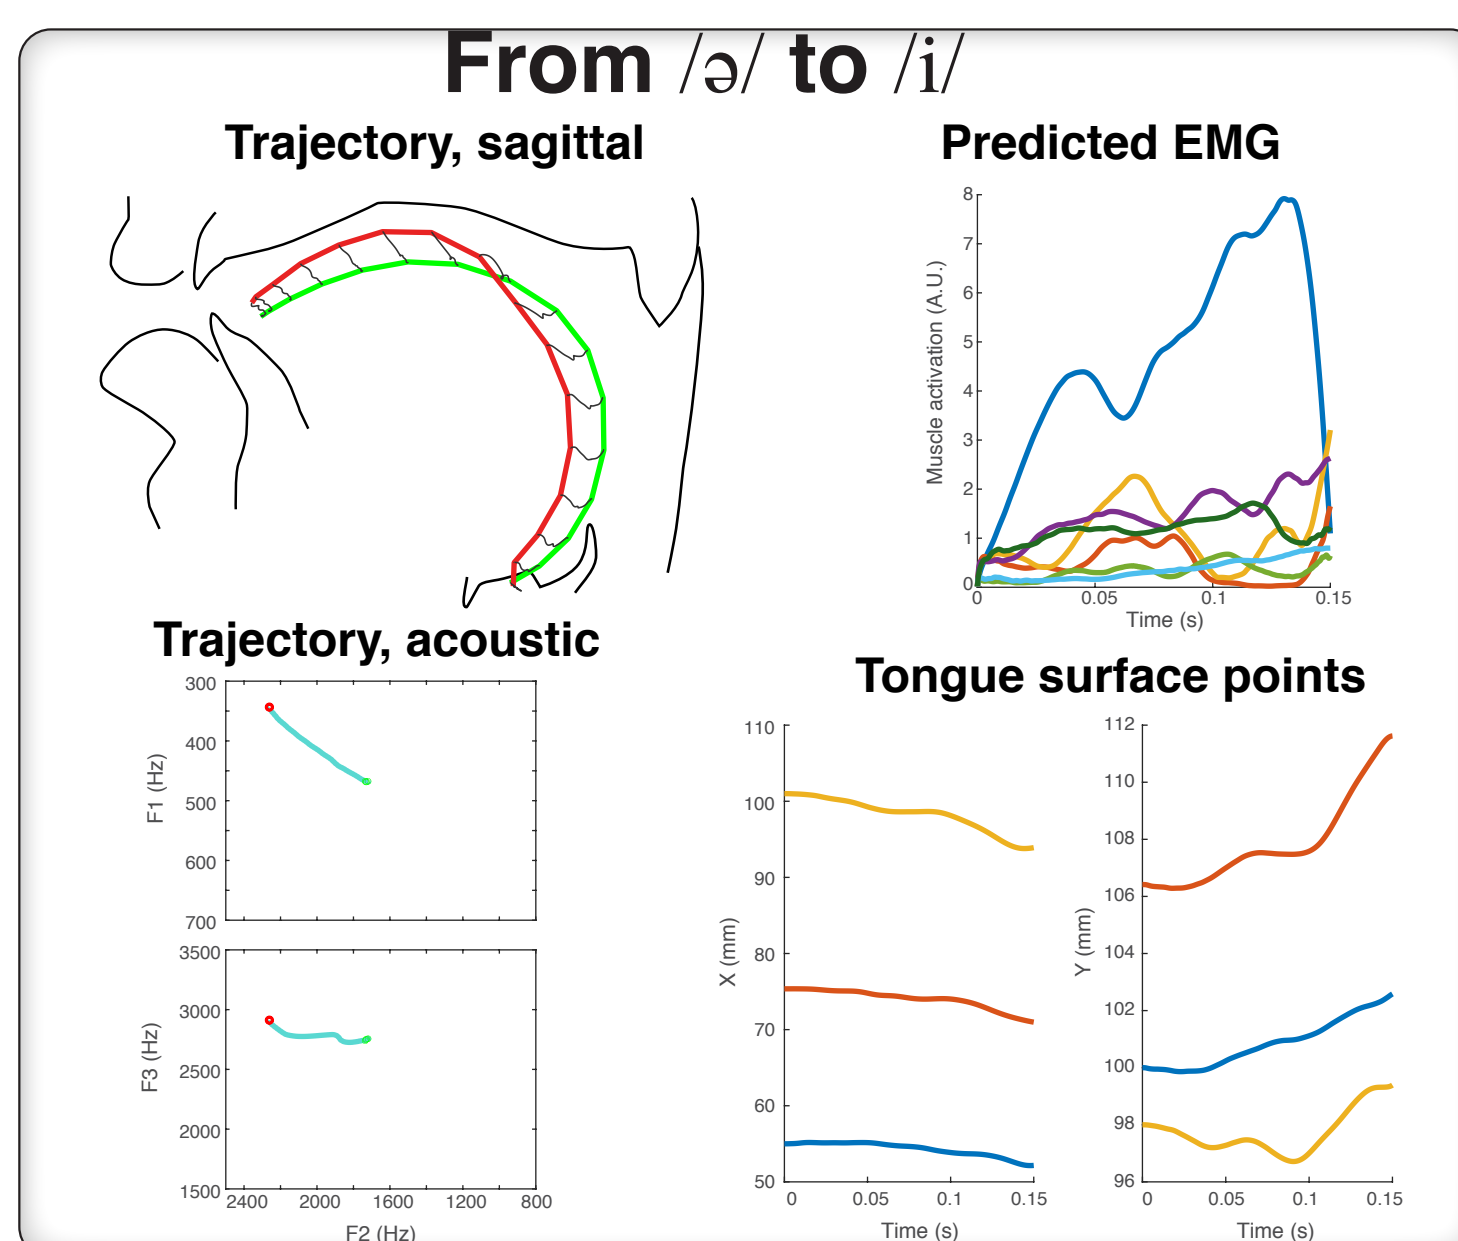

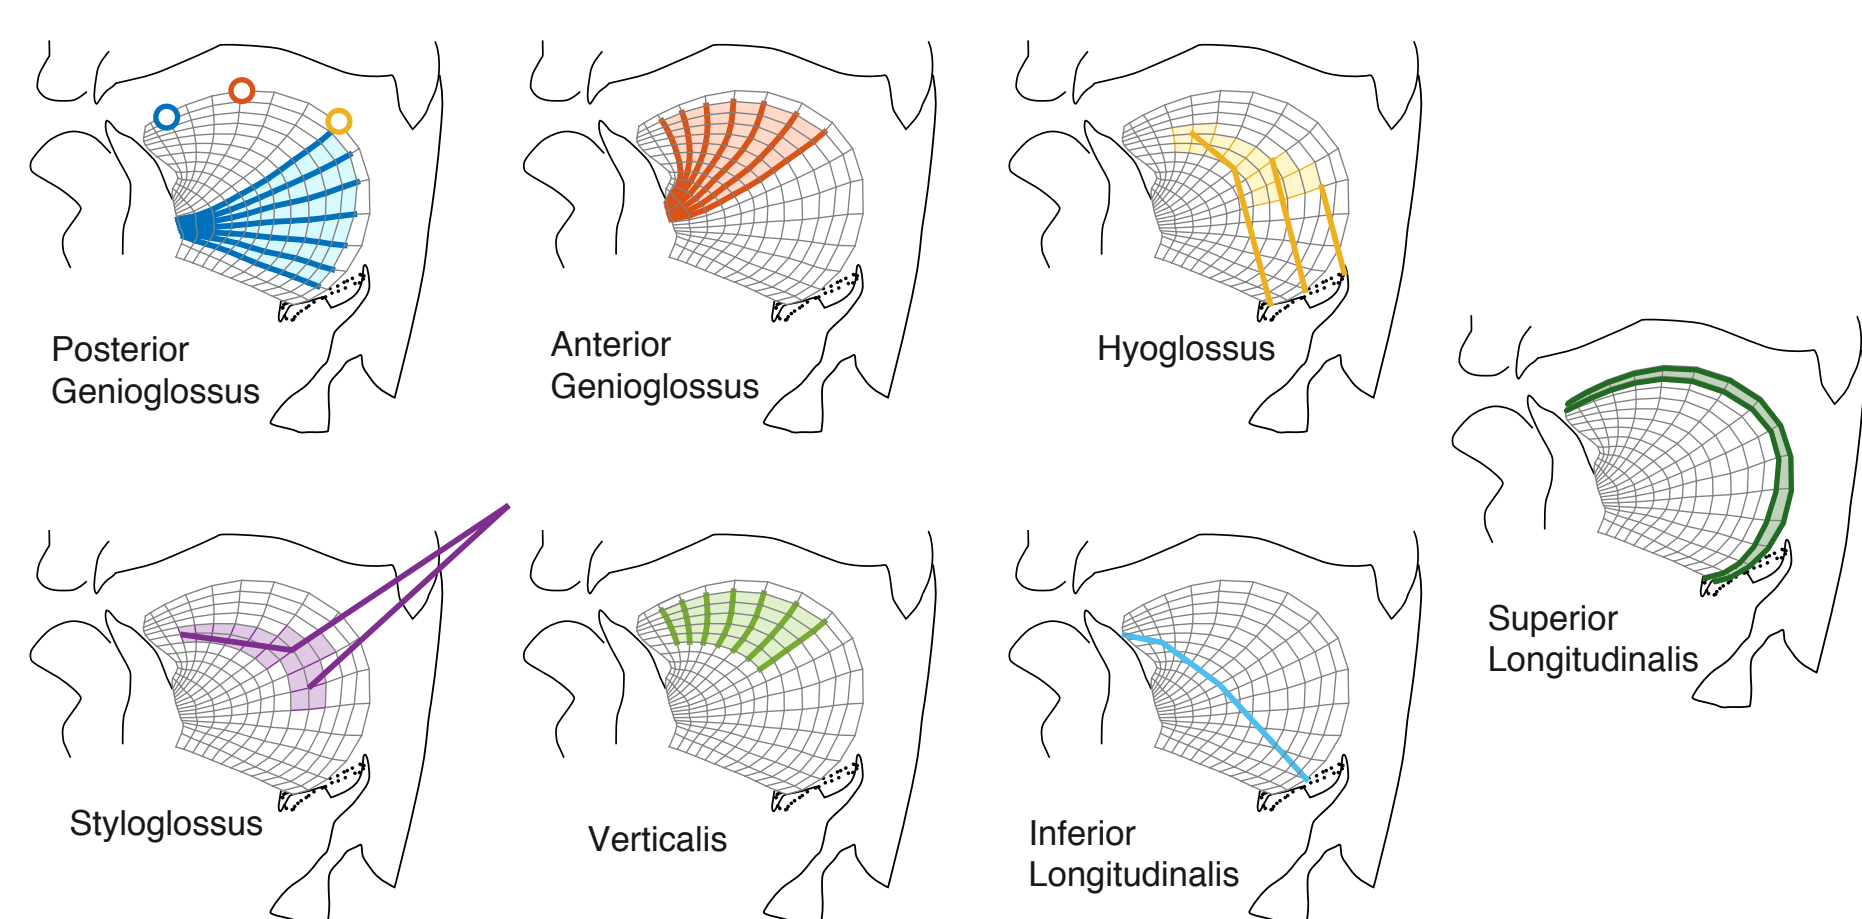

- Unconstrained optimization: cost function includes neuromotor effort and precision penalty:

$$C = \int_0^T \|u(t)\|^2 dt + \alpha \|p(T) - p_{goal}\|^2$$

- Indirect optimal control (Pontryagin based), gradient descent and/or Newton-Raphson method [4]
- Some checks of sensitivity to initial parameters

RESULTS

Key to simulation results

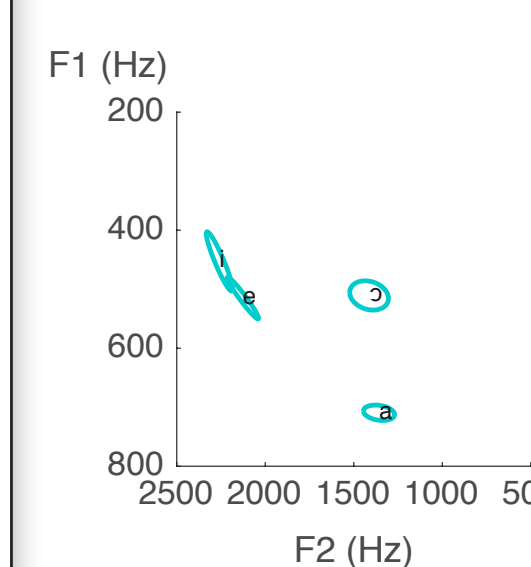

Vowel sequences (not center-out):

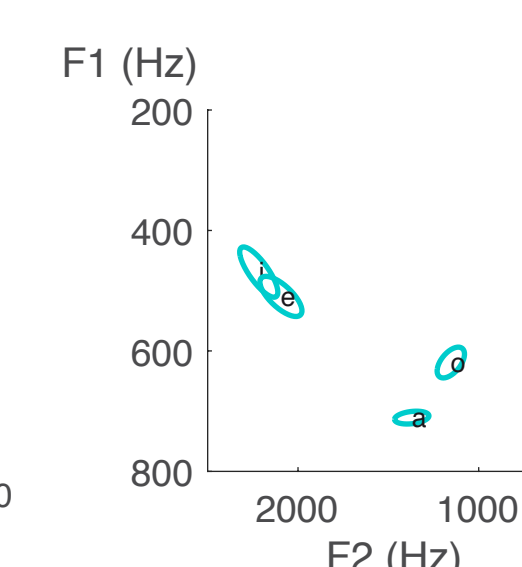

- Effort optimization leads to loopy trajectories in formant space
- Though goals are acoustic, intermediate postures (red) seem very similar to final postures from /ə/

Acoustic variability (linear reduced model):

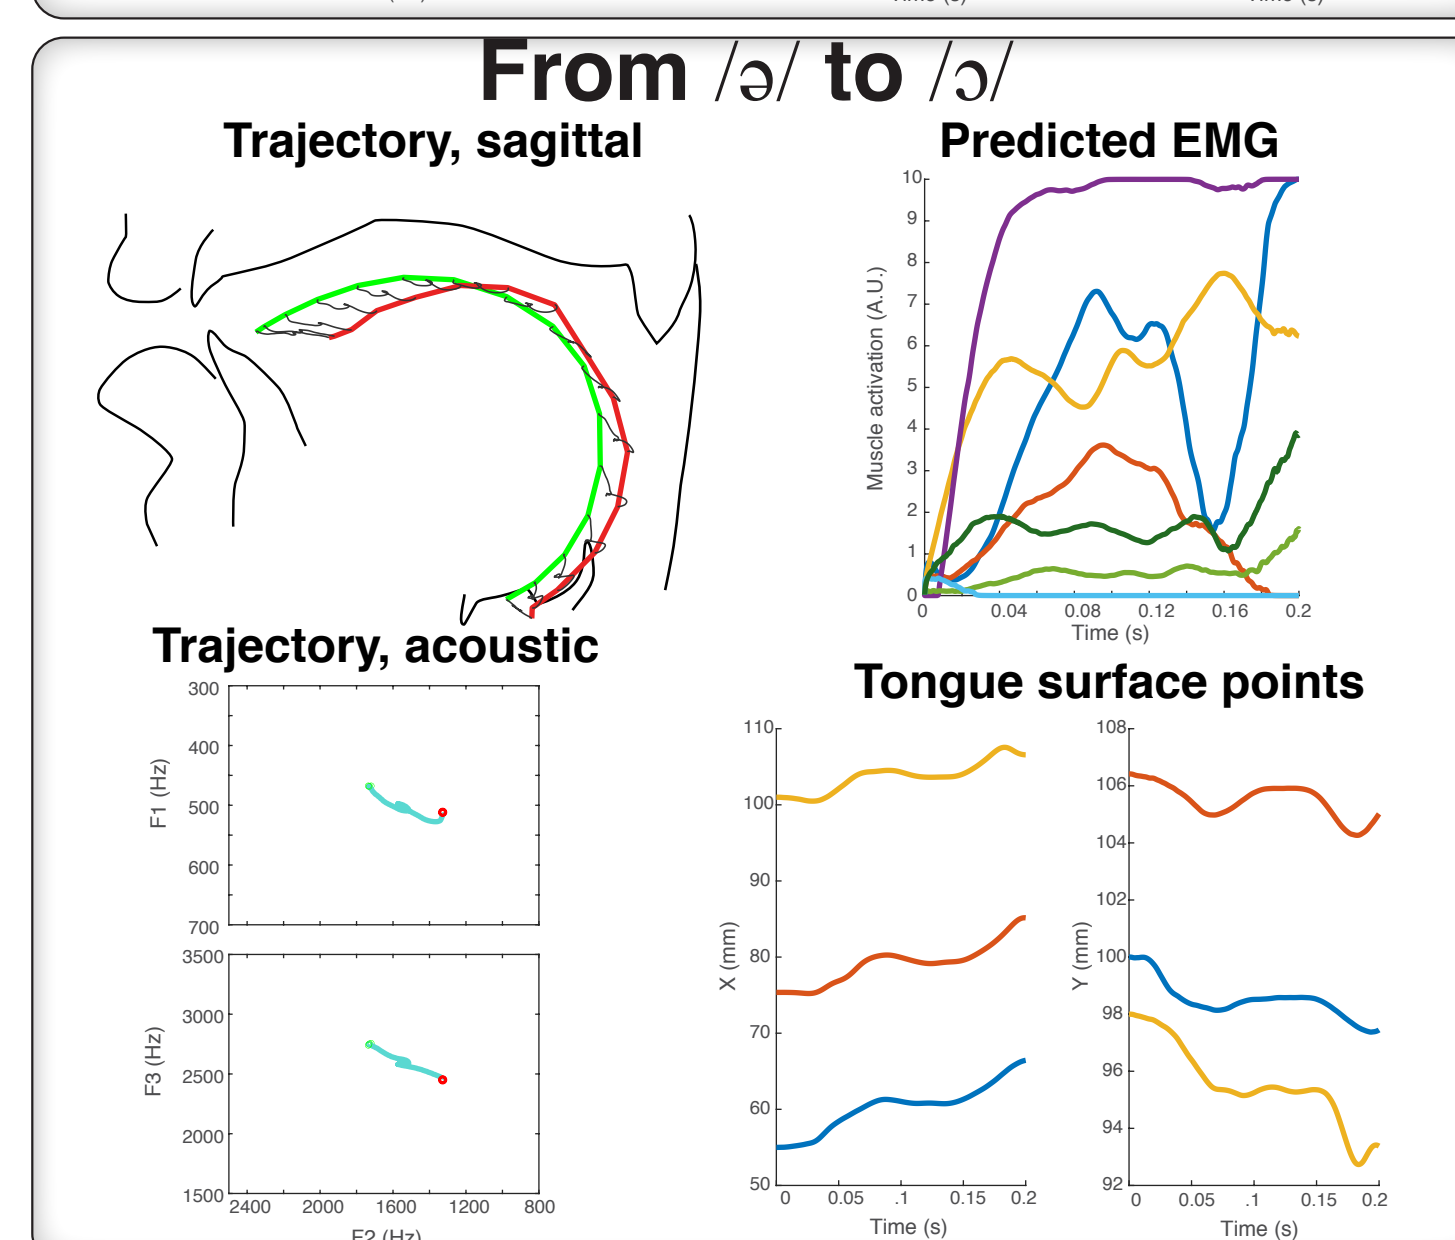

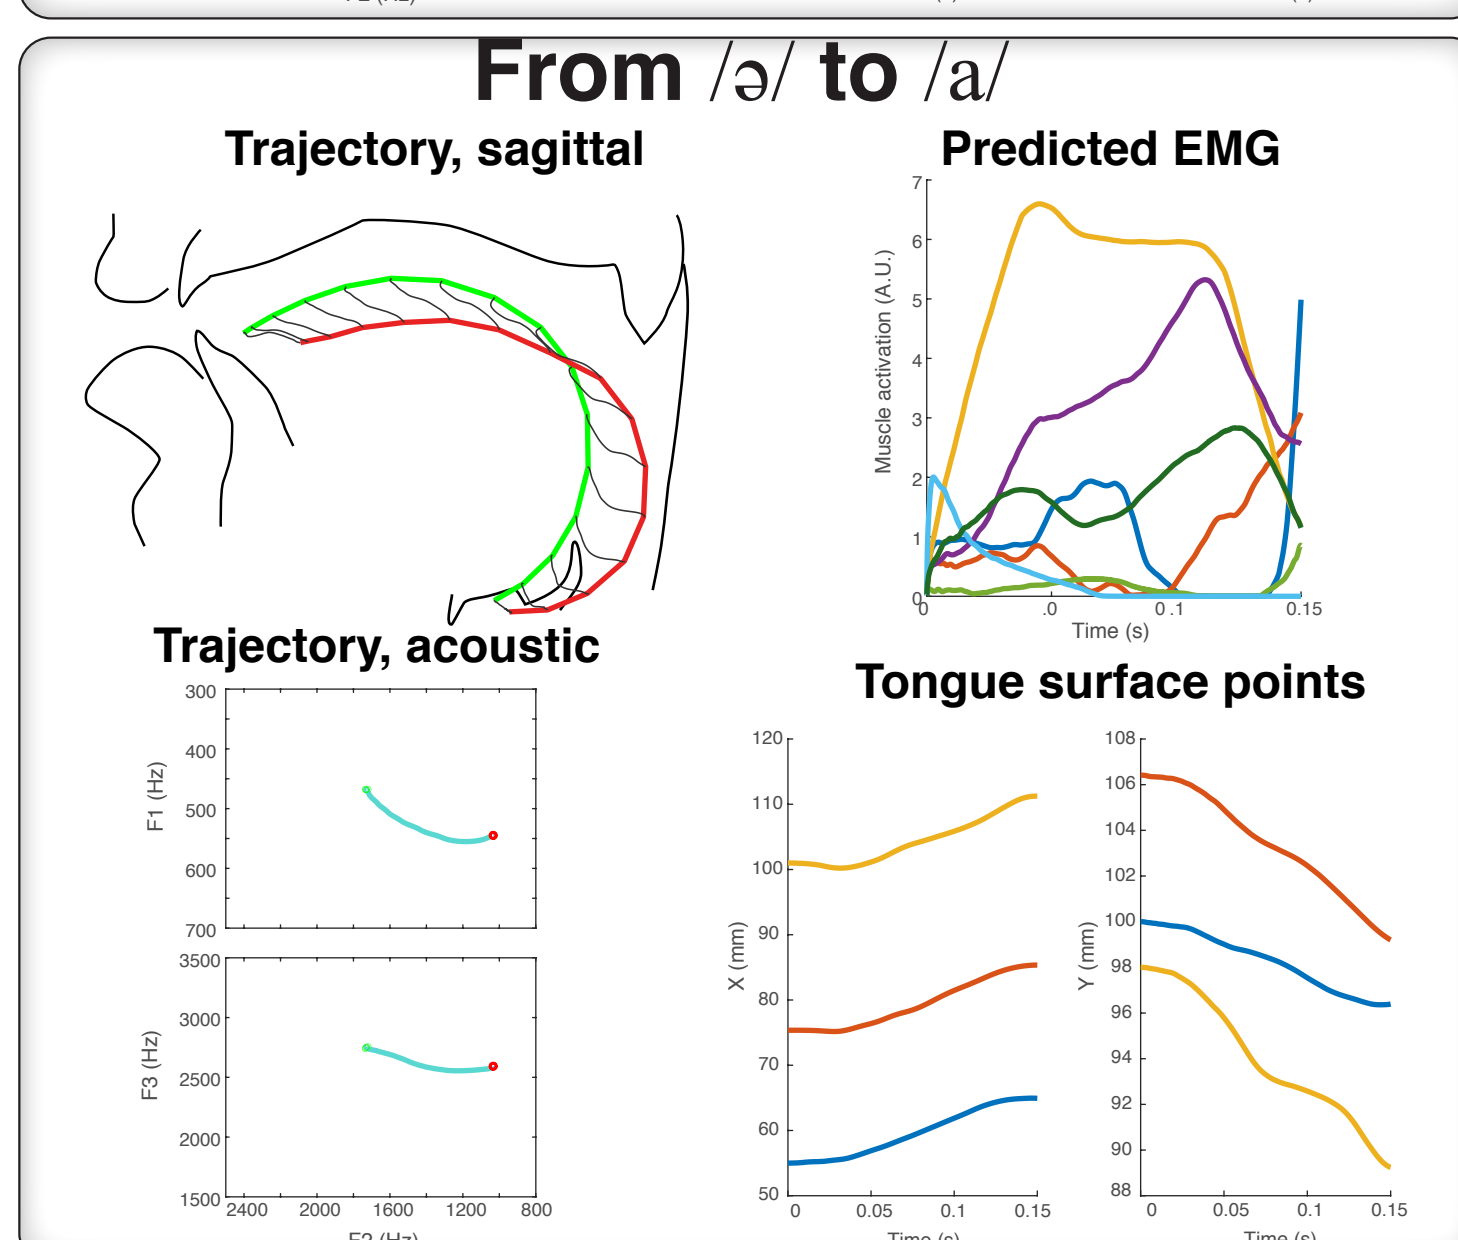

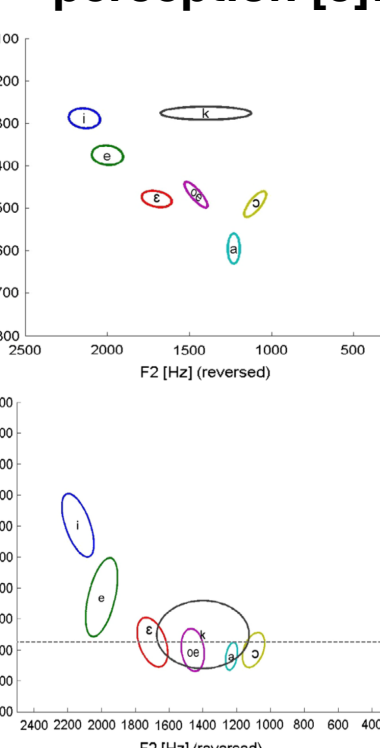

Postural goal

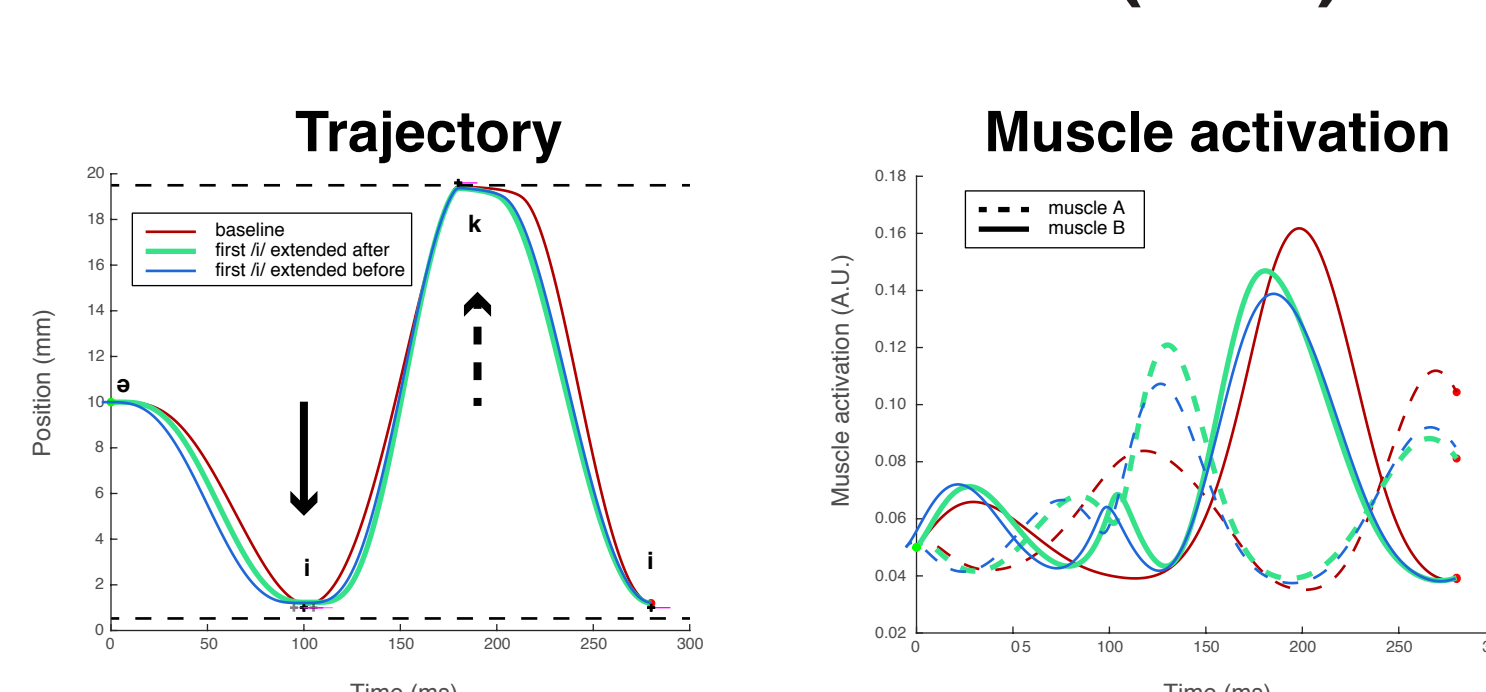

Acoustic goal

Data, perception [5]:

Control of contacts (VCV):

- Coarticulation emerges from effort optimization
- Delayed effects of earlier constraints
- (and large difference in optimization algorithms)

CONCLUSIONS

- Minimization of effort produces plausible tongue trajectories (kinematics, EMG)
- Part of phonemic variability linked to aspects of sensorimotor control?
- Toy model suggests coarticulation can be tackled by this method
- Model predictions should be validated with formant tracking, EMA recordings and intramuscular EMG
