Abstract—Stateful and stateless web tracking gathered much attention in the last decade, however they were always measured separately. To the best of our knowledge, our study is the first to detect and measure cookie respawning with browser and machine fingerprinting. We develop a detection methodology that allows us to detect cookies dependency on browser and machine features.

Our results show that 1,150 out of the top 30,000 Alexa websites deploy this tracking mechanism. We further uncover how domains collaborate to respawn cookies through fingerprinting. We find out that this technique can be used to track users across websites even when third-party cookies are deprecated. Together with a legal scholar, we conclude that cookie respawning with browser fingerprinting lacks legal interpretation under the GDPR and the ePrivacy directive, but its use in practice may breach them, thus subjecting it to fines up to 20 million €.

Index Terms—fingerprinting; cookie respawning; GDPR

I. INTRODUCTION

In the last decades, the usage of the web has considerably increased, along with the web browsers sophistication. In parallel, numerous companies built their business models on profiling and tracking web users. Therefore, browsers evolution does not only provide a better user experience, but also allows the emergence of new tracking techniques exploited by companies to collect users' data. There are two main categories of tracking techniques: stateful and stateless.

Stateful tracking is a standard technique that relies on browser storage such as cookies [56], [2], [8], [26]. Trackers store a unique identifier in the cookie and later use it to recognize a user and track her activity across, possibly, different websites. The simplest way to protect from such tracking is to delete the unique identifier by, e.g., cleaning the cookie storage. However, trackers can recreate deleted cookies using a technique called *cookie respawning* to track users. For instance, a tracker can use multiple browser storages that store identifiers, in addition to the cookie storage, such as the HTML5 localStorage [8]. Consequently, even if the user cleans the cookie storage, the tracker can still recreate cookies using other storages [64], [8], [2], [56].

Stateless tracking allows to track a user without storing identifiers in her browser storage. Using *browser fingerprinting* [51], [15], [25], [3], [37], [34], trackers can identify a user through a combination of the user's browser and machine features, such as the user agent or IP address. Whereas it is hard to prevent it, browser fingerprinting is not stable over time. Vastel et al. [71] showed that fingerprints change frequently: out of 1,905 studied browser instances, 50% changed their fingerprints in less than 5 days, and 80% in less than 10 days.

This instability is caused either by automatic triggers such as software updates or by changes in the user's context such as travelling to a different timezone.

In summary, stateful tracking is a stable way to track a user until she cleans cookies and other browser storages. Stateless tracking is not stable over time, but does not require any storage and can't be easily stopped by the user. So given that each technique is not perfect, *how can a tracker take advantage of the best of the two worlds?* The tracker can first use a browser fingerprint to create an identifier and store it in the browser's cookie. In this way, even if a user cleans this cookie, the identifier can be recreated with a browser fingerprint. Moreover, even if the fingerprint changes over time, the identifier stored in the cookie can help to match the new fingerprint with the old fingerprint of the same user. We refer to this tracking technique as *cookie respawning with browser fingerprinting*, that ensures continuous tracking even if all cookies are deleted or if the fingerprint changes over time.

Several studies measured the prevalence of stateful [2], [56], [26] or stateless [51], [15], [25], [3] tracking techniques separately. However, to the best of our knowledge, *we are the first to study how trackers profit from both stateful and stateless techniques* by combining them.

The aim of this paper is to propose a robust methodology to detect and measure the prevalence of cookie respawning with browser fingerprinting, followed by a technical and legal analysis of the privacy implications of this tracking technique. In this paper, we make the following contributions.

- 1) **We designed a robust method to identify which features are used to respawn a cookie.** Our contribution lays in the design of a method to automatically identify the set of fingerprinting features used to generate a cookie, hence, to conclude which user information is collected. We additionally perform a permutation test ($N=10,000$, $p<0.05$) to provide certainty on the dependency between the features and the cookies.
- 2) **We make the first study of cookie respawning with browser fingerprinting.** We show that the stateful and stateless tracking techniques that were studied separately are, in fact, actively used together by trackers. We found that 1,150 (3.83%) of the Alexa top 30,000 websites use cookie respawning with browser fingerprinting.
- 3) **We identify who is responsible of cookie respawning with browser fingerprinting.** We made a detailed study of the responsibility delegation of cookie respawning

with browser fingerprinting. We show that multiple actors collaborate to access user features, set and own the cookies: we uncovered collaborations between 35 distinct domains that together respawn 67 different cookies.

- 4) **We show that cookie respawning with browser fingerprinting is highly deployed in popular websites.** Cookie respawning with browser fingerprinting is also happening on websites from different categories including highly sensitive ones such as adult websites.
- 5) **We show that cookie respawning with browser fingerprinting lacks legal interpretation and its use, in practice, violates the GDPR and the ePrivacy directive.** We are the first to assess the legal consequences of this practice together with a legal expert co-author. Despite the intrusiveness of this practice, it has been overlooked in the EU Data Protection Law and it is not researched in legal scholarship, nor audited by supervisory authorities.

II. BACKGROUND

A. Scope of cookies: host and owner

In this paper, we make a distinction between the notion of cookie *host* and cookie *owner*. When a cookie is stored in the browser, it's identified by a tuple (*host*, *key*, *value*). If the cookie is set via an HTTP(S) response header, then the *host* of the cookie represents a domain that set the cookie. However, when the cookie is set programmatically via a JavaScript script included in the website, the script gets executed in the context, or "origin" where it is included. Due to the Same Origin Policy (SOP) [58], the *host* of a cookie set by the script is the origin of the execution context of the script, and not the domain that contains the script. Given a cookie stored in the browser with its (*host*, *key*, *value*), when a browser sends a request to a domain, it attaches a cookie to the request if the cookie *host* matches the domain or the subdomain of the request [45].

A cookie *owner* is the responsible of setting the cookie. It is either a domain that sets a cookie via HTTP(S) response header (and in this case, matches with the cookie *host*), or the domain that hosts a script that sets the cookie programmatically (generally speaking, here the owner is different from host). For example, `site.com` is a website that includes a third party script from `tracker.com`. After loading, the script sets a cookie in the context of the visited website `site.com`. In this case, the cookie owner is `tracker.com`, but the cookie host is `site.com`.

B. Web Tracking Technologies

Cookie-based tracking. Websites are composed of first party content and numerous third-party content, such as advertisements, web analytic scripts, social widgets, or images. Following the standard naming [41], for a given website we distinguish two kinds of domains: *first-party* domain that is the domain of the website, and *third-party* domains that are domains of the *third-party* content served on the website.

Using HTTP request (or response), any content of the webpage can set (or receive) cookies. Additionally, cookies can be set programmatically via an included JavaScript library. Every cookie is stored in the browser with an associated domain and path, so that every new HTTP request sent to the same domain and path gets a cookie associated thereto attached to the request. First-party cookies set by first-party domains are capable to track users *within the same website*. Third party cookies set by third-party domains allow third parties to track users *cross-websites* [56].

Browser fingerprinting. Browser fingerprinting is a stateless tracking technique that provides the ability to identify and track users without using their browser storage [23], [3], [15], [5], unlike cookie-based tracking. When a user visits a web page that includes a fingerprinting script, this script will return to a fingerprinter server a list of features composed of user's browser and machine characteristics, such as user agent or time zone. The trackers use these collected features to build a unique identifier.

Cookie respawning. Cookie respawning is the process of automatically recreating a cookie deleted by the user (usually by cleaning the cookie storage). Several techniques can be used to respawn a cookie. While related works focused on exploiting another browser storage (e.g., the HTML5 local storage) that duplicates the information contained in the cookie, in this work, we focus on the usage of a browser fingerprint to recreate a cookie. Section IV describes how a tracker can exploit a browser fingerprint to respawn a cookie.

III. RELATED WORK

Cookie based tracking is a classical tracking technique which has been widely studied in the past decade [64], [56], [8], [52], [25], [23], [3], [51], [41], [55], and is now commonly blocked by modern browsers [50], [35] and add-ons [32], [20]. In this paper, we explore a more sophisticated technique combining cookie based tracking with fingerprinting.

In 2010, the Panopticlick study showed that fingerprints can be potentially used for web tracking [23]. Following this study, several fingerprinting tracking techniques were discovered. Acar et al. studied canvas based fingerprinting [3]. Englehardt et al. presented a new fingerprinting technique based on the AudioContext API. Cao et al. presented a fingerprinting study mainly based on hardware features including WebGL [15]. Al-Fannah et al. studied fingerprinting in Majestic top 10,000 websites [5]. Solomos et al. [63] combined browser fingerprinting and favicons caches to identify users.

The term *respawning* was first introduced in 2009 by Soltani et al. [64]. They showed that trackers are abusing the usage of the Flash cookies in order to respawn or recreate the removed HTTP cookies. This work attracted general audience attention [46], [47] and triggered lawsuits [39], [40]. Following Soltani et al. work, other studies started analyzing the usage of other storages for respawning such as ETags and localStorage [8]. Sorensen studied the usage of browser cache in cookie respawning [66]. Acar et al. automated the detection of cookie respawning and found that IndexedDB can be used to respawn

cookies as well [3]. Roesner et al. showed that cookies can be respawned from local and Flash storages [56].

Laperdrix et al. [37] surveyed recent advancement in measurement and detection of browser fingerprinting. The survey mentions [37, §5.1] that browser fingerprint together with IP address can be used to regenerate deleted cookies, however no previous work studied this phenomena.

Unlike previous works that studied the usage of browser storages to respawn cookies, or measured fingerprinting independently, our study analyzes the usage of fingerprinting to respawn cookies.

IV. METHODOLOGY

When a user visits a web page with some content located on a tracker’s server, the user’s browser sends an HTTP(s) request to the server to fetch this content. This request contains several HTTP headers, such as user agent, and an IP address that tracker’s server receives *passively*. We refer to such information as *passive features*. To collect additional information, the tracker can include in the visited web page a script that gets executed on the user’s browser. The script retrieves multiple browser and machine information, such as the time zone, and sends them to a server of the remote tracker. We refer to such information as *active features*. In the following, we define a *browser fingerprint* as the set of active and passive features accessed by the tracker.

We say that a tracker *respawns a cookie* when it recreates the exact same cookie after the user revisit the website in a clean browser.

A. How can trackers benefit from a combination of cookies and browser fingerprint?

To benefit from both techniques, the tracker can first use a browser fingerprint to create an identifier and store it in the browser’s cookie. In this way, even if a user cleans this cookie, the identifier can be recreated with a browser fingerprint. Moreover, even if the fingerprint changes over time, the identifier stored in the cookie can help to match the new fingerprint with the old fingerprint of the same user. We explain these scenarios and benefits in details below.

Figure 1(a) shows that the tracker first receives a set of user’s active and/or passive features (step ①). In step ②, the tracker generates an identifier from the received features, that it might store on the server’s matching table. The tracker then stores the created identifier in the user’s browser cookie, either via the `Set-cookie` header (step ③) or programmatically via JavaScript (not shown in Figure 1(a)). As a result, an identifier is stored in the browser’s cookie database (step ④).

Figures 1(b) shows what happens when the user does not have a cookie *123* in her browser, however the fingerprint *fp456* remains the same. In this case, the fingerprint *fp456* is sent to the server of `tracker.com` (step ⑤), and it allows the tracker to match the known fingerprint and the cookie previously set for this user (step ⑥). As a result, the tracker is able to set again the same cookie *123*, previously deleted by

the user (step ⑦). This allows the tracker to respawn deleted user cookies with browser fingerprinting and continue tracking her via such cookies (step ⑧).

Figure 1 (c) presents the consequences of cookie respawning with browser fingerprinting. When the browser fingerprint of the user is updated from *fp456* to *fp789*, the server of `tracker.com` receives an old cookie *123* with a new fingerprint *fp789* (step ⑨). The cookie *123* helps the server to recognize the user’s browser and update the corresponding record in the matching table and substitute a fingerprint *fp456* to *fp789* associated to cookie *123* (step ⑩). This allows the tracker to match different fingerprints of the same user, given that fingerprinting is not stable over time.

As a result, cookie respawning with browser fingerprinting allows trackers to respawn deleted cookies, and also to link different browser fingerprints of the same user. This makes the tracking robust to either cookie deletion or fingerprint change. Only in case the browser fingerprint changes and the cookie is deleted at the same time, the tracker will not be able to recognize the user and hence to continue tracking this user.

In this paper, we propose a robust methodology to detect the mechanisms presented in Figures 1 (a) and (b). In this section, we first introduce our methodology to crawl Alexa top 30,000 websites (Section IV-B). Next, we present our method to detect cookie respawning with browser fingerprinting (Section IV-C). Then, we describe the fingerprinting features used in our study and spoofing techniques (Section IV-D). Finally, we list the limitations of our methodology (Section IV-E).

B. Measurement setup

We performed passive web measurement on March 2021 of the Alexa top 30,000 websites extracted on March 2020¹. All measurements are performed using the OpenWPM platform [53] on the Firefox browser. OpenWPM provides browser automation by converting high-level commands into automated browser actions. We used two machines to perform the crawls in our study. The versions of OpenWPM and Firefox, the time period of the crawl, and the characteristics of the two machines used in this study are presented in Table IX of the Appendix (Section A).

We used different characteristics with two machines so that they appear as different users, as done by previous works [31], [2], [26], [25]. Ideally, we would have used two distinct machines with different locations to detect user specific cookies, however, both machine A and machine B are located in France. Hence, to change the Machine B geolocation, we spoofed the parameters latitude and longitude by modifying the value of `geo.wifi.uri` advanced preference in the browser and point it to Alaska.

All our crawls are based on the notion of *stateless crawling instances*. We define a stateless crawling instance of a website *X* as follows: (1) we visit the home page of the website *X* and keep the page open until all content is loaded to capture all cookies stored (we set the timeout for loading the page to

¹We made this list of websites publicly available [6].

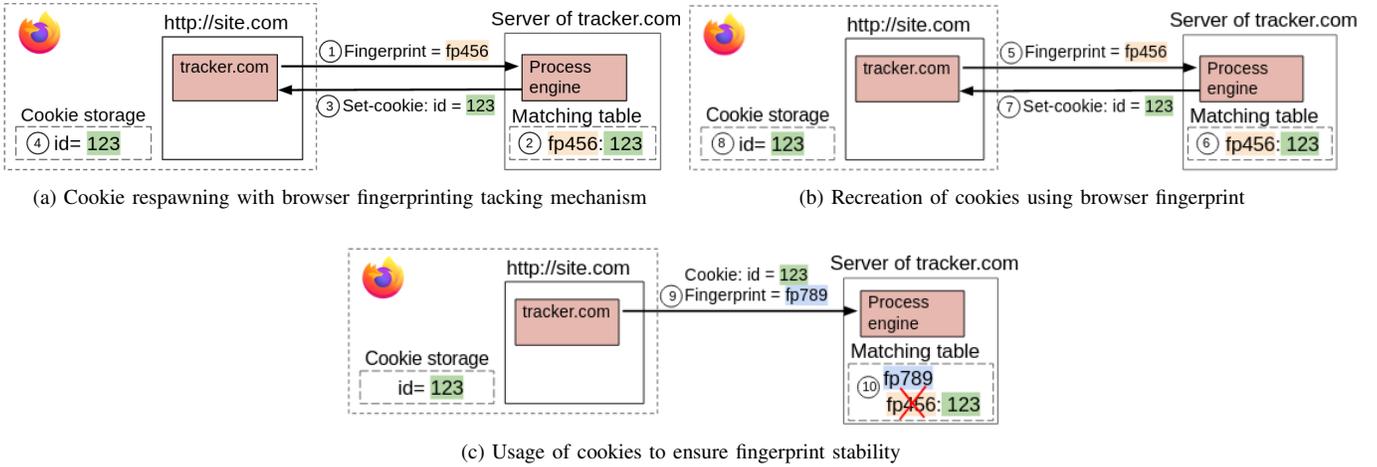

Fig. 1: **Cookie respawning with browser fingerprinting tracking technique.** (a) (step 1) The tracker receives user’s features, (step 2) then stores a fingerprint $fp456$ associated with the features and generates a corresponding cookie 123 . (step 3) Next, the tracker sets the cookie in the user’s browser. (step 4) As a result an identifier is stored in the browser cookie storage. (b) When the user cleans her browser and revisit the website, (step 5) the tracker receives the fingerprint $fp456$, (step 6) extracts the corresponding cookie from the matching table, (step 7) and re-sets it in the user’s browser. (step 8) As a result, the cookie 123 is recreated in the user’s browser. (c) The fingerprint is not stable over time, (step 9) thus the user fingerprint might change. (step 10) The tracker can use the cookie received with the fingerprint to update the latest on the server side.

JavaScript calls	API
HTML5 Canvas	HTMLCanvasElement, CanvasRenderingContext2D
HTML5 WebRTC	RTCPeerConnction
HTML5 Audio	AudioContext
Plugin access	Navigator.plugins
MIMEType access	Navigator.mimeTypes
Navigator properties	window.navigator
Window properties	Window.screen, Window.Storage, window.localStorage, window.sessionStorage, and window.name

TABLE I: **Recorded JavaScript calls.**

90s), (2) we clear the profile by removing the Firefox profile directory that includes all cookies and browser storages. The rational behind the stateless crawling instance is to ensure that we do not keep any state in the browser between two crawling instances. This guarantees that respawned cookies do not get restored from other browser storages.

We perform stateless crawling instances of the Alexa top 30,000 websites and for *each stateless crawling instance*, we extract the following from the information automatically collected during the crawls by OpenWPM:

- 1) For each HTTP request: the requested URL, the HTTP header.
- 2) For each HTTP response: the response URL, the HTTP status code, the HTTP header.
- 3) All JavaScript method calls described in Table I.
- 4) All cookies set both by JavaScript and via HTTP Responses. On these collected cookies, we perform the following filtering as shown in Figure 2: first, we select cookies recreated after cleaning the cookies database; second, we filter out cookies that are not user-specific;

finally, we filter out cookies that are not respawn with studied features (Section IV-C).

C. Detecting cookie respawning with browser fingerprinting with sequential crawling

Figure 2 presents our sequential crawling methodology that detects which fingerprinting features are used to respawn cookies. Our method consists of two main steps explained in this section:

- **Create the initial set of candidate respawned cookies:** we identify candidate respawned cookies by collecting all cookies that get respawned in a clean browsing instance, and we remove cookies that are not user-specific.
- **Identify dependency of each respawned cookie on each fingerprinting feature:** we spoof each feature independently to detect whether the value of a respawned cookie has changed when the feature is spoofed. We perform a permutation test ($N = 10,000$, $p < 0.05$) to add statistical evidence on the dependency between a feature and the respawned cookie.

1) *Creation of the initial set of candidate respawned cookies:* To build the initial set of candidate respawned cookies, we perform two stateless crawling instances from machine A as described in Figure 2 (see *initial crawl* and *reappearance crawl*). Via these two crawls, we ensure that all browser storages are cleaned and the only possible way for cookies to be respawn is with browser fingerprinting.

We define a cookie as the tuple $(host, key, value)$ where *host* is the domain that can access the cookie. To create the set of candidate respawned cookies, we only collect cookies that appear in both the *initial crawl* and *reappearance crawl*

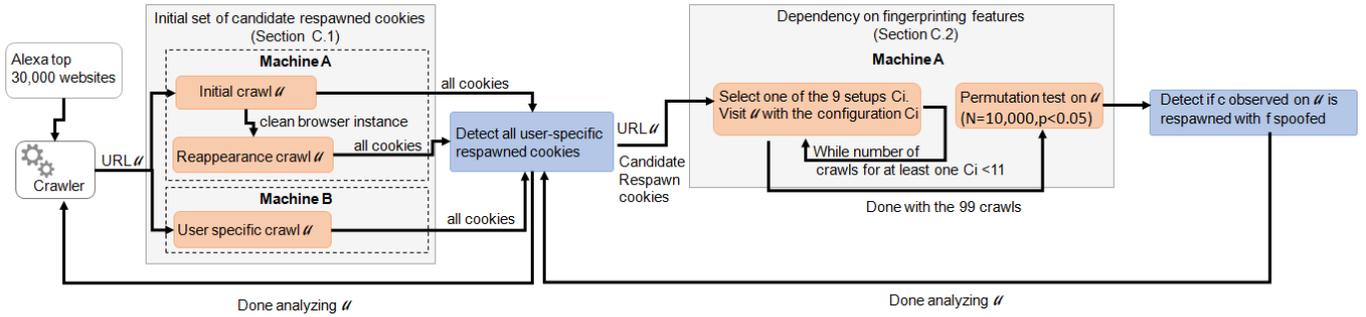

Fig. 2: **Sequential crawling of 30,000 top Alexa websites to identify cookie respawning with browser fingerprinting.** For each website, we perform an *initial crawl* from machine A and, a *user specific crawl* from machine B to detect machine unrelated cookies. After *initial crawl* finishes, we start a *reappearance crawl* from machine A to detect reappearance of cookies. Using *initial crawl*, *user specific crawl*, and *reappearance crawl* we detect *user-specific* cookies that reappear in *reappearance crawl*, but not in *user specific crawl*. For such cookies, we randomly chose one configuration C_i : either spoof one feature at a time or to set all features to initial value. We perform 99 stateless crawls (11 *spoofing crawls* per feature and 11 *control crawls* where the studied features are unspoofed). Finally, we perform a permutation test for each feature ($N=10,000, p<0.05$), and we consider that the cookie is *feature dependent* if the resulting p-value < 0.05 . All these steps are discussed in Section IV-C.

when visiting the same website in the two crawls. Note that due to our sequential crawling (that is, we visit websites in a sequence), we only consider candidate respawned cookies within the same website.

Previous research [31], [2], [26], [25] considered that cookies are non specific to the users and hence unlikely to be used for tracking when their values are identical for several users. Therefore, using distinct machines to remove non user-specific cookies became a common method in this research area. We follow this methodology and remove cookies that are not user-specific from our set of candidate respawned cookies. To do so, we performed an additional *user specific crawl*² from a different machine B that appears to trackers as a different user. It’s important that machines A and B have different fingerprinting features (see Table IX of the Appendix) to avoid wrong categorization of cookies that depend on these features as non user-specific.

We hence remove the following cookies from the candidate set of respawned cookies and keep only user-specific cookies:

- a cookie (*host, key, value*) if it appears on both the *initial crawl* on machine A and *user specific crawl* on machine B with the same *host, key, and value*.
- a cookie (*host, key, value*) if a cookie with the same *host* and *key* is not present in a *user specific crawl*. We adopt a conservative strategy to remove such cookies because we do not have a proof that such cookies are user-specific.

Our robust deletion method for cookies that are not user-specific or do not re-appear in a *user specific crawl* allows us to ensure that only user-specific cookies are further analysed.

2) *Identifying dependency of each respawned cookie on each fingerprinting feature.*: The set of candidate respawned cookies contains cookies that are both user-specific and respawn when crawled a second time after we used a new

browser instance with a cleaned browser storage. Therefore, cookies in this set are very likely to be respawned with the use of browser fingerprinting. To detect which fingerprinting features are used to respawn the collected cookies, we performed the following steps. We first identified 8 fingerprinting features from previous research (see more details on the choice of features and methods to spoof them in Section IV-D). Then, for each website u where we have at least one candidate respawned cookie, we perform 99 crawls, 11 spoofing crawls per studied fingerprinting feature f , and 11 crawls with all features set to their initial values (as in *initial crawl*) that we refer to as *control crawls*. In each of the total 88 spoofing crawls, we first spoof the feature f and perform a stateless *spoofing crawl* of the website u . For each user-specific respawned cookie from the candidate set, we perform the following algorithm.

- For each of the 99 crawls, we label the cookie as respawned if the cookie’s *host* and *key* are identical but *value* are different from the initial crawl. As a result we get 11 observations for each configuration (either one of the 8 features is spoofed or no feature spoofed.)
- For every feature, we perform a permutation test with the 11 observations from the *control crawls* using 10,000 permutations. The statistical test assess the difference of the probability to have the cookie respawned between the feature crawls and the control crawls.
- We consider that the cookie is *feature dependent* if the p-value for the test statistic is lower than 0.05.

D. Selection of fingerprinting features and spoofing techniques

To achieve a high uniqueness of an identifier built from a browser fingerprint, trackers use a combination of both passive and active browser and machine features. Though browser features are useful for fingerprinting, using them alone might be problematic for trackers because the usage of multiple browsers is recommended and common among users [70],

²Practically, we perform the *initial crawl* and *user specific crawl* in parallel, and the *reappearance crawl* right after the *initial crawl* completes (Figure 2).

Browser features	Accept language [38], [5]	Active/Passive
	Geolocation [5]	Active
	User agent [38], [12], [33], [5]	Active/Passive
	Do not track [38], [33]	Active/Passive
Machine features	WebGL [38], [15], [33], [5], [49]	Active
	Canvas [38], [15], [33], [2], [19], [25], [49]	Active
	IP address [12], [5], [19], [25]	Passive
	Time zone [38], [12], [33]	Active

TABLE II: Studied fingerprinting features.

[61], [15]. To improve the accuracy of the fingerprint, trackers also use machine related features such as the IP address, or the OS version [12], [5].

Table II presents a full list of studied browser and machine features that we selected based on the most common features in prior works for browser fingerprinting [38], [12], [33], [5], [15], [2], [19], [25], [49].

We have used two methods to spoof fingerprinting features: 1) via Firefox preferences and 2) add-ons. We have validated that each feature has been properly spoofed on our own testing website with a fingerprinting script and also by using *whoer* website [73] that verifies the information sent by the user’s browser and machine to the web.

1) *Spoofing using Firefox preferences*: Firefox allows to change its settings in the browser preferences of *about:config* page. With this method, we spoofed the following features.

User agent. The *User-Agent* HTTP header allows the servers to identify the operating system and the browser used by the client. The *initial crawl* run in Firefox under Linux (see Table IX in the Appendix for details). To spoof the user agent, we changed the `general.useragent.override` preference in the browser to Internet Explorer under Windows: (*Mozilla/5.0 (Windows NT 6.1; WOW64; Trident/7.0; AS; rv:11.0) like Gecko*). We checked the spoofing efficiency on our testing website with an injected script. The script returns the user agent value using the `navigator.userAgent` API. We tested the user agent value returned with the HTTP header using the *whoer* website. We found that the user agent value was spoofed both in JavaScript calls and HTTP headers.

Geolocation. The geolocation is used to identify the user’s physical location. The *initial crawl* has as location *Cote d’Azur, France*. We spoofed the geolocation parameters latitude and longitude by modifying the value of `geo.wifi.uri` preference in the browser and point it to the *Time Square, US* (“lat”: 40.7590, “lng”: -73.9845). We validated the spoofing efficiency using a script call to `navigator.geolocation` API.

WebGL. The WebGL API is used to give information on the device GPU. In our study, we focus on the WebGL renderer attribute that precises the name of the model of the GPU. We spoofed the WebGL renderer using the `webgl.renderer-string-override` preference in the browser. We changed the value of WebGL renderer to *GeForce GTX 650 Ti/PCIe/SSE2*. To retrieve information about the graphic driver and read the WebGL renderer value, we used the `WEBGL_debug_renderer_info` add-on. We validated

the WebGL spoofing efficiency by using the add-on in our customized website.

Do Not Track. The Do Not Track (DNT) header indicates user’s tracking preference. The user can express that she doesn’t want to get tracked by setting the DNT to True. In the *initial crawl*, the DNT was set to *null*. We enabled the Do Not Track header, and we set it to True using the *privacy.donottrackheader.enabled* preference. We validated that the DNT returned value in the HTTP header is set to True using the *whoer* website.

2) *Spoofing using browser add-ons*: The browser preferences do not provide a spoofing mechanism for all fingerprinting features. We used browser add-ons to spoof such features.

Canvas. The HTML canvas element is used to draw graphics on a web page. The difference in font rendering, smoothing, as well as other features cause devices to draw images and texts differently. A fingerprint can exploit this difference to distinguish users. We spoofed the canvas by adding a noise that hides the real canvas fingerprint. To do so, we used the Firefox add-on *Canvas Defender* [14]. To test the add-on efficiency, we built a customized website where we inject a canvas fingerprinting script. The script first draws on the user’s browser. Next, the script calls the Canvas API *ToDataURL* method to get the canvas in dataURL format and returns its hashed value. This hashed value can then be used as a fingerprint. To evaluate the add-on efficiency against the canvas fingerprinting, we revisited the customized website and compared the rendered canvas fingerprint. We found that the returned canvas hashed values were different upon every visit.

IP address. We run the *initial crawl* with an IP address pointing to France. We spoofed the IP address using a VPN add-on called *Browsec VPN* [72]. We used a static IP address pointing to the Netherlands. Consequently, the spoofed IP address remain constant during the runs of spoofed crawls. We checked that the IP address changed using the *whoer* website.

Time zone. We launched the *initial crawl* with *Paris UTC/GMT +1* timezone. We spoofed the timezone to *America/Adak (UTC-10)* using the *Chameleon* add-on [17].

Accept-language. The *Accept-language* header precises which languages the user prefer. We used English as *Accept-language* in *initial crawl*. We spoofed the accept-language header using the *Chameleon* add-on [17] to Arabic. We checked that it was properly spoofed using the *whoer* website.

E. Limitations

Spoofing features and implementing the spoofing solution with the OpenWPM crawler requires substantial engineering effort. Therefore, we limit our study to 8 browser features that are commonly used by previous works and that can be spoofed either directly using browser settings, or using the add-on (*Canvas Defender*, *Browsec VPN*, and *Chameleon*) that we successfully run with OpenWPM. Consequently, cookies respawnd using other features are excluded from this study. The number of excluded cookies is 2,976 (see Section V-A). This is a limitation that does not impact the main goal of our

Crawls	Initial	Reappearance	User specific	Feature dependent
Collected cookies	428,196	88,470	5,144	1,425
Occurrence on websites	30,000	18,117	4,093	1,150

TABLE III: **Cookie respawning with browser fingerprinting is common on the web.** We detected 1,425 respawed cookies that appear on 1,150 websites. We define the Initial, Reappearance, User specific crawls and Feature dependent cookies in Section IV-C.

study, as we do not intend to be exhaustive in the identification of respawed cookies, but we aim to understand and describe the mechanisms behind respawning, and propose a robust methodology to detect features that are used by trackers to respawn cookies.

Given that we spoof one feature at a time, we may introduce inconsistency between different features. For example, when we spoof the geolocation API, we don't modify the time zone or the IP address. This method doesn't invalidate our results because we detect dependency on each feature separately. Nevertheless, we may miss trackers that modify their behaviour when some features are spoofed.

Non user-specific cookies are not intrusive for the user's privacy because they are identical among different users. We are aware that the cookies we classify as non user-specific might have been respawed due to features we do not consider.

V. RESULTS

In this section, we present findings on prevalence of cookie respawning with browser fingerprinting, identify responsible parties, and analyze on which type of websites respawning occurs more often. Our results are based on Alexa top 30,000 websites where we extracted a total of 428,196 cookies. We study the respawning of both first and third party cookies.

A. How common is cookie respawning with browser fingerprinting?

Table III presents an overview of the prevalence of cookie respawning with browser fingerprinting. We extracted 428,196 cookies from the visited 30,000 websites. Using the *reappearance crawl*, we extracted a set of cookies that did reappear in the crawl. As a result, we obtained a set of 88,470 (20.66%) reappearing cookies that appear on 18,117 (60.39%) websites.

Next, we filtered out cookies that are not user-specific – they appear with the same (host, key, value) on *initial crawl* and *user specific crawl* – and cookies that only appear on *initial crawl* but not in *user specific crawl* (Section IV-C1). We found that out of 88,470 reappearing cookies, 5,144 (5.81%) are user specific. The set of user specific cookies is observed on 4,093 (22.59%) websites.

After filtering out non reappearing cookies and keeping only user specific cookies, we identified cookies whose value depend on at least one of the studied features following our methodology detailed in Sections IV-C2. As a result, we extracted 1,425 respawed cookies that appear on 1,150

	Passive	Active/Passive			Active			
Features	IP	UA	Lang	DNT	CV	GEO	GL	TZ
Occurrence	672	486	278	277	231	249	292	310

TABLE IV: **IP address is the most commonly used feature to respawn cookies.** Occurrence: number of times a feature has been used to respawn a cookie (either independently or in combination with other features). CV: Canvas, IP: IP address, UA: User agent, GEO: Geolocation, GL: WebGL, TZ: Time zone, Lang: Accept language, DNT: Do Not Track.

(3.83%) websites. Out of the remaining 3,719 set of cookies, 743 were excluded from the statistical test because they did not appear on the 99 spoofing and control crawls. The remaining 2,976 cookies that are user specific and not detected as feature dependent can be respawed via other features that are out of scope of our study.

Summary. We found 1,425 cookies respawed using at least one of the studied features. These cookies were respawed in 1,150 websites that represent 3.83% of the visited websites.

B. Which features are used to respawn cookies?

In this section, we present the results we obtained from the sequential crawling methodology (Section IV-C). For each of the 1,425 respawed cookies, we detected features on which the cookie value depends (see all studied fingerprinting features in Table II).

Given that a cookie can be respawed with several features, we consider that a cookie C is respawed with a set of features F if the value of C depends on every feature in F (such detection was done independently for each feature as described in Section IV-C2).

Table IV presents the number of times each feature is used to respawn a cookie. IP address is the most commonly used feature to respawn cookies and is used in respawning of 672 (47.15%) cookies. The second most popular feature to respawn cookies is User-Agent (UA) – it is observed with 486 (34.10%) cookies. Note that features that can be easily collected passively, like IP address and UA, are more frequently used than features that can only be accessed actively, such as Canvas or Geolocation.

We found that cookies are usually respawed with a set of different fingerprinting features. In our dataset, cookies are respawed with 184 distinct sets of features. Figure 3 shows the sets of features most often used for cookie respawning. We see that the IP address alone is the most commonly used feature to respawn cookies, and moreover no other set of features is more popular than the IP address alone.

The IP address is used alone to respawn 366 (25.68%) cookies. Mishra et al. [48] studied the stability and uniqueness of the IP address over a duration of 111 days on a dataset of 2,230 users. They showed that 87% of participants retain at least one IP address for more than a month. Hence, IP addresses are both stable and unique, therefore, they can be used to uniquely identify and track user's activity. Interestingly, the top-2 sets of features, {IP}, and {UA}, contain only passive

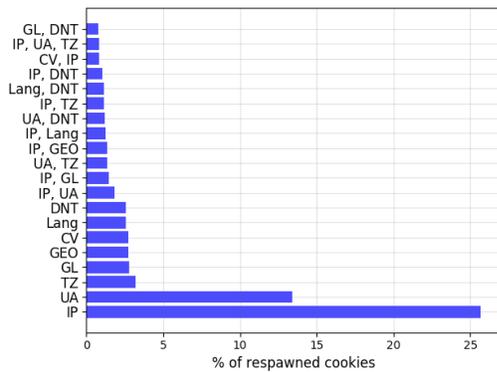

Fig. 3: **Top 20 set of features used to respawn cookies.** IP addresses alone are used to respawn over 25% of the cookies. CV: Canvas, IP: IP address, UA: User agent, GEO: Geolocation, GL: WebGL, TZ: Time zone, Lang: Accept language, DNT: Do Not Track.

features that are easier to collect. Active features are rarely use, timezone, the most popular active feature for respawning, is used alone for 46 (3.23%) cookies.

Summary. We show that trackers use multiple combinations of features to respawn cookies and that the IP address, which is overlooked in a number of fingerprinting studies [38], [15], [33], [2], [49], is the most used feature to respawn cookies.

C. Discovering owners of respawnd cookies

Cookie respawning opens new opportunities for different companies to collaborate together to track users. Usually, the *host* of a cookie defines the domain that can access the cookie. We introduce in this paper a notion of cookie *owner* that has set the cookie via an HTTP header or programmatically via JavaScript (see Section II-A). However, additional stakeholders can help to respawn a cookie by serving a fingerprinting script. We explore each of these new potential stakeholders in the rest of this section.

1) *Identifying cookie owners:* Due to the the Same Origin Policy (SOP) [58], the domain that is responsible for setting a cookie can be different from the domain that receives it (see Section II-A). Therefore, we differentiate two stakeholders: *Owner* – the domain that is responsible for setting the cookie, and *Host* – the domain that has access to the cookie and to whom the cookie is sent by the browser. In the following, we define both owner and host as 2^{nd} -level TLD domains (such as `tracker.com`).

It’s important to detect the cookie owner – for instance, in order to block its domain via filter lists [21], [22], [20] and prevent cookie-based tracking. Indeed, the notion of cookie owner is often overlooked when the reasoning is only based on the cookie host [13]. When one cookie owner sets a cookie in the context of several websites (the owner’s script can be embedded directly on a visited website or in a third-party *iframe*), the host of this owner’s cookie is the context where the cookie is set because of the SOP [58]. To identify cookie

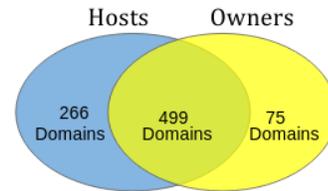

Fig. 4: **Emergence of new domains when considering cookie owners.** The 1, 425 respawnd cookies have 765 distinct hosts and 574 distinct owners. The notion of cookie owner allows to identify 75 cookie owner domains that never appear as a cookie host. We also found 266 cookie host domains that are never used to set the cookie.

owners in the context of our paper, we distinguish two cases, as described below.

Cookie set by a script. `document.cookie` property is the standard way for a JavaScript script to set a cookie [36] programmatically. To check whether a cookie is set via JavaScript and to extract its *owner* (the domain who serves the script) when crawling a website, we (1) extract the set of scripts S that set a cookie on the website using `document.cookie`, (2) for every script in S , we extract the set of cookies C set by this script, and (3) check whether there is an overlap between the set of respawnd cookies identified in Section V-A and in the set C . If it is the case, we conclude that the cookies in the overlap are set via JavaScript, and their *owner* is the 2^{nd} -level TLD domain that served the script.

Cookie set by HTTP(S) header. If the cookie is set by the HTTP(S) `Set-Cookie` response header, then the *owner* of the cookie is the same as its host because it corresponds to the 2^{nd} -level TLD of the server that set the cookie.

For each of the 1,425 respawnd cookies, we identified its *owner* depending on how the cookie was set. Figure 4 shows domains appearing as host only (left blue part), as owner only (yellow part), or both (middle overlap). In total, 1,425 respawnd cookies are labeled with 765 distinct hosts, however they were set by 574 distinct owners. Figure 4 also depicts that 75 domains appear as owners and never as cookies hosts. These domains serve JavaScript scripts that set cookies, but never serve cookies directly via an HTTP(S) response header. Hence, when only considering cookies hosts, these domains are not detected. We evaluated the efficiency of disconnect [20] filter list in detecting these 75 domains. We found that disconnect miss 53 (70.66%) owners domains. We also found that 266 domains that appear as cookie hosts are never identified as cookie owners. Cookies associated with these domains were set in the context of the hosts domain because of the SOP, but these domains were never actually responsible of setting these cookies.

Figure 5 presents the top 10 domains responsible for cookie respawning that are either cookie hosts, cookie owners, or both. Two domains, `rubiconproject.com` and `casalemedia.com`, represent the largest fraction of websites. All cookies served by these two domains are served

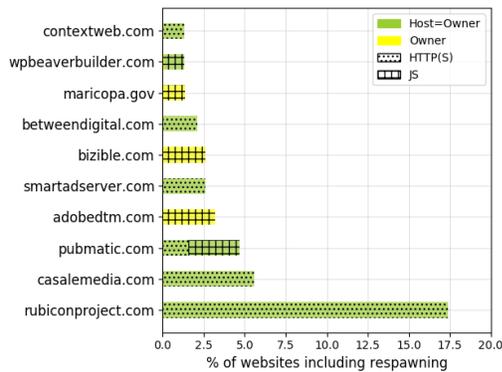

Fig. 5: **The top 10 respanned cookies owners.** The bar is green when the domain is both host and owner, and yellow when the domain only appears as owner. For each domain, we show when cookies are set via an HTTP(S) header and when they are set via JavaScript. When considering cookie owners, new domains are identified such as `adobedtm.com`.

via HTTP(s). Three out of the top 10 domains are exclusively cookie owners: `adobedtm.com`, `bizible.com`, and `maricopa.gov`. These domains are only setting respanned cookies via JavaScript and never directly through HTTP(S). Out of the 1,425 respanned cookies, 514 (36.07%) are set via JavaScript.

Summary. Previous studies that only looked at the cookie host can miss the trackers responsible for setting the cookies. In our study, 75 domains could be missed if we only considered cookie hosts. We found that disconnect miss 70.66% of these domains. Considering cookie owners improves the understanding of the tracking ecosystem.

2) *Identifying scripts used for respanning:* A cookie can be respanned using a set of different features. These features can be all accessed by a single script or by multiple collaborating scripts as we describe in this section. To identify the scripts that are responsible of accessing browser or machine features used for respanning a cookie, we use the recorded JavaScript calls described in Table I.

Every feature can be accessed only actively, only passively or actively and passively (see Table II). In this section, we focus *only on the active features* collected using the following JavaScript calls: `window.navigator.geolocation` (to access the Geolocation) and `HTMLCanvasElement` (to access the Canvas). As OpenWPM does not log calls to Time zone and WebGL, we do not consider these active features in this section. For every respanned cookie C , we identified the set of features F used for respanning C as described in Section IV-C2. To extract the scripts that are responsible of respanning C via the set of features F , we analyze the features used to respawn each cookie. If the cookie is respanned with only passive or active/passive features, then no conclusions can be made for both HTTP(S) and JavaScript cookies. In fact, these features are sent passively, therefore no conclusion can be made on which scripts used them in respanning.

Owner	# of cookies
<code>adobedtm.com</code>	10
<code>ssl-images-amazon.com</code>	3
<code>hdslib.com</code>	2
<code>bitmedia.io</code>	2
19 Others	20
Total	37

TABLE V: **Top domains suspect to set and respan the cookies.**

In total, we found that 931 (65.33%) cookies are respanned with only passive or mixed features. For the remaining 494 cookies depending on active features, 95 (19.23%) are only using WebGL or Time Zone that are out of the scope of this study. In the rest of this section, we consider the 399 respanned cookies that are respanned with only active features for which we can access method calls.

We refer to the set of active features used to respawn a cookie as f_a . We extract the set of features accessed by every script on the website where the cookie is respanned, and distinguish three cases.

1 - The owner of the cookie is suspect to be the responsible of respanning. We identify such cases when (1) the cookie is set via JavaScript, and all active features f_a used to respawn it are accessed by the owner of the cookie, or (2) the cookie is set via HTTP(S) and a script hosted by the same 2nd-level TLD accesses all active features. If one of the two cases is validated, then we suspect that the owner of the cookie is the responsible of respanning it. In total, we found 37 (9.27%) cookies that are respanned by their owners. Out of these 37 cookies, 17 are set via HTTP(S) and respanned by scripts that belong to the same domain. These 37 respanned cookies are owned by 23 distinct owners. Table V presents the top 4 owners that are suspect to respawn the cookies as well.

We found that `adobedtm.com` [4] (the tag manager owned by adobe) is the top domain that both owns and respawns cookies. Though respanning is not explicitly indicated in their policy, the policy states that they collect browser and machine features. We didn't find any information regarding cookies respanned either by `ssl-images-amazon.com`, `hdslib.com` or `bitmedia.io` [10].

2 - The respanning is a result of a potential collaboration between the cookie owner and other scripts. If the set of active features used to respawn the cookie are not accessed by the owner, but are accessed by other scripts on the same website, then we suspect that the cookie is potentially a result of collaboration between the owner of the cookie and other scripts on the same website. In this study, we don't assess whether the domains are actively collaborating, or if one domain is leveraging scripts from other domains to glean fingerprint information. In total, we found that 67 (16.79%) cookies are suspect to be a result of collaboration between multiple domains. The 67 cookies are a result of collaboration of 35 distinct domains.

Table VI presents the top domains that are suspect

Owner	Collaborator	# of cookies
rubiconproject.com	googlesyndication.com	8
rubiconproject.com	pushpushgo.com	3
adobedtm.com	morganstanley.com	2
adobedtm.com	provincial.com	2

TABLE VI: **Top domains suspect to collaborate to respawn cookies.** The reported domains are both first- and third- party.

to collaborate in order to respawn cookies. We define the collaborator as the only domain accessing the features used for respawning the cookie and not accessed by the owner of the cookie. The top collaboration involves googlesyndication.com owned by Alphabet (parent company of Google). Googlesyndication.com is accessing and potentially sharing user’s Canvas information³.

3 - The responsible of respawning the cookie are not all known. If not all the active features used to respawn the cookie are accessed on the website where the cookie is respawed via JavaScript calls, then we assume that the owner is accessing the features via other means. This happens with 295 (73.93%) cookies. In 186 (63.05%) cookies out of the 295, the owner is not accessing the geolocation API and do access other active features it used for respawning the cookie. This can potentially be a result of the dependency between geolocation and IP addresses. When we spoof the geolocation to Time Square in the US, we keep an IP address that points to France because we only spoof one feature at time. Hence, companies may detect this incoherence, and not use the IP address to respawn the cookie, which, in our experiment will be identified as dependency on the geolocation feature.

Summary. Identifying the responsible of respawning can prove to be a complex task. While 23 owners respawn cookies themselves, 35 domains collaborate to respawn cookies.

D. Where does respawning occur?

In section V-C, we studied the domains that are responsible of setting and respawning cookies. In this section, we analyse on which types of websites respawning occurs. In the following, we refer to these websites as *websites including respawning*. We analyse Alexa ranking distribution and impact of websites category on the usage of cookie respawning, present websites including respawning that process special categories of data, and present the geolocation of owners of respawed cookies and websites.

Popularity of websites including respawning. We detected 1,150 websites where at least one cookie is respawed. Table VII presents the number of websites including respawning for each Alexa ranking distribution. We observe that cookie respawning with browser fingerprinting is heavily used on popular websites: out of the top 1k visited websites, 4.9% are websites including respawning. This percentage decrease to 3.70% in less popular websites.

Categorization of websites including respawning. We used the *McAfee service* [43] to categorize the visited websites.

Alexa rank interval	Websites including respawning	# of owners
0 — 1k	49 (4.9%)	49
1k — 10k	360 (4%)	213
10k+	741 (3.70%)	382

TABLE VII: **Popular websites are more likely to include cookie respawning.** Number of owners: presents the total number of distinct respawed cookies owners in the Alexa ranking interval.

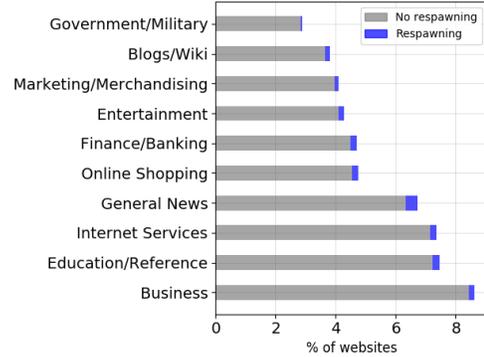

Fig. 6: **General news is the top category including cookie respawning with browser fingerprinting.** We consider that a website U is including respawning if it contains at least one respawed cookie. The bar is gray when we don’t detect respawning in the website, and is blue when we do.

The McAfee uses various technologies and artificial intelligence techniques, such as link crawlers, and customer logs to categorise websites. It is used by related works [69]. A description of the reported McAfee categories can be found in the McAfee reference guide [44].

We successfully categorized Alexa 29,900 visited websites. For every category, we present the percent of respawn websites. We found that the visited websites belong to 669 categories and the 1,150 websites including respawning belong to 143 different categories.

Figure 6 gives an overview of the 10 most prominent categories within the Alexa visited websites. We found that all top 10 categories contain websites that include respawning. Business is the top websites category, 8.62% of the visited websites are categorized as business.

Most of websites including respawning are categorized as *General News*. Out of the 29,900 visited websites, 6.73% are categorized as *General News*, and 5.95% of these *General News* websites contain at least one respawed cookie. *General News* is known for using more third parties than other categories [65], which can be the reason behind the high deployment of respawning in this category of websites.

Websites processing special categories of data. The GDPR [67, Recital 51] stipulates that personal data which are particularly sensitive by their nature, merit specific protection, as their processing could create significant risks to the fundamental rights of users. Such data include personal data revealing sensitive information such as data concerning a

³We will make the data available upon paper acceptance.

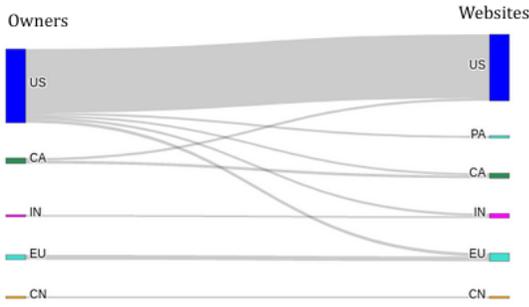

Fig. 7: **Cookie respanning with browser fingerprinting is geolocally distributed.** Corresponding countries of owners (left) and websites including respanning (right) of respanned cookies. We present the top 10 (owner,website) geolocation. "EU" label represents the 27 member states of the EU.

natural person's sex life or sexual orientation [67, Article 9]. Processing such categories of data is *forbidden*, unless allowed by the user's explicit consent [67, Article 9(2)].

We studied tracking via the third-party respanned cookies on websites processing sensitive data. As a result, we detected 21 cookies respanned in *Adult* websites that are set by 19 different owners. The top domain respanning cookies on sensitive websites is *adtng.com* (no corresponding official website was found for *adtng.com*). It respanned cookies on 3 different adult websites, and therefore, can track and link user's activity within adult websites in a persistent way, *without explicit consent to legitimize such operation*, rendering such respanning practise unlawful.

Geolocation of websites including respanning and respanned cookies owners. Independently of the country of registration of a website, if a website *monitors* the behavior of users while they are in the EU, the GDPR applies to such monitoring [67, Article 3(2)(b)]. Notice that any form of web tracking will be deemed as "monitoring", including cookie respanning with browser fingerprinting. Since our experiments simulate users located in France (EU), both EU and non-EU organizations must comply with the GDPR.

We extracted the country of registration of the owners of respanned cookies and the websites including them using the *whois library* [74]. We successfully identified the country of registration of 362 (63.07%) out of 574 total distinct owners, and 670 (58.26%) out of 1,150 websites including respanning. We found that the owners and websites are distributed across the globe, ranging respectively over 29 and 47 different countries, including EU. Out of these 670 websites, 52 (7.76%) are in the EU.

Figure 7 presents the registration countries of respanned cookies owners and websites where they are set. We observe that top countries of both respanned cookies and websites including respanning are not in the EU: 356 (24.98%) of the respanned cookies are both originated and included by domains from the US. We also observed that respanned cookies on Chinese websites are only set by Chinese owners,

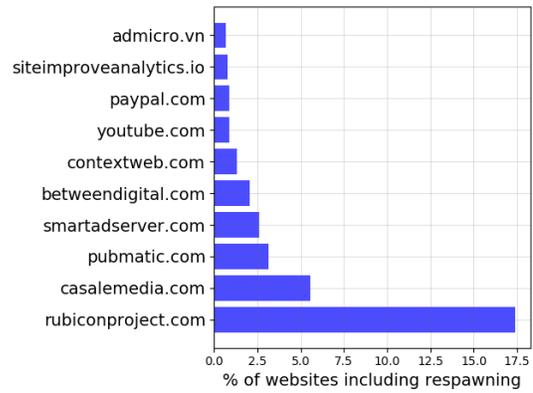

Fig. 8: **Persistent third-party tracking based on respanned cookies.** Top 10 cross-site trackers using respanned cookies.

and interestingly, websites registered in Panama are active in respanning as well (22 (3.28%) of the studied 670 websites including respanning are from Panama).

Summary. Cookie respanning with browser fingerprinting is commonly used: 5.95% of *General News* websites contain at least one respanned cookie. We found that cookies are respanned in sensitive *adult* websites as well, which leads to serious privacy implications: Cookie respanning with browser fingerprinting is distributed across the globe, however, only 7.76% of the websites that include respanning are in the EU. Nevertheless, both EU and non-EU websites must comply with the GDPR as it is applicable independently of the country of registration of the website where EU users are monitored.

E. Tracking consequences of respanning

1) Persistent cross-site tracking with respanned cookies:

Basic tracking via third-party cookies [56], [30] is the most known tracking technique that allows third parties to track users across websites, hence to recreate her browsing history. When a third party cookie that enables cross-site tracking is respanned, such tracking becomes *persistent*. That is, in contrast to regular third-party tracking, the user can not prevent it by deleting cookies. Hence, respanned cookies enable persistent tracking that allows trackers to create larger users' profiles by linking users activity before and after they clean their browser. Since the host is the domain to whom browser automatically sends the cookies, we focus on the cookie *host* and not on cookie owner.

Third party cookies allow trackers to track users *cross-websites* [56]. In this section, we only analyse third-party respanned cookies that can be used to track users across websites. Note that all extracted respanned cookies are user specific (Section IV-C1) and therefore can be considered as *unique identifiers*. Out of 1,425 respanned cookies, 528 (37.05%) are third-party cookies. In total, we identified 144 unique hosts that have access to these cookies. Figure 8 presents the top 10 cross-site trackers that have access to respanned cookies. We found that *rubiconproject.com* is the top domain: it has

access to at least one respawnd cookie on 200 (17.39%) of the visited websites out of 1,150. `Rubiconproject.com` defines itself as a publicly traded company, as it is automating the buying and selling of advertising [57].

2) *Cookie respawning with browser fingerprinting beyond deprecation of third-party cookies*: Web browsers are moving towards deprecation of third party cookies which are the core of cross-site tracking [59]. *Can this deprecation prevent cross-site tracking?* In the following, we show how cookie respawning with browser fingerprinting can overcome browsers preventions.

Via *persistent tracking with respawnd cookies*, domains can track users across websites without third-party cookies. Consider the following scenario: `example.com` and `news.com` include a fingerprinting script from `tracker.com`. When the user visits these websites, the script from `tracker.com` accesses the user's browser and machine features, and sets a corresponding first-party cookie. As a result, two first-party cookies are set in the user's browser and labeled with two different hosts: `example.com` and `news.com`, but the values of these two cookies are identical, because they are created from the user's browser and machine features. By respawning these two cookies on both websites, the owner `tracker.com` shows to be able to track the user in a persistent way across sites with a first-party cookie only.

We analyzed the usage of the same (owner, key, value) first-party respawnd cookie across different websites. The 1,425 cookies correspond to 1,244 respawnd (owner, key, value) instances, out of which 40 (3.21%) are respawnd on multiple websites in a first party context with the same value (see Table X in Appendix). `wpbeaverbuilder.com` [75] is the top owner setting identical first party respawnd cookies across websites. It respawnd the same cookie on 15 distinct websites. It defines itself as a WordPress page builder. Its policy declare to collect user's information, but it does not precise the type of this information.

Summary. Cookie respawning with browser fingerprinting enable tracking across websites even when third party cookies are deprecated. We found 40 first party cookies that can serve for cross-site tracking.

VI. IS RESPAWNING LEGAL?

In this section, with a legal expert which is a co-author, we evaluate the legal compliance of 1,425 respawnd cookies and reflect upon the applicability of current regulations in practice. Our legal analysis is based on the General Data Protection Regulation (GDPR) [67] and the ePrivacy Directive (ePD) [27], as well as in its recitals (which help legal interpretation of provisions in a specific context, but they are not mandatory for compliance). The GDPR applies to the processing of personal data [29] and requires that companies need to choose a legal basis to lawfully process personal data (Article 6(1)(a)). The ePD provides *supplementary* rules to the GDPR in particular in the electronic communication sector, such as websites, and requires those, whether inside

or outside the EU, to obtain *consent* from users located in the EU for processing of their personal data. We have additionally consulted the guidelines of both the European Data Protection Board (an EU advisory board on data protection, representing the regulators of each EU member state) [1] and the European Data Protection Supervisor (EDPS, the EU's independent data protection institution) [24]. While these guidelines are not enforceable, they are part of the EU framework for data protection which we apply in this work to discern whether respawning is compliant.

To assess the legal consequences of respawning, the legal expert analysed legal sources to interpret cookie deletion. To our surprise, we found that there is *no explicit legal interpretation of cookie deletion*. Only the EDPS [24, Section 4.3.4] noted that "*if cookies requiring consent have disappeared, this is most probably because the user deleted them and wanted to withdraw consent*". As a result, *cookie respawning also does not have a clear legal interpretation* and merits attention for its plausible legal consequences. These consequences can arguably be derived, not only from the consent perspective, but also from the core principles of data protection, as discussed in the following sections (fairness, transparency and lawfulness principles). Thus, owners of respawnd cookies and website owners that embed those may be jointly responsible for their usage (Article 26 [67]) and may then be subject to fines of up to 20 million EUR (or 4% of the total worldwide annual turnover of the preceding financial year, Article 83(5)[67]).

A. Fairness Principle.

This principle requires personal data to be processed fairly (Article 5(1)(a)). It requires that i) *legitimate expectations of users are respected* at the time and context of data collection, and ii) there are no "surprising effects" or potential negative consequences occurring in the processing of user's data.

Findings: We consider that *all 1,425 respawnd cookies plausibly violate the fairness principle*, as respawning seems to be inconsistent with the user's expectations regarding respawnd cookies after its deletion from her browser, and also considering the cookie's duration.

Suggestions for policymakers: It's hard to operationalize the high-level fairness principle into concrete requirements for website owners and map it into legitimate expectations of users. Policy makers need to provide more concrete guidelines on the operationalization of this principle in the Web.

B. Transparency principle.

Personal data processing must be handled in a transparent manner in relation to the user (Article 5(1)(a)). This principle presents certain obligations for websites: i) inform about the *scope and consequences* [68] and the *risks* in relation to the processing of personal data (Recital 39); ii) inform about the purposes, legal basis, etc. before processing starts (as listed in Art. 13); iii) provide the above information in a concise, transparent, intelligible and easily accessible form (Art. 12).

Findings: We analyzed the privacy policies of the 10 top popular respawnd cookie owners: `rubiconproject.com` [57],

casalemedia.com [16], *pubmatic.com* [54], *adobedtm.com* [4] *smartadserver.com* [62], *bizable.com* [11], *betweendigital.com* [9], *maricopa.gov* [42], *wpbeaverbuilder.com* [75], and *contextweb.com* (Figure 5). Some policies [57], [16], [4], [62], [11] refer to the use of browser’s features without referencing the consequences or risks thereof. Also, none of the policies refer to cookie respawning. As such, these seem to be in breach of the transparency principle.

Suggestions for policymakers: In practice, the description of data (purposes, legal basis, types of personal data collected, features used and its consequences) is often mixed within the text, which makes harder to extract concrete information therefrom [31]. Policy-makers need to converge on harmonized requirements and standard format for privacy policies.

C. Lawfulness Principle.

The ePD requires websites to obtain user consent to lawfully process personal data using cookies. When a cookie recreates itself without consent, every data processed henceforth could be considered unlawful due to lack of legal basis for personal data processing [28]. This practice incurs in violation with the lawfulness principle (Articles 5(1)(a) and 6(1) of the GDPR, and 5(3) of the ePD). The EDPS [24] already advised against the use of cookie respawning if the processing relies on users’ consent. It mentions that *“cookie respawning would circumvent the user’s will. In this case (...) institutions must collect again user’s consent”*.

To evaluate compliance with the lawfulness principle, we need first to evaluate whether cookies are exempted or subject to consent. The 29WP [7] asserts that *“it is the purpose that must be used to determine whether or not a cookie can be exempted from consent”*.

Given that only a small percentage of cookies include a description of their purposes [31], we adopted the Cookiepedia open database [18] which has over 11 million cookies used across 300,000 websites and has been used in prior work [69]. It uses the classification system developed by “The UK International Chamber of Commerce” (ICC) and relies on four common purposes of cookies: i) Strictly Necessary (which includes authentication and user-security); ii) Performance (also known as analytics, statistics or measurement cookies); iii) Functionality (includes customization, multimedia content); and iv) Targeting (known as advertising). Even though this classification is not binding, we point to the fact that it is the largest database of pre-categorized cookies.

The 29WP [7] adds two other characteristics contributing to determine whether cookies are exempted or subject to consent: duration (*session and persistent cookies*) and context (*first and third-party cookies*). Building on the analysis made by Santos et al. [60, Table 5] on the list of *purposes* that are subject to consent and those that are exempted therefrom, we firstly studied the Cookiepedia purposes and then we derived which are the purposes subject to consent according to their duration and context. Table VIII summarizes the Cookiepedia purposes requiring consent depending on the duration and the context on which it is running.

	Session	Persistent
First-party	Targeting/ Advertising	Targeting/ Advertising
Third-party	Targeting/ Advertising Performance Strictly necessary	Targeting/ Advertising Performance Strictly necessary Functionality

TABLE VIII: **Purposes of Cookiepedia [18] that require consent according to their context and duration.**

Findings: In our study we crawled websites and even if a website provided a consent banner, we did not give consent thereto. We evaluated whether respawned cookies are subject to or exempted from consent (as described in Table VIII). As a result of our evaluation, we found that out of 336 respawned cookies categorized by Cookiepedia, 130 (38.69%) are subject to consent. Hence, these 130 cookies are in breach of the lawfulness principle.

Suggestions for policymakers: Companies can embed respawning and still claim respawned cookies are exempted of consent. We analysed that both the duration and context of cookies contribute to determine whether cookies are exempted or subject to consent. However, from a technical point of view, these criteria can be bypassed by domains that embed respawning. As per *duration*, session cookies can get recreated even after their elimination by the user. Functionality cookies are exempted of consent when used as session cookies and are subject to consent when used in a persistent way [7]. When respawned, such cookies can be used for a longer duration than previously envisaged. We found that out of 1,425 respawned cookies, 446 (31.30%) are session cookies. Regarding *context*, performance cookies are exempted of consent when used in a first party context and are subject to consent when used as third party cookies. However, in practice, a cookie set in the first party context can be considered as a third party cookie in a context of a different website. We found that 4 respawned cookies (host,key,value) appear as first- and third-party in different websites. These cookies are respectively set by *pornhub.com*, *mheducation.com*, *hujiang.com* and *fandom.com*. Given that a cookie context and duration can be altered, these should not be used as a criteria to evaluate the need of consent.

VII. CONCLUSION

This work presents a large scale study of cookie respawning with browser fingerprinting, a tracking technique that is devoid of a clear legal interpretation in the EU legal framework. We employed a novel methodology to reveal the prevalence of cookie respawning with browser fingerprinting in the wild. The detection of such behavior and the identification of responsible domains can prove to be hard to achieve, which impacts both the ability to block such behavior, and its legal assessment. We believe this work can serve as a foundation for improvement of future regulation and protection mechanisms.

VIII. APPENDIX

A. Machines characteristics

Table IX presents the characteristics of machine A and machine B used in our study.

Characteristics	Machine A	Machine B
Date of the crawl	March 2021	March 2021
OS	Fedora 25	Fedora 31
Firefox version	68.0	45.0.1
Location	France	France
IP address	193.51.X.X	138.96.Y.Y
OpenWPM version	v0.9.0	v0.7.0
Language	English (en_US)	German (de_DE)
Time zone	CET	AKST
Geolocation	France	Alaska
Do not track	Null	True

TABLE IX: Crawls Characteristics. *All crawls were performed from machine A except user specific crawl that was done from machine B.*

B. Additional results

Table X presents the top first-party cookies respawnd across websites. This practice is studied in Section V-E2.

Owner	Occurrence
wpbeaverbuilder.com	15
clarip.com	13
maricopa.gov	9
google-analytics.com	7

TABLE X: Top first-party cookies respawnd across websites. Every line in the table represents a cookie, hence the same owner can appear on multiple lines. Occurrence: presents the number of websites where the instance (owner,key,value) was respawnd. T0:
