**HAL** is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers. L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

## K-NARAYANA SEQUENCE SELF-SIMILARITY

ENGIN ÖZKAN, BAHAR KULOĞLU, AND JAMES F. PETERS

ABSTRACT. This paper introduces self-similarity inherent in planar Milich centered flip graphs derived from the Narayana sequence. We show that self-similarity found in a Narayana sequence yields a connected spanning subgraph with a centered flip. This paper has several main results (1) Every Narayana sequence constructs a flip graph, (2) Every Narayana sequence is self-similar and (3) Every Pascal 3-triangle has a free group presentation.

#### 1. INTRODUCTION

In this paper, both population growth as well as population decline are represented by the bipolar form of the Narayana sequence, namely,

 $\ldots, -13, -9, -6, -4, -3, -2, -1, -1, -1, 0, 1, 1, 1, 2, 3, 4, 6, 9, 13, \ldots$ 

There is an inherent self-similarity in Narayana sequences (see, e.g., the partial plot of three different forms of this sequence shown in Fig. 1.

For the  $k^{th}$  member  $N_k$  of a population, the Narayana growth model is defined by the linear recurrence sequence  $N_k = N_{k-1} + N_{k-3}, k \ge 3$ , starting with  $N_0, N_1, N_2, N_3 =$ 

<sup>2010</sup> Mathematics Subject Classification. 11B39 (Fibonacci numbers); 05C10 (planar graphs). Key words and phrases. Flip Graphs, k-Narayana sequence, Pascal 3-triangle, Planar Graph, Self-Similarity.

FIGURE 1. Narayana population growth & decline plot over [-13, 13]

0, 1, 1, 1 representing 3 generations that starts growing at  $N_3 = N_2 + N_0 = 1 + 1 = 2$ . This population growth model was introduced 1356 by Nārāyana Paṇḍita [14]. Similarly, this sequence has a population decline model defined by  $N_k = N_{k-1} + N_{k-3}, k \leq -3$ , starting with  $N_0, N_{-1}, N_{-2}, N_{-3} = 0, -1, -1, -1$  representing 3 declining generations that starts delining at  $N_{-4} = N_{-1} + N_{-3} = -1 + (-1) = -2$ .

The self-similarity in Fig. 1 is a result of considering the generalized Narayana sequence [18] defined by

$$N_{k,n} = kN_{k,n-1} + N_{k,n-3}, n \ge 0, k \ge 3$$
  
= 0, 1, 1, 1, 2, 3, 4, 6, 9, 13,

with the initial values  $N_{k,0} = 0, N_{k,1} = 1$  and  $N_{k,2} = k$ , yielding the sequence  $0, 1, k, k^2, k^3 + 1, k^4 + 2k, k^5 + 3k^2$ . In the study of Narayana sequence self-similarity, we consider  $\pm N_{k,n}, k \geq 3$ , representing population growth as well as population decline.

It is well-known graph self-similarity such that shown for  $\pm N_{k,n}$  in Fig. 1 leads to generalizations of self-similarity [5, §4.4,p. 120]. From the edges in graph similarity, it is possible to construct examples of border (outline) fractals [5, §6.1]. The self-similarity of the Narayana sequence  $\pm N_{k,n}$  leads to the following result.

**Theorem** Every Narayana sequence is self-similar.

A flip graph is a form of undirected, simple graph, which we consider next in a closer look at Narayana sequences and their self-similarities.

#### 2. Preliminaries

In this section the construction of self-similar graphs via bipolar Narayana sequences. A **bipolar Narayana sequence**  $\pm N_{k,n}$  represents two extremes, namely, the growth of a population at one extreme and the decline of a population at the other extreme, representable in a planar self-similar graph.

This paper also considers Pascal-like triangles [2] with corresponding finite cyclic group presentations derived from k-Narayana sequences.

**Definition 1.** [11, 10] A planar flip graph is a 2D graph whose vertexes represent combinatorial objects of interest and an edge between any two objects that differ only by a small change operation called a flip.

**Example 1.** A flip graph representing the beginning of a population and its decline is shown in Fig. 2.1. This flip graph exhibits the simplest form self-similarity centered at the origin, i.e., -2,-1-1,-1,0,1,1,1,2. The altitude 2 to the right of the

2.2: flip graph over  $-6, -4, -3, -2, \dots, 0, \dots, 2, 3, 4, 6$ 

origin represents initial of a population. The altitude 2 to the left of the origin represents initial decline of the same population.

**Example 2.** A flip graph representing the beginning of a population and its decline is shown in Fig. 2.2. This flip graph exhibits 4th generation self-similarity centered at the origin, i.e., -6-4, -3, -2, -1-1, -1, 0, 1, 1, 1, 2, 3, 4, 6. The altitudes 2,3,4,6 to the right of the origin represent initial population growth. The altitudes 2,3,4,6 to the left of the origin represents initial decline of the same population.

**Remark 1.** Positive altitudes to the left of the origin in Fig. 2.1 and Fig. 2.2 represents count of those generatations in a population that failed to appear.

Lemma 1. A bipolar Narayana sequence constructs a flip graph.

*Proof.* Let  $\pm N_{k,n}$  be a bipolar Narayana sequence. We start with  $k = \pm 3$  with three vertexes, namely, vertexes at  $\pm 1, \pm 3$  on the horizontal axis and a vertexes at (3,2), (-3,2), which we triangulate. The edge from (1,0) to (3,2) represents a small change (a flip) in population growth, which contrasts another flip along the edge

from (-1,0) to (-3,2). Continuing this triangulation on additional triple vertexes derived from a Narayana sequence constructs a flip graph.

#### **Theorem 1.** Every bipolar Narayana sequence is self-similar.

*Proof.* From what has been observed about the relationship between self-similarity and flip graphs and from Lemma 1, the result follows.  $\Box$ 

**Remark 2.** From Theorem 1, we obtain a natural basis for a free group presentation of the flip graph for a Narayana sequence. That is, a flip graph viewed as a pair of cycles along the edges of the triangles in the graph make it possible to travel in either the positive or negative direction. In effect, every  $+^{ve}$  traversal a to the right in a Narayana flip graph has a corresponding  $-^{ve}$  traversal -a to the left, giving us inverse elements, which sum to zero, a - a = 0. For more about this, see Section 5 and Appendix C.

The k-Narayana numbers are given by Binet's formula.

(1) 
$$N_{k,n} = \frac{\alpha_k^{n+1}}{(\alpha_k - \beta_k)(\alpha_k - \gamma_k)} + \frac{\beta_k^{n+1}}{(\beta_k - \alpha_k)(\beta_k - \gamma_k)} + \frac{\gamma_k^{n+1}}{(\gamma_k - \beta_k)(\gamma_k - \alpha_k)}$$

where

$$\alpha_{k} = \frac{1}{3} \left(k + k^{2} \sqrt[3]{\frac{2}{27 + 2k^{3} + 3\sqrt{81 + 12k^{3}}}} + \sqrt[3]{\frac{27 + 2k^{3} + 3\sqrt{81 + 12k^{3}}}{2}}\right).$$
  
$$\beta_{k} = \frac{1}{3} \left(k - wk^{2} \sqrt[3]{\frac{2}{27 + 2k^{3} + 3\sqrt{81 + 12k^{3}}}} + w^{2} \sqrt[3]{\frac{27 + 2k^{3} + 3\sqrt{81 + 12k^{3}}}{2}}\right).$$
  
$$\gamma_{k} = \frac{1}{3} \left(k + w^{2}k^{2} \sqrt[3]{\frac{2}{27 + 2k^{3} + 3\sqrt{81 + 12k^{3}}}} + w \sqrt[3]{\frac{27 + 2k^{3} + 3\sqrt{81 + 12k^{3}}}{2}}\right).$$

 $w=\frac{1+i\sqrt{3}}{2}$  is the primitive cube root of unity [18]. Characteristic equation of these numbers is

(2) 
$$x^3 + kx^2 - 1 = 0$$

For any integer number  $k, k \neq 0$ , we have

$$Q_k = \left(\begin{array}{rrr} k & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{array}\right)$$

and for  $n \geq 3$ ,

$$(Q_k)^n = \begin{pmatrix} N_{k,n+1} & N_{k,n-1} & N_{k,n} \\ N_{k,n} & N_{k,n-2} & N_{k,n-1} \\ N_{k,n-1} & N_{k,n-3} & N_{k,n-2} \end{pmatrix}$$

Then  $Q_k$  is a generating matrix of the k-Narayana sequence [18].

Theorem 2. [Cassini's Identity]

$$N_{k,n-1}N_{k,n+1} - N_{k,n}^2 = -N_{k,-n-1}.$$

*Proof.* By using the Binet's formula, we get

$$\begin{split} & \left(\frac{\alpha_{k}^{n}}{(\alpha_{k}-\beta_{k})(\alpha_{k}-\gamma_{k})} + \frac{\beta_{k}^{n}}{(\beta_{k}-\alpha_{k})(\beta_{k}-\gamma_{k})} + \frac{\gamma_{k}^{n}}{(\gamma_{k}-\beta_{k})(\gamma_{k}-\alpha_{k})}\right) \\ & \left(\frac{\alpha_{k}^{n+2}}{(\alpha_{k}-\beta_{k})(\alpha_{k}-\gamma_{k})} + \frac{\beta_{k}^{n+2}}{(\beta_{k}-\alpha_{k})(\beta_{k}-\gamma_{k})} + \frac{\gamma_{k}^{n+2}}{(\gamma_{k}-\beta_{k})(\gamma_{k}-\alpha_{k})}\right) \\ & - \left(\frac{\alpha_{k}^{n+1}}{(\alpha_{k}-\beta_{k})(\alpha_{k}-\gamma_{k})} + \frac{\beta_{k}^{n+1}}{(\beta_{k}-\alpha_{k})(\beta_{k}-\gamma_{k})} + \frac{\gamma_{k}^{n+1}}{(\gamma_{k}-\beta_{k})(\gamma_{k}-\alpha_{k})}\right)^{2} \\ & = \frac{\alpha_{k}^{n}\beta_{k}^{n+2} - 2\alpha_{k}^{n+1}\beta_{k}^{n+1} + \alpha_{k}^{n+2}\beta_{k}^{n}}{(\alpha_{k}-\beta_{k})(\alpha_{k}-\gamma_{k})(\beta_{k}-\alpha_{k})(\beta_{k}-\gamma_{k})} \\ & + \frac{\alpha_{k}^{n}\gamma_{k}^{n+2} - 2\alpha_{k}^{n+2}\gamma_{k}^{n} + \alpha_{k}^{n+2}\gamma_{k}^{n}}{(\alpha_{k}-\beta_{k})(\alpha_{k}-\gamma_{k})(\gamma_{k}-\alpha_{k})(\gamma_{k}-\beta_{k})} \\ & + \frac{\beta_{k}^{n}\gamma_{k}^{n+2} - 2\beta_{k}^{n+1}\gamma_{k}^{n+1} + \beta_{k}^{n+2}\gamma_{k}^{n}}{(\beta_{k}-\alpha_{k})(\beta_{k}-\gamma_{k})(\gamma_{k}-\alpha_{k})(\gamma_{k}-\beta_{k})} \\ & + \frac{\beta_{k}^{n}\gamma_{k}^{n+2} - 2\beta_{k}^{n+1}\gamma_{k}^{n+1} + \beta_{k}^{n+2}\gamma_{k}^{n}}{(\beta_{k}-\alpha_{k})(\beta_{k}-\gamma_{k})(\gamma_{k}-\alpha_{k})(\gamma_{k}-\beta_{k})} \\ & + \frac{\beta_{k}^{n}\gamma_{k}^{n+2} - 2\beta_{k}^{n+1}\gamma_{k}^{n+1} + \beta_{k}^{n+2}\gamma_{k}^{n}}{(\beta_{k}-\alpha_{k})(\beta_{k}-\gamma_{k})(\gamma_{k}-\beta_{k})} \\ & + \frac{\beta_{k}^{n}\gamma_{k}^{n}(\alpha_{k}-\gamma_{k})(\gamma_{k}-\alpha_{k})(\gamma_{k}-\alpha_{k})(\gamma_{k}-\beta_{k})}{(\beta_{k}-\alpha_{k})(\beta_{k}-\gamma_{k})(\gamma_{k}-\beta_{k})(\beta_{k}-\gamma_{k})} \\ & + \frac{\beta_{k}^{n}\gamma_{k}^{n}(\alpha_{k}-\gamma_{k})^{2}}{(\alpha_{k}-\beta_{k})(\alpha_{k}-\gamma_{k})(\beta_{k}-\gamma_{k})(\beta_{k}-\gamma_{k})}} \\ & + \frac{\beta_{k}^{n}\gamma_{k}^{n}(\beta_{k}-\gamma_{k})^{2}}{(\gamma_{k}-\alpha_{k})(\gamma_{k}-\beta_{k})(\beta_{k}-\gamma_{k})(\beta_{k}-\gamma_{k})}} \\ & = -\left(\frac{\alpha_{k}^{n}\beta_{k}^{n}}{(\alpha_{k}-\gamma_{k})(\beta_{k}-\gamma_{k})} + \frac{\beta_{k}^{n}\gamma_{k}^{n}}{(\alpha_{k}-\beta_{k})(\gamma_{k}-\beta_{k})} + \frac{\beta_{k}^{n}\gamma_{k}^{n}}{(\beta_{k}-\alpha_{k})(\gamma_{k}-\alpha_{k})}}\right) \\ & = -\left(\frac{\gamma_{k}^{n}}{(\alpha_{k}-\gamma_{k})(\beta_{k}-\gamma_{k})} + \frac{\beta_{k}^{-n}}{(\alpha_{k}-\beta_{k})(\gamma_{k}-\beta_{k})} + \frac{\beta_{k}^{-n}}{(\beta_{k}-\alpha_{k})(\gamma_{k}-\alpha_{k})}}\right) \\ & = -N_{k,-n-1} \end{aligned}$$

**Remark 3.** A 3D flip graph exhibiting the self-similarity of the Narayana sequence using Binet's formula is shown in Fig. 3.

Theorem 3.

$$\lim_{n \to \infty} \frac{N_{k,n}}{N_{k,n-1}} = \alpha_k$$

*Proof.* Symmetric with the proof of Theorem 2.

**Theorem 4.** For any integer  $n \geq 2$ , we have

$$\begin{aligned} \alpha_k^{n+3} &= k \alpha_k^{n+2} + 1, \\ \beta_k^{n+3} &= k \beta_k^{n+2} + 1, \\ \gamma_k^{n+3} &= k \gamma_k^{n+2} + 1. \end{aligned}$$

where  $\alpha_k, \beta_k, \gamma_k$  are the roots of the characteristic equation 2.

FIGURE 3. 3D flip graph of Narayana population growth & decline

Proof. Since  $\alpha_k, \beta_k, \gamma_k$  are the roots of the characteristic equation 2 then

$$\alpha_k^{n+3} = k\alpha_k^{n+2} + 1 \beta_k^{n+3} = k\beta_k^{n+2} + 1 \gamma_k^{n+3} = k\gamma_k^{n+2} + 1$$

multiplying both sides of these equations by  $\alpha_k^n, \beta_k^n$  and  $\gamma_k^n$  respectively, we obtain the desired result.

**Theorem 1.** For any integer  $n \ge 0$ , we write

$$\sum_{i=0}^{n} k^i N_{k,2i} = 0.$$

*Proof.* Symmetric with the proof of Theorem 2.

**Theorem 5.** For  $n \ge 3$ , we have

$$\begin{vmatrix} N_{k,n+1} & N_{k,n-1} & N_{k,n} \\ N_{k,n} & N_{k,n-2} & N_{k,n-1} \\ N_{k,n-1} & N_{k,n-3} & N_{k,n-2} \end{vmatrix} = 1$$

*Proof.* If we are making some algebraic operation:

$$N_{k,n+1}^3 + N_{k,n}^3 + N_{k,n-1}^3 - 2N_{k,n+1}^2 N_{k,n} + N_{k,n}^2 N_{k,n+1} + N_{k,n+1} N_{k,n-1}^2 + N_{k,n}^2 N_{k,n-1} - 3N_{k,n-1} N_{k,n+1} N_{k,n} = 1$$

We get the equation.

For example, n = 3, we have

$$\begin{vmatrix} N_{k,4} & N_{k,2} & N_{k,3} \\ N_{k,3} & N_{k,1} & N_{k,2} \\ N_{k,2} & N_{k,0} & N_{k,1} \end{vmatrix} = \begin{vmatrix} k^3 + 1 & k & k^2 \\ k^2 & 1 & k \\ k & 0 & 1 \end{vmatrix} = 1$$

**Theorem 6** (Sum of first terms). Let  $S_{k,n}$  be the sum of the first (n + 1) terms of the k-Narayana sequence, that is

$$S_{k,n} = \sum_{i=0}^{n} N_{k,i}.$$

Then

$$S_{k,n} = \frac{N_{k,1} + N_{k,n} + N_{k,n+1} + N_{k,n+2}}{k} - N_{k,n+1}.$$

4. The Pascal 3-triangle

We deduce the value of any k-Narayana number by simple substitution on the corresponding  $N_{k,n}$ . The sequence  $N_{1,n}$  is the classical Narayana sequence. By the definition of the k-Narayana numbers [18], the first of them are:

$$N_{k,1} = 1$$

$$N_{k,2} = k$$

$$N_{k,3} = k^{2}$$

$$N_{k,4} = k^{3} + 1$$

$$N_{k,5} = k^{4} + 2k$$

$$N_{k,6} = k^{5} + 3k^{2}$$

$$N_{k,7} = k^{6} + 4k^{3} + 1$$

$$N_{k,8} = k^{7} + 5k^{4} + 3k$$

$$N_{k,9} = k^{8} + 6k^{5} + 6k^{2}$$

$$N_{k,10} = k^{9} + 7k^{6} + 10k^{3} + 1$$

It is worth to be noted that the obtained coefficients can be written in a triangular position, in this way that every side of the triangle is triple, and for this reason this triangle has been called Pascal 3-triangle. See table 1.

5. Free Abelian Group Presentation of a Pascal 3-Triangle

This section introduces free finitely-generated (fg) Abelian group presentations that correspond to Pascal 3-triangles in a planar CW space. Briefly, a planar CW space is a collection of cells in a finite, bounded region of the Euclidean plane. A *cell* in the Euclidean plane is either a 0-cell (vertex  $K_0$ ) or 1-cell (edge  $K_1$ ) or 2-cell (filled triangle  $K_2$ ). A **cell complex** is a collection cells attached to each other by 0- or 1-cells or by having one or more common cells. A nonvoid collection of cell complexes K has a *Closure finite Weak* (CW) topology, provided K is Hausdorff (every pair of distinct cells is contained in disjoint neighbourhoods [12, §5.1, p. 94]) and the collection of cell complexes in K satisfy the Whitehead [24, pp. 315-317] conditions, namely, containment (the closure of each cell complex is in K) and intersection (the nonempty intersection of cell complexes is in K) (for the details, see App. A).

TABLE 1. The Pascal 3-triangle

FIGURE 4. Pascal 3-triangle Nested Cycle Shapes  $\mathrm{sh}E$ ,  $\mathrm{sh}E'$ 

Pascal 3-triangles like those in Table 1 form collections of nested cycles.

**Example 3.** A pair of Pascal 3-triangle cycles are shown in Fig. 4, namely,

- 1° Pascal 3-triangle in Fig. 4.1 with 3 nested cycles: 1,1;1,2;1,3. The leftmost single vertex labelled 1 in Fig. 4.1 is a cycle that spins on itself (this single vertex represents traversal back to 1 for each of the three cycles shown). The Pascal 3-triangle 1;1,1 in Fig. 4.1 forms a triangle cycle. The Pascal 3-triangle 1;1,1;1,2;1,3 in Fig. 4.1 forms a collection of nested cycles.
- 2° Next, the Pascal 3-triangle in Fig. 4.1 is attached to 1,4,1;1,5,3 to form an expanded collection of nested cycles shown in Fig. 4.2.

Notice that the pair of collections of nested cycles derived from Pascal 3-triangles form a pair of distinct shapes, namely, shape hE in Fig. 4.1 and shape hE' in Fig. 4.2. The boundary of hE is denoted by bdy(hE) (represented by its vertexes).

Each of these shapes has a distinct boundary, which is a source of generators of a free fg Abelian group presentation derived from a Pascal 3-triangle. For the details concerning CW shape complexes, see App. B.

**Example 4.** The pair of Pascal 3-triangle nested cycles form planar shapes as shown in Fig. 4, namely,

1° Shape shE in Fig. 4.1 with

**Boundary in Fig. 4.1:**  $bdy(shE) = \{1, 1', 2, 3\}$ , limited to the upper boundary vertexes of shE.

 $2^{\circ}$  Shape shE' in Fig. 4.2 with

**Boundary in Fig. 4.2:**  $bdy(shE') = \{1, 1', 2, 3, 4, 5, 3'\}$ , limited to the upper boundary vertexes of shE'.

FIGURE 5. Pasal 3-triangle Cycles cycE1, cycE'2

#### Theorem 7. Every Pascal 3-triangle has a free group presentation.

*Proof.* From Theorem 8 in App. C, every shape boundary is a 1-cycle CW space K (see, *e.g.*, Fig. 4.1) and in the CW space K' (see, *e.g.*, Fig. 4.2) has finitely-generated cyclic group presentation.

**Example 5.** Each of the collections of nested cycles in Fig. 5 has an Abelian group presentation, e.g.,

- 1° Cycle cyc**E1** in Fig. 5.1 is represented by  $G(\langle 1' \rangle, +)$  with 1 as the generator, i.e., every vertex in the cycle can be reached from vertex 1'.
- 2° Cycle cycE'2 in Fig. 5.2 is represented by  $G(\langle 2 \rangle, +)$  with 2 as the generator, i.e., every vertex in the cycle can be reached from vertex 2.

From Theorem 9 in App. C, a Pascal 3-triangle leads to a collection of nested cycles in the CW space in K (Fig. 4.1) and in the CW space in K' (Fig. 4.2), each of which as a free finitely-generated (fg) Abelian group presentation.

**Example 6.** Each of the of the collections of nested cycles in Fig. 4 has a free fg Abelian group presentation, e.g.,

- 1° The collection of nested cycles in shE in Fig. 4.1 is represented by  $G(\langle 1', 2, 3 \rangle, +)$ with vertexes 1',2,3 as the generators, i.e., every vertex in the cycle can be reached from vertexes 1',2,3.
- 2° The collection of nested cycles in shE' in Fig. 4.2 is represented by  $G(\langle 1', 2, 3, 4, 5, 3' \rangle, +)$ with vertexes 1',2,3,4,5,3' as the generators, i.e., every vertex in the cycle can be reached from vertexes 1',2,3,4,5,3'.

#### 6. VIEWS AND PROPERTIES OF THE PASCAL 3-TRIANGLE

Let us examine two points on x and y lines in orthogonal coordinate system. One can see clearly, a way between an x-point and a y-point is not inverting way in the first sestet from x to y by horizontal and vertical unit section. For instance, there are four way from the point x = (3, 0) to the point y = (0, 1):

```
 \{ (3,0)(2,0)(1,0)(0,0)(0,1) \} \\ \{ (3,0)(2,0)(1,0)(1,1)(0,1) \} \\ \{ (3,0)(2,0)(2,1)(1,1)(0,1) \} \\ \{ (3,0)(3,1)(2,1)(1,1)(0,1) \}
```

The number of ways between an x-point and a y-point can be seen on diagonals in Pascal 3-triangle. In table 2, each element is obtained the sum of the elements on previous row from the left to element above.

Χ	Y								
	0	1	2	3	4	5	6	7	
0	1	1	1	1	1	1	1	1	
1	1	2	3	4	5	6	7	8	
2	1	3	6	10	15	21	28	36	
3	1	4	10	20	35	56	84	120	
4	1	5	15	35	70	126	210	330	
5	1	6	21	56	126	252	462	792	
6	1	7	28	84	210	462	924	1716	
7	1	8	36	120	330	792	1716	3432	
8	1	9	45	165	495	1287	3003	6435	
9	1	10	55	220	715	2002	5005	11440	

TABLE 2. Number of paths between x-points and a y-points

For example, number 21 in the third row is the conclusion of summing up the elements of the second row: 1 + 2 + 3 + 4 + 5 + 6 = 21.

One of the properties of this table is each entrance in the diagonal beginning  $\{i, j, ...\}$  reports the number of terms in the expansion of  $(a_1 + a_2 + a_3 + ... + a_{n+3-j})^n$  for  $n \ge j-2$ . For instance, diagonal  $\{1, 3, 10, 35, 126, \}$  means the number of terms in the expansion of  $(a_1 + a_2 + a_3 + ... + a_{n-1})^n$ , for  $n \ge 2$ , which is  $\binom{2n-2}{n-2}$ . Obviously, one can be obtained the sequence of Catalan's numbers by dividing each term of this diagonal by 1, 2, 3, 4, ..., respectively.

The *i*th row of antidiagonals in Table 2 is equivalent to the *i* th row of the classical Pascal triangle. The term  $a_{i,j}$  of Table 2 satisfies  $a_{i,j} = a_{i-1,j} + a_{i,j-1}$ .

10

The determinants of matrices generated by the term  $a_{1,1}$  are equal to 1. Also, the square matrices obtained from the term  $a_{1,1}$  are symmetric in accordance with the diagonal  $\{1, 2, 6, 20, 70, \}$ .

As well as, if in 2 each row is moved two places to the right according as the prior row, table 3 existed. Take into account each column of Table 3 is equal to

1	1	1	1	1	1	1	1	1	1	1	1
		1	2	3	4	5	6	7	8	9	10
				1	3	6	10	15	21	28	36
						1	4	10	20	35	56
								1	5	15	35
										1	6

TABLE 3. Rectangular Pascal 3-triangle

the corresponding diagonal of the Pascal 3-triangle which is also known as the "deformed" Pascal triangle [21].

6.1. Some Properties of the Pascal 3-triangle Diagonals. It will be called here triple diagonal to each of the different lines of triples of contiguous numbers on the Pascal 3-triangle as shown in Table 1, from right to left and the from first row to bottom. For instance, the second triple diagonal is  $\{1-3-6, 10-15-21, \}$  these lines are also called ' anti-diagonals'.

It is clear that the n th diagonal terms of the Pascal 3-triangle are definitely the coefficients of the Taylor expansion of function  $g_n(x) = \frac{1}{(1-x)^n}$  centered at the origin.

For a small value  $x = 10^{-r}$   $(r \in \mathbf{N})$ , when the function  $g_n(x)$  written as a decimal number has its integer part equal to 1, and its decimal number can be seen as r-uplas showing the first terms of the n th antidiagonal of the Pascal 3-triangle. For instance,

$$g_5(10^{-3}) = \frac{1}{(1-10^{-3})^5} = 1.005015035070 \quad \dots \to \{1, 5, 15, 35, 70, \dots\}$$

which are the fifth anti-diagonal terms of the Pascal 3-triangle. Some characteristic properties of the Pascal 3-triangle are as follow:

1. The second diagonal is positive integer numbers. The third and fourth diagonal equal to the triangular and tetrahedral numbers, respectively. In general, i th diagonal equal to the (i - 1)-dimensional simplex number [7].

2.Each element is obtained the sum of the preceding element at same row and the previous element in the preceding diagonal.

3. The sum of the consecutive terms in the third diagonal is a perfect square.

4. By subtracting the odd number sequence from the triangular number sequence, the triangular number sequence is obtained again.

5. The n th element of the i th anti-diagonal denoted by  $A_r(n)$ . Then  $A_r(n) = \binom{n+r-2}{r-1}$  here (r-1) is (i-1) th anti-diagonal.

6.2. **Properties of the rows the Pascal 3-triangle.** Some properties of the Pascal 3-triangle rows are as follow:

1. The sum of the elements of the i th row is equal to the i th term of Narayana sequence.

2. The sum of the *i* th row elements and the (i + 1) th row elements is the corresponding  $\{2, 2, 3, 5, 7, 10, 15, 22, 32, 47, 69, \}$  which are on OEIS, as A097333 and A058278 in http://oesis.org

3. Beginning with 1 on the left, and writing down the following number on its right in the immediately lower row, and so on the classical Pascal triangle is obtained.

# 7. Expression of $k^n$ as a k-Narayana number

Firstly, the equations for the  $k\mbox{-Narayana}$  number is written in matrix form as follow

$$N = B \cdot K$$

. Here,  $N = (N_{k,1}, N_{k,2}, N_{k,3}, ...)^T$ ,  $K = (1, k, k^2, k^3, ...)^T$  and B is the lower triangular matrix with elements the coefficients appearing in the expansion of the k-Narayana number in increasing powers of k:

$$B = \begin{pmatrix} 1 & & & & & & \\ 0 & 1 & & & & & \\ 0 & 0 & 1 & & & & \\ 1 & 0 & 0 & 1 & & & & \\ 0 & 2 & 0 & 0 & 1 & & & \\ 0 & 0 & 3 & 0 & 0 & 1 & & \\ 1 & 0 & 0 & 4 & 0 & 0 & 1 & & \\ 0 & 3 & 0 & 0 & 5 & 0 & 0 & 1 & \\ 0 & 0 & 6 & 0 & 0 & 6 & 0 & 0 & 1 & \\ 1 & 0 & 0 & 10 & 0 & 0 & 7 & 0 & 0 \end{pmatrix}$$

It is clear that, the non-zero elements in matrix B are same the terms of diagonals of the Pascal triangle. The sum of the elements of i th row is equal to the i th term of the classical Narayana sequence. Furthermore, the inverse of matrix B is

$$B^{-1} = \begin{pmatrix} 1 & & & & & \\ 0 & 1 & & & & & \\ 0 & 0 & 1 & & & & \\ -1 & 0 & 0 & 1 & & & \\ 0 & -2 & 0 & 0 & 1 & & \\ 0 & 0 & -3 & 0 & 0 & 1 & \\ 3 & 0 & 0 & -4 & 0 & 0 & 1 & \\ 0 & 7 & 0 & 0 & -5 & 0 & 0 & 1 \\ 0 & 0 & 12 & 0 & 0 & -6 & 0 & 0 & 1 \end{pmatrix}$$

Also, it is clear that  $k^n$  is equal to linear combination of k-Narayana number:

$$\begin{split} 1 &= N_{k,1} \\ k &= N_{k,2} \\ k^2 &= N_{k,3} \\ k^3 &= N_{k,4} - N_{k,1} \\ k^4 &= N_{k,5} - 2N_{k,2} \\ k^5 &= N_{k,6} - 3N_{k,3} \\ k^6 &= N_{k,7} - 4N_{k,4} - 3N_{k,1} \\ k^7 &= N_{k,8} - 5N_{k,5} + 7N_{k,2} \\ k^8 &= N_{k,9} - 6N_{k,6} + 12N_{k,3} \end{split}$$

### 8. Catalan transform of the k-Narayana sequence

#### Catalan number

For  $n \ge 0$ , the n th Catalan number is showed by [1].

$$C_n = \frac{1}{n+1} {\binom{2n}{n}}$$
 or  $C_n = \frac{(2n)!}{(n+1)!n!}$ 

For some n, the first Catalan numbers are

 $\{1, 1, 2, 5, 14, 42, 132, 429, 1430, 4862, 16796, ...\}$ 

From now on OEIS, as A000108 in http://en.wikipedia.org/wiki/Catalan number. Following [3][23], we define the Catalan transform of the k-Narayana sequence as  $\{N_{k,n}\}$ 

$$CN_{k,n} = \sum_{i=1}^{n} \frac{i}{2n-i} {2n-i \choose n-i} N_{k,i}, \text{ for } n \ge 1 \text{ with } CN_{k,0} = 0$$

We can give some members of Catalan transform of the first k-Narayana number. These are the polynomials in k:

$$CN_{k,1} = \sum_{i=1}^{1} \frac{i}{2-i} \binom{2-i}{1-i} N_{k,i} = 1$$
$$CN_{k,2} = \sum_{i=1}^{2} \frac{i}{4-i} \binom{4-i}{2-i} N_{k,i} = 1+k$$
$$CN_{k,3} = \sum_{i=1}^{3} \frac{i}{6-i} \binom{6-i}{3-i} N_{k,i} = k^2 + 2k + 2$$

$$CN_{k,4} = \sum_{i=1}^{4} \frac{i}{8-i} \binom{8-i}{4-i} N_{k,i} = k^3 + 3k^2 + 5k + 6$$
$$CN_{k,5} = \sum_{i=1}^{5} \frac{i}{10-i} \binom{10-i}{5-i} N_{k,i} = k^4 + 4k^3 + 9k^2 + 14k + 18$$
$$CN_{k,6} = \sum_{i=1}^{6} \frac{i}{12-i} \binom{12-i}{6-i} N_{k,i} = k^5 + 5k^4 + 14k^3 + 31k^2 + 52k + 56$$

We can show  $\{N_{k,n}\}$  as the  $n \times 1$  matrix  $N_k$  and the product of the lower triangular matrix C as

$$\begin{pmatrix} CN_{k,1} \\ CN_{k,2} \\ CN_{k,3} \\ CN_{k,4} \\ \dots \end{pmatrix} = \begin{pmatrix} 1 & & & \\ 1 & 1 & & \\ 2 & 2 & 1 & & \\ 5 & 5 & 5 & 3 & \\ \dots & \dots & \dots & \dots & \dots \end{pmatrix} \begin{pmatrix} N_{k,1} \\ N_{k,2} \\ N_{k,3} \\ N_{k,4} \\ \dots \end{pmatrix} = \begin{pmatrix} 1 & & & \\ k^2 + 2k + 2 \\ k^3 + 3k^2 + 5k + 6 \\ \dots & \dots \end{pmatrix}$$
$$= \begin{pmatrix} 1 & & & \\ 1 & 1 & & \\ 2 & 2 & 1 & & \\ 5 & 5 & 5 & 3 & \\ \dots & \dots & \dots & \dots & \dots \end{pmatrix} \begin{pmatrix} 1 \\ k \\ k^2 \\ k^3 + 1 \\ \dots & \end{pmatrix}$$

where

$$C_{i,j} = \sum_{i=j-1}^{i-1} C_{i-1}$$

The lower triangular matrix  $C_{n,n-i}$  is known as the Catalan triangle and its elements verify the formula

$$C_{n,n-i} = \frac{(2n-i)!(i+1)}{(n-i)!(n+1)!}$$
 with  $0 \le i \le n$ .

### 9. HANKEL TRANSFORM

Let  $A = \{a_0, a_1, a_2, ...\}$  be a sequence of real numbers [1]. The Hankel transform of A is the sequence of determinants  $H_n = Det[a_{i+j-2}]$ , i.e.

$$H_n = \begin{pmatrix} a_0 & a_1 & a_2 & a_3 & \dots \\ a_1 & a_2 & a_3 & a_4 & \dots \\ a_2 & a_3 & a_4 & a_5 & \dots \\ a_3 & a_4 & a_5 & a_6 & \dots \\ \dots & \dots & \dots & \dots & \dots \end{pmatrix}.$$

The upper-left  $n \times n$  subdeterminant of  $H_n$  is called the Hankel determinant of order n of the sequence A. The Hankel transform of the Catalan sequence is the sequence  $\{1, 1, 1, \}$  [20]. In [17], hey show that the Hankel transform of the sum of consecutive generalized Catalan numbers is equal to the bisection of the Fibonacci sequence.

Considering the Catalan transform of the k-Narayana sequence, we get:

$$HCN_{k,1} = Det[1] = 1$$
$$HCN_{k,2} = \begin{vmatrix} 1 & 1+k \\ 1+k & k^2+2k+2 \end{vmatrix} = 1$$

$$HCN_{k,3} = \begin{vmatrix} 1 & 1+k & k^2+2k+2 \\ 1+k & k^2+2k+2 & k^3+3k^2+5k+6 \\ k^2+2k+2 & k^3+3k^2+5k+6 & k^4+4k^3+9k^2+14k+18 \end{vmatrix} = -2k-2$$

#### 10. CONCLUSION

We give some properties and theorems related to the k-Narayana numbers and show Cassini's identity and limit of the k-Narayana sequence. We also calculate the determinant of the k-Narayana numbers and show that their determinant are fixed terms. Also, we give sum of the first terms of the k-Narayana sequence and we deduce many properties of the k-Narayana numbers and relate with the so-called Pascal 3-triangle. As well as we give an expression of  $k^n$  as a k-Narayana number. Finally, we give the  $CN_{k,n}$  description of the Catalan transformation of k-Narayana  $N_{k,n}$  sequences. Furthermore, we write  $CN_{k,n}$  transformation as the multiplying of Catalan matrix C which is the lower triangular matrix, and the  $N_k$  matrix of  $n \times 1$  type. We calculate determinants of matrixes which are formed with  $CN_{k,n}$ by using Hankel transform. These identities can be used to develop new identities of sequences.

#### APPENDIX A. CELL COMPLEXES

A planar Whitehead cell complex K [16] (usually called a CW complex) is a collection of n-dimensional minimal cells  $e_{\alpha}^{n}, n \in \{0, 1, 2\}, i.e.,$ 

$$K = \left\{ e_{\alpha}^{n} \subset \mathbb{R}^{2} : n \in \{0, 1, 2\} \right\}.$$

in the Euclidean plane  $\pi$ .

**Definition 2.** A cell subcomplex  $shE := \{e_{\alpha}^n\} \in 2^K$  (shape complex) is a closed subcomplex, provided the subcomplex includes both a nonempty interior (denoted by  $int(e_{\alpha}^n)$ ) and its boundary (denoted by  $bdy(e_{\alpha}^n)$ ). In effect, shE is closed, provided

 $shE = int(shE) \cup bdy(shE)$  (Closed subcomplex).

Let  $2^{\pi}$  be the collection of all subsets in the Euclidean plane  $\pi$ . In the plane, a Whitehead **Closure-finite Weak (CW)** cell complex  $K \in 2^{\pi}$  has two properties, namely,

- **C:** A cell complex K is **closure-finite**, provided each cell  $e_{\alpha}^{n} \in K$  is contained in a finite subcomplex of K. In addition, each cell  $e_{\alpha}^{n} \in K$  has a finite number of immediate faces. One cell  $e_{\alpha}^{n}$  is an **immediate face** of another cell  $e_{\alpha}^{m}$ , provided  $e_{\alpha}^{n} \cap e_{\alpha}^{m} \neq \emptyset$  [22] (also called a **common face** [13, p. 3]).
- W: The plane  $\pi$  has a **weak topology** induced by cell complex K, *i.e.*, a subset  $S \in 2^{\pi}$  is closed, if and only if  $S \cap e_{\alpha}^{n}$  is also closed in  $e_{\alpha}^{n}$  for each  $n, \alpha$  [22, §5.3, p. 65].

A collection  $K \in 2^{\pi}$  is called a **CW complex**, provided it has the closure-finite property and  $\pi$  has the weak topology property induced by K.

Minimal cell planar complexes are given in Table 4.

**Remark 4.** Closure finite cell complexes with weak topology (briefly, CW complexes) were introduced by J.C.H. Whitehead [24], later formalized in [25]. In this work<sup>1</sup>, a **cell complex** K (or complex) [25, §4, p. 221] is a Hausdorff space (union

<sup>&</sup>lt;sup>1</sup>Here, we use  $cl(e^n)$  (closure of a cell) and  $bdy(e^n)$  (contour of a cell) used in this paper, instead of Whitehead's  $e^{\bar{n}}$  and  $\partial(e^n)$ .

THE THE THE TAKE CON COMPTON OF	TABLE 4.	Minimal	Planar	Cell	Complexes
---------------------------------	----------	---------	--------	------	-----------

Minimal Complex	Cell $e^n : n \in \{0, 1, 2\}$	Planar Geometry	Interior
٠			
	$e^0$	Vertex	nonempty
/	$e^1$	Edge	line segment w/o end points
	$e^2$	Filled triangle	nonempty triangle interior w/o edges

of disjoint open cells  $e, e^n, e_i^n$  such that the closure of an n cell  $e^n \in K$  (denoted by  $cl(e^n)$  is the image of a map  $f : \sigma^n \to cl(e^n)$ , where  $\sigma^n$  is a fixed n-simplex and where the boundary  $bdy(e^n)$  (otherwise known as the **contour** of a complex) is defined by

 $\begin{array}{l} \textbf{Complex contour} \rightarrow \textbf{closure cl}(e^n) \ \textbf{minus } Int(e^n) \ \textbf{interior} \\ bdy(e^n) = \overbrace{f(bdy(e^n)) = cl(e^n) - int(e^n).}^{\textbf{Complex contour}} \end{array}$ 

Notice that a subcomplex  $X \subset K$  has the weak topology, since X is the union of a finite number intersections  $X \cap cl(e)$  for single cells  $e \in K$  [25, §5, p. 223]. From a geometric perspective, a cell complex is a triangulation of the CW space K [24, p. 246].

#### Appendix B. Shape Complexes

A shape complex has two basic parts, namely, contour and interior, introduced in [15].

**Definition 3.** A planar shape contour of a shape complex shE (denoted by bdy(shE)) is a simple, closed curve with no self-loops.

Each shape complex hE has a nonempty interior that excludes all points on the shape contour.

# Definition 4. Shape complex interior.

Set of points bounded by shE contour

$$int(shE) = shE \setminus bdyE$$
.

The fundamental parts of every shape complex are gathered together in the closure of a shape complex, definite using the Hausdorff distance [8] (see, also, [9,  $\S23$ , p. 128]) between all points in a CW complex K and a shape shE.

**Definition 5.** Closure of a planar shape shE (denoted by cl(shE)) in a CW space K is defined by

Hausdorff distance 
$$D(x, \operatorname{sh} E) = \inf \{ \|x - p\| : p \in \operatorname{sh} E \}.$$
  
 $\widehat{cl(\operatorname{sh} E) = \inf \{ x \in X : D(x, \operatorname{sh} E) = 0 \}}.$ 

In other words, we have the closure of a planar shape hE is a finite bounded region of the Euclidean plane such that

 $cl(shE) \text{ includes its contour } \& \text{ its interior} \\ \overbrace{cl(shE) = bdy(shE) \cup Int(shE).}^{cl(shE)}$ 

Appendix C. Finite 1-cycles and their Cyclic Group Presentation

Finite 1-cycles in a CW space and their cyclic group presentations [16], [4] are briefly considered in this section. In arriving at cyclic group presentation derived from Pascal 3-triangles, we first consider 1-cycles, filled 1-cycles and shape complexes in a CW space.

**Definition 6.** A 1-cycle E (denoted by cycE) in a CW space is a finite, nonempty collection of path-connected vertexes  $\{e^0 \in K : e_i^0, i \ge 1, is \ a \ zero \ cell\}$  on 1-cells (edges) with no end vertex.

**Definition 7.** A filled 1-cycle in a CW space is a 1-cycle cycE has a boundary bdy(cycE) (called its **contour**) that is a simple, closed curve with a nonempty interior int(cycE).

**Definition 8.** In a CW space K, a shape complex E (denoted by shE) is a finite region of K bounded by a simple closed curve with nonempty interior.

**Theorem 8.** Every filled 1-cycle in a CW complex K is a shape complex of K.

*Proof.* Immediate from Def. 7 and Def. 8.

We can select what is known as a generator vertex in each 1-cycle.

**Definition 9.** A generator vertex  $v_0$  in a 1-cycle cycE is the first vertex at the beginning of every path leading to any other vertex in cycE. Let |cycE| be the number of vertexes in cycE and let the set  $\langle v_0 \rangle$  be defined [19, p. 21] by

$$\langle v_0 \rangle = \{ v \in cycE : v = kv_0, k \in \{1, \dots, |cycE|\} \}$$

Recall that a **finite group** G is a nonempty set equipped with an associative binary operation  $\circ$  (denoted by  $G(\circ)$ ) such that G has the following members:

**identity** e: :  $g \circ e = g$  for every  $g \in G$ .

**inverse** -g:  $: g \circ -g = e$  for every  $g \in G$ .

A group G is Abelian, provided  $g \circ g' = g' \circ g$  for every  $g, g' \in G$ .

**Definition 10.** A finite Abelian group G with a generator element  $v_0 \in G$  (denoted by  $G(\langle v_0 \rangle, \circ)$ ) is a **cyclic Abelian group**, provided

$$G = \{g \in G : g \in \langle v_0 \rangle\}.$$

A cyclic group with p generators is denoted by  $\mathbb{Z}_p$  [6].

Intuitively, every boundary of a cell complex is a cycle [6, §4.8, p. 104]. This intuition leads to the following useful Lemma.

**Lemma 2.** Every finite 1-cycle in a CW space has a corresponding Abelian cyclic group.

*Proof.* Let cyc*E* be a 1-cycle in a CW space *K* and let  $v_0$  be a vertex in cyc*E*. From Def. 6, cyc*E* is path-connected. Let + be a forward move (traversal) of an edge between adjacent vertexes in cyc*E* and let  $v \in \langle v_0 \rangle$ , *i.e.*,  $v = kv_0$ . For each pair  $v, v' \in \text{cyc}E$ , we have

$$v + v' = kv_0 + k'v_0 = (k + k')v_0 = (k' + k)v_0 = v + v'.$$

Consequently, + is Abelian. Similarly, it can be shown that + is associative. For every  $v \in \operatorname{cyc} E$ , there is a reverse move -v (the additive inverse of v). Let  $0v_0 \in \langle v_0 \rangle$ represent 0 moves from  $v_0$ , *i.e.*,  $0v_0 = v_0$ . The element  $0v_0$  serves as an identity element. For each  $v = kv_0 \in \langle v_0 \rangle$ , we have

$$v + 0v_0 = kv_0 + 0v_0 = (k+0)v_0 = kv_0 = v$$
, and  
 $v - v = kv_0 - kv_0 = (k-k)v_0 = 0v_0 = v_0$ .

Hence,  $\operatorname{cyc} E(\langle v_0 \rangle, +)$  is an Abelian cyclic group.

From Lemma 2, we obtain the following result for shape contours defined by the boundary of a collection of nested cycles.

**Theorem 9.** The contour of every planar shape complex in a CW space has a cyclic Abelian group presentation.

*Proof.* Let cycE be a 1-cycle in a CW space K and let  $2^K$  be the collection of all subsets of K. Further, let the mapping  $f : 2^k \to 2^K$  be defined by

$$f(\operatorname{cyc} E) = \{kg : 0 \le k \le |cycE| \& g \in cycE\} (from \ Lemma \ 2)$$
$$= G(\langle g \rangle, +)$$
$$= \mathbb{Z}_1.$$

Hence, cycE has a cyclic Abelian group presentation.

From Theorem 8, we obtain the following result for shapes defined by a collection of path-connected vertexes in nested cycles, attached to each other to form a vortex. Recall that a finite free Abelian group has n generators,  $n \ge 1$ .

**Theorem 10.** Every shape complex that is a collection of nested 1-cycles attached to each other pairwise via edges in a CW space, has a free finitely-generated Abelian group presentation.

*Proof.* Let vor E be a vortex, which is a collection n 1-cycles  $\{cyc_iE, 1 \leq i \leq n\}$  attached to each other via edges in a CW space K and let  $2^K$  be the collection of all subsets of K. Each 1-cycle  $cyc_iE$  has its distinguished vertex  $g_i \in cycE_i$  that is a generator of a cyclic group. Further, let the mapping  $f: 2^k \to 2^K$  be defined by

$$f(\text{vor}E) = \{\{kg_i\} : 0 \le k \le |cycE_i| \& g_i \in cycE_i, , 1 \le i \le n\} \text{ (from Lemma 2)}.$$
$$= G(\langle g_1, \dots, g_n \rangle, +)$$
$$= \mathbb{Z}_n.$$

Hence, vorE has a finite free Abelian group presentation.
