1 **Abstract :**

2 Insulin-degrading enzyme, IDE, is a metalloprotease implicated in the metabolism of key
3 peptides such as insulin, glucagon, β -amyloid peptide. Recent studies have pointed out its
4 broader role in the cell physiology. In order to identify new drug-like inhibitors of IDE with
5 optimal pharmacokinetic properties to probe its multiple roles, we ran a high-throughput drug
6 repurposing screening. Ebselen, cefmetazole and rabeprazole were identified as reversible
7 inhibitors of IDE. Ebselen is the most potent inhibitor ($IC_{50} \text{ (insulin)} = 14 \text{ nM}$). The molecular
8 mode of action of ebselen was investigated by biophysical methods. We show that ebselen
9 induces the disorder of the IDE catalytic cleft, which significantly differs from the previously
10 reported IDE inhibitors. IDE inhibition by ebselen can explain some of its reported activities
11 in metabolism as well as in neuroprotection.

14 ADMA, asymmetrical dimethylarginine; DDAH, dimethylarginine dimethylaminohydrolase;
15 DMSO, dimethylsulfoxide; EDTA, Ethylenediaminetetraacetic acid; IDE, Insulin-degrading
16 enzyme; IDE-CF, cysteine-free IDE; GNAT, Gcn5-related N-acetyltransferase; HDAC,
17 histone desacetylase; NDM-1, New Delhi metallo- β -lactamase; nitric oxide synthase, NOS;
18 PBP, penicillin-binding protein; PBS, phosphate buffered saline; rt, room temperature;

19

1 **1. Introduction**

2 Insulin-Degrading Enzyme (IDE) is known for decades, yet its function remain poorly
3 understood [1,2]. It is a ubiquitous, 110 kDa protease found in both intra- and extra-cellular
4 compartments. IDE is a proteolytic enzyme involved in the degradation of many substrates
5 [3]. In particular, it is the main enzyme responsible for the intracellular hydrolysis of insulin
6 [4]. Glucagon [5] and amylin [6], other peptidic hormones secreted by the pancreas, are also
7 substrates of IDE. Interestingly, along with insulin, these hormones regulate the metabolism
8 of glucose and other energetic substrates like fatty acids. IDE was also proposed as one the
9 enzymes involved in the catabolism of A β [7,8]. The involvement of IDE in the degradation
10 of all these substrates suggests a potential role of IDE in processes modulated by these
11 proteins. Interestingly, many substrates of IDE share a propensity to be amyloidogenic
12 peptides [9].

13 IDE has an atypical structure that was solved in 2006 [10]. The displacement of IDE-N and
14 IDE-C likely mediates the open-closed conformational switch required for the entrance of
15 diverse substrates and the exit of products. Crystal structures of human IDE (hIDE) have
16 revealed an IDE dimer with the fully closed catalytic chamber, though other experiments
17 revealed that the open states are preferred in solution and allow the entry of large substrates
18 (e.g. A β , or insulin) in the chamber. An unexpected displacement (swinging-door) of a
19 subdomain that creates an 18Å opening to the chamber, which permits the entry of short
20 peptides, has been postulated [11]. Recently, cryoEM structures of IDE open states and
21 insulin-bound states revealed the mechanism by which amyloidogenic peptides, like insulin,
22 are captured and hydrolyzed by IDE [12].

23 IDE has emerged as an atypical protein that is involved in many pathways [13]. It has been
24 shown to behave as a dead-end chaperone for aggregating peptides [14] and to interact with
25 the proteasome-ubiquitin system [15]. IDE has thus been shown to be involved in many

1 processes at the cellular level, but the phenotype of KO animals is very mild. Importantly,
2 IDE's sequence is strikingly conserved amongst distantly related species, suggesting critical
3 functions, Although these properties of IDE have raised the interest of biologists since many
4 years without revealing its exact role, only a few teams have looked for inhibitors with probe-
5 like properties, as a result only a couple of inhibitors that can be used *in vivo* are available.

6 First, Leissring *et al* disclosed a peptidomimetic inhibitor **li1** [16] (Fig. 1). Due to low
7 permeability, this inhibitor was not tested in cellular assays. Our team has developed a series
8 of carboxylic acids and ester pro-drugs like **BDM43079** and **BDM43124** respectively, that
9 bind both a permanent exosite and the discontinuous, conformational catalytic site [17-18]
10 (Fig. 1). Maianti *et al* disclosed **6bk** a macrocyclic peptide, binding at distance from the
11 catalytic site, in the primary exosite pocket [19] (Fig. 1). Eli Lilly discovered the dual site
12 inhibitor **NTE-1**, not interacting with the catalytic site, by a fragment-based strategy [20]
13 (Fig. 1). Our team discovered drug-like compound **BDM44768** from an *in situ* click chemistry
14 strategy [21] (Fig. 1). Surprisingly, **BDM44768**, **NTE-1** and **6bk** displayed different effects
15 on glucose tolerance *in vivo*, underlying the complex role of IDE.

16

1 **Fig. 1:** Inhibitors of *hIDE*.

2 **2. Results and Discussion**

3 *2.1. Screening of a 1120-member library.*

4 With the aim of discovering new chemical probes having desired drug-like properties,
5 to explore the complex role of *hIDE*, we screened at 30 μM a library of 1120 compounds that
6 have reported clinical data (Fig. 2). The average Z' factor value for assays is 0.61 and the
7 percentage of inhibition of reference inhibitor EDTA 71% (Supporting information Table S1
8 and Fig. S1). Out of these compounds, 12 molecules displayed a percentage of inhibition
9 above threshold (30%) at the screening concentration (Fig. 2). Dose-response curves were
10 performed and 5 compounds (**1-5**) were confirmed (0.44% hit rate), with IC_{50} s ranging from
11 42 nM to 100 μM : rolitetracycline, myricetine, ebselen, cefmetazole and rabeprazole which
12 display unique structural motifs and activities (Fig. 3 and Table 1). This hit rate is comparable
13 to those published with other drug libraries (Prestwick, LOPAC...) screened on isolated
14 targets (Supporting information Table S2).

15 **Table 1:** Inhibitory potencies of confirmed positives.

Cpd #	Name	IC_{50} (μM) ^a

2	myricetine	100
3	cefmetazole	7
4	rabeprazole	11
5	ebselen	0.042

16 ^a ATTO 655- Cys-Lys-Leu-Val-Phe-Phe-Ala-Glu-Asp-Trp substrate

17

1 **Fig. 2:** Screening cascade.

2

3 Out of these compounds we selected cefmetazole (3), rabeprazole (4) and ebselen (5) for

4 further investigation of mode of action and/or binding.

6 **Fig. 3:** Structures and DRCs of confirmed positives 1-5.

7

8 2.2. Cefmetazole 3

9 2.2.1. Reported activities.

10 Cefmetazole **3** ($IC_{50} = 7 \mu M$) is a cephalosporin that inhibits irreversibly bacterial
11 penicillin-binding proteins (PBP), the transpeptidases implicated in the peptidoglycan
12 synthesis. Its mechanism is driven by the electrophilicity of the lactam function that forms an
13 adduct with the catalytic serine in PBPs. It has been shown that cefmetazole behaves as a *pan*
14 autophagy inhibitor suggesting the existence of eukaryotic targets [22]. It also inhibits the
15 intracellular accumulation of $\alpha 1$ -antitrypsin in a phenotypic screening in *C.elegans*. [23].

16

17 2.2.2. Reversibility of inhibition of 3.

18 As cefmetazole (**3**) can react with nucleophile centers because its electrophilic
19 behavior, we evaluated the reversibility of the binding of **3** to IDE (Fig. 4A). Cefmetazole at

1 50 μ M inhibits hIDE (68% inhibition, green bar) while 0.5 μ M of cefmetazole is inactive
2 (cyan bar). Recovery of hIDE activity after large dilution (magenta bar) shows that
3 cefmetazole (**3**) is a reversible inhibitor of hIDE (Fig. 4A), like **BDM44768** (Fig. 4C) while
4 **N-ethylmaleimide** (**NEM**, Fig. 4D) is an irreversible inhibitor.

5
6 **Fig. 4:** Assessment of irreversible/reversible mechanism of inhibition.
7 Compounds identified in screening: cefmetazole **3** (A) and ebselen **5** (B) were pre-incubated 30 minutes at room
8 temperature with hIDE before adding substrate (5 μ M), at final concentrations C (green bar) and 0.01C (cyan
9 bar) respectively. Pre-incubate at C was diluted 100-fold (magenta bar) before adding the substrate. Percent of
10 inhibition are mean of 4 experiments. **BDM44768** (C) a reversible inhibitor of hIDE and N-ethylmaleimide
11 **NEM** (D) an irreversible inhibitor are used as controls. Recovery of hIDE activity minutes after large dilution
12 (magenta bars) for cefmetazole **3** (A) and ebselen **5** (C) show that these compounds are reversible inhibitors of
13 IDE.

15 2.2.3. Binding of **3**.

16 We docked **3** within hIDE (Fig. 6). In our model, cefmetazole **3** makes contacts with
17 both N-term and C-term domains of hIDE. It interacts with the catalytic Zinc²⁺ ion via its
18 carboxylate group (Fig. 5). The lactam function makes a hydrogen bond with Gln111. The N-
19 acetylated side chain of the cephalosporin is engaged in three interactions: an hydrogen bond

1 between the sulfur and the hydroxyle side-chain of Ser₁₂₈, interaction of NH with Arg₈₂₄ and
2 Asp₁₈₂ via a hydrogen bond network with water molecules, and a hydrogen bond between the
3 nitrile group and the backbone NH Ser₁₃₈ (Fig. 5). In the model, no nucleophilic amino-acid
4 could be seen in the vicinity of the lactam function. This binding mode is consistent with the
5 reversible inhibition. Cefmetazole is the only cephalosporin displaying the nitrile side
6 function, explaining why no other cephalosporin in the set was found to inhibit hIDE.

7
8 **Fig. 5:** Binding mode of cefmetazole in IDE.

9 Docked in PDB 4NXO. Oxygens, Nitrogens and Sulfurs are in red, blue and orange respectively, Carbons are in
10 in gray (N-term) or light pink (C-term) for catalytic site amino-acids and in cyan for compounds. Polar
11 hydrogens of cefmetazole are in white. Zinc ion is represented as a magenta sphere. Polar contacts and
12 interactions are represented as black dashed lines. Nitrile function is pointed by black arrow.

13

14 2.3. Rabeprazole 4.

15 2.3.1. Reported activities.

16 Rabeprazole (IC₅₀ = 11 μM) is a prodrug that inhibits covalently the proton H⁺/K⁺
17 ATPase pump after activation into a sulphenamide. As such, it is used to inhibit gastric acid
18 secretion and thus treat ulcers and gastro-intestinal reflux. All approved proton-pump
19 inhibitors (PPI) contain the 2-pyridylmethylsulfinylbenzimidazole scaffold. Rabeprazole has

1 also been reported, along with other PPI, as an inhibitor ($IC_{50} = 53 \mu M$) of dimethylarginine
2 dimethylaminohydrolase (DDAH), an enzyme that metabolizes asymmetrical
3 dimethylarginine (ADMA), an endogenous and competitive inhibitor of nitric oxide (NO)
4 synthase (NOS) [24]. More recently, rabeprazole was disclosed to be an inhibitor of endo-
5 beta-N-acetylglucosaminidase (ENGase) ($IC_{50} = 4 \mu M$) [25]. We show here that IDE is
6 another point of interaction of rabeprazole with the proteome

7 *2.3.2. Mode of inhibition, binding and preliminary SAR.*

8 In our model, rabeprazole interacts with both N-term and C-term domains of hIDE.
9 Both the N-3 of benzimidazole ring and the oxygen of the sulfoxide function of rabeprazole
10 interact with the Zn^{2+} ion (Fig. 6). The N-1 of the benzimidazole ring makes a hydrogen bond
11 with Asn139. Pyridine and Arg824 are engaged in a cation- π interaction. Of note, 3-
12 methoxypropyl-oxy side-chain makes a hydrogen-bond with Ser128 and a hydrogen- π
13 interaction with Phe115 (Fig. 6).

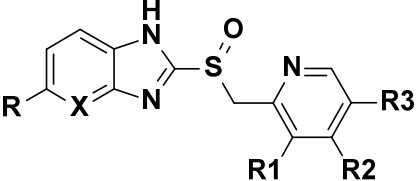

14
15 **Fig. 6:** Binding mode of rabeprazole in IDE.

16 Docked in PDB 4NXO. Oxygens, Nitrogens and Sulfurs are in red, blue and orange respectively, Carbons are in
17 gray (N-term) or light pink (C-term) for catalytic site amino-acids and in cyan for rabeprazole. Polar hydrogens
18 of rabeprazole are in white. Zinc ion is represented as a magenta sphere. Polar contacts and interactions of
19 rabeprazole with hIDE are represented as black dashed blacklines.

1 Interestingly, several other PPI were in the screening library. Comparison of activities
 2 revealed that rabeprazole was by far the most potent analogue. Absence of substituent on the
 3 benzimidazole along with a long propylether chain in R2 may account for the better activity
 4 of rabeprazole in comparison with other pharmacological class members (Table 2). Indeed,
 5 docking studies show that the oxygen of the sulfoxide moiety of rabeprazole interacts with the
 6 Zn²⁺ ion while the long propyl ether chain is engaged in a unique interaction with Ser₁₂₈ and
 7 Phe₁₁₅.

8 **Table 2:** Compared activities of proton-pump inhibitors on hIDE

9

10 2.4. Ebselen 5.

11 2.4.1. Reported activities.

12 Ebselen, the most potent inhibitor (IC₅₀ = 42 nM), is a seleno-organic compound that
 13 is known to make covalent bonds with cysteines [26]. Multiple bioactivities have reported in
 14 the literature for ebselen (Supporting information Table S3 and S4). Historically, ebselen was
 15 described as a glutathione peroxidase mimic. Zhao *et al.* suggested then that the antioxidant
 16 and anti-inflammatory actions of ebselen were due to its activity as a substrate of thioredoxine
 17 reductase [27]. Ebselen also reacts with hydroperoxides in membranes to protect cells from
 18 free radical damage [28-29]. Along with these activities, ebselen inhibits directly several
 19 enzymes involved in inflammation processes like NO synthases, NADPH oxidase, protein

1 kinase C and H⁺/K⁺-ATPase, lipoxygenases [29,30] by reacting with cysteines to form
 2 selenosulfide complexes (Supplementary Table S2). Due to these properties, it has been
 3 evaluated in the protection of the brain after ischemia and stroke both in animal models [31]
 4 and in humans [32]. In the latter trial, ebselen, at 10 mg kg⁻¹, significantly reduced the volume
 5 of infarction in brain. Ebselen was recently proposed as an anticancer agent on the basis of
 6 histone desacetylases (HDAC) inhibition or methionine aminopeptidases (MetAP), a protease
 7 involved in angiogenesis [33,34]. Finally, a recent report describes the inhibition of glutamate
 8 dehydrogenase (GDH) by ebselen [35].

9 Ebselen has also been tested against infectious diseases (Supporting information Table S4).
 10 Most recent examples include inhibition of New Delhi metallo-β-lactamase (NDM-1) [36],
 11 activity against resistant staphylococci [37] or binding to antigen 85C from *Mycobacterium*
 12 *tuberculosis* [38]. Ebselen is also an inhibitor of TbHK1 from the parasite *Trypanosoma*
 13 *brucei* [39]. Finally, several antiviral activities have been reported recently. Ebselen is an
 14 inhibitor of HIV-1 capsid dimerization [40] and of Hepatitis C Helicase NS3 binding to
 15 nucleic acids [41]. Importantly, in most cases, ebselen was shown to be a covalent,
 16 irreversible ligand (inhibitor) of these proteins. Recently, ebselen was found by screening to
 17 be an inhibitor of bacterial and human inosine 5'-monophosphate dehydrogenase [42].

18 2.4.2. Mode of inhibition.

19 Ebselen is a thiol reactive compound. IDE contains 13 cysteines (Fig. 7), some of which have
 20 been proven important for catalytic activity [43]. We used the cysteine-free IDE (IDE-CF),
 21 that is still catalytically active, to probe the implication of the cysteines in the inhibition mode
 22 of ebselen [44]. In these conditions, ebselen is not active (2% inhibition at 100μM) (Table 3).

23 **Table 3:** Activity of ebselen on hIDEwt and hIDE-CF.

	hIDEwt	hIDE-CF
	IC ₅₀ (μM)	
ebselen	0.042	> 100
	0.014 ^a	^b –

BDM44768	0.30	0.33
	0.056 ^a	$\frac{b}{-}$
cefmetazole	7.0	(70%) ^c

1 ^a with insulin as substrate; ^b not determined; ^c percent of inhibition at 30 μ M.

2
3 **Fig. 7:** Cysteines in *hIDE*.

4 From PDB 4NXO. N-terminal part in cyan, C-term part in warm pink, hinge in orange, Zinc ion represented as
5 magenta sphere, C- α of 11 cysteines represented as yellow spheres.

6
7 Many thiol-reactive agents act through irreversible binding but some act as reversible
8 inhibitors. Ebselen at 1.25 μ M inhibits *hIDE* (88% inhibition, green bar, Fig. 4B) while
9 0.0125 μ M of ebselen is inactive (cyan bar). Ebselen was pre-incubated at 1.25 μ M for 30
10 minutes at room temperature with *hIDE*. Pre-incubate was diluted 100-fold (magenta bar)
11 before adding the substrate. Recovery of *hIDE* activity after large dilution (magenta bar)
12 shows that ebselen is a reversible inhibitor. As we showed that its activity is dependent on
13 cysteines, this suggests that ebselen could be a reversible covalent inhibitor of IDE. Recently,
14 IDE was identified (among 461 other proteins) as a putative binding protein of ebselen in
15 HeLa cells, using a biotinylated probe [45].

16
17 *2.4.3. Binding mode of ebselen.*

1 Attempts to dock ebselen within hIDE did not allow to find relevant pockets
2 containing cysteines to rationalize previous results. Thus, we characterized the interaction of
3 IDE with ebselen experimentally. Human IDE has 10-20 nM affinity to each other to form a
4 dimer [1]. We used the size exclusion chromatography (SEC), Superdex 200 10/300 GL to
5 examine if ebselen affected IDE dimerization. As expected, 110 kDa IDE migrates mostly as
6 dimer (Fig. 8). The addition of ebselen shifted IDE from mostly a dimer into a mixture of
7 dimer and monomer (Fig. 8). The monomeric IDE is shown to be less active than the dimeric
8 IDE [2, 3]. This suggests that a part of inhibitory effect by ebselen could be mediated by
9 disrupting IDE dimerization.

10

11 **Figure 8 The effect of ebselen on the profile of IDE on size exclusion column.** The top insert
12 is the Coomassie stained 9% SDS-PAGE of peak fractions. M=marker.

13 Hydrogen/deuterium exchange mass spectrometry (HDX-MS) has been shown to
14 effectively map the binding regions of two potent IDE inhibitors as well as depict the
15 substrate-induced conformational changes of IDE [4]. We thus performed HDX-MS to probe
16 the effect of ebselen on IDE (Fig. 9, Supporting information Fig. S3 and S4). While overall

1 differences of HD exchange of IDE were subtle when ebselen is present, such change
2 provides insights into the action of ebselen. IDE dimer structure in conjunction with
3 biochemical studies have shown that the C-terminal region of IDE plays a key role in IDE
4 dimerization [2, 3, 5]. Consistent with this, we found that the C- terminal residues of IDE,
5 981-994 have enhanced HD exchange in the presence of ebselen. This corroborates with our
6 gel-filtration data that ebselen promotes the dissociation of IDE dimer. The effect of ebselen
7 to disrupt IDE dimerization could explain our failure to co-crystallize IDE with ebselen
8 because all current hIDE crystallization conditions are for IDE dimer.

9 HDX-MS also provides additional information how ebselen affects IDE activity. We
10 observed that residues 824-830 had significant enhanced HD exchange in the presence with
11 ebselen. This region is part of the substrate binding cleft of IDE and the binding of substrates,
12 e.g., insulin and amyloid [4]. Interestingly, two potent inhibitors of IDE, **6bK** and
13 **BDM44768** significantly reduced the HD exchange of this region [4]. We also found that
14 ebselen slightly reduced the HD exchange in residues 181-198, the region for the zinc binding
15 catalytic cleft; such reduction was also observed when **6bk** and **BDM44768** were present [4].
16 Interestingly, close to both these regions stand cysteine residues (C178, C812 and C819).
17 Together, the finding confirms that ebselen disrupts IDE dimerization and shows that it
18 induces the disorder of the IDE catalytic cleft, which significantly differs from the previously
19 reported IDE inhibitors, **BDM44768** and **6bK**.

1 **Figure 9 Changes in H/D exchange of IDE induced by ebselen.**

2 The changes in H/D are mapped onto IDE structure and the progress curve of regions with significant changes
 3 are shown.
 4

5
 6
 7 *2.4.4. Target engagement in cells.*

8 IDE is an enzyme that is both secreted and cytosolic [46]. We thus evaluated the
 9 ability of ebselen to bind IDE in insulin sensitive cells (HepG2) using the cellular thermal-
 10 shift assay (CETSA) technique [47] (Table 4). A quantification of the compounds in CETSA
 11 samples allowed to measure the cell/medium ratio of the compounds. These results show that
 12 ebselen and BDM44768 do penetrate cells to the same extend of 10%. Ebselen and
 13 **BDM44768** bind IDE in cells as shown by the shifts in the aggregation temperature in the
 14 presence of the compound. However the lower value for ebselen could reflect the titration of
 15 this compound by thiols within cells.

16 **Table 4:** Aggregation temperatures of hIDE in the presence of inhibitors and permeation.

Compound	T Agg (°C)	Delta Agg (°C)	Cell/medium ratio
BDM44768	54.4 ± 0.5	6.4 ± 0.5	0.11 ± 0.02
ebselen	49.2 ± 0.2	1.3 ± 0.3	0.10 ± 0.01

17

3 Aggregation temperature shifts of hIDE in the presence of inhibitors **BDM44768** and ebselen **5** normalized to
4 DMSO.

5
6
7 **3. Conclusion.**

8 We have successfully identified, through a drug-repurposing high-throughput screen, 3
9 potent inhibitors of insulin-degrading enzyme with drug-like properties: ebselen ($IC_{50} = 14$
10 nM), cefmetazole ($IC_{50} = 7 \mu M$) and rabeprazole ($IC_{50} = 11 \mu M$). All three compounds are
11 reversible inhibitors of IDE. Docking of cefmetazole and rabeprazole in hIDE allowed to
12 rationalize screening results for other compounds in their respective pharmacological class.

13 Proton-pump inhibitors, have a beneficial impact on the glycemic control of patients with
14 type 2 diabetes, via the possible indirect production of gastrin [48]. Also, this
15 pharmacological class inhibits organic-cation transporters, for which metformin is a substrate,
16 thus impacting metformin pharmacokinetics. Interestingly, though rabeprazole has the same
17 impact on pharmacokinetics of metformin than pantoprazole, it induced a slightly larger
18 decrease in glycemia at 20 mg [49]. Differences of IDE inhibition between rabeprazole and
19 pantoprazole could explain these observations.

20 Ebselen is the most potent IDE pan-inhibitor described yet ($IC_{50} = 14$ nM). Unlike
21 rabeprazole and cefmetazole, inhibition of IDE by ebselen is thiol-dependent. HDX-MS and
22 SEC showed that ebselen could impact the dimerization of IDE and that it induces the

1 disorder of the IDE catalytic cleft significantly differently from **BDM44768** and **6bK**.
2 CETSA on Hep-G2 cells showed IDE-engagement by ebselen in lived cells, illustrating the
3 validation of IDE as a target for this compound. Previously described activities of ebselen in
4 the metabolic field show that ebselen has an insulin-mimetic action. For example, it reduces
5 hyperglycemia induced by diazinon *in vivo* and enhances glucose uptake by peripheral tissues
6 *in vitro* [50]. As well, it restores glucose-stimulated insulin secretion in β -pancreatic cells
7 [51]. Ebselen also controls post-stroke hyperglycemia by improving hepatic insulin signaling
8 and restoring glucose tolerance, in ischemic gerbils [52]. The strong inhibition of IDE by
9 ebselen could participate in these observations. Outside the field of metabolism, a recent
10 clinical trial shows that ebselen is active on the prevention of hearing loss [53]. Ebselen is
11 thought to act by the mimicry and induction of glutathione peroxidase in that context.
12 Interestingly though, one of the substrates of *hIDE* is Insulin-growth factor-I (IGF-I) that is
13 considered as a novel and potent treatment for hear-loss based on various *in vivo* and *in vitro*
14 experiments and clinical trials [54]. As a consequence, ebselen activity in hear-loss could then
15 also be partially mediated by its inhibition of IDE that could increase IGF-I levels.

16 Altogether, as the inhibitory activity of ebselen towards IDE is the highest listed activity
17 on a human target, we suggest to revisit some of the cellular and *in vivo* effects of ebselen in
18 the light of these results.

19
20

21 **4. Experimental section**

22 *4.1.1. In vitro IDE activity assays*

23 Wild type human IDE was expressed in *E. coli* BL21 (DE3) cells (at 25 °C and 20 h, 0.5mM
24 IPTG induction using T7 medium) and recombinant IDE were purified by Ni-NTA, source-Q,
25 and three runs of Superdex 200 columns as previously described [10]. Ac-Cys-Lys-Leu-Val-
26 Phe-Phe-Ala-Glu-Asp-Trp-NH₂ was synthesized by NeomPS. *In vitro* IDE activity was

1 measured with either a quenched substrate ATTO 655- Cys-Lys-Leu-Val-Phe-Phe-Ala-Glu-
2 Asp-Trp (substrate1) or insulin (Actrapid) from Novo Nordisk. The quantity of insulin was
3 determined using a commercial kit from Perkin Elmer: Human Insulin Kit (catalog#AL204C).

4 4.1.1.1. *Screening assay*

5 Human IDE (1.87 ng/ μ L) was incubated 10 min at 37 °C with compound in Hepes 50
6 mM, NaCl 100 mM, pH 7.4 and the enzymatic reaction is started by adding the substrate1
7 (final concentration 5 μ M). After 30 min, samples (1% DMSO final) are excited at 635 nm
8 and fluorescence emission at 750 nm is measured on a Victor3 V1420 Perkin Elmer
9 spectrophotometer. EDTA was used as a reference inhibitor (100% inhibition at 2 mM). The
10 Z and Z' factors were calculated according to J.-H. Zhang, T.D.Y. Chung, K.R. Oldenburg, A
11 Simple Statistical Parameter for Use in Evaluation and Validation of High Throughput
12 Screening Assays, J. Biomol. Screen., 4 (1999) 67-73. Data analysis was performed using
13 Xlfit® v 5.0.

14 4.1.1.2. *Dose-Response Curves*

15 Percentages of inhibition at different concentrations were obtained as for screening. All
16 measurements were carried out as 8-point dose response curves and reported as the average of
17 at least three independent measurements. EDTA was used as a reference inhibitor (100%
18 inhibition at 2 mM). Data analysis was performed using Xlfit® v 5.0 and GraphPad Prism® v
19 4.0. Nonlinear curve fitting and statistical analysis was done using built-in functions.

20 4.1.1.3. *Dose-Response Curves Insulin assay*

21 400nL of test compounds were added in 96 well microtiter plates (dark, non-binding surface)
22 by acoustic dispensing with Echo (Labcyte), diluted with 9.6 μ L of buffer (Hepes at 50 mM
23 with 100 mM NaCl, pH 7,4) and pre-incubated 10 minutes at ambient temperature with 10 μ L
24 of hIDE wt at 1 μ g/mL. The enzymatic reaction was started with the addition of 20 μ L of
25 insulin at 40 nM for 15 minutes at ambient temperature and stopped with 40 μ L of EDTA at

1 200 mM. Samples were diluted with immunoassay buffer and the content of Insulin was
2 determined by alphaLISA™ according to the manufacturer recommendations. AlphaLISA™
3 signal is detected with a Mithras (Berthold) using a excitation at 680nm and a emission at
4 620nm (bandwidth 10nm).

5 4.1.1.4. *Reversibility.*

6 Compounds were pre-incubated 30 minutes at room temperature with hIDE before adding
7 substrate (5μM), at final concentrations C and 0.01C respectively as controls. C and 0.01C
8 should surround IC₅₀. C = 1.25 μM for BDM44768 and ebselen, 50 μM for rabeprazole and
9 cefmetazole and 1 mM for N-ethylmaleimide. Pre-incubate at C was diluted 100-fold before
10 adding the substrate. Percents of inhibition are mean of 4 experiments.

11

12 4.1.1.5. *Analytic size exclusion chromatography*

13 IDE (0.2 mM) in the presence or absence of ebselen (4 mM) were incubated on ice for 1 hr
14 prior to the injection to Superdex S200 column. The molecular weight is estimated based on
15 molecular standard.

16 4.1.2. *Library.*

17 APTEEUS-Université de Lille Library: 1120 compounds including drugs with at least
18 one marketed authorization and active compounds with published record of utilization in
19 humans.

20 4.1.3. *Docking.*

21 Modeling and simulations were performed using 2018.0101 (Chemical Computing
22 Group, Inc.) using non-aged X-ray crystal structure of hIDE PDB code 4NXO with
23 BDM44768 ligand. A monomer including solvent was selected and compounds were docked.
24 Before analysis, ligands, solvents and proteins were protonated at 300 °K, pH 7.0 with a salt
25 concentration equal to 0.1 mol/L for the generalized Born / Volume integral (GB/VI) with a

1 cutoff value of 15. The dielectric constants of solute and solvent are set to 1 and 80,
2 respectively. The method 800R3 was applied to simulate the repulsive part from the van der
3 Waals energy. Then for each compound the industry standard molecular mechanics
4 forcefields MMFF94(s) was used in association with a MOPAC quantum code. The structures
5 were rendered in PyMOL (Delano, W. L. *The PyMOL Molecular Graphics System*. DeLano
6 Scientific LLC: San Carlos, CA, 2002).

7 *4.1.4. Hydrogen-Deuterium Exchange Mass Spectrometry.*

8 HDXMS of IDE in the presence and absence of ebselen was performed similar to the previous
9 reported procedure. Briefly, 14 μ M IDE in 8.3 mM Tris-HCl, 50m NaCl, 1.4% DMSO, pH7.2
10 H₂O buffer was mixed with 140 μ M ebselen and incubated at room temperature for 30 min,
11 then kept on ice for 15 min. Functional hydrogen-deuterium exchange reactions were
12 initiated by dilution of 3 μ l of stock solution into 9 μ l of D₂O buffer (8.3 mM Tris, 50 mM
13 NaCl, pDREAD 7.2) and incubation at 0 °C. The exchange reactions were quenched after
14 various exchange time points (10, 100, 1000, 10000, 100000 sec at 0 °C, and 100000 sec at
15 RT) by adding 18 μ l of ice-cold quench buffer containing 0.8% formic acid, 1.6M GuHCl,
16 16.6% glycerol for a final pH of 2.5. Quenched samples were digested on an immobilized
17 pepsin column (16 μ l bed volume). Proteolytic products were collected on a C18 trap column
18 (Michrom Magic C18 AQ 0.2x1 mm) for 1 min desalting and separated using a reverse phase
19 analytical column (Michrom Magic C18 AQ 0.2 x 50 mm, 3 μ M) with an acetonitrile linear
20 gradient (6.4%-38.4% over 30min). MS analysis was performed on an OrbiTrap Elite Mass
21 Spectrometer (ThermoFisher Scientific, San Jose, CA). The data was acquired in both data-
22 dependent MS/MS mode and MS1 profile mode and Proteome Discoverer software
23 (ThermoFisher) was used to identify proteolytic peptides. The deuterium content of the
24 peptides for each time point was calculated by DXMS Explorer (Sierra Analytics Inc,
25 Modesto, CA), with corrections for back-exchange [6]. H/D exchange experiments performed

1 using our automated system typically produce deuterium incorporation measurements with a
2 standard deviation of less than 2% of the mean of triplicate determinations [7-9].

3

4 *4.1.5. Target engagement by CETSA.*

5 *4.1.5.1. Cell culture and drug treatments*

6 HepG2 cells provided by Dr. Nathalie Hennuyer (Pasteur Institute of Lille, France) were
7 cultured in gelatin (Sigma-Aldrich, G-1890, 1 mg/mL) pre coated T75 flasks in MEM Alpha
8 Medium (1X) + GlutaMax™ (Gibco, 32561-029) containing 10% heat-inactivated fetal calf
9 serum (Life Technologies, 10270-106) and 5 µg/mL penicillin/streptomycin (Life
10 Technologies, 15070-063), in 37°C humidified incubator with 5% CO₂ atmosphere. Drug
11 treatment was initiated after the cells had grown to confluence with compounds at a final
12 concentration of 30 µM or DMSO for two hours (final vehicle content 0.3%).

13 *4.1.5.2. Whole cell CETSA*

14 Suspension of HepG2 cells were washed in PBS and detached using trypsin/EDTA solution
15 (Life Technologies, 25300054). Cells were transferred in medium in 15 mL Falcon and
16 centrifuged at 300 g during 4 min. Then, the supernatant was discarded and cells were washed
17 in phosphate buffer saline (Gibco, DPBS (1X), 14190-094), counted and centrifuged at 300 g
18 during 4 min. After removing PBS, cells are suspended in Tris Buffered Saline 1X (TBS 10X,
19 Euromedex, ET220-B) at the concentration of 10 million per mL and aliquoted in 10 PCR 0.2
20 ml microtubes (Thermo Scientific, AB-0622) for each condition with 50 µL. These tubes were
21 then transiently heated to a range of temperature from 40 °C to 67 °C for 3 minutes using a
22 SureCycler 8800 Thermal Cycler (Agilent Technologies), cooled at room temperature for 3
23 minutes and followed by three freeze/thaw cycles in liquid nitrogen. Insoluble proteins were
24 separated by centrifugation (20000 g, 20 min, 4 °C) and 35 µl of supernatant corresponding to

1 soluble proteins were kept for Western blot. Three independent experiments were performed
2 for each compound effect characterization.

3

4 *4.1.5.3. SDS PAGE Electrophoresis with CETSA samples*

5 10 µL of each total protein sample was prepared and heated at 70 °C for 10 min with 1,5 µL
6 of NuPAGE™ Sample Reducing Agent (10X) (Thermofischer Scientific, NP0004) and
7 NuPAGE™ LDS Sample Buffer (4X) (Thermofischer Scientific, NP0007), loaded in NuPage
8 3-8% Polyacrylamide gel for migration (150V, 1 hour) and then transfer on nitrocellulose
9 membrane (Amersham Protran® supported 0.2 µm NC, 10600080) with iBlot™ 2 Gel
10 Transfer Device (Thermofischer Scientific, IB21001).

11

12 *4.1.5.4. Immunoblotting for Western Blot*

13 Blots and printed membranes were blocked in dry milk (5%) diluted in Phosphate Buffer
14 Saline (PBS) for 1 hour at RT and washed 3 times of 10 min in PBS 0,1% Tween 20. Mouse
15 monoclonal anti-IDE antibody (Santa Cruz Biotechnology, clone F-9, sc-393887) were used
16 as primary antibody diluted at 1:1000 in 2% BSA PBS 0,1% Tween20 solution and incubated
17 1h30 at RT. After 3 washes in 0,1% PBS Tween 20, Anti-Mouse IRDye 800 CW (Licor
18 IRDye® 800CW Goat anti-Mouse IgG, P/N 925-32210) was used as secondary antibody in
19 2% BSA PBS 0,1% Tween 20 solution at 1:15000 for 1h30 at RT and blots were washed 3
20 times of 10 min in PBS Tween 0,1% before fluorescence intensities detection by Odyssey®
21 CLx Imaging System.

22 *4.1.5.5. Data analysis and aggregation curve*

23 Signal intensities (corresponding to Fluorescence minus Background) of each protein band or
24 spot on the Western blots were quantified using Image Studio™ Lite Analysis Software
25 (Licor). For each condition of treatment, fold-changes were calculated in percentage of the

1 lowest temperature. These relative signals were *plotted* against temperature using Graphpad™
2 (Prism) and a variable slope sigmoidal curve was fitted using the chemical denaturation
3 theory equation.

$$4 \quad f(T) = \left(\frac{1 - plateau}{1 + e^{-\left(\frac{a}{T-b}\right)}} \right) + plateau$$

5 Initial values for top and bottom plateau were set at 100% and 0% respectively for curve
6 fitting. Aggregation curves were expressed as means of multiple experiments (n = 3) +/- SEM.
7 Thermal shifts were calculated using ΔT_{Agg50} , which is the difference in temperatures
8 between the control and treatment, at which 50% signal intensity (protein denaturation) was
9 observed.

10 *4.1.5.6. LC-MS/MS analysis of CETSA samples*

11 To determine the incorporated fraction of compounds in cells for BDM_44768 and ebselen,
12 CETSA samples (10 million cells per ml in TBS) and culture medium containing drugs at 30
13 μ M or vehicle were prepared in a 1 to 20 ratio in an acetonitrile/methanol solution (5:5, v/v).
14 Then, the samples were vigorously mixed with a vortex and centrifuged at 10,000 rpm at 4°C
15 for 10 min, and the supernatants were transferred into tubes for liquid chromatography-mass
16 spectrometry (LC-MS/MS) analysis. Chromatography of 1 μ l of the sample was performed on
17 an Acquity BEH C18 column (50*2,1mm 1,7 μ m, Waters®) by elution with a gradient from
18 Ammonium acetate 10 mM (spontaneous pH) (A) to acetonitrile 0,1 % formic acid (B). The
19 gradient was controlled as follows: 0-0.2 min, 2% B, 0.2-2 min, 2 to 98% B, 2-2.5 min, 98%
20 B, 5.5-2.6 min, 98 to 2% B, 2.6-4 min, 2%B. Flow rate was 0.6 mL/min. Column oven and
21 autosampler temperatures were maintained at 40°C and 10°C respectively. The column outlet
22 of the LC was either connected to Xevo TQD triple Quadrupole Mass Spectrometry (Waters)
23 for MS/MS detection in positive electrospray ionization (ESI) mode. The source temperature
24 was 150 °C, desolvation temperature 600 °C, cone gas flow 50 L/h and desolvation gas flow

1 1200 L/h. The analytes were monitored in multireaction monitoring mode (MRM). Analyses
2 were processed using MassLynx software (Waters®). The ratio between cellular and medium
3 fraction peak areas permitted to compare the membrane permeability capacities of drugs.
