18 **Abstract:**
19

20 Methyl moieties are highly valuable probes for quantitative NMR studies of large proteins.
21 Hence, their assignment is of the utmost interest to obtain information on both interactions and
22 dynamics of proteins in solution. Here, we present the synthesis of a new precursor that allows
23 connection of leucine and valine pro-*S* methyl moieties to backbone atoms by linear ¹³C-chains.
24 This optimized ²H/¹³C-labelled acetolactate precursor can be combined with existing ¹³C/²H-
25 alanine and isoleucine precursors in order to directly transfer backbone assignment to the
26 corresponding methyl groups. Using this simple approach leucine and valine pro-*S* methyl
27 groups can be assigned using a single sample without requiring correction of ¹H/²H isotopic
28 shifts on ¹³C resonances. The approach was demonstrated on the N-terminal domain of human
29 HSP90, for which complete assignment of Ala-β, Ile-δ₁, Leu-δ₂, Met-ε, Thr-γ and Val-γ₂ methyl
30 groups was obtained.

1 **Introduction:**

2
3 Solution state NMR is the method of choice to characterize proteins at atomic level and
4 to probe their dynamics over a wide range of biologically relevant timescales. However, for a
5 long-time, study of high molecular weight proteins by NMR remained a challenge, notably due
6 to the extensive line broadening of NMR signals in large proteins. Methyl groups have been
7 widely studied and are extremely useful to overcome this issue that has hampered, in the past,
8 quantitative NMR studies on large proteins. Indeed, due to the proton multiplicity and their
9 favorable relaxation properties, methyl groups allow the detection of NMR signals even for
10 large proteins (Tugarinov et al. 2003). Nowadays, methyl groups are important probes to
11 investigate molecular dynamics (Sprangers and Kay 2007) and to provide functional insight
12 (Rosenzweig et al. 2013; Mas et al. 2018) on assemblies weighing up to 1 MDa. Specific
13 labelling of methyl groups on perdeuterated large proteins allows the measurement of long-
14 range distance restraints, up to 12 Å. (Sounier et al. 2007; Ayala et al. 2020) and enables, in
15 combination with other structural biology techniques such as SANS/SAXS (Lapinaite et al.
16 2013) or Cryo-EM (Gauto et al. 2019), to solve the structure of complexes of several hundreds
17 of kDa.

18 For the past 20 years, a plethora of protocols overexpressing proteins in M9²H₂O based
19 *E.coli* growth medium and leading to specific protonation of methyl groups in perdeuterated
20 proteins without scrambling of protons to other sites have been elaborated. On one hand, the
21 direct incorporation of the methyl labelled amino acid in M9²H₂O is employed for the specific
22 labelling of ¹³C¹H₃-alanine (Isaacson et al. 2007; Ayala et al. 2009), ¹³C¹H₃-methionine (Gelis
23 et al. 2007; Stoffregen et al. 2012) and ¹³C¹H₃-threonine (Velyvis et al. 2012; Ayala et al. 2020).
24 On the other hand, as leucine, valine and isoleucine residues are at the end of irreversible
25 metabolic pathways in *E.coli*, precursors can be incorporated in the growth medium for their
26 cost-effective labelling. The first precursors introduced to label isoleucine or leucine and valine
27 residues were 2-keto acids: α-ketobutyrate (Gardner et al. 1997) and α-ketoisovalerate (Goto et
28 al. 1999; Hajduk et al. 2000; Gross et al. 2003), respectively. However, α-ketoisovalerate used
29 as a precursor for leucine and valine residues is leading to a non-stereospecific labelling of both
30 pro-*S* and pro-*R* ¹³C¹H₃ groups resulting in overcrowded spectra for high molecular weight
31 proteins, even when both sensitivity and resolution have been improved using a non-
32 stereospecific ¹³C¹H₃/¹²C²H₃ α-ketoisovalerate (Tugarinov and Kay 2004b).

33 To prevent peak overlaps and to facilitate studies of large molecular weight assemblies,
34 methyl labelled acetolactate has been used as an alternative precursor (Gans et al. 2010). This

1 latter enables the stereospecific $^{13}\text{C}^1\text{H}_3$ -labelling of valine and leucine methyl groups and
2 therefore halves the number of peaks observed whilst improving by two the sensitivity of the
3 spectrum as compared to labelling at 50% pro-*S* and 50% pro-*R* methyl moieties using
4 optimized $^{13}\text{C}^1\text{H}_3/^{12}\text{C}^2\text{H}_3$ α -ketoisovalerate (Tugarinov and Kay 2004b). This interesting
5 precursor also enhances the intensity of NOE cross peaks and increases the distance threshold
6 at which NOE cross peaks can be detected by 20 % (Gans et al. 2010).

7 However, despite the tremendous progress made in protocols to selectively introduce
8 protonated methyl groups in perdeuterated proteins, sequence specific assignment, essential for
9 analyzing a variety of NMR data, remains an important challenge for large molecular
10 assemblies. Several methods to solve the bottleneck of assignment of large proteins have been
11 developed including parallel mutagenesis strategies (Amero et al. 2011), structure based
12 approaches using the analysis of NOE cross peaks with various programs (Pritišanac et al.
13 2020), MAP-XSII (Xu and Matthews 2013), FLAMEnGO 2.0 (Chao et al. 2014), MAGMA
14 (Pritišanac et al. 2017), MAGIC (Monneau et al. 2017), MethylFLYA (Pritišanac et al. 2019),
15 MAUS (Nerli et al. 2021) or the “divide-and-conquer” approach (Gelís et al. 2007; Sprangers
16 and Kay 2007) which is based on separation of large proteins into smaller fragments, assigning
17 these and transferring the assignment back to the full-length protein. For proteins of moderate
18 molecular weight or fragments of large assemblies for which backbone assignment is available,
19 it is possible to connect methyl resonances to those of the backbone. This requires a sample
20 with $^{13}\text{C}^1\text{H}_3$ labelled methyl groups connected to the backbone by a linear ^{13}C -chain. With such
21 a sample, transfer from the assigned backbone to the methyl groups can be achieved using either
22 unidirectional transfer from methyl groups to HN using (HM)CM(CGCBNA)NH experiments
23 (Tugarinov and Kay 2003) or ‘out and back’ HCC relay triple resonance experiments
24 (Tugarinov and Kay 2003; Ayala et al. 2012; Mas et al. 2013).

25 A combination of these techniques to assign methyl groups in addition with a
26 stereospecific labelling, enhancing the sensitivity of the spectrum by a factor two and
27 significantly reducing signal overlap, should lead to straightforward leucine and valine methyl
28 group assignment. Labelling schemes, connecting non-stereospecifically both leucine and
29 valine methyl groups (Tugarinov and Kay 2003), or only pro-*R* methyl moieties (Mas et al.
30 2013; Kerfah et al. 2015a), to the assigned backbone are already available. However, with such
31 precursors additional samples are required either to stereospecifically assign the methyl group
32 (Tugarinov and Kay 2004a; Gans et al. 2010) or to link the pro-*S* methyl to the pro-*R* one (Mas
33 et al. 2013; Kerfah et al. 2015a). Here we introduce the synthesis of a new dissymmetric $^{13}\text{C}^2\text{H}$ -
34 labelled acetolactate, a precursor that allows to directly connect the assigned leucine and valine

1 backbone atoms to the pro-*S* methyl groups via a linear ^{13}C chain using only one sample. This
2 new labelling scheme has been applied to the N-terminal domain of human HSP90 (HSP90-
3 NTD) and we present here the full assignment of methyl moieties of this protein.

1 **Materials and Methods**

2 **Synthesis of 1, 2, 3-[¹³C₃]- 4, 4, 4-[²H₃]-acetolactate.**

3 a) Synthesis of ethyl 1, 2, 3-[¹³C₃]-3-oxo-butanoate. A solution of LiHMDS (7.80 g, 46.6
4 mmoles, 2.1 equiv.) in freshly dried THF (150 mL) was cooled to -78°C under argon. 1, 2-
5 [¹³C₂]-ethyl acetate (2.00 g, 22.2 mmoles, Cambridge Isotope Laboratory, CIL) was added
6 dropwise. The resulting solution was stirred at -78°C for 15 min, then 1-[¹³C]-acetyl chloride
7 (1.60 mL, 22.2 mmoles, 1 equiv., CIL) was added dropwise. The resulting mixture was stirred
8 at -78 °C for additional 30 min then quenched by addition of a 20% aqueous solution of ¹HCl
9 (15 mL). After 3 extractions with Et₂O, the organics were combined, washed with saturated
10 Na¹HCO₃ solution then dried over Na₂SO₄. Concentration under vacuum affords the desired
11 product (2.88g) which was used in the next step without further purification).

12 ¹H NMR:(C²HCl₃), δ: 4.21 (dq, O-CH₂, ³J(¹H-¹H) = 7.1 Hz, ³J(¹H-¹³C) = 3.2 Hz, 2H); 3.46 (dt,
13 ¹³C-¹³CH₂-¹³C, ²J(¹H-¹³C) = 6.5 Hz, ¹J(¹H-¹³C) = 130.1 Hz, 2H); 2.28 (dd, CH₃-¹³C, ³J(¹H-¹³C)
14 = 1.4 Hz, ²J(¹H-¹³C) = 6.1 Hz, 3H), 1.30 (t, OCH₂-CH₃, ³J(¹H-¹H) = 7.1 Hz, 3H).

15
16
17 b) Synthesis of ethyl 1, 2, 3-[¹³C₃]-2-[¹³C¹H₃]-3-oxo-butanoate. ¹³C¹H₃-I (752 mL, 11.99
18 μmoles, 1.1 equiv, CIL) was slowly added to a solution of ethyl 1, 2, 3-[¹³C₃]-3-oxo butanoate
19 (1.45 g, 10.90 mmoles) in EtO¹H (50 mL) cooled to 0°C before addition of K₂CO₃ (1.66 g,
20 11.99 mmoles, 1.1 equiv.). The resulting suspension was warmed to room temperature then
21 stirred for 18 h. The mixture was concentrated to the fifth before addition of a large volume of
22 Et₂O. Excess of K₂CO₃ was filtered off and the filtrate concentrated under vacuum to the fifth
23 before a further addition of Et₂O and a second filtration. Concentration under vacuum affords
24 the desired product (1.03 g) as a colorless oil which was used in the next step without further
25 purification.

26 ¹H NMR:(C²HCl₃), δ: 4.21 (dq, O-CH₂, ³J(¹H-¹H) = 7.1 Hz, ³J(¹H-¹³C) = 3.0 Hz, 2H); 3.50
27 (dm, ¹³C-¹³CH-¹³C, ¹J(¹H-¹³C) = 129.0 Hz, 1H); 2.24 (dd, CH₃-¹³C, ³J(¹H-¹³C) = 1.3 Hz, ²J(¹H-
28 ¹³C) = 6.0 Hz, 3H), 1.36 (dm, ¹³CH₃, ¹J(¹H-¹³C) = 129.0 Hz, 3H), 1.28 (t, OCH₂-CH₃, ³J(¹H-
29 ¹H) = 7.1 Hz, 3H).

30
31 c) Synthesis of ethyl 1, 2, 3-[¹³C₃]-2-[¹³C¹H₃]-2-[O¹H]-3-oxo-butanoate. To a solution of ethyl
32 1, 2, 3-[¹³C₃]-2-[¹³C¹H₃]-3-oxo butanoate (995 mg, 6.72 mmoles) in DMSO (8 mL), Cs₂CO₃
33 was added (440 mg, 1.35 mmoles, 0.2 equiv.). After O₂ bubbling for 15 min., P(OEt)₃ (233 mL,
34 1.35 mmoles, 0.2 equiv.) was added. The resulting solution was stirred under O₂ atmosphere

1 for 20 h. A large volume of Et₂O was then added followed by a saturated NaCl solution. The
2 resulting phases were separated and the aqueous one was extracted one more time with Et₂O.
3 The organics were combined, dried over Na₂SO₄ then concentrated under vacuum to obtain
4 ethyl 1, 2, 3-[¹³C₃], 2-[¹³C¹H₃], 2-[O¹H]-3-oxobutanoate as a yellow oil (1.142 g) and pure
5 enough to be used in the next step without further purification.

6 ¹H NMR:(C²HCl₃), δ: 4.25 (dq, O-CH₂, ³J(¹H-¹H) = 7.1 Hz, ³J(¹H-¹³C) = 3.2 Hz, 2H); 4.17-
7 4.24 (m, OH, 1H), 2.27 (dd, CH₃-¹³C, ³J(¹H-¹³C) = 1.1 Hz, ²J(¹H-¹³C) = 6.1 Hz, 3H), 1.36 (dm,
8 ¹³CH₃, ¹J(¹H-¹³C) = 134.2 Hz, 3H), 1.28 (t, OCH₂-CH₃, ³J(¹H-¹H) = 7.1 Hz, 3H).

9
10 d) Synthesis of sodium 1, 2, 3-[¹³C₃]-2-[¹³C¹H₃]-2-[O²H]-3-oxo-4, 4, 4-[²H₃]-butanoate. To a
11 solution of ethyl 1, 2, 3-[¹³C₃]- 2-[¹³C¹H₃]-2-[O¹H]-3-oxobutanoate (1.09 g) in ²H₂O (4 mL),
12 0.4 equivalents of a solution of NaO²H (2.5 M) in ²H₂O were added dropwise in 40 min, using
13 a syringe pump under argon. As soon as the addition was completed, ¹H NMR was carried out
14 on a sample (few μL) in ²H₂O in order to calculate the conversion percentage (*ratio* between
15 the amount of hydrolyzed product (quadruplet at 1.60 ppm) and the amount of starting material
16 (quadruplet at 1.7 ppm)). 1.1 equivalent of NaO²H solution (2.5 M) was added over 30 min
17 with the syringe pump. As soon as the addition was completed, an extraction with diethyl ether
18 was carried out in order to remove the by-product coming from the previous step whose NMR
19 signals prevent a good follow-up of the hydrogen/deuterium (¹H/²H) exchange on the 4-CH₃
20 (2.2 ppm). The ¹H/²H exchange on 4-CH₃ was then monitored by ¹H NMR and carried out by
21 successive addition of NaO²H (2.5 M) until the integral of the doublet corresponding to the CH₃
22 reaches the value of 0.1 when the quadruplet at 1.6 ppm integrates for 1.5. The reaction was
23 immediately neutralized with a concentrated ²HCl solution to neutral pH and then buffered with
24 Tris-¹HCl, (1.0 M, pH 7.5 in ²H₂O). The concentration of the resulting solution was then
25 determined by ¹H NMR using methanol or acetonitrile as internal reference. The final product
26 (3.02 mmoles) was stored at -80°C.

27 ¹H NMR:(C²HCl₃), δ: 1.37 (dq, ¹³CH₃, ¹J(¹H-¹³C) = 129.3 Hz, ²J(¹H-¹³C) = 3.9 Hz, 1H).

28

29 **Preparation of isotopically labelled HSP90-NTD samples.**

30 *E. coli* BL21-DE3-RIL cells transformed with a pET-28 plasmid encoding the N-Terminal
31 domain of HSP90 α from *Homo Sapiens* (HSP90-NTD) with a His-Tag and a TEV cleavage
32 site were progressively adapted in three stages over 24 h to M9/²H₂O. In the final culture,
33 bacteria were grown at 37°C in M9 medium with 99.85 % ²H₂O (Eurisotop), 1 g/L ¹⁵N¹H₄Cl

1 (Sigma Aldrich) and 2 g/L D-glucose-d₇ (for U-[²H, ¹²C, ¹⁵N] HSP90-NTD samples) or D-
2 glucose-¹³C₆-d₇ (CIL) (for U-[²H, ¹³C, ¹⁵N] HSP90-NTD samples).

3 For methyl specifically labelled samples, the methyl labelled precursors or amino-acids were
4 added to the media when the O.D at 600 nm reached 0.6 (Kerfah et al. 2015c):

- 5 - Labelling scheme (A): for production of the U-[²H, ¹⁵N, ¹³C], Ile-[2, 3, 4, 4-²H₄; 1, 2,
6 3, 4-¹³C₄; ¹³C¹H₃]^{δ1}/[¹²C²H₃]^{γ2}], Leu-[2, 3, 3, 4-²H₄; 1, 2, 3, 4-¹³C₄; [¹³C¹H₃]^{pro-S}/
7 [¹²C²H₃]^{pro-R}], Val-[2, 3-²H₂; 1, 2, 3-¹³C₃; [¹³C¹H₃]^{pro-S}/¹²C²H₃]^{pro-R}] HSP90-NTD, a
8 solution containing the sodium 1, 2, 3-[¹³C₃]-2-[¹³C¹H₃]-2-[O²H]-3-oxo-4, 4, 4-[²H₃]-
9 butanoate precursor was added at a concentration of 172 mg/L 1 h before induction. 40
10 min later (20 minutes before induction) a solution containing 60 mg/L of sodium (S)-2-
11 hydroxy-2-(1',1'-[²H₂], 1', 2'-[¹³C₂])ethyl-3-oxo-1,2,3-[¹³C₃]-4,4,4-[²H₃]butanoate
12 (Kerfah et al. 2015a) was added to the medium.
- 13 - Labelling scheme (B): for production of the U-[²H, ¹⁵N, ¹²C], Ala-[¹³C¹H₃]^β, Met-
14 [¹³C¹H₃]^ε, Leu/Val-[¹³C¹H₃]^{pro-S}, Ile-[¹³C¹H₃]^{δ1}, Thr-[¹³C¹H₃]^γ HSP90-NTD, a HLAM-
15 A^βI^{δ1}M^εLV^{proS}T^γ kit, purchased from NMR-Bio, was added before induction according
16 to the manufacturer's protocol.
- 17 - Labelling scheme (C): U-[²H, ¹⁵N, ¹²C] samples labelled on a single type of methyl
18 group were produced in small scales (21 mL) to identify A^β, M^ε, T^γ methyl type (3
19 samples) or to complete assignment using single point mutants (Amero et al. 2011) (33
20 samples, list of mutants presented in the legend of Fig. S4). Single point amino acid
21 mutations were generated by GeneCust. For each of these samples a single type of
22 methyl groups was labelled by addition of the corresponding NMR-Bio kit (SLAM-A^β,
23 SLAM-M^ε, SLAM-I^{δ1}, SLAM-T^γ or DLAM-LV^{proS}) in M9/²H₂O media 1 h before
24 induction.

25
26 Protein production was induced by the addition of IPTG to a final concentration of 0.5
27 mM. The cultures were grown overnight at 20°C before harvesting. Cells were collected by
28 centrifugation at 5500 g for 20 min at 4°C then lysed by sonication on ice in a buffer containing
29 20 mM phosphate sodium buffer at pH 7.4, 0.5 M NaCl, 0.05% β-ME, antiprotease (cOmplete®
30 EDTA free, 1 tablet for 50 mL), 50 µg/mL DNase (Sigma Aldrich), 50µg/mL RNase
31 (Euromedex), and 0.25 mg/mL Lysozyme (Euromedex). After removal of cell debris by
32 centrifugation (45,000×g, 30 min, 4 °C), the supernatant was purified using an affinity
33 chromatography step (Ni-NTA, Superflow, QIAGEN) (labelling scheme A, B and C), followed
34 by a size exclusion chromatography step (16/600 Superdex 75 PG, GE Healthcare) (labelling

1 schemes A and B only). The gel filtration column was run with an isocratic step of the NMR
2 buffer (20 mM Hepes, 150 mM NaCl, 1 mM TCEP, pH 7.5).

3 The HSP90-NTD proteins were concentrated, using an Amicon® 4 Centrifugal Filter
4 Unit with a 10,000 MWCO (Merck), either in a 90%/10% $^1\text{H}_2\text{O}/^2\text{H}_2\text{O}$ or in a 100% $^2\text{H}_2\text{O}$ buffer
5 containing 20 mM Hepes, 150 mM NaCl, 1 mM TCEP, pH 7.5. For labelling schemes A and
6 B, samples were concentrated to 0.5 mM and 200 μL of each sample was loaded in 4 mm
7 shigemi tube. The wild type and single point mutants of HSP90-NTD proteins labelled on only
8 one methyl type (labelling scheme C) were concentrated at [0.1-0.4] mM and 40 μL of each
9 sample was loaded in a 1.7 mm NMR tube.

10

11 NMR Spectroscopy

12 All NMR experiments acquired on HSP90-NTD samples were recorded at 298 K. 2D
13 ^1H - ^{13}C SOFAST methyl TROSY (Amero et al. 2009) experiments to identify each methyl type
14 as well as to assign individual methyl signals using single point mutants were recorded for an
15 average duration of ~ 1.5 h each, on a spectrometer operating at a ^1H frequency of 850 MHz
16 and equipped with a 1.7 mm cryogenically cooled, pulsed-field-gradient triple-resonance probe.
17 All other NMR experiments were acquired using Bruker Avance III HD spectrometers equipped
18 with 5 mm cryogenic probes (operating at a ^1H frequency of 600 or 950 MHz).

19 The 3D HCC, HC(C)C and HC(CC)C experiments (Tugarinov and Kay 2003; Ayala et
20 al. 2009, 2012; Mas et al. 2013) were acquired on a spectrometer operating at a ^1H frequency
21 of 600 MHz for a total duration of 4 days, using a 0.5 mM sample of U- $[\text{}^2\text{H}, \text{}^{15}\text{N}, \text{}^{13}\text{C}]$, Ile-[2,
22 3, 4, 4- $^2\text{H}_4$; 1, 2, 3, 4- $^{13}\text{C}_4$; $^{13}\text{C}^1\text{H}_3$] $^{\delta 1}/[\text{}^{12}\text{C}^2\text{H}_3]^\gamma 2$], Leu-[2, 3, 3, 4- $^2\text{H}_4$; 1, 2, 3, 4- $^{13}\text{C}_4$; $[\text{}^{13}\text{C}^1\text{H}_3]^{\text{pro-}}$
23 $S/[\text{}^{12}\text{C}^2\text{H}_3]^{\text{pro-R}}$], Val-[2, 3- $^2\text{H}_2$; 1, 2, 3- $^{13}\text{C}_3$; $[\text{}^{13}\text{C}^1\text{H}_3]^{\text{pro-S}}/[\text{}^{12}\text{C}^2\text{H}_3]^{\text{pro-R}}$] HSP90-NTD. The
24 interscan delay was adjusted to 0.5-0.6 s, the heteronuclear $^1\text{H} \rightarrow ^{13}\text{C}$ transfer delay was set to
25 4 ms ($1/(2 \times J_{\text{HC}})$) and the homonuclear $^{13}\text{C} \rightarrow ^{13}\text{C}$ transfer delay was fixed to 12.5 ms. The
26 acquisition times were adjusted to 8-10.7 ms in the ^{13}C indirect dimension, and to 70 ms in ^1H
27 direct dimension.

28 For the sequential assignment of backbone resonances, a set of 6 BEST-TROSY 3D
29 triple resonance experiments (HNCA, HN(CA)CB, HNCO, HN(CA)CO, HN(CO)CA and
30 HN(COCA)CB (Favier and Brutscher 2019) were acquired on a Bruker Avance III HD
31 spectrometer equipped with a cryogenic probe and operating at a ^1H frequency of 600 MHz for
32 a total duration of 11 days using a 0.5 mM sample of the U- $[\text{}^2\text{H}, \text{}^{15}\text{N}, \text{}^{13}\text{C}]$ HSP90-NTD.

33 The 3D CCH HMQC-NOESY-HMQC NMR experiment (Tugarinov et al. 2005; Törner
34 et al. 2020) was recorded over 3 days on a spectrometer operating at a ^1H frequency of 950 MHz

1 using a 0.5 mM sample of U-[²H, ¹⁵N, ¹²C], Ala-[¹³C¹H₃]^β, Met-[¹³C¹H₃]^ε, Leu/Val-[¹³C¹H₃]^{pro-}
2 ^δ, Ile-[¹³C¹H₃]^{δ1}, Thr-[¹³C¹H₃]^γ HSP90-NTD. The interscan delay was set to 1.1s. The
3 heteronuclear ¹H -> ¹³C transfer delay was set to 4 ms (1/(2 x ¹J_{HC})). The acquisition times in
4 the ¹³C indirect dimension were set to 24.6 ms, (t_{1max}) and to 18.6 ms (t_{2max}). In the ¹H direct
5 dimension t_{3max} was fixed to 80 ms. The NOE mixing period was set to 500 ms to detect a
6 maximum number of long-range intermethyl NOEs.

8 **Data processing and analysis**

9 All data were processed and analyzed using nmrPipe/nmrDraw (Delaglio et al. 1995)
10 and CcpNMR (Vranken et al. 2005). Automated methyl assignment was performed using
11 MAGIC software (Monneau et al. 2017) using the reference structure of HSP90-NTD (PDB:
12 1YES). Input NOE lists for MAGIC were created with CcpNMR. MAGIC was run with a score
13 threshold factor of 1 and distance thresholds of 7–10 Å using all inter methyl NOEs detected
14 (S/N threshold of 5 was used) and given the assignment of isoleucines, leucines and valines
15 previously obtained by the three ‘out and back’ HCC experiments as well as alanine, methionine
16 and threonine methyl groups assigned by mutagenesis as additional input.

1 Results and Discussion

2
3 To assign methyl groups of large perdeuterated proteins, previously assigned backbone
4 resonances of these proteins can be used (Tugarinov and Kay 2003; Ayala et al. 2012; Mas et
5 al. 2013). Nonetheless, to do so, methyl groups need to be connected, via a linear chain of ^{13}C ,
6 to the backbone atoms in order to be able to apply optimized experiments to high molecular
7 weight proteins. Strategies to label stereospecifically leucine and valine pro-*R* methyl groups
8 and to connect them to backbone nuclei have already been proposed (Mas et al. 2013).
9 However, it has to be noted that pro-*S* methyl groups are often chosen over pro-*R* methyl groups
10 as they are both easier and cheaper to label stereospecifically (Gans et al. 2010). In order to
11 simplify assignment of pro-*S* methyl groups using already assigned backbone resonances and
12 to avoid the need of an additional sample to link the pro-*S* methyl to the pro-*R* one, a sample
13 connecting the pro-*S* $^{13}\text{C}^1\text{H}_3$ -methyl groups to the backbone atoms by a linear ^{13}C -chain and
14 labelled with $^{12}\text{C}^2\text{H}_3$ on pro-*R* methyl moieties to avoid signal loss would be optimal.

16 Synthesis of optimally labelled acetolactate precursors and proteins.

17 Taking into account the specificity of leucine/valine metabolic pathway in *E. coli*, such
18 an optimal labelling scheme can be achieved in $\text{M9}^2\text{H}_2\text{O}$ medium using $^{13}\text{C}^2\text{H}$ glucose (Kerfah
19 et al. 2015c) as a carbon source together with 1, 2, 3- $^{13}\text{C}_3$ -2- $^{13}\text{C}^1\text{H}_3$ -2- $[\text{O}^2\text{H}]$ -3-oxo-4, 4, 4-
20 $^2\text{H}_3$ -butanoate as suitably labelled acetolactate precursor. However, this latter cannot be
21 synthesized from commercially available materials by the traditional route starting from
22 acetoacetate (Gans et al. 2010) since the corresponding labelled starting material is not
23 commercially available. Indeed, acetolactate chemical synthesis is achieved by reaction of
24 iodomethane on acetoacetate (Gans et al. 2010). Whilst both $^{13}\text{C}^1\text{H}_3$ labelling of the methyl
25 substituent in position 2 and deuteration of the methyl group in position 4 can be obtained using
26 $^{13}\text{C}^1\text{H}_3\text{I}$ as a starting synthesis material and hydrogen/deuterium exchange in controlled basic
27 conditions (Gans et al. 2010), respectively, the ^{13}C labelling of only the first three carbons of
28 the main chain using commercially available labelled acetoacetate materials is not achievable.
29 Therefore, as acetoacetate can be obtained by condensation of two acetate moieties (Epstein J
30 et al. 1977), we decided to set up a synthesis of dissymmetrically labelled acetoacetate starting
31 from commercially available ethyl 1, 2- $^{13}\text{C}_2$ -acetate with 1- ^{13}C -acetyl chloride. Based on
32 reported procedures, we established a 4-step synthesis (Fig. 1) allowing to prepare the desired
33 precursor with an overall yield of 27%. In brief, the dissymmetry is achieved by the Claisen
34 condensation of ethyl-1,2, $^{13}\text{C}_2$ -acetate with 1- ^{13}C -acetyl chloride using an optimization of a

1 reported procedure (Epstein J et al. 1977) (a), followed by an alkylation in position 2 using
2 $^{13}\text{C}^1\text{H}_3\text{I}$ (b) and a subsequent hydroxylation in position 2 (c). Finally, the last step combining
3 both saponification of the ester and a hydrogen/deuterium exchange in position 4 is performed
4 under controlled basic conditions (d). This last step is very delicate and requires a fine control
5 of the basic condition as a methyl rearrangement above a pH of 13.5 can take place resulting in
6 the interconversion of both methyl groups (Gans et al. 2010). Steps (b) and (c) are not
7 stereoselective, hence, products of these latter steps were produced as racemic mixtures. The
8 optimally labelled acetolactate, unstable at room temperature, was aliquoted and stored at -
9 80°C .

10 The synthesized acetolactate precursor was incorporated in *E. coli*. $\text{M9}^2\text{H}_2\text{O}$ culture
11 media without any further purification steps to label the overexpressed protein. Frozen
12 acetolactate vials were thawed right before addition in the culture medium to avoid degradation
13 or methyl rearrangement. It has to be noted that only the 2-(*S*) stereoisomer of acetolactate is
14 converted *in vivo* by ketol–acid reductoisomerase (EC1.1.1.86) and dihydroxyacid dehydratase
15 (EC 4.2.1.9) to form the stereospecifically labelled 2-keto-isovalerate. This latter is afterwards
16 directly converted into valine or combined with $^{13}\text{C}^2\text{H}$ -pyruvate, derived from the $^{13}\text{C}^2\text{H}$ -
17 glucose, to produce leucine with the desired labelling pattern. The 2-(*R*) stereoisomer of
18 acetolactate is, itself, not a substrate of ketol–acid reductoisomerase and hence, induces no
19 scrambling (Gans et al. 2010). The synthesized 1, 2, 3- $^{13}\text{C}_3$ -2- $^{13}\text{C}^1\text{H}_3$ -2- $[\text{O}^2\text{H}]$ -3-oxo-4, 4, 4-
20 $^{2}\text{H}_3$ -butanoate can be mixed with other known precursors allowing also to connect methyl
21 groups, such as Ile- δ_1 (Kerfah et al. 2015b, a; Törner et al. 2020), Ile- γ_2 (Ayala et al. 2012) or
22 Ala- β (Ayala et al. 2009; Kerfah et al. 2015a; Törner et al. 2020), to backbone nuclei using a
23 linear ^{13}C chain. In this study, we chose to label our sample on both leucine/valine pro-*S* and
24 isoleucine- δ_1 methyl moieties, by adding Ile- δ_1 precursor (sodium (S)-2-hydroxy-2-(1',1'-
25 $^{2}\text{H}_2$], 1', 2'- $^{13}\text{C}_2$)ethyl-3-oxo-1,2,3- $^{13}\text{C}_3$]-4,4,4- $^{2}\text{H}_3$ -butanoate – (Kerfah et al. 2015a,b))
26 together with our new optimized acetolactate. The isoleucine precursor was added in the culture
27 medium 40 min later than the new precursor in order to take into account co-incorporation
28 incompatibilities between both the leucine/valine precursor and the isoleucine one. Indeed,
29 enzymes from ILV-pathway have a tendency to process preferentially isoleucine precursor
30 instead of leucine/valine precursors (Kerfah et al. 2015b, c). Incorporation of both precursors
31 during the protein expression did not lead to a significantly different HSP90-NTD yield with
32 regards to the yields obtained in standard $\text{M9}^2\text{H}_2\text{O}$ media. No scrambling was detected neither
33 to the pro-*R* methyls groups of leucine and valine nor to the isoleucine- γ_2 site (Fig. S1a).

34

1 **Connection of $I^{\delta^1}L^{\delta^2}V^{\gamma^2}$ methyl groups to C_α and C_β atoms.**

2 Using this new precursor, it is possible to directly correlate pro-*S* methyl groups of
3 leucine and valine residues to their respective C_α and C_β . We decided to apply this strategy to
4 the N-terminal domain of human HSP90 (HSP90-NTD), an extensively studied protein, whose
5 isoform assignment (α and β), including partial assignment of its methyl groups, is available
6 (Jacobs et al. 2006; Elif Karagöz et al. 2011; Park et al. 2011; Lescanne et al. 2017, 2018).
7 Here, we have focused on the N-terminal domain of the α isoform, a 29 kDa protein that
8 contains 20 isoleucine, 18 leucine and 11 valine residues. This dynamic protein is particularly
9 challenging to assign using automatic methyl assignment methods and reported success rates
10 are ranging from 27 % to 69 % (Pritišanac et al. 2017; Monneau et al. 2017; Pritišanac et al.
11 2019, 2020). In our hands, only 34 % of the methyl groups (30/87) could be assigned
12 automatically with 1) a single assignment, 2) a high NOE assignment completeness of the strip
13 related to each peak (> 50 %) and 3) a high total confidence score value (≥ 7) (Table S1) using
14 the HSP90-NTD X-ray structure (PDB: 1YES) and experimentally detected NOE network.
15 Therefore, this protein is a good candidate to assess our experimental strategy based on new
16 precursors.

17 To do so, 200 μ L at 0.5 mM of an optimally labelled sample was used to acquire three
18 ‘out and back’ HCC, HC(C)C and HC(CC)C experiments (Tugarinov and Kay 2003; Ayala et
19 al. 2009, 2012; Mas et al. 2013) connecting labelled $I^{\delta^1}L^{\delta^2}V^{\gamma^2}$ methyls groups to $I^{\gamma^1}L^{\gamma}V^\beta$, $I^\beta L^\beta V^\alpha$
20 and $I^\alpha L^\alpha$ resonances. 100 % and 94 % of the expected C_β and C_α coherences, respectively, were
21 observed for the 29 kDa HSP90-NTD at 298 K (τ_C *c.a.* 20 ns) (Fig. 2). The three missing C_α
22 resonances correspond to residues L56, I26 and I110, two of them being affected by extensive
23 line broadening due to conformational exchange. With such a high percentage of observed C_α
24 and C_β resonances we demonstrate the applicability of this method for medium size proteins.
25 In order to validate the strategy for larger proteins, the labelling scheme was applied to the 87
26 kDa hetero hexameric protein prefoldin from *Pyrococcus horikoshii*, containing 2 α and 4 β -
27 subunits. Only the β -subunits were labelled with the optimal labelling schemes described above,
28 whilst the α -subunits remained perdeuterated (Fig. S1b). Three HCC experiments were
29 collected on this 0.2 mM sample of prefoldin at 310 K (τ_C *c.a.* 60 ns). 95% and 60% of the
30 expected C_β and C_α coherences, respectively, were observed (Fig. S2) despite the high
31 molecular weight of the protein and the presence of doubled peaks due to the presence of two
32 inequivalent β -subunits in the $\alpha_2\beta_4$ hexameric prefoldin (Ohtaki et al. 2008). Such HCC
33 experiments were also acquired at 343 K (τ_C *c.a.* 30 ns) on this hyperthermophilic prefoldin

1 sample, enabling transfer of assignment between backbone atoms and methyl groups (Törner
2 et al. 2021).

3

4 **Application to the sequence specific assignment of $I^{\delta 1}L^{\delta 2}V^{\gamma 2}$ methyl groups of HSP90-NTD**

5 Backbone sequential assignment was performed using 6 ‘BEST-TROSY’ triple
6 resonance experiments (Favier and Brutscher 2019). C_{α} and C_{β} resonances were assigned for
7 89 % and 80 % of the residues of HSP90-NTD respectively, excluding the loosely structured
8 N-terminal [1-16] and C-terminal [225-236] regions. The segment L103-T115, that covers the
9 ligand binding site, is invisible by NMR due to dynamics in the μ s-ms timescale. Transfer of
10 sequentially assigned backbones resonances to isoleucine- δ_1 , leucine- δ_2 and valine- γ_2 methyl
11 groups was achieved using ‘out and back’ HCC experiments acquired on a U- $[^2H, ^{15}N, ^{13}C]$,
12 Ile-[2, 3, 4, 4- 2H_4 ; 1, 2, 3, 4- $^{13}C_4$; $^{13}C^1H_3$] $^{\delta 1}/[^{12}C^2H_3]^{\gamma 2}$], Leu-[2, 3, 3, 4- 2H_4 ; 1, 2, 3, 4- $^{13}C_4$;
13 $[^{13}C^1H_3]^{pro-S}/[^{12}C^2H_3]^{pro-R}$], Val-[2, 3- 2H_2 ; 1, 2, 3- $^{13}C_3$; $[^{13}C^1H_3]^{pro-S}/[^{12}C^2H_3]^{pro-R}$] labelled
14 HSP90-NTD sample. 2D extracts from the HCC experiments were compared with the
15 corresponding ones from the 3D HNCA and HN(CA)CB experiments and using C_{α} and C_{β}
16 resonances, all the $I^{\delta 1}L^{\delta 2}V^{\gamma 2}$ methyl groups could be unambiguously connected to previously
17 assigned backbone atoms (Fig. 2). The assignment was transferred in one step, very simply and
18 efficiently without having to correct for the isotopic shifts (Kerfah et al. 2015a). One must note
19 that the methyl- δ_1 of Ile-33 and Ile-128 are superimposed in the 2D methyl-TROSY spectrum,
20 but were unambiguously connected to the C_{α} resonances of both amino acids (Fig. S3).
21 Remained unassigned only methyl groups of L103, I104, L107 and I110 for which backbone
22 atoms are NMR-invisible due to extensive conformational exchange. Therefore, single point
23 mutagenesis was used to assign three of these last four $I^{\delta 1}$ or $L^{\delta 2}$ resonances (I104, L107 and
24 I110) (Fig. 3). The remaining residue, L103, was assigned by a careful re-analysis of both HCC
25 and backbone triple resonance experiments performed after the assignment of I104.

26

27 **Sequence specific assignment of $A^{\beta}M^{\epsilon}T^{\gamma}$ methyl groups of HSP90-NTD**

28 In the previous U- $[^2H, ^{15}N, ^{13}C]$, Ile-[2, 3, 4, 4- 2H_4 ; 1, 2, 3, 4- $^{13}C_4$; $^{13}C^1H_3$] $^{\delta 1}/[^{12}C^2H_3]^{\gamma 2}$],
29 Leu-[2, 3, 3, 4- 2H_4 ; 1, 2, 3, 4- $^{13}C_4$; $[^{13}C^1H_3]^{pro-S}/[^{12}C^2H_3]^{pro-R}$], Val-[2, 3- 2H_2 ; 1, 2, 3- $^{13}C_3$;
30 $[^{13}C^1H_3]^{pro-S}/[^{12}C^2H_3]^{pro-R}$] HSP90-NTD sample, only $I^{\delta 1}L^{\delta 2}V^{\gamma 2}$ methyl groups were connected
31 to backbone by a linear ^{13}C -chain. We did not incorporate labelled alanine in HSP90-NTD
32 culture for the sample used to acquire the HCC experiments although it is commercially
33 available with an optimal labelling pattern (1, 2, 3- $^{13}C_3$, 2- 2H -Ala). We recommend for future
34 studies to incorporate labelled alanine in the culture medium to decrease the numbers of mutants

1 required to complete the assignment. Regarding methionine and threonine residues, their
2 assignment cannot be undertaken using HCC experiments. Indeed, the sulfur atom present on
3 methionine residues prevents the use of HCC experiments to assign methionine methyl moieties
4 from available backbone assignment and the Thr-[1, 2, 3- ^{13}C , 2, 3- $^2\text{H}_2$, $^{13}\text{C}^1\text{H}_3$ - γ] labelled amino
5 acid is not commercially available impeding the use of HCC 3D experiments to transfer
6 assignment from backbone to threonine methyl groups in large proteins. Therefore, in order to
7 assign the remaining 38 A^β , M^ϵ and T^γ methyl groups, we decided to use a combination of both
8 single point mutations and through space intermethyl NOE correlation peaks. To assign the
9 remaining A^β , M^ϵ and T^γ methyl groups using inter-methyl NOE-connectivities a U-[^2H , ^{15}N ,
10 ^{12}C], Ala-[$^{13}\text{C}^1\text{H}_3$] $^\beta$, Met-[$^{13}\text{C}^1\text{H}_3$] $^\epsilon$, Leu/Val-[$^{13}\text{C}^1\text{H}_3$] $^{\text{pro-S}}$, Ile-[$^{13}\text{C}^1\text{H}_3$] $^{\delta 1}$, Thr-[$^{13}\text{C}^1\text{H}_3$] $^\gamma$ HSP90-
11 NTD sample was required. Indeed, intermethyl NOE connectivities between previously
12 assigned isoleucine, leucine and valine residues and unassigned A^β , M^ϵ and T^γ methyl groups
13 simplify the assignment of methionine, threonine and alanine methyl moieties.

14 First small-scale samples with only one type of methyl group labelled A^β , M^ϵ or T^γ were
15 prepared to identify the amino acids type corresponding to each correlation remaining to assign
16 in the 2D methyl-TROSY spectrum. Then, we overexpressed and purified in small scale 30
17 single point $^{13}\text{C}^1\text{H}_3$ -labelled mutants. In order to minimize secondary chemical shifts
18 replacement amino acids that were structurally similar to the substituted amino acid were
19 chosen (Crublet et al. 2014) (Fig. S4).

20 Each of these samples containing 100 to 500 μg of $^{13}\text{C}^1\text{H}_3$ -labelled single point mutant
21 of HSP90-NTD were used to acquire a 2D SOFAST-methyl-TROSY spectrum (Amero et al
22 2009; Amero et al 2011) on a NMR spectrometer operating at a ^1H frequency of 850 MHz and
23 equipped with a sample changer and a 1.7 mm cryogenic probe head. This mutant library
24 allowed us to assign unambiguously 27 methyl groups. Three spectra of single point mutants
25 were more complex to analyze due to chemical shift perturbations that result from the
26 introduced mutation (Fig. S5). Out of the 38 A^β , M^ϵ and T^γ methyl groups, eleven remained
27 unassigned after the first analysis of the mutant library, among them eight methyls (one M^ϵ , two
28 A^β and five T^γ methyl groups) for which mutants were not available and three T^γ methyl groups
29 whose mutant spectra were challenging to analyze. The sole unassigned methionine methyl
30 signal was unambiguously assigned as the last remaining methionine residue (M98).

31 To complete the assignment for the last 10 methyl groups, a 0.5 mM sample of U-[^2H ,
32 ^{15}N , ^{12}C], Ala-[$^{13}\text{C}^1\text{H}_3$] $^\beta$, Met-[$^{13}\text{C}^1\text{H}_3$] $^\epsilon$, Leu/Val-[$^{13}\text{C}^1\text{H}_3$] $^{\text{proS}}$, Ile-[$^{13}\text{C}^1\text{H}_3$] $^{\delta 1}$, Thr-[$^{13}\text{C}^1\text{H}_3$] $^\gamma$
33 labelled HSP90-NTD was prepared to acquire a 3D HMQC-NOESY-HMQC. A total of 344
34 intermethyl NOEs cross peaks with a $\text{S/N} \geq 5$ were detected between methyls distant by up to

1 10 Å. Examples of intermethyl NOE and a matrix presenting all the observed NOEs are
2 displayed in Fig. 4. To assign the remaining 2 alanines and 8 threonines, the NOE connectivities
3 and the previously assigned methyls (49 I^{δ1}L^{δ2}V^{γ2} and 28 A^βM^ε and T^γ methyl groups) were
4 used as input for the program MAGIC. Six methyl groups (2 alanines (A141 and A145) and 4
5 threonines (T90, T88, T115 and T149)) were unambiguously assigned with both a high
6 percentage of NOE correlation peaks assigned and a high confidence score. Four threonines
7 (T94, T109, T176 and T184) were left either with multiple assignments or an assignment with
8 a low confidence score. However, taking into account the information obtained from the NOE-
9 based assignment, the mutant spectra displaying chemical shift perturbations (Fig. S5) were
10 carefully reanalyzed allowing us to assign the four remaining threonine methyl signals.

11 Finally, all the 87 methyl groups of HSP90-NTD were assigned using both isoleucine
12 precursor and the newly labelled acetolactate for isoleucine, leucine and valine methyl groups
13 and this mixed NOE/mutants strategy for alanine, methionine and threonine methyl moieties
14 (Fig. 5, Table S2). It can be noted that, there is, indeed, an overlap of two isoleucines (I33/I128)
15 explaining only 86 visible peaks. Even though dynamics in the intermediate regime broaden
16 the backbone resonances of the segment which is covering the ATP binding site [103-115]
17 beyond the detection threshold, the according methyl probes are visible. The assignment of
18 L103, I104, L107, T109, I110, A111 and T115 render this previously invisible region amenable
19 to NMR studies.

1 **Conclusion:**

2
3 This research reports the synthesis of a new dissymmetric $^{13}\text{C}/^2\text{H}$ -labelled acetolactate, a
4 precursor that allows to connect directly, via linear ^{13}C chains, backbone atoms to the pro-*S*
5 methyl groups of leucine and valine residues. This optimized precursor can be combined with
6 isoleucine precursor and $^2\text{H}/^{13}\text{C}$ -alanine to enable the transfer of assignment from backbone to
7 methyl groups with only one sample without requiring the correction of $^1\text{H}/^2\text{H}$ isotopic chemical
8 shift for the ^{13}C resonances. We expect that this new precursor will ease the assignment of
9 leucine and valine pro-*S* methyl groups of proteins using already assigned backbone resonances
10 as it simplifies the analysis of the NMR experiments. This innovative labelling scheme was
11 applied to the 29 kDa N-terminal domain of human HSP90 protein and to the 87 kDa hetero
12 hexameric prefoldin complex. Using both isoleucine precursor and the newly labelled
13 acetolactate, we managed to simply and efficiently transfer the backbone sequential assignment
14 to all the isoleucine- δ_1 , leucine and valine pro-*S* methyl moieties of HSP90-NTD. This allowed
15 us to confirm or correct the residue specific assignment of most isoleucine, leucine and valine
16 methyl groups (2 assignments were corrected for the 49 ILV residues – Table S2) and the
17 stereospecific assignment of prochiral methyl groups (5 stereospecific assignments were
18 inverted for the 29 leucine and valine residues – Table S2). In addition to the full assignment
19 of $\text{I}^{\delta_1}\text{L}^{\delta_2}\text{V}^{\gamma_2}$ methyl groups, we have used a mixed strategy based on mutagenesis and
20 intermethyl NOEs to assign 38 new methyl resonances corresponding to the $\text{A}^{\beta}\text{M}^{\epsilon}\text{T}^{\gamma}$ methyl
21 moieties of HSP90-NTD. Hence, we show that, despite extended conformational exchange that
22 impedes the complete backbone assignment, we managed to detect and assign signals for all
23 methyl probes including the ones belonging to the segment covering HSP90 ATP binding site.

5 **Fig. S1** 2D ^1H - ^{13}C SOFAST methyl TROSY spectrum of U- $[\text{}^2\text{H}$, ^{15}N , ^{13}C], Ile-[2, 3, 4, 4- $^2\text{H}_4$;
6 1, 2, 3, 4- $^{13}\text{C}_4$; $^{13}\text{C}^1\text{H}_3$] $^{\delta_1}$ / $[\text{}^{12}\text{C}^2\text{H}_3]^\gamma$], Leu-[2, 3, 3, 4- $^2\text{H}_4$; 1, 2, 3, 4- $^{13}\text{C}_4$; $[\text{}^{13}\text{C}^1\text{H}_3]^{\text{pro-S}}/[\text{}^{12}\text{C}^2\text{H}_3]^{\text{pro-}}$
7 R], Val-[2, 3- $^2\text{H}_2$; 1, 2, 3- $^{13}\text{C}_3$; $[\text{}^{13}\text{C}^1\text{H}_3]^{\text{pro-S}}/[\text{}^{12}\text{C}^2\text{H}_3]^{\text{pro-R}}$] HSP90-NTD **a)** and prefoldin **b)**
8 samples (labelling scheme A applied to prefoldin β subunit only), recorded before the HCC
9 experiments to check the sample quality. The labelling strategy used Ile- δ_1 precursor: sodium
10 (S)-2-hydroxy-2-(1',1'- $[\text{}^2\text{H}_2]$, 1', 2'- $[\text{}^{13}\text{C}_2]$) ethyl-3-oxo-1,2,3- $[\text{}^{13}\text{C}_3]$ -4,4,4- $[\text{}^2\text{H}_3]$ -butanoate)
11 and the suitably labelled acetolactate precursor: 1, 2, 3- $[\text{}^{13}\text{C}_3]$ -2- $[\text{}^{13}\text{C}^1\text{H}_3]$ -2- $[\text{O}^2\text{H}]$ -3-oxo-4, 4,
12 4- $[\text{}^2\text{H}_3]$ -butanoate for the labelling of Leu and valine pro-S methyl groups. No additional peaks
13 were detected neither to the pro-R methyls groups of leucine and valine nor to the isoleucine-
14 γ_2 site, confirming the absence of isotopic scrambling. The peaks are splitted in the carbon
15 dimension due to the presence of $^1J_{\text{CC}}$ coupling as expected from the labelling scheme of the
16 produced samples.

Fig. S5 Assignment of methyl groups using mutagenesis. Examples of 2D ^1H - ^{13}C SOFAST methyl TROSY spectra of HSP90-NTD mutants, for which chemical shift perturbations. Spectra were acquired on an NMR spectrometer operating at a proton frequency of 850 MHz. Each mutant spectrum extract (colored) is superimposed with the corresponding spectra acquired using wild type HSP90-NTD methyl labelled spectra (black). The signal corresponding to each mutant is annotated in color. Black arrows represent secondary chemical shifts.

Table S1: Output file from MAGIC software for the assignment of HSP90-NTD methyl groups.

The 1st column displays the best assignment. The 2nd and 3rd columns give the ¹³C and ¹H chemical shifts, respectively. The 4th column represents the sum of all peak-peak connection confident scores for each peak. The 5th column shows the NOE assignment completeness of the strip related to each peak and the 6th column displays the list of all possible assignment with their scores (Monneau et al. 2017).

The automated methyl assignment was performed using the reference structure of HSP90-NTD (PDB: 1YES). MAGIC was run with a score threshold factor of 1, distance thresholds of 7–10 Å and using the 344 inter methyl NOE cross peaks (S/N ≥ 5) detected (Fig. 4e). In addition, MAGIC was given the methyl type for each methyl group, previously identified using specific methyl labelling. In blue are the methyl groups assigned automatically by MAGIC that have 1) a single assignment, 2) a high NOE assignment completeness of the strip related to each peak (> 50 %) and 3) a high total confidence score value (≥ 7).

4 ^a Residues assigned by (Park et al. 2011) and confirmed by this study.

5 ^b Assignment was inverted for these two residues in our study compared to (Park et al. 2011).

6 ^c Residues stereospecifically assigned by (Lescanne et al. 2018) and confirmed by this study.

7 ^d Stereospecific assignment was inverted compared to (Lescanne et al. 2018).
