HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Efficient Exact Computation for Incremental Discrete Rotations using Continued Fraction

Phuc NGO, Yukiko KENMOCHI, Hugues TALBOT
LIGM, University PARIS-EST/CNRS

Motivation

For **incremental discrete rotations** based on *hinge angles*. We need to sort all the hinge angles defined for a given digital image.

Definition: An angle α is a **hinge angle** for a discrete point $(p, q) \in \mathbb{Z}^2$ if the rotation of (p, q) by α is a point in the half-grid. [Nouvel, 2006]

A hinge angle α for an image of size $N \times N$ can be presented by a triplet of integers $(p, q, k) \in N^3$, such that

$$\cos \alpha = \frac{p\lambda + q(k + \frac{1}{2})}{p^2 + q^2}$$

$$\sin \alpha = \frac{p(k + \frac{1}{2}) - q\lambda}{p^2 + q^2},$$

where $\lambda = \sqrt{p^2 + q^2 - (k + \frac{1}{2})^2}$ and $k < \sqrt{p^2 + q^2}$.

In order to sort the hinge angles, we need to compare their cos and sin values, which are *quadratic irrational* numbers.

Problem formulation

Given two quadratic irrationals Q_1 and Q_2 that have the forms:

$$Q_i(p_i, q_i, r_i) = \frac{p_i + \sqrt{q_i}}{r_i}$$

where $p_i, q_i, r_i \in \mathbb{Z}$, $q_i > 0$ and $r_i \neq 0$ for $i = 1, 2$, we would like to **compare Q_1 and Q_2 , with an exact calculation by using only integers.**

Mathematical tools

Quadratic Irrational

Definition: A real number $x \in \mathbb{R}$ is a **quadratic irrational** (QI) if there exist $A, B, C \in \mathbb{Z}$, $A \neq 0$ such that $Ax^2 + Bx + C = 0$ and $B^2 - 4AC > 0$ is not a perfect square.

The quadratic irrational can be expressed as:

$$x = \frac{-B \pm \sqrt{B^2 - 4AC}}{2A}.$$

Continued Fraction

Definition: A **continued fraction** (CF) has an expression of the form

$$[a_0; a_1, a_2, a_3, \dots] = a_0 + \frac{1}{a_1 + \frac{1}{a_2 + \frac{1}{a_3 + \dots}}}$$

where $a_0 \in \mathbb{Z}$ and $a_i \in \mathbb{Z}_+$ for $i = 1, 2, 3, \dots$

Every rational number has a *finite continued fraction*, while every irrational number can be represented by an *infinite continued fraction*.

Definition: An infinite continued fraction is **periodic**, if its terms eventually repeat from some point.

If the repeating terms are from a_k to a_{k+m} , it is denoted by:

$$[a_0; a_1, a_2, \dots, a_{k-1}, \overline{a_k, a_{k+1}, \dots, a_{k+m}}].$$

Properties

Theorem: There is a **unique correspondence** between a real number and a continued fraction, which is either finite or infinite.

Theorem: A **quadratic irrational** is a real number that can be exactly represented by a **periodic continued fraction**.

Our solution

In order to compare exactly two QIs, we use **periodic continued fractions**. Given two triplets of integers, representing two QIs, we calculate their corresponding periodic CFs. By examining the terms of these CFs, we obtain the comparison result. The algorithm is described as follows:

Two QIs are given with their corresponding CFs, such that:

$$Q_1(p_1, q_1, r_1) = [a_0; a_1, a_2, \dots],$$

$$Q_2(p_2, q_2, r_2) = [b_0; b_1, b_2, \dots].$$

Let $k \in \mathbb{Z}_+$ be the smallest index for which a_k is unequal to b_k . Then,

1. $Q_1 = Q_2$ if and only if $p_1 = p_2$, $q_1 = q_2$ and $r_1 = r_2$,
2. $Q_1 < Q_2$ if $E < 0$,
3. $Q_1 > Q_2$ if $E > 0$,

where $E = (-1)^k (a_k - b_k)$.

Advantage: This method does not need to compute all the terms of the CF expansions. The comparison is made for each pair of terms (a_i, b_i) in ascending order; it stops when $a_i \neq b_i$. There must be an i such that $a_i \neq b_i$, otherwise $Q_1 = Q_2$.

Recursive computing of continued fraction

Let us consider the CF of a QI: $Q(p_0, q_0, r_0) = [a_0; a_1, a_2, a_3, \dots]$. The following function is used to calculate the $i + 1$ -th term a_{i+1} of Q .

Function Calculate $i + 1$ -th term of the CF of a QI

Input: A quadruplet of integer: q_0, a_i, p_i and r_i

Output: A triplet of integer: a_{i+1}, p_{i+1} and r_{i+1}

$$p_{i+1} \leftarrow a_i r_i - p_i$$

$$r_{i+1} \leftarrow \frac{q_0 - p_{i+1}^2}{r_i}$$

$$a_{i+1} \leftarrow \lfloor \frac{p_{i+1} + \sqrt{q_0}}{r_{i+1}} \rfloor$$

Note: It is assumed that q_0 is not a perfect square.

Important remarks

1. The **algorithm complexity** depends on the number of terms of the periodic CF expansions to examine. In the worst case, it is the period of CF, which is $O(\sqrt{q} \ln q)$ for $Q(p, q, r)$.
2. The **largest partial denominator** a_i of the CF of $Q(p, q, r)$ is smaller than $2\lfloor Q \rfloor$.
3. We carried out a comparison with **IEEE floating point numbers**, on image $N \times N$ for $N=5, 10, \dots, 70$. We observed that this approximative approach exhibit an average error rate of 1.12% for all sorted hinge angles.
