Abstract

This contribution contains the 3D models of the set of Famennian conodont elements belonging to the species *Polygnathus glaber* and *Polygnathus communis* analyzed in the following publication: Renaud et al. 2021: Patterns of bilateral asymmetry and allometry in Late Devonian *Polygnathus*. *Palaeontology*, <https://doi.org/10.1111/pala.12513>.

Keywords: Conodonts, Late Devonian, *Polygnathus communis*, *Polygnathus glaber*

Submitted:2020-08-11, published online:2021-03-03. <https://doi.org/10.18563/journal.m3.126>

INTRODUCTION

This contribution presents 3D models of 64 Famennian (Late Devonian) conodont elements belonging to two *Polygnathus* species (see Table 1 and Fig. 1). All elements correspond

to platform (P1) elements, located at the rear of the conodont feeding apparatus. *Polygnathus communis* was sampled by 34 elements from two levels of the Col des Tribes section (CTB; Montagne Noire, France) (Girard *et al.* 2014) and *Polygnathus glaber* by 30 elements from one level of the Buschteich section (BUS; Saxo-Thuringia, Germany) (Girard *et al.* 2017). They illustrate the morphological variation between and within the species, including bilateral asymmetry and growth.

The 3D surface of these elements were used in a geometric morphometric analysis complementing an extensive 2D quantitative study (Renaud *et al.* 2021). Based on a set of sliding semi-landmarks located at the edge of the platform and on the carina, this study aimed at disentangling the different components of the morphological variation in Late Devonian *Polygnathus* P1 elements. The 3D morphometric analysis improved the description of the geometric changes involved in growth and bilateral asymmetry and provided evidence that the balance between the two components of shape variance varies across species. Allometry was most pronounced in *Polygnathus communis*, leading from small, heart-shaped to large, lanceolate platforms. In contrast, bilateral asymmetry was most pronounced in *Po. glaber*, suggestive in this species of a strict directional asymmetry. On the mean shape of left elements, the posterior margin extended more ventrally, the posterior platform was more elevated and displayed a shallower groove, as confirmed by the example of actual elements (Fig. 1). The reverse is true for the right element, with, however, less offset between the ventral extension of the posterior and anterior margins. Knowing that the left blade is assumed to insert behind the right one, based on existing clusters (Donoghue and Purnell 1999; Martínez-Pérez *et al.* 2016), the geometric differences between right and left elements, evidenced on the 3D models, could be associated with the asymmetrical pairing of the elements during occlusion.

METHODS

Digitization of the specimens was performed using an X-ray microtomograph (μ CT) Phoenix nanotomeS on the AniRA-Immos platform of the SFR Biosciences (UMS 3444, ENS Lyon) at a cubic voxel resolution of 1 μ m. The scanning parameters were as follow: 100 kV, 70 μ A, 3000 projections at 360° with no filter. The 3D surfaces were extracted semi-automatically within AVIZO 9 (Thermofisher Scientific) using the segmentation threshold selection tool. The 3D surfaces are provided in .ply format, and can therefore be opened with a wide range of freeware.

ACKNOWLEDGEMENTS

We acknowledge the contribution of SFR Biosciences (UMS3444/CNRS, US8/Inserm, ENS de Lyon, UCBL) AniRa-ImmOs facility. We particularly thank Mathilde Bouchet for her kind assistance during the scanning sessions. The research was supported by the ANR ECODEV (ANR-13-BSV7-005) and the Project Marcon (Labex CeMEB). This is contribution ISEM 2020-226.
