## Apophis 2029: Decadal Opportunity for the Science of Planetary Defense

### Executive Summary:

Many advancements in planetary science are achieved by seizing upon the opportunity created by rare natural events (e.g. comet Shoemaker-Levy 9 Jupiter impact; 1994) and by planned physical interactions (e.g. Deep Impact into comet Tempel 1; 2005). A forthcoming opportunity to seize upon a natural physical “experiment” occurs on April 13, 2029 with the unprecedentedly close Earth encounter by the large 340m asteroid (99942) Apophis. On that date, nature is performing the “experiment” of subjecting the physical body of Apophis to Earth’s tidal torques as it approaches to within 31,000 km of Earth’s surface, a distance that is *closer than orbiting geosynchronous satellites*.

A potentially hazardous asteroid (PHA) as large as Apophis encountering Earth this closely (within 0.1 lunar distances) is, on average, a *once-per-thousand year event*. (In context, Apophis is 7 times larger and 350 times more massive than the Tunguska 1908 impactor; 5000 times more massive than Chelyabinsk 2013.) Because of this event’s incredible rarity, knowledge gained through measurements and outcomes of the Apophis 2029 “natural experiment” are clearly a *decadal*, if not millennial, opportunity for planetary science. Most specifically, this knowledge opportunity is for the science supporting planetary defense. Further, on April 13, 2029 all of Earth will be watching: Apophis will be visible to the naked eye speeding across the evening sky for an estimated *2 billion people* spanning western Europe and northern Africa.

In this White Paper we outline our current best understanding, and uncertainties, for scientific advances in the physical study of potentially hazardous asteroids that may be achievable by measuring physical changes of Apophis’ spin, surface structure, and/or shape configuration in response to Earth’s tidal torques. If tidal torques themselves, or surface configuration changes induce any measurable seismic vibration signal inside Apophis, a new field of asteroid seismology has the potential to be born. *Over six decades of planetary science*, seismology has been achieved beyond Earth for *only two* planetary worlds: Moon and Mars.

With this White Paper, we take no position on how to implement specific investigations capable of achieving the science advances offered by the Apophis 2029 opportunity. Instead we advocate that competitive selection of investigations, be they theoretical or observational (ground-based, space-based, or *in situ*), be executed under the direction of NASA’s Planetary Defense Coordination Office, with a projected and perhaps necessarily augmented budget capable of supporting them. International collaboration is strongly encouraged.

Thus, summarizing in four specific points, we urge the framers of the Decadal Survey to:

- **Recognize the decadal, if not millennial, opportunity for the science of planetary defense presented by the Apophis 2029 once-per-thousand-year “natural experiment.”**
- **Prioritize as a top-level planetary defense science goal modeling and measuring the physical outcome on Apophis exerted by Earth’s tidal torques so as to achieve the greatest possible new insights into the physical nature, including the internal structure, of PHAs.**
- **Recognize that *time is of the essence* for defining and implementing investigations of physical effects on Apophis, particularly if *in situ* measurements are to be considered. An Apophis 2029 Science Definition Team may be prescribed.**
- **Recognize that the achievable knowledge of PHAs presented by the Apophis 2029 opportunity could have immeasurable benefits to the future of humanity, in the highly unlikely, but not impossible necessity to mitigate a future impact threat.**

## Apophis 2029: Decadal Opportunity for the Science of Planetary Defense

### 1 Asteroid Close Encounters: Separating Fact from ‘Media Sensation’

Weekly, if not daily, news stories declare warnings of impending asteroid “close encounters” with Earth. While tabloids are easily dismissed, mainstream media outlets are not immune, even for objects passing more than 10 lunar distances away (**Figure 1**). The cacophony of asteroid sensationalism by the media dulls the context for truly spectacular close encounter opportunities.

**Figure 2** displays a timespan of two centuries to give context for the frequency of known asteroid encounters *within less than one-half lunar distance*. Objects a few meters in size pass inside the lunar distance weekly, and the modern uptick in their discovery efficiency is apparent in the data. However, over this two-century window, one event spectacularly stands out.

### 2 Apophis April 13, 2029: A Decadal *If Not Millennial* Close Encounter Opportunity

As shown in **Figure 2**, the 340m asteroid Apophis is the largest known object encountering Earth within 0.1 lunar distance over the span of two centuries (Brozović 2018). Apophis is 7 times larger and 350 times more massive than estimates for the Tunguska 1908 impacting body (Robertson & Mathias 2019) and 5000 times more massive than Chelyabinsk (Popova 2013).

On April 13, 2029 (a Friday), Apophis approaches within 31,000 km of Earth’s surface, a miss distance that is *closer than orbiting geosynchronous satellites*. Time averaged, an object as large as Apophis approaches Earth within 0.1 lunar distance approximately once-per-thousand years, making Apophis 2029 a once-per-millennium type of science opportunity. In fact, we can also expect that all of Earth will be watching. In the early evening hours of April 13, 2029 Apophis’ rapid trek across the sky (brightening to 3<sup>rd</sup> magnitude) will be visible to the unaided eye for an estimated *2 billion people* spanning western Europe and northern Africa.

### 3 Apophis 2029: Decadal Opportunity for the Science of Planetary Defense

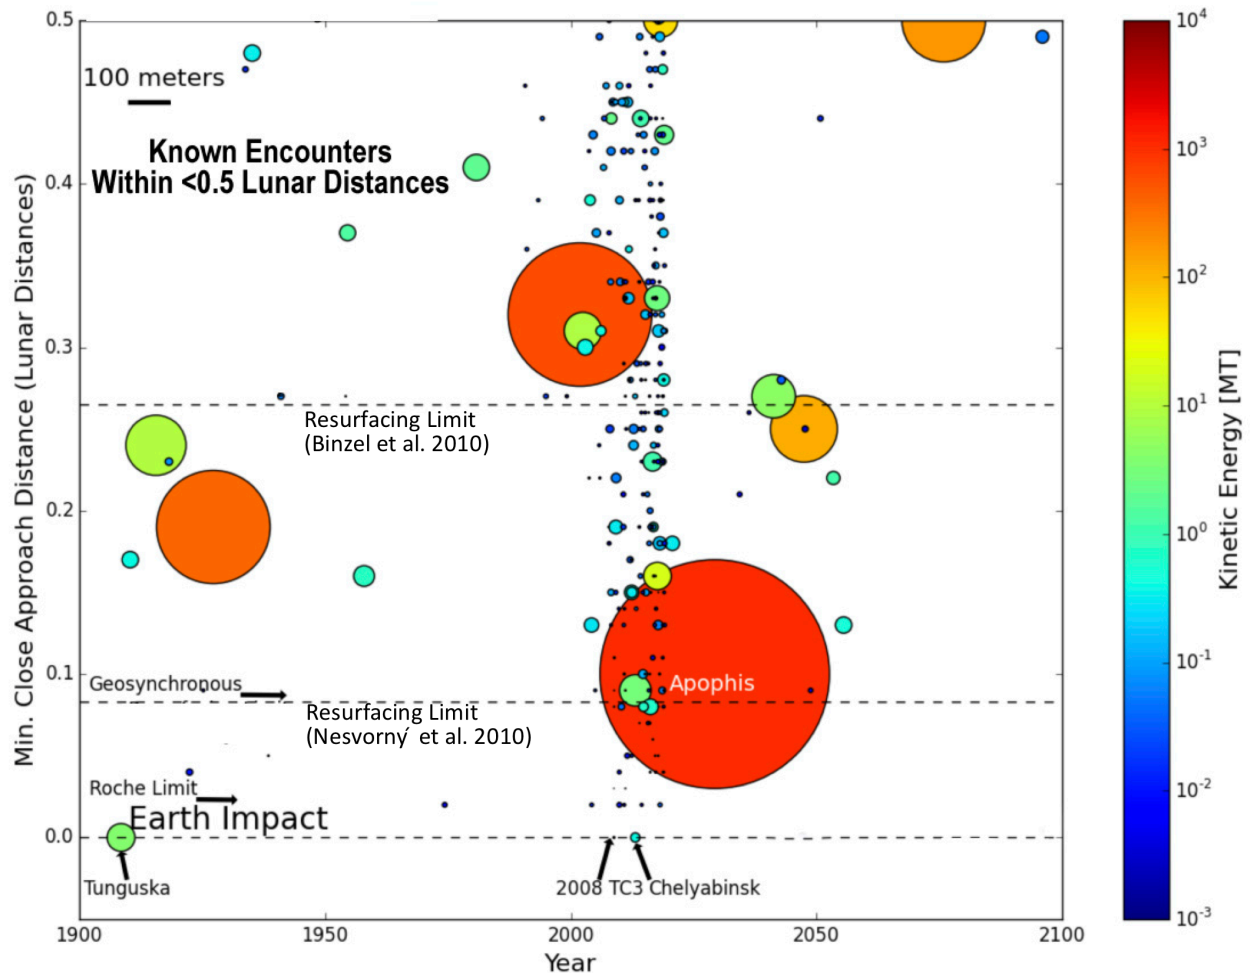

The science opportunity of the Apophis 2029 encounter arises not only because of the proximity for Earth observers. *The Apophis 2029 encounter presents an unprecedented science opportunity because of the Earth’s physical interactions on the body of Apophis itself.* At its geocentric miss distance of six Earth radii, Apophis will pass well outside the canonical Roche limit (~2 planetary radii). Recall however, that the Roche limit describes *destruction* of a passing body. At a miss distance of six Earth radii, significant tidal torques will be exerted on the body of Apophis. The consequences of Earth’s tidal torques on Apophis include altering its rotation state, with the possibility of creating internal structural alteration within the asteroid itself, possibly resulting in measurable seismic waves and real-time surface disturbances.

As discussed in Section 5, considerable uncertainty remains in predicting which, if any, of these observable effects will occur on Apophis and be measurable within the precision limits of applicable technology. The greatest uncertainty factor for the outcome is the lack of knowledge of the internal structure of potentially hazardous asteroids. Thus, we urge the framers of the Decadal Survey to *recognize the Apophis 2029 encounter as a “natural experiment” whose measurable outcomes could be transformative in understanding the internal structure for PHAs.*

Herein we argue that the Apophis 2029 encounter event has an historical planetary science parallel: The 1994 Jupiter impact by comet Shoemaker-Levy 9 (SL9). Significant resources were allocated and extensive observational campaigns were organized for reasons that included: i) the event was unprecedented to modern science and modern measurement technology;

**FIGURE 1:** June 2020 example of mainstream media carrying “asteroid alert” stories that dull attention from meaningful close approach events. Despite the depiction shown, 2002 NN4 missed the Earth by  $>13$  lunar distances.

**FIGURE 2:** A two-century view (1900 to 2100) of known Earth-approaches within 1/2 the lunar distance. Apophis 2029 stands out as an extremely rare event. Object sizes are depicted according to the scale bar, top left. For the “news story” object 2002 NN4 shown in Figure 1), its miss distance is off the scale of this figure by a factor of 25.

[Figure from R. P. Binzel, A.M. Earle; *Planetary Defense Conference 2019*. Data are from NASA/JPL Center for NEO Studies <https://cneos.jpl.nasa.gov/ca/>, Low orbital certainty data omitted.]

ii) the SL9 impact was a “natural experiment” whose outcome was unpredictable and ultimately surprising, see Table I; iii) detailed observations and measurements of the impact consequences promised (and delivered) interdisciplinary advances in understanding the structure of comets, the structure and chemistry of Jupiter’s atmosphere, and impact physics. Further, the “impact” of SL9 on public and Congressional awareness of asteroid hazards cannot be understated.

Herein we also point out precedents for planetary science *mission expenditures* up to the level of Discovery Class missions for conducting *active experiments*: Deep Impact into Tempel 1; Double Asteroid Redirection Test (DART). *For each, the mission motivation was driven by the potential new knowledge to be gained by resolving the wide-ranging uncertainty of the outcome.* Thus, we argue for Apophis 2029: The uncertainty of the outcome creates a strong motivation to seize upon this unprecedented learning opportunity for insights into the physical characteristics of potentially hazardous asteroids. This argument also revolves around a central motivation for planetary defense itself: In the highly unlikely, but not impossible necessity to mitigate a future asteroid threat, the physical insights gained from the Apophis 2029 encounter could be one of the most important science products ever delivered to humanity by planetary science investigations.

#### 4 Implementation of Apophis 2029 Investigations

Within this White Paper, we take no position on how to implement specific prediction or observational investigations capable of achieving measurement and science advances offered by the Apophis 2029 opportunity. (Rationale for *in situ* investigation are given by Barbee 2020; Cheng 2020. Taylor 2020 describes the essential role of radar; Haynes 2020 describes the potential of radar tomography.) As outlined in Section 5, predictions for measurable outcomes are highly uncertain at this time. We advocate the knowledge potential of the Apophis 2029 opportunity *merits a directed Science Definition Team study.* We note particularly that time is of the essence for considering *in situ* measurements. For example, a student-led study (*MIT Project Apophis*, 2017) identified low cost mission opportunities opening as early as 2026.

While planetary science expertise and techniques enable the path forward, we argue that the new knowledge gained has its greatest value to the science of planetary defense. In colloquial terms, Apophis is the “Poster Child for Planetary Defense.” For this reason, we advocate that Apophis 2029 investigations be supported under NASA’s Planetary Defense budget, in accordance with a specific recommendation of the Melosh (2019) National Academy Report:

“Missions meeting high-priority planetary defense objectives should not be required to compete against missions meeting high-priority science objectives.”

We thus propose as a Decadal Report recommendation: *Competitively selected or directed Apophis science investigations, be they theoretical or observational, ground-based, space-based, or in situ, be executed under the direction of NASA’s Planetary Defense Coordination Office (PDCO).* Commensurate with this recommendation, an appropriate budget must be allocated within the NASA Science Mission Directorate that is capable of specifically supporting Apophis investigations. International collaboration is strongly encouraged. We note that the PDCO is currently supporting, and should be encouraged to continue support, international planning efforts toward the Apophis 2029 opportunity.

#### 5 Apophis 2029 Model Predictions, Science Implications, Measurements and Uncertainties

While Apophis is coming for certain, and it will miss the Earth for certain, the actual physical consequences of the encounter on Apophis itself are *uncertain.* As noted in Section 3, the Apophis 2029 miss distance of 6 Earth radii is outside the canonical Roche limit (for destruction), but still close enough to subject the physical body of Apophis to tidal torques.

**Table I** summarizes a variety of physical effects that have been studied to date by a variety of independent models. {Covid-19 Note: A more detailed compilation was to be a product of a

planned *Apophis T-9 Workshop* in April 2020, postponed to November 2020.} As a first table entry, the 2029 encounter will result in Apophis undergoing a definitive orbit change (semi-major axis altered from 0.9 AU to >1 AU; Farnocchia et al. 2013). Current models are also certain for a change occurring in Apophis’ rotational properties (e.g. Scheeres et al. 2005; see Table I). Apophis is presently in a tumbling non-principal axis state with precession and rotation periods of 27.38h and 263h, respectively (Pravec et al. 2014; Brozović et al. 2018). The tumbling state of Apophis may be a result of torques exerted during one or more previous (but not calculable with precision) Earth encounters. As Apophis experiences new torques on its angular momentum vectors during the 2029 encounter, the physical (and observable) consequences of the new body axis misalignments remain uncertain (e.g. Yu et al. 2014). In the most substantial case, any re-arrangement of Apophis’ (presumed) interior rubble pile structure could result in a gross reconfiguration of its shape. Models to date (e.g. Scheeres et al. 2020), however, deem that a gross reconfiguration is unlikely for such a “far” encounter outside of the canonical Roche limit.

Minor internal reconfigurations, or just the body’s adjustment to a new rotation state, has the potential to spur downslope movement of regolith and/or generate seismic waves inside of Apophis (Souchay et al. 2014, 2018; Yu et al. 2014; DeMartini et al. 2019). Beyond Earth, natural seismic waves have been measured for only two planetary bodies in the history of solar system exploration: Moon by *Apollo* and Mars by *InSight*. In the context of priorities set by past Decadal Surveys for seismological investigations, and the considerable planetary mission expense allocated toward achieving these seismic measurements, we propose a specific finding:

***The potential for measuring seismic waves in Apophis, thereby providing the first direct insight into the internal structure of a potentially hazardous asteroid, is the most enticing and transformative outcome that may be achievable through Apophis 2029 investigations.***

Observational evidence supports finding that planetary encounters outside of the Roche limit generate enough (presumably) seismic activity to rearrange the upper surface layer (Binzel et al. 2010). Terentjeva (2014) suggests a possibly associated meteor stream. “Refreshing” by Earth encounters was suggested by Nesvorný et al. (2005) and subsequently modeled by Nesvorný et al. (2010). The ‘seismic limit’ inside which the encounter is close enough to effect surface changes is uncertain, with Binzel et al. (2010) finding spectrally fresh surfaces consistent with a limiting distance inside of ~15 Earth radii. More detailed theoretical modeling by Nesvorný et al. (2010) places the ‘seismic limit’ inside of ~5 Earth radii. We note that the Apophis 2029 encounter is inside or very close to these suggested thresholds for tidally induced seismicity.

As noted in Section 4, within this White Paper we take no position on any methodology that should be employed or any architecture for executing Earth-based and/or *in situ* investigations. *Entries on methodology in Table I are purely notional in order to demonstrate the range of potential options.* Detailed efforts moving forward are needed, both in terms of physical prediction and technological capabilities, to create science definitions for what may be achieved through Apophis 2029 measurements. *The Decadal Survey report may consider prescribing the formation of an Apophis 2029 Science Definition Team to discern the achievable objectives.* As argued in Section 3, uncertainties in the outcome is a strong driver for making direct measurements of a completely new phenomenon. However, because the uncertainties may include the possibility of no measurable outcome, *we recommend science definitions of measurement objectives should include a science value assessment for meaningful constraints gained on the physical nature of PHAs in the event that any attempted investigation yields a null result (signal below the limit of measurement sensitivity).*

## 6 Precedents and Lessons in Planetary Science: Applications to Apophis 2029 Planning

The lower sections in **Table I** recall the state of predictions in advance of previous “experiments:” the 1994 Jupiter impact of comet Shoemaker-Levy 9 and the 2005 Deep Impact penetration of Tempel 1. The parallels to Apophis 2029 are striking in the considerable range of uncertainties in outcomes up until the moment each “experiment” occurred. The lesson is that *only through dedicated planning and measurement can the true outcome be learned, and from that outcome, considerable new insights be gained into the physical nature of planetary bodies.* Apophis is coming. Will we be ready? It’s up to you to make Apophis 2029 a Decadal priority.

| Physical Effects on Apophis   | Degree of Certainty <sup>a</sup>                    | Implications of Measurement  | Possible Measurement Methods <sup>b</sup>      |  |
|---|---|--|--|--|
|   |   |  | Earth-based                                    | <i>In situ</i>   |
