Abstract

Mechanical allodynia, a painful sensation caused by innocuous touch, is a major chronic pain symptom, which often remains without an effective treatment. There is thus a need for new anti-allodynic treatments based on new drug classes. We recently synthesized new 3,5-disubstituted pyridin-2(1*H*)-one derivatives. By substituting the pyridinone at the 3-position by various aryl/heteroaryl moieties and at the 5-position by a phenylamino group, we discovered that some derivatives exhibited a strong anti-allodynic potency in rats. Here, we report that varying the substitution of the pyridinone 5-position, the 3-position being substituted by an indol-4-yl moiety, further improves such anti-allodynic potency. Compared with **2**, one of the two most active compounds of the first series, eleven out of nineteen newly synthesized compounds showed higher anti-allodynic potency, with two of them completely preventing mechanical allodynia. In the first series, hit compounds **1** and **2** appeared to be inhibitors of p38 α MAPK, a protein kinase known to underlie pain hypersensitivity in animal models. Depending on the substitution at the 5-position, some newly synthesized compounds were also stronger p38 α MAPK inhibitors. Surprisingly, though, anti-allodynic effects and p38 α MAPK inhibitory potencies were not correlated, suggesting that other biological target(s) is/are involved in the analgesic activity in this series. Altogether, these results confirm that 3,5-disubstituted pyridine-2(1*H*)-one derivatives are of high interest for the development of new treatment of mechanical allodynia.

1. Introduction

Pain is one of the most common reasons for seeking medical care, and pain management should be considered as a major public health concern [1]. The capacity to experience acute pain has a protective role. By contrast, persistent, chronic pain initiated by tissue damage/inflammation (inflammatory pain) or nervous system lesion (neuropathic pain) offers no biological advantage and causes suffering and distress. Chronic pain affects more than 20% of Europeans and costs several hundred billions each year in medical treatments and societal burden [2]. Currently available therapies are not always effective (some pathologies lack efficacious analgesic solution) and can produce side-effects or have abuse potentials, such as opioid pain relievers. Chronic pain thus constitutes an unmet medical need: it is critical to discover more effective and safer treatments, with novel drug classes and modes of action.

Chronic pain syndromes are characterized by persistent pain hypersensitivity. This includes spontaneous pain, hyperalgesia and allodynia (pain in response to normally innocuous stimuli). It is now well established that each of these pain symptoms relies on different cellular and molecular mechanisms. Peripheral sensitization of nociceptors is obviously involved in acute pain and its transition to chronic pain [3]. However, the role of central sensitization – *i.e.* enhancement in the function of neurons and circuits in central pain pathways – in the manifestation of pain symptoms is increasingly recognized [4].

Protein kinases represent an important class of signaling proteins that are involved in numerous cellular process and act in the coordination of responses to extra- and intracellular signals, such as controlling cell growth and proliferation. Thus, numerous protein kinase inhibitors reached the market as anticancer drugs [5]. However, due to their pleiotropic role, protein kinases can be targeted for other application such as the treatment of pain [6–8]. It appears that some protein kinases are pivotal in the setting of central sensitization. Activation of several protein kinases, including the neuronal extracellular signal-regulated protein kinases (ERK), the γ isoform of protein kinase C (PKC γ) and the microglial p38 mitogen-activating protein kinase (p38), within the superficial spinal dorsal horn or medullary dorsal horn were shown to contribute to pain hypersensitivity. Thus, in animal models (rats, mice), local administration of protein kinase inhibitors produced analgesic effects. For example, targeting p38 [9,10] suppresses spontaneous pain behavior (formalin test). Inhibition of ERK [11], PKC γ [12–15], and p38 [16–18] prevents inflammatory mechanical allodynia (MA). Application of p38 inhibitors [18–21] can also reduce neuropathic MA. Thus, protein kinases appear to be relevant biological targets for developing new analgesics.

As part of our ongoing program dedicated to the design and synthesis of small molecules with potent protein kinase inhibitory activities and analgesic properties, we previously reported the identification of a new 3,5-disubstituted pyridin-2(1*H*)-one series with potent *in vivo* activity in rat models of inflammatory and neuropathic MA [18]. The best anti-allodynic agent of the series (compound **2**, Fig. 1A) was screened toward a panel of 62 protein kinases leading to the identification of p38 α as a potential biological target (Fig. 1B). In addition, **2** was selective of p38 α over protein kinases representative of the human kinome or close to p38 α in the kinome phylogenetic tree. IC₅₀ values toward p38 α , determined for the two best anti-allodynic agents, showed moderate inhibitory potency in the micromolar range (compounds **1** and **2**, Fig. 1A).

This work describes the enlargement of the structure-activity relationship study (SAR) performed on this series, in order to identify new compounds with improved *in vivo* anti-MA potency. Synthesis of new analogues, *in vivo* assessment of the antiallodynic effect, and evaluation toward p38 α MAPK are described.

2. Results and discussion

2.1. Synthesis of novel analogues

According to the good results obtained *in vivo* with compounds **1** and **2**, we decided to extend our structure-activity relationship study. In the previous series, position 3 of the pyridinone core was diversely arylated/heteroarylated whereas position 5 was substituted by a phenylamino group. Therefore, in the present work, we synthesized more analogs by varying the substituent at position 5, while the 3-substitution remained unchanged. At this position, indol-4-yl moiety was selected because of the high *in vivo* activity of compound **1** bearing this heterocycle, and for synthetic feasibility. For the majority of new compounds, we used the synthetic pathway described in our previous work (Scheme 1, Table 1, pathway 1). Thus, the amino group of pyridine derivative **3** was substituted in the presence of iodinated aryl/heteroaryl coupling partners in the presence of palladium acetate, Xantphos and cesium carbonate, leading to products **4–19** in yields ranging from 50% to 90%. The next step was a Suzuki cross-coupling using pinacol boronate **20** to give compounds **21–36** in good overall yields. For compounds **40–42** bearing a bromophenylamino group at the 5-position, to prevent regioselectivity issues due to competing bromoaryl moieties, Buchwald-Hartwig and Suzuki-Miyaura coupling steps were reversed, leading to synthetic pathway

2 (Scheme 1, Table 1). Compound **37**, we previously reported [18], was substituted by the indol-4-yl group leading to **38** in 81% yield. Reduction of the nitro group led to **39** and Buchwald-Hartwig coupling produced compounds **40–42** in moderate yields.

2.2. Biological activity of compounds **43–55** and **57–63**.

2.2.1. *In vivo* assessment of anti-allodynic effect.

We compared the *in vivo* efficacy of new compounds **43–45**, **47–55** and **57–63** with that of compound **2**, one of the most active compounds of the first series [18] (Fig. 1), on the facial Complete Freund's Adjuvant (CFA) model (Fig. 2) [15]. Compound **46** was not tested due to its insufficient solubility. Similarly, compound **56** was not assayed due to an HPLC purity <95%, despite its apparent good ¹H NMR spectra. After receiving a subcutaneous injection of CFA (25 µL; 2.5 mg/kg) into the right vibrissa pad, rats develop a facial MA that lasts days. We found that all intracisternally (i.c.) applied compounds prevented the development of inflammatory MA. However, it is difficult to draw conclusions about the structure-activity relationships. Nevertheless, compared with compound **2**, most of the nineteen newly synthesized compounds produced equal (three compounds: **48**, **52** and **59**) or enhanced MA inhibition (≥ 80% inhibition of allodynic score; eleven compounds: **44**, **45**, **47**, **49**, **50**, **53–55**, **57**, **58** and **60**), including two compounds (**55** and **60**) which completely prevented MA. Notably, there were also two compounds (**43** and **51**) with much less anti-MA efficacy than compound **2**. Therefore, according to these results, the nature of the arylamino group at the pyridinone 5-position appears to greatly impact on the capacity of compounds to prevent MA. The presence of a nitrogen atom (**60**) or highly polar nitro group (**55**) at the aryl 4-position provided compounds with the strongest anti-allodynic effects. On the other hand, bromine atom (**63**), ethoxycarbonyl (**48**) or methoxyl (**51**) groups at the very same position drastically reduced the anti-allodynic activity of the corresponding compounds. This confirms that

the nature of the atom/group at this place is critical for MA inhibition. Various substituents at the phenyl 2-, 3-, or 4-positions are also consistent with strong anti-allodynic activity (> 80%, larger than that of compound **2**) such as 2- and 3-nitro (**53**, **54**), 3-methoxyl (**50**), 2-methyl (**57**) groups, 3-F and 4-F atoms (**44**, **45**) or when the phenyl group was replaced by a pyridin-2-yl moiety (**58**). In summary, compared with **2**, compounds **55** and **60** are the most interesting compounds of the new series, with an enhanced effect and a complete MA inhibition.

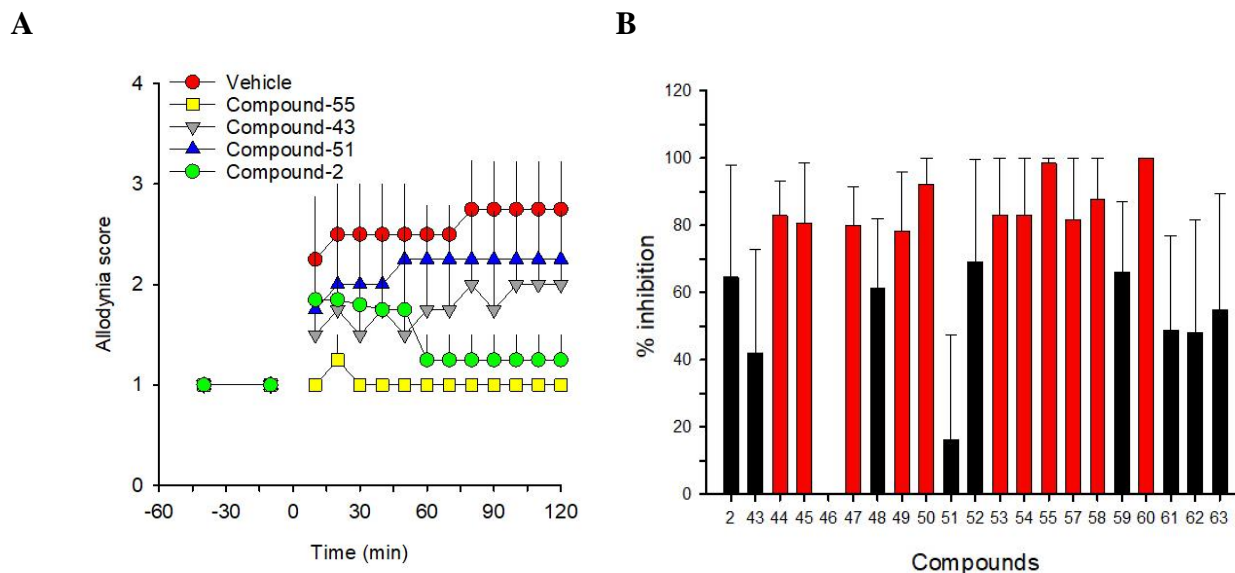

Figure 2. Intracisternal (i.c.) application of new 3,5-disubstituted pyridin-2(1H)-one derivatives prevent MA in a rat model of facial inflammatory pain (Complete Freund's Adjuvant; CFA). **A.** I.c. application of compounds **2**, **43**, **51** or **55** variably prevents inflammatory MA. Time courses of changes in behavioral responses (allodynic score) evoked by static mechanical stimuli (6-g von Frey filament) applied on the face of rats intracisternally treated with compounds **2**, **43**, **51** or **55** or vehicle. Compound **51** produced a 16% inhibition, compound **43**, a 42% one and compound **55**, an almost complete inhibition (98%), therefore stronger than that of compound **2** (65%) of inflammatory MA. **B.** I.c. application of compounds **2**, **43–45**, **47–55** or **57–63** prevents inflammatory MA. Bar histograms summarizing MA inhibitions by compound **2**, one of the two most active compounds of the first series, and new compounds **43–45**, **47–55** and **57–63**. Compounds **55** and **60** almost completely (98%) or completely (100%) inhibited inflammatory MA, respectively. In **A** and **B**, compounds (5 μ L at 10 μ M) or vehicle were intracisternally injected 30 min before CFA subcutaneous injection (at time 0 in **A**). Results are presented as mean + s.e.m.; n = 4 rats (**A**) and n = 4 rats (**B**, except compound **48**: n = 1 rat and compound **59**: n = 2 rats) in each group. Allodynic score (from 0 to 4) according to Vos *et al.* [23]. MA score in each group of treated rats is compared with that in control rats (injected with vehicle) using the unpaired Student *t* test. Red bars: MA score in treated rats vs. MA score in control rats: *P* < 0.05. Thus, when using such low doses of compounds (5 μ L at 10 μ M), 11 compounds of this second series (**44**, **45**, **47**, **49**, **50**, **53–55**, **57**, **58** and **60** – but not compound **2**, one of the two most potent compounds of the first series), significantly inhibit MA. For the computing of MA inhibition, see 4. Experimental section.

2.2.2. p38 α MAPK inhibitory potency.

Compounds **43–55** and **57–63** were evaluated for their p38 α MAPK inhibitory potency (International Center for Kinase Profiling, ICKP, Dundee, Scotland) [24]. First, compounds **43–55** and **57–63** were screened at a concentration of 1 μ M (Table 3) and IC₅₀ values were determined when the percentage of p38 α residual activity was found <50% at this concentration. Compared to previous results obtained from compounds **1** and **2**, data showed improved kinase inhibition for

fluorinated derivatives **43** and **45**, *meta*-phenol **52**, *ortho*-tolyl **57** and *meta*-bromophenyl derivative **62**. Conversely, ethyl ester and nitro derivatives (**46–48**, **53–55**) were almost inactive whereas pyridinyl analogues **58–60** showed low potency at 1 μ M. Thus, best IC₅₀ values were found in the submicromolar range for compounds **43**, **45** and **62**, with an improved potency compared to compounds **1** and **2**.

2.2.3. Correlation anti-allodynic potency/p38 α MAPK inhibition.

We next examined whether the *in vivo* antiallodynic potency of compounds was correlated with their inhibitory effects toward p38 α MAPK. Surprisingly, there was no correlation. For example, compound **60**, exhibiting the strongest antiallodynic activity, showed only a modest p38 α MAPK inhibition (33% inhibition at 1 μ M), lower than that of compound **2** (41% inhibition at 1 μ M). Conversely, compound **43**, the best p38 α MAPK inhibitor, with an IC₅₀ value of 0.23 μ M (72% inhibition at 1 μ M) only produced 42% inhibition of MA (Fig. 2A). These results cannot be explained only by a cellular localization/penetration difference of the various compounds, but strongly suggest that other(s) biological target(s) is/are involved in the anti-allodynic activity, without ruling out p38 α MAPK inhibition.

3. Conclusion

In a work aiming at designing novel anti-allodynic drugs, we synthesized a new series of pyridine-2(1*H*)-one derivatives in three or four steps from precursors **3** and **37**, respectively. The heterocyclic core was substituted at the 3-position by an indol-4-yl moiety whereas the 5-position was substituted by various aryl/heteroaryl amino moieties. Compared with compound **2**, one of the two most active compounds of the previously reported series, most of the new derivatives (eleven out of nineteen) were more potent in preventing MA. Moreover, two of them completely suppressed MA in the conditions used. We also investigated the biological target(s) involved in such anti-allodynic potency. Since previously reported derivatives appeared to be selective p38 α MAPK inhibitors, the new compounds were assessed for their p38 α MAPK inhibitory activity. Some of them exhibited submicromolar p38 α MAPK inhibitory potency. Their *in vitro* efficacy depended on the substitution at the 5-position and could be stronger than that of compound **2**. Surprisingly, though, anti-allodynic effects and p38 α MAPK inhibitory potencies were not correlated, suggesting that other biological target(s) is/are involved in the analgesic activity in this series. Additional *in vivo* and *in vitro* work to identify this/these target(s) as well as to test other routes of administration (*e.g.* systemic) and assess putative adverse effects such as motor impairment or sedation – of note, we used very low doses and animals behaved normally – is under progress. Thus, these results show that, compared with our first series of pyridin-2(1*H*)one derivatives, substitution at the 5-position can improve the anti-allodynic potency. They confirm that, altogether, pyridin-2(1*H*)one derivatives are of high interest for the development of novel analgesics for the treatment of MA.

4. Experimental section

4.1. Chemistry.

4.1.1. General. Starting materials were obtained from commercial suppliers and used without further purification. IR spectra were recorded on a Perkin-Elmer Spectrum 65 FT-IR spectrometer ($\bar{\nu}$ in cm⁻¹). NMR spectra, performed on a Bruker AVANCE 400 III HD (¹H: 400 MHz, ¹³C: 101 MHz) are reported in ppm using the solvent residual peak as an internal standard; the following abbreviations are used: singlet (s), doublet (d), triplet (t), quadruplet (q), doublet of doublets (dd), doublet of doublet of doublets (ddd), doublet of doublet of doublet of doublet (dddd), doublet of triplets (dt), triplet of doublets (td), multiplet (m), broad signal (br s). Coupling constants are expressed in Hertz. High resolution mass spectra were determined on a high-resolution Waters Micro Q-ToF or Thermo Scientific Q Exactive Q-Orbitrap apparatus (UCA Partner, Université Clermont Auvergne, Clermont-Ferrand, France). Chromatographic purifications were performed by column chromatography using 40–63 μ m silica gel. Reactions were monitored by TLC using fluorescent silica gel plates (60 F254 from Macherey Nagel). Melting points were measured on a Stuart SMP3 apparatus and are uncorrected.

The purity of compounds **43–63** was established by HPLC analysis using an Agilent infinity 1260 chromatograph with DAD detector and an Agilent Zorbax SB-Phenyl column (4.6 mm x150 mm, 3.5 μ m). Flow rate was 0.8 mL/min and the analysis was performed at 25 °C. Detection wavelength is indicated for each compound. Solvents were (A) water/0.1% formic acid, (B) Acetonitrile. Gradient was 100:0 A/B to 30:70 A/B in 8 min and then 30:70 A/B for 3 min.

4.1.2. General procedures.

Procedure A: Buchwald-Hartwig cross-coupling between compound **3** and iodide derivatives.

A 5–9 mL screw-cap tube under argon was charged with compound **20** (1 equiv), Pd(OAc)₂ (0.05 equiv), Xantphos (0.05 equiv) and Cs₂CO₃ (2 equiv). Then, anhydrous 1,4-dioxane (amount for 0.2 M substrate concentration, unless otherwise indicated) degassed with argon and the iodide derivative (1 equiv) were added. The tube was sealed and the mixture was stirred at 100 °C for several hours. The resulting suspension was filtered through a pad of Celite which was then washed with ethyl acetate. After evaporation of the filtrate, the brown residue was purified by column chromatography.

Procedure B: Suzuki cross-coupling, conventional heating.

To a solution under argon of brominated derivative (1 equiv) in 1,4-dioxane (amount for 0.1 M substrate concentration) were added the indole-4-boronic acid pinacol ester **20** (1.5 equiv) and 2 M Na₂CO₃ aqueous solution (5 equiv). The mixture was degassed with argon for 10 min before the addition of PdCl₂(PPh₃)₂ (0.05 equiv). The solution was refluxed overnight. Ethyl acetate was added and the resulting mixture was washed with water. The organic phase was dried over MgSO₄ and filtered. After evaporation under reduced pressure, the crude was purified by column chromatography.

Procedure C: Debenzylation by BBr₃.

A solution under argon of benzylated compound (1 equiv) in anhydrous dichloromethane (amount for 0.02 M substrate concentration) was cooled to 0 °C (procedure C1) or to –10 °C (procedure C2). A solution of BBr₃ in dichloromethane (1 M, 4 equiv unless otherwise indicated) was added dropwise. The mixture was stirred at room temperature (C1) or at 0 °C (C2) in the dark. The reaction mixture was then quenched by addition of NEt₃ and methanol. After evaporation under reduced pressure, EtOAc was added. The mixture was washed with water and saturated aqueous NaCl solution, dried over MgSO₄ and filtered. After evaporation under reduced pressure, the crude was purified by column chromatography.

Procedure D: Debenzylation by catalytic hydrogenolysis.

To a solution under argon of benzylated derivative (1 equiv) in MeOH degassed with argon was added 20% Pd(OH)₂/C (0.08 equiv, unless otherwise indicated). The mixture was then hydrogenated at room temperature for 6 h in the dark. The mixture was filtered through a pad of Celite and then washed with ethyl acetate. The filtrate was evaporated under reduced pressure and the obtained crude was purified by column chromatography.

4.1.3. 6-(Benzyloxy)-5-bromo-N-(2-fluorophenyl)pyridin-3-amine (**4**)

Compound **4** was prepared according to general procedure A, starting from **3** (199 mg, 0.713 mmol) in 7 mL of anhydrous 1,4-dioxane. The mixture was heated for 20 h. The crude oil was purified by column chromatography (SiO₂, cyclohexane to EtOAc/cyclohexane 8:92) to give **4** (134 mg, 0.360 mmol, 50%) as a beige solid. *R*_f = 0.55 (EtOAc/cyclohexane 1:9); Mp 67 °C; IR (ATR) 3306, 1619, 1443, 1356, 1295, 1219, 1181, 1098, 1056, 1012, 733 cm⁻¹; ¹H NMR (400 MHz, DMSO-*d*₆) δ (ppm) 7.96 (s, 1H), 7.94 (d, *J* = 2.5 Hz, 1H), 7.73 (d, *J* = 2.5 Hz, 1H), 7.48–7.44 (m, 2H), 7.42–7.37

Compound **62** was prepared according to general procedure C2, starting from **41** (81 mg, 0.172 mmol). The mixture was stirred for 3 h 30 min. The reaction mixture was then quenched by addition of NEt_3 (21 equiv) and MeOH (7 equiv). The crude was purified by column chromatography (SiO_2 , $\text{CH}_2\text{Cl}_2/\text{MeOH}$ 97:3 to 94:6). After evaporation, the product was washed with CH_2Cl_2 to give **62** (44.7 mg, 0.118 mmol, 68%) as light green powder. $R_f = 0.31$ ($\text{CH}_2\text{Cl}_2/\text{MeOH}$ 95:5 + 0.5% NEt_3); Mp > 155 °C (decomposition); IR (ATR) 3500–3000, 1649, 1614, 1588, 1556, 1333, 892, 755 cm^{-1} ; ^1H NMR (400 MHz, $\text{DMSO}-d_6$) δ (ppm) 11.64 (br s, 1H), 11.15 (s, 1H), 7.77 (s, 1H), 7.50 (d, $J = 2.9$ Hz, 1H), 7.36 (dt, $J_1 = 8.0$ Hz, $J_2 = 0.9$ Hz, 1H), 7.35 (t, $J = 2.8$ Hz, 1H), 7.27 (d, $J = 7.2$ Hz, 1H), 7.26 (br s, 1H), 7.12–7.07 (m, 2H), 6.89 (t, $J = 2.1$ Hz, 1H), 6.82 (ddd, $J_1 = 7.9$ Hz, $J_2 = 2.1$ Hz, $J_3 = 1.0$ Hz, 1H), 6.73 (dd, $J_1 = 8.3$ Hz, $J_2 = 2.2$ Hz, 1H), 6.37–6.35 (m, 1H); ^{13}C NMR (101 MHz, $\text{DMSO}-d_6$) δ (ppm) 159.8 (C=O), 148.7 (C), 138.6 (CH), 136.1 (C), 131.1 (CH), 130.8 (C), 128.3 (CH), 128.1 (C), 126.1 (C), 125.4 (CH), 122.4 (C), 121.1 (C), 120.4 (CH), 120.0 (CH), 119.9 (CH), 115.6 (CH), 112.5 (CH), 111.0 (CH), 100.4 (CH); HRMS (ESI+) calcd for $\text{C}_{19}\text{H}_{15}\text{BrN}_3\text{O}$ ($\text{M}+\text{H}$) $^+$ 380.0393, found 380.0396; HPLC purity $\geq 99\%$, $t_R = 8.26$ min, $\lambda = 278$ nm.

4.1.60. 5-((4-Bromophenyl)amino)-3-(1H-indol-4-yl)pyridin-2(1H)-one (**63**)

Compound **63** was prepared according to general procedure C2, starting from **42** (74.8 mg, 0.159 mmol). The mixture was stirred for 3 h 30 min. The reaction mixture was then quenched by addition of NEt₃ (23 equiv) and MeOH (8 equiv). The crude was purified by column chromatography (SiO₂, CH₂Cl₂/MeOH 97:3 to 95:5). After evaporation, the product was washed with CH₂Cl₂ to give **63** (31.4 mg, 0.083 mmol, 52%) as yellow solid. *R*_f = 0.30 (CH₂Cl₂/MeOH 95:5 + 0.5% NEt₃); Mp > 167 °C (decomposition); IR (ATR) 3500–3000, 1651, 1610, 1586, 1556, 1487, 1333, 752 cm⁻¹; ¹H NMR (400 MHz, DMSO-*d*₆) δ (ppm) 11.61 (s, 1H), 11.14 (s, 1H), 7.68 (s, 1H), 7.49 (d, *J* = 3.0 Hz, 1H), 7.38–7.33 (m, 2H), 7.29 (d, *J* = 8.9 Hz, 2H), 7.26 (d, *J* = 7.2 Hz, 1H), 7.23 (br s, 1H), 7.09 (t, *J* = 7.7 Hz, 1H), 6.71 (d, *J* = 8.9 Hz, 2H), 6.36–6.34 (m, 1H); ¹³C NMR (101 MHz, DMSO-*d*₆) δ (ppm) 159.7 (C=O), 146.2 (C), 138.3 (CH), 136.1 (C), 131.8 (2CH), 130.8 (C), 128.2 (C), 127.6 (CH), 126.1 (C), 125.4 (CH), 121.7 (C), 120.4 (CH), 119.9 (CH), 115.6 (2CH), 110.9 (CH), 108.4 (C), 100.5 (CH); HRMS (ESI+) calcd for C₁₉H₁₅BrN₃O (M+H)⁺ 380.0393, found 380.0396; HPLC purity ≥ 97%, *t*_R = 8.27 min, λ = 278 nm.

4.2. Assessment of anti-allodynic activity

4.2.1. Facial Complete Freund's Adjuvant (CFA) model.

CFA (Becton Dickinson) was dissolved in saline solution containing Tween 80 and paraffin oil and conserved at 4 °C. For behavioral testing, animals were briefly (< 2 min) anesthetized using a mask with 2% isoflurane and received a subcutaneous injection of 25 μL of CFA (2.5 mg/kg,) solution into the right vibrissa pad using a 27 Ga needle coupled to a 25 μL Hamilton syringe, as described previously [15]. After recovery from anesthesia (< 2 min), rats were placed into an observation field (0.6 x 0.6 m square) under red light for mechanical testing. 6-g von Frey filament – a normally innocuous static mechanical stimulation – was gently applied every 10 min onto the orofacial region by a first experimenter for a 120 min mechanical testing period. Behavioral responses were observed and quantified by a second, blinded, experimenter (see below).

4.2.2. Intracisternal injection.

For investigating the effects of synthesized compounds upon CFA-induced MA, animals were briefly (≈ 3 min) anesthetized using a mask with 2% isoflurane and received an intracisternal injection of either compound (10 μM in 5 μL aCSF) or vehicle alone (aCSF + 1% DMSO) using a 10 μL Hamilton syringe [25]. aCSF consisted of 150 mM Na⁺, 3 mM K⁺, 0.8 mM Mg²⁺, 1.4 mM Ca²⁺, 155 mM Cl⁻, pH 7.4, 295 mosmol.kg⁻¹. After recovery (≈ 2 min), rats were placed in an observation field (0.6 x 0.6 msquare) under red light for a 30-min habituation session. During this period, rats were adapted to the observation field and red light. The experimenter also reached into the cage to apply innocuous mechanical (6-g von Frey filament) stimulation on the face of the animal, to which animals responded with only a simple detection, showing a non-aversive response. Immediately after the 30 min habituation period, animals were again briefly (≈ 3 min) anesthetized using a mask with 2% isoflurane and received intradermal injection of CFA. Behavioral responses to the very same 6-g von Frey filament as during the habituation session were then evaluated as described in the Behavioral Testing section (see below).

4.2.3. Behavioral responses to normally innocuous static (6-g von Frey filament) mechanical stimulation.

The behavioral responses procedure was previously developed by Vos *et al.* [23]. A rat's response to mechanical stimulation consisted of one or more of the following elements: (1) detection, rat turn head toward stimulus; (2) withdrawal reaction, rat pull paw away or turn head away or pull it briskly backward when stimulation is applied (a withdrawal reaction is assumed to include a detection element preceding the head withdrawal and therefore consists of two responses elements); (3) escape/attack, rats avoid further contact with the stimulus, either passively by moving their bodies away from the stimulus, or actively by attacking the tip of the pump; (4) asymmetric grooming, rats display an uninterrupted series of at least three wash strokes directed to the stimulated area.

The level of MA inhibition of a given compound was computed as following: $[(AUC \text{ vehicle} - AUC \text{ compound})/AUC \text{ vehicle}] \times 100$ (AUC being the area under the curve; see Figure 2A)
