A Reduced Order Observer for Switching-Mode Model State Estimation

Hirsh Majid, Hassane Abouaïssa, Daniel Jolly, Gildas Morvan

Abstract—In this paper, we investigate the application of a reduced-order observer for state estimation of freeway traffic flow described by the so-called Switching Mode Model (SMM). SMM is derived from the Cell Transmission Model and then applied to the reconstruction of the traffic density, considered as state variable. As the SMM is a hybrid system which switches depending on the traffic conditions along the freeway, the paper shows how, the proposed estimation method takes into account such different modes. Several numerical simulation with different data demonstrate the relevance of the proposed algorithm.

Index Terms—Reduced-order observer, traffic flow simulation, Switching mode model.

I. INTRODUCTION

Freeway traffic control and the development of intelligent transportation systems, which are able to provide continuous forecasting of the traffic and allow to alleviate the congestion phenomena, are closely related to the ability to have all needed information about the traffic state. Indeed the performance of any dynamic management action, usually requires the knowledge of both the present and the future traffic behaviour. Such information are provided by a set of sensors (detectors) which are already installed along the freeway infrastructure. The future traffic behaviour can be computed via a suitable traffic model. The most used sensors are the loop detectors, the video cameras, etc. Nevertheless, like any other device, the sensors are facing problems of cost, maintenance, and dysfunction. Moreover, loop detectors, for example could undermine the road surface (paved), and accelerates the deterioration of the infrastructure. Thus, reducing the number of sensors, can help to alleviate the costs of system. In this context, state estimation and reconstruction of missing data plays an important role.

The work proposed in this paper deals with traffic flow state estimation using a reduced order observer which was proposed by Luenberger [1].

The amount of attention devoted to the development of an estimation strategy using a traffic flow model has been relatively small compared to the modelling stage. Here we mention some works; Nahi [2] shows the ability to estimate the density closely in homogeneous situations. Various authors like Gazis and Knapp [3], and Knapp [4] have used Kalman Filtering techniques, they proposed a method which utilizes the time series of speed and flow data from each detector and

generates crude estimates of vehicles count. These estimates are then filtered using a Kalman Filter. Extended Kalman Filters have also been utilized in traffic state estimation using second-order models [5]. Rashid R.Kohan [6] has designed a sliding mode state estimator for estimating state variables of traffic flow (speed, density) which is an estimator robust with respect to bounded modelling errors and disturbances. In 2003, Muñoz and al [7] derived a switching mode model (SMM) from the cell transmission model (CTM) which has been applied to the estimation of traffic densities at unmonitored locations along highway. In (2004) Sun and al [8], proposed an estimator using a mixture Kalman filtering (MKF) algorithm on the switching-mode traffic model, their estimator is able to provide estimated vehicle densities at unmeasured locations. In (2010) Staňková and al [9] dealt with the problem of the real time freeway traffic density estimation/prediction for a jump Markov linear model based on Daganzo's cell transmission model, to solve this problem they proposed a particle filtering-based estimation/prediction method. In 2011 Morărescu and al [10] proposed a new state estimation technique to reproduce the state variable (density) in the real time traffic forecasting by using switching mode model.

In this paper, an approach to estimate hybrid discrete-time linear systems using Luenberger observer is presented. The proposed Luenberger observer for such kind of systems relies on the switching among different gains. Convergence conditions have been found to ensure the stability of error dynamics and the related gains may be selected by solving a set of linear matrix inequalities. The model used in the system is the switching mode traffic model (SMM). It is a macroscopic linear time-varying traffic flow model. It can be also defined as a hybrid system that switches among different sets of linear difference equations, or modes.

This paper is organized as follows:

- Section II, recalls the used macroscopic model.
- Section III, outlines the basis of the state reconstructor scheme used.
- in section IV, we apply the estimator on a section freeway. The section provides some numerical simulations and results.
- The conclusion, section V, summarizes the main gained results and lists some promising perspectives and further researches.

II. TRAFFIC FLOW MODELLING

Highway traffic flow system is an interesting but complex phenomenon to model. Many efforts have been made to

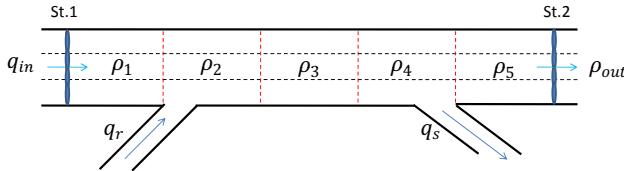

Figure 1. freeway Section

establish and validate models of highway traffic at different scales (microscopic, macroscopic). However, they are not easy to be used precisely for online estimation of the traffic states. Here, we are interesting on the macroscopic model. The first macroscopic model was developed by Lighthill and Whitham in 1955 [11] and Richard 1956 [12]. The model rests on the comparability of traffic flow on long crowded roads with flood movements in long rivers. Thus, the model is based on the equation of fluid dynamic, ($q = \rho v$), where, q is the traffic flow in vehicles/h. ρ , the traffic density in vehicles/km and (v), the mean speed in km/h, and on the equation of conservation law (see equation 1), in which $\rho(x, t)$ is the density of vehicles at point x and at time t , $q(x, t)$ is the flow function defined on [0 and ρ_m], where ρ_m is called jam density. This model suppose that traffic is in steady state.

$$\frac{\partial \rho(x, t)}{\partial t} + \frac{\partial q(x, t)}{\partial x} = 0 \quad (1)$$

The switching mode model is a macroscopic linear time-varying traffic flow model; it has been derived from a modified cell transmission model CTM [13], [14] that uses density instead of occupancy as its state variable and consider the triangular form of diagram fundamental. In the switching mode model, the cell transmission model is described as a hybrid system that switches between 5 sets of linear difference equations or modes (see table I), depending on the congestion status of the cells and the traffic situation of the mainline boundaries. At each time step, the densities and flows at boundary mainline segments are measured. There is at most one status transition (or wave front) [7] in the highway section. If both adjacent mainline segments are in the same traffic situation, i.e., both congested or free flow, so it is assumed that all mainline cells have the same traffic situation, either all congested, or all free flow. While, if the adjacent mainline segments are in different traffic situations, there exists a single wave front in one of the cells mainline, upstream of which all cells have congested (free flow) status, and downstream of which all cells have congested (free flow) status.

The highway segment divided into 5 cells shown in figure (1) is considered. The measured aggregate flows and densities at the upstream and downstream mainline detectors are denoted q_{in} , ρ_{in} and q_{out} , ρ_{out} respectively. All 5 modes of the SMM can be summarized as follows:

$$\rho_i(t+1) = R_{i,s} \rho_i(t) + M_{i,s} u_i(t) + N_{i,s} \rho_{m,i} + O_{i,s} Q_{m,i} \quad (2)$$

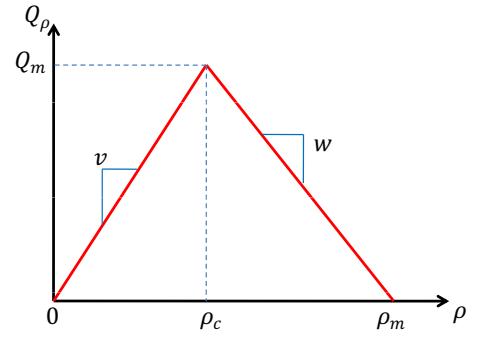

Figure 2. Fundamental Diagram

where:

$s\dots$ indicates the mode ¹ (1:FF, 2:CC, 3:CF, 4:FC1, 5:FC2).
 $\rho_i\dots$ is the state (density) $= [\rho_1 \dots \rho_5]^T$.
 $u_i\dots$ is the flow input q_{in} , measured on-ramp q_r , measured off-ramp q_s , and density output ρ_{out} , $= [q_{in}, 0, q_r, q_s, \rho_{out}]^T$.
 $\rho_{m,i}\dots$ is the vector of maximum (jam) density $= [\rho_{m,1} \dots \rho_{m,5}]^T$, and, see figure (2)
 $Q_{m,i}\dots$ is the vector of maximum flow rates (capacity) $[Q_{m,1} \dots Q_{m,5}]^T$.

Here, we mention the state matrices in the FF, CC and CF modes, because these modes can be observed [7], [10], while the other modes (FC1, FC2) cannot be observed (see table I), therefore, we found that it is not necessary to mention them.

- 1) In the FF mode, the state matrices are:

$$R_{1-5,1} = \begin{bmatrix} -\frac{v_1}{L_1} & 0 & 0 & 0 & 0 \\ \frac{v_1}{L_2} & -\frac{v_2}{L_2} & 0 & 0 & 0 \\ 0 & \frac{v_2}{L_3} & -\frac{v_3}{L_3} & 0 & 0 \\ 0 & 0 & \frac{v_3}{L_4} & -\frac{v_4}{L_4} & 0 \\ 0 & 0 & 0 & \frac{v_4}{L_5} & -\frac{v_5}{L_5} \end{bmatrix} \quad (3)$$

$$M_{1-5,1} = \begin{bmatrix} \frac{1}{L_1} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & \frac{1}{L_3} & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -\frac{1}{L_5} & 0 \end{bmatrix} \quad (4)$$

$$N_{1-5,1} = 0_5 \times 6, O_{1-5,1} = 0_5 \times 5 \quad (5)$$

- 2) In the CC mode, the state matrices are:

¹Free flow-Free flow (FF), Congested-Congested (CC), Congested-Free flow (CF), Free flow-Congested1 (CF1), Free flow-Congested2 (CF2).

Table I
OBSERVABILITY FOR DIFFERENT SMM MODES

Free-flow	Free-flow	Downstream meas.
Congested	Congested	upstream meas.
Congested	Free-flow	Up. & Down. meas.
Free-flow	Congested 1	Unobservable
Free-flow	Congested 2	Unobservable

$$R_{1-5,2} = \begin{bmatrix} -\frac{w_1}{L_1} & \frac{w_2}{L_1} & 0 & 0 & 0 \\ 0 & -\frac{w_2}{L_2} & \frac{w_3}{L_2} & 0 & 0 \\ 0 & 0 & -\frac{w_3}{L_3} & \frac{w_4}{L_3} & 0 \\ 0 & 0 & 0 & -\frac{w_4}{L_4} & \frac{w_5}{L_4} \\ 0 & 0 & 0 & 0 & -\frac{w_5}{L_5} \end{bmatrix} \quad (6)$$

$$M_{1-5,2} = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & \frac{1}{L_2} & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -\frac{1}{L_4} & 0 \\ 0 & 0 & 0 & 0 & \frac{w_6}{L_5} \end{bmatrix} \quad (7)$$

$$N_{1-6,2} = \begin{bmatrix} \frac{w_1}{L_1} & -\frac{w_2}{L_1} & 0 & 0 & 0 & 0 \\ 0 & \frac{w_2}{L_2} & -\frac{w_3}{L_2} & 0 & 0 & 0 \\ 0 & 0 & \frac{w_3}{L_3} & -\frac{w_4}{L_3} & 0 & 0 \\ 0 & 0 & 0 & \frac{w_4}{L_4} & -\frac{w_5}{L_4} & 0 \\ 0 & 0 & 0 & 0 & \frac{w_5}{L_5} & -\frac{w_6}{L_5} \end{bmatrix} \quad (8)$$

$$O_{1-5,2} = 0_5 \times 5 \quad (9)$$

- 3) In the CF mode. For the simulation, it is assumed that the wave front is located in between cells 3 and 4 and the state matrices are:

$$R_{1-5,3} = \begin{bmatrix} -\frac{w_1}{L_1} & \frac{w_2}{L_1} & 0 & 0 & 0 \\ 0 & -\frac{w_2}{L_2} & \frac{w_3}{L_2} & 0 & 0 \\ 0 & 0 & -\frac{w_3}{L_3} & 0 & 0 \\ 0 & 0 & 0 & -\frac{v_4}{L_4} & 0 \\ 0 & 0 & 0 & \frac{v_4}{L_5} & -\frac{v_5}{L_5} \end{bmatrix} \quad (10)$$

$$M_{1-5,3} = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & \frac{1}{L_2} & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -\frac{1}{L_5} & 0 \end{bmatrix} \quad (11)$$

$$N_{1-6,3} = \begin{bmatrix} \frac{w_1}{L_1} & -\frac{w_2}{L_1} & 0 & 0 & 0 & 0 \\ 0 & \frac{w_2}{L_2} & -\frac{w_3}{L_2} & 0 & 0 & 0 \\ 0 & 0 & \frac{w_3}{L_3} & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix} \quad (12)$$

$$O_{1-5,3} = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -\frac{1}{L_3} & 0 \\ 0 & 0 & 0 & \frac{1}{L_4} & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix} \quad (13)$$

III. REDUCED-ORDER OBSERVER

In this section, we will investigate how the state variable (density) of traffic flow can be estimated using a mathematical model (SMM model) and a few measurement. This is done by building an observer that uses measurements of the inputs and outputs of a linear system, along with a model of the system dynamics, to estimate the state.

The estimator design method called Full-Order Estimators reconstructs the entire state vector using measurements of some of the state variables. If sensors have no noise, then a full-order estimator contains redundancies, and it seems reasonable to question the necessity of estimating state variables that are measured directly [15].

The reduced-order observer reduces the order of the observer by the number of sensed outputs. To derive this observer, we start with the assumption that the output equals the first state as, for example $y = x_1$. We now partition the state vector into two parts: x_1 , which is directly measured, and x_2 , which represents the remaining state variables that need to be observed. If we partition the system matrices accordingly, the complete description of the system is given by:

$$\begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \end{bmatrix} = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} + \begin{bmatrix} B_1 \\ B_2 \end{bmatrix} u \quad (14)$$

$$y = [1 \ 0] \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} \quad (15)$$

The dynamics of the unmeasured state variables are given by

$$\dot{x}_2 = A_{21}x_1 + A_{22}x_2 + B_2u \quad (16)$$

where the rightmost two terms are known and can be considered as an input into the x_2 dynamics. Because $x_1 = y$, the measured dynamics are given by the scalar equation

$$\dot{x}_1 = \dot{y} = A_{11}x_1 + A_{12}x_2 + B_1u \quad (17)$$

If we collect the known terms of equation (17) on one side,

$$A_{12}x_2 = \underbrace{\dot{y} - A_{11}x_1 - B_1u}_{\text{known measurement}} \quad (18)$$

We obtain a relationship between known quantities on the right side, which we consider measurements, and unknown state variable on the left. Therefore, equation (17) and equation (18) have the same relationship to the state x_2 that the original equation (16) had to the entire state x . Following this line of reasoning, we can establish the following substitutions in the original estimator equations² to obtain a (reduced-order) observer of x_2 .

$x \leftarrow x_2$, $F \leftarrow A_{22}$, $Gu \leftarrow A_{21}x_1 + B_2u$, $y \leftarrow \dot{y} - A_{11}x_1 - B_1u$ and $H \leftarrow A_{12}$

Therefore, the reduced-order observer equation obtained by substituting these items in equation (19)

$$\dot{\hat{x}}_2 = A_{22}\hat{x}_2 + \underbrace{A_{21}x_1 + B_2u}_{\text{input}} + L(\underbrace{\dot{y} - A_{11}x_1 - B_1u}_{\text{measurement}}) \quad (20)$$

If we define the estimator error to be $\tilde{x}_2 \triangleq \hat{x}_2 - x_2$. Then the dynamics of the error are given by subtracting equation (16) from equation (20) to get

$$\dot{\tilde{x}}_2 = (A_{22} + LA_{12})\tilde{x}_2 \quad (21)$$

and its characteristic equation of the error is given by

$$\det[sI - (A_{22} + LA_{12})] = 0 \quad (22)$$

L is a matrix that tells how the error \tilde{x}_2 is weighted and distributed among the states. If we choose L so that $(A_{22} + LA_{12})$ has stable and reasonably fast eigenvalues, then the error will decay to zero. This means that \hat{x}_2 will converge to x_2 . Now equation (20) can be rewritten as

$$\dot{\hat{x}}_2 = (A_{22} + LA_{12})\hat{x}_2 + (A_{21} + LA_{11})x_1 + (B_2 + LB_1)u - L\dot{y} \quad (23)$$

The fact that we must form the derivative of the measurements (\dot{y}) in equation (23) appears to present a practical difficulty. It

²The original estimator equations means the golden rule [15]. When in trouble, use feedback. Consider feeding back the difference between the estimated and measured outputs and correcting the model continuously with this error signal. The equation for this scheme is:

$$\dot{\hat{x}} = F\hat{x} + Gu + L(H\hat{x} - y) \quad (19)$$

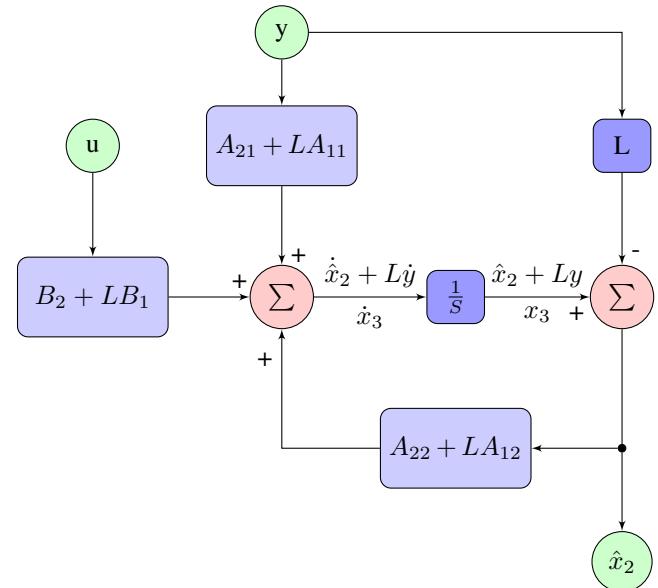

Figure 3. flow chart (Reduced-order estimator)

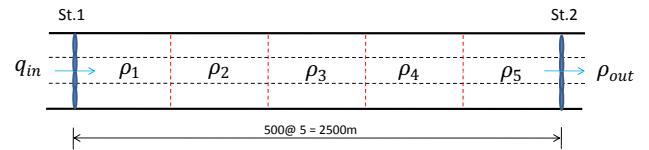

Figure 4. Simulated Road Section

is known that differentiation amplifies noise, so if (y) is noisy, the use of (\dot{y}) is unacceptable. To get around this difficulty, we define the new controller state to be:

$$x_3 \triangleq \hat{x}_2 + Ly \quad (24)$$

In terms of this new state the implementation of the reduced-order observer is given by:

$$\dot{x}_3 = \dot{\hat{x}}_2 + L\dot{y} = (A_{22} + LA_{12})\hat{x}_2 + (A_{21} + LA_{11})x_1 + (B_2 + LB_1)u \quad (25)$$

and \dot{y} no appears directly. A block diagram representation of the reduced-order estimator is shown in figure 3.

IV. SIMULATION AND RESULTS

Figure 4 is a schematic diagram of the freeway portion used in the simulation. It shows the mainline segment partitioned into 5 identical cells, 2.5 km in length (each cell length = 500 meters). Two mainline loop detector (sensor) stations are labeled (St.1) and (St.2).

The traffic model (SMM) is a hybrid model with 5 different modes. At any time, the system can change from one mode to another. In order to the system functions permanently, the observer is designed and implemented for the modes FF and CC, that have been simulated. For the case of CF mode, it is assumed that there is a wave front between cell 3 and Cell 4. It means that the capacity at between cells 3 and 4 is

reduced. Thus, the traffic cannot flow with maximum capacity. In consequence, congestion is produced from cell 3 to the upstream, and traffic situation will be free flow from cell 4 to the downstream.

- 1) In the case of FF mode, the equations of state variable (density) are implemented as follows:

$$\begin{bmatrix} \dot{\hat{\rho}}_1 \\ \dot{\hat{\rho}}_2 \\ \dot{\hat{\rho}}_3 \\ \dot{\hat{\rho}}_4 \\ \dot{\hat{\rho}}_5 \end{bmatrix} = \begin{bmatrix} (R_{11} + LR_{21})\hat{\rho}_1 + LR_{22}\rho_2 + M_{11}q_{in} - L\dot{\rho}_2 \\ (R_{22} + LR_{32})\hat{\rho}_2 + R_{21}\rho_1 + LR_{33}\rho_3 - L\dot{\rho}_3 \\ (R_{33} + LR_{43})\hat{\rho}_3 + R_{32}\rho_2 + LR_{44}\rho_4 - L\dot{\rho}_4 \\ (R_{44} + LR_{54})\hat{\rho}_4 + R_{43}\rho_3 + LR_{55}\rho_5 - L\dot{\rho}_5 \\ R_{54}\hat{\rho}_4 + R_{55}\hat{\rho}_5 \end{bmatrix}$$

- 2) In the case of CC mode, the equations of state variable (density) are implemented as follows:

$$\begin{bmatrix} \dot{\hat{\rho}}_1 \\ \dot{\hat{\rho}}_2 \\ \dot{\hat{\rho}}_3 \\ \dot{\hat{\rho}}_4 \\ \dot{\hat{\rho}}_5 \end{bmatrix} = \begin{bmatrix} R_{11}\hat{\rho}_1 + R_{12}\hat{\rho}_2 + N_{11}\rho_{m1} + N_{12}\rho_{m2} \\ (R_{22} + LR_{12})\hat{\rho}_2 + R_{23}\rho_3 + LR_{11}\rho_1 + N_{22}\rho_{m2} + N_{23}\rho_{m3} + L(N_{11}\rho_{m1} + N_{12}\rho_{m2}) - L\dot{\rho}_1 \\ (R_{33} + LR_{23})\hat{\rho}_3 + R_{34}\rho_4 + LR_{22}\rho_2 + N_{33}\rho_{m3} + N_{34}\rho_{m4} + L(N_{22}\rho_{m2} + N_{23}\rho_{m3}) - L\dot{\rho}_2 \\ (R_{44} + LR_{34})\hat{\rho}_4 + R_{45}\rho_5 + LR_{33}\rho_3 + N_{44}\rho_{m4} + N_{45}\rho_{m5} + L(N_{33}\rho_{m3} + N_{34}\rho_{m3}) - L\dot{\rho}_3 \\ (R_{55} + LR_{45})\hat{\rho}_5 + LR_{44}\rho_4 + M_{55}\rho_{out} + N_{55}\rho_{m5} + N_{56}\rho_{m,out} + LN_{44}\rho_{m4} + LN_{45}\rho_{m5} - L\dot{\rho}_4 \end{bmatrix}$$

- 3) In the case of CF mode, the equations of state variable (density) are implemented as follows:

$$\begin{bmatrix} \dot{\hat{\rho}}_1 \\ \dot{\hat{\rho}}_2 \\ \dot{\hat{\rho}}_3 \\ \dot{\hat{\rho}}_4 \\ \dot{\hat{\rho}}_5 \end{bmatrix} = \begin{bmatrix} R_{11}\hat{\rho}_1 + R_{12}\hat{\rho}_2 + N_{11}\rho_{m1} + N_{12}\rho_{m2} \\ (R_{22} + LR_{12})\hat{\rho}_2 + R_{23}\rho_3 + LR_{11}\rho_1 + N_{22}\rho_{m2} + N_{23}\rho_{m3} + L(N_{11}\rho_{m1} + N_{12}\rho_{m2}) - L\dot{\rho}_1 \\ (R_{33} + LR_{23})\hat{\rho}_3 + LR_{22}\rho_2 + N_{33}\rho_{m3} + O_{34}q_{m4} + L(N_{22}\rho_{m2} + N_{23}\rho_{m3}) - L\dot{\rho}_2 \\ (R_{44} + LR_{54})\hat{\rho}_4 + LR_{55}\rho_5 + O_{44}q_{m4} - L\dot{\rho}_5 \\ R_{55}\hat{\rho}_5 + R_{54}\hat{\rho}_4 \end{bmatrix}$$

The theoretical results are illustrated by some simulations. The maximum (jam) density $\rho_m = 180 \text{ veh/km}$, the free flow speed $v_i = 90 \text{ km/h}$ and the congestion speed $w_i = 22.5 \text{ km/h}$. The L values for FF, CC and CF modes respectively are $1/5, -1$ and 1 . The macroscopic simulation has been done during 100 minutes. In order to produce different modes of the SMM model, several types of data are used, one for producing the mode FF, one for producing CC and the other for producing CF. So the upstream flow q_{in} and the downstream density ρ_{out} of the main line are given a way that the system can produce these three different modes (see figure 5). As we can realize (see figure 5-top), the flow used at the upstream, is always inferior to the capacity in the case of FF mode. While, the flow is superior or equal to capacity

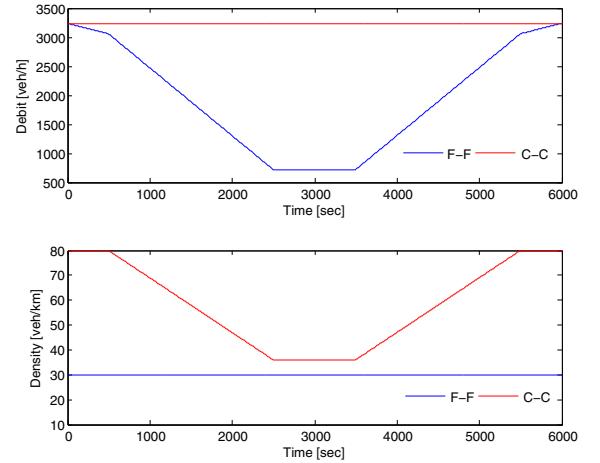

Figure 5. Debit of upstream and density of downstream of the boundary line

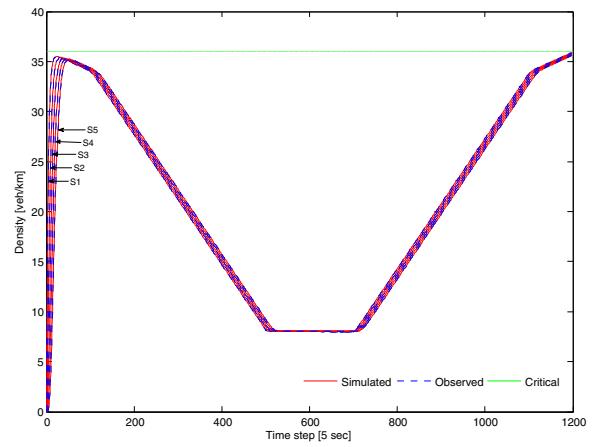

Figure 6. Simulated and observed density for all the 5 cells in the FF mode

in the case of CC and CF modes. However, the density used at the downstream of the mainline is given in figure 5-bottom, it is obvious that the density for FF and CF modes is inferior the critical density. While the density in the CC mode is always superior or equal to critical density.

In figure 6, results of the FF mode is shown, it can be noted that the observer reproduce the same trajectory as the SMM model for all the cells. Figures 7, 8 and 9 show the same results for the CC and CF modes respectively. The simulation with noisy data (Mean = 0 and variance = 0.0016) is also tested, it is shown in figure 10, and 11 for the FF and CC mode respectively.

V. CONCLUSION

In this paper, we have demonstrated the relevance of reduced-order observer introduced by Luenberger in the intelligent transportation systems area and particularly in freeway traffic flow domain. The used macroscopic model rests on the so-called SMM, which is linear time-varying model. Several numerical simulations conducted for different modes of the

traffic, show robust and efficient results even with noisy data. Further works will consider this identification method for more complex system including field real data, and will introduce some control algorithm for ramp metering in order to alleviate the congestion phenomena.
