39 Abstract

40 An expected consequence of climate warming is an expansion of the geographic distribution of biting insects
41 and associated arthropod-borne diseases (arboviruses). Emerging and reemerging arboviruses that can affect human
42 health are likely to pose significant consequences for Northern communities where access to health resources is
43 limited. In the North American Arctic, little is known about arboviruses. Thus, in 2019, we sampled biting insects in
44 Nunavik (Kuujuuaq), Nunavut (Igloolik, Karrak Lake and Cambridge Bay), Northwest Territories (Igloolik and
45 Yellowknife) and Alaska (Fairbanks). The main objective was to detect the presence of California serogroup viruses
46 (CSGv) – a widespread group of arboviruses across North America and that is known to cause a wide range of
47 symptoms, ranging from mild febrile illness to fatal encephalitis. Biting insects were captured twice daily for a 7-day
48 period in mid-summer, using a standardized protocol consisting of 100 figure-eight movements of a sweep net.
49 Captured specimens were separated by genus (mosquitoes) or by superfamily (other insects), and then grouped into
50 pools of 75 by geographical locations. In total, 5079 *Aedes* mosquitoes and 1014 Simuliidae flies were caught. We
51 report the detection of CSGv RNA in mosquitoes captured in Nunavut (Karrak Lake) and Nunavik (Kuujuuaq). We
52 also report, for the first time in North America, the presence of CSGv RNA in Simuliidae flies. These results highlight
53 the potential of biting insects for tracking any future emergence of arboviruses in the North, thereby providing key
54 information for public health in Northern communities.

55 Key words

56 Mosquitoes, Biting insects, California serogroup viruses, Arctic, Vector-borne

57 Introduction

58 Rapid climate warming is altering ecological communities in the Arctic at an alarming rate (IPCC 2007; Post
59 et al. 2009), thereby creating new habitats for biting insects and the diseases that they can carry (Bartlow et al. 2019).
60 In spite of our increased awareness that the Arctic is experiencing climate warming twice as fast as the rest of the
61 world (Jansen et al. 2020), studies documenting arthropod-borne viruses (arboviruses) in Northern regions are
62 outdated (McLean et al. 1975, 1976, 1977a; McLean 1983), or in some cases, non-existent (i.e. vector species and
63 arbovirus prevalence).

64 The most commonly reported arboviruses associated with biting insects in the Arctic are California serogroup
65 viruses (CSGv; family *Bunyaviridae*, genus *Orthobunyavirus*) (Kurstak et al. 1979; Calisher 1996). They include the
66 Snowshoe hare (SSH) and Jamestown Canyon (JC) viruses, which are occasionally associated with febrile and
67 neuroinvasive disease in humans (LeDuc 1987). Their predominant arthropod vectors are mosquitoes of the genera
68 *Aedes* and *Culiseta* (LeDuc 1987). For the SSH virus, the primary amplification hosts are snowshoe hares, squirrels
69 and other small mammals, while for the JC virus, they are believed to be wild free-ranging ungulates (Drebot 2015).
70 Even though serological studies have shown that antibodies of both SSH and JC viruses are present in wildlife and
71 people in the Arctic (Zarnke et al. 1983; Walters et al. 1999; Miernyk et al. 2019), there have only been a few reports
72 documenting these viruses in mosquitoes captured in the field (McLean et al. 1975, 1977a, b).

73 There is less information available about other possible vectors for the CSGv, such as black flies (Simuliidae)
74 and biting midges (Ceratopogonidae), both of which are present in Northern regions. Here, we report the results from
75 our 2019 sampling effort aimed at detecting the presence of California serogroup viruses in Northern biting insects.
76 For simplicity, the term *biting flies* will be used hereafter to describe biting insects that are not mosquitoes.

77 Materials and methods

78 Insects were captured in the summer of 2019 in Northern Canada and Alaska (**Figure 1**). Locations were
79 chosen based on a set of cities, villages or remote field sites identified by the Canadian Arctic One Health Network
80 and the presence of local research partners willing to participate in surveillance activities. Sampling took place in
81 Alaska (Fairbanks: 64.9152, -147.966), the Northwest Territories (Hendrickson Island: 69.8405, -133.975;
82 Yellowknife: 62.5183, -114.320), Nunavut (Cambridge Bay: 62.1204, -105.045; Karrak Lake: 67.2359, -100.257;
83 Igloolik: 69.3940, -81.3894) and the Nunavik region of Northern Québec (Kuujuuaq: 58.1272, -68.3848).

84 Manual capture, using a standardized protocol consisting of 100 figure-eight movements with an 18” sweep
85 net (~46 cm), was carried out twice daily (dawn and dusk) for 7 consecutive days in mid-summer of 2019. This
86 technique is well-adapted to remote field site sampling where low equipment volume/weight and short sampling times
87 are ideal (Silver 2008). It is also suitable for citizen scientists. Insects collected in the field were placed in a labeled
88 plastic container and frozen at -18 °C until they were shipped to the Faculty of Veterinary Medicine, Université de
89 Montréal, in Saint-Hyacinthe, QC.

90 All sorting of collected insects was conducted by a single observer (C.-A.V.) using a dissecting microscope
91 and a chill tray. Mosquitoes and biting flies were separated from other insects. Subsequently, mosquitoes were sorted
92 on a chill tray by genus using dichotomous keys (Wood et al. 1979; Thielman and Hunter 2004). Mosquitoes and
93 biting flies were further grouped into pools by geographical location. Pools were stored at -80 °C until further analysis.

94 The pooled specimens were sent to the National Microbiology Laboratory in Winnipeg, MB for RNA
95 extraction and real-time reverse transcriptase-polymerase chain reaction (RT-PCR) analysis. A sterile copper-coated
96 steel bead (BB) and 1 ml of BA (made up of 10 ml of 10x M199 medium with Earls salts, 5 ml 1 M Tris buffer pH
97 7.6, 13.3 ml 7.5 % bovine serum albumin Fraction V and 1ml 100X penicillin/streptomycin) were added to each pool
98 of mosquitoes and flies. Pools were homogenized using a TissueLyser (QIAGEN, Valencia, CA, USA) for 1 min at
99 30 Hz, and then centrifuged for 30 s at 13,000 rpm. RNA extraction was performed according to the manufacturer’s
100 protocol for a RNeasy 96 Kit (QIAGEN). For each pool, 5 µl of eluted RNA was used for the RT-PCR reaction testing.
101 The eluted RNA was combined with Applied Biosystems™ TaqMan™ Fast Virus 1-step master mix (ThermoFisher,
102 Waltham, MA, USA). The target regions for the CSG, JC and SSH viruses were amplified using their respective
103 primer pairs and probe (Wang et al. 2009) (**Table 1**). Positive controls were also used to test for CSG, JC and SSH
104 viruses. Results were given as quantification cycle (Cq) units, i.e., the number at which the fluorescence of the probes
105 increases, which is inversely related to the amount of RNA present (Williams 2009). Pools were considered positive
106 when Cq units were ≤ 40 .

107 Positive pools were expressed as frequencies and 95% confidence interval calculated with R (R Core Team
108 2020) using *prop.test* (Newcombe 1998).

109 **Results**

110 Between June 28th and August 2nd 2019, a total of 5079 mosquitoes and 1014 biting flies were caught (**Table**
111 **2**). Mosquitoes were collected across the seven sampling sites, forming 70 pools with an average of 75 specimens/pool
112 (range: 12-86). Kuujuaq was the only site where enough biting flies were collected to allow pooled analysis, forming
113 6 pools with an average of 169 specimens/pool (range: 114-237).

114 All collected mosquitoes were *Aedes* spp. females. This observation is consistent with our capture techniques,
115 as sweep netting predominately captures females seeking a blood meal (Silver 2008). Biting flies appear to be
116 predominantly black flies (Simuliidae) because of their morphological characteristics: small, dark coloured with short
117 legs, broad wings and a humpback appearance. A few smaller flies, probably biting midges, were also observed.
118 Morphological observations were not made beyond the sorting process. Since biting flies were all pooled together, we
119 decided to extend their identification to the superfamily level, Simulioidae, which consists of black flies and biting
120 midges (Ceratopogonidae). For biting flies, 6 pools were made with an average of 169 specimens/pool (range: 114-
121 237).

122 We tested each pool for CSG viruses, and then further tested CSG-positive pools specifically for JC and
123 SSH viruses (**Table 2**). None of the 42 pools of mosquitoes collected in Fairbanks, Hendrickson Island, Yellowknife,
124 Cambridge Bay or Igloolik tested positive for CSG viruses (**Table 2**). One of the 16 (6.2 %; 95 % CI [1.1, 28.3])
125 mosquito pools from Karrak Lake tested positive for CSG viruses. However, the quantity of viral RNA (cq of 40) in
126 this sample was too low to further test for JC and SSH viruses with RT-PCR. For mosquitoes collected in Kuujuaq,
127 six of the eight (75 %; 95 % CI [40.9, 92.9]) pools tested positive for CSG viruses. Of these six pools, one (16.6 %;
128 95 % CI [3.0, 56.3]) also tested positive for both JC and SSH viruses, while the five others (83.3 %; 95 % CI [43.7,

129 97.0] tested positive only for JC virus. We detected CSG viruses in biting flies in Kuujuaq. Four of the six (66.6 % ;
130 95 % CI [30.0, 90.3]) pools of biting flies tested positive for CSG viruses, which subsequently tested positive for JC
131 virus.

132 Discussion

133 In 2019, we detected CSGv RNA in mosquitoes at two of seven field sites across Northern Canada and
134 Alaska. For the first time in North America, we also report CSGv in biting flies (Simuliidae).

135 All captured mosquitoes were from the genus *Aedes*, which is not surprising since *Aedes impiger*, *Aedes*
136 *nigripes*, and *Aedes hexodontus* are the three main Arctic mosquito species (Ward and Darsie 2005). Moreover *Aedes*
137 mosquitoes, like *Aedes communis*, are common vectors of CSGv, even in a sub-arctic environment (McLean et al.
138 1976, 1977b; Kurstak et al. 1979). However, species-specific results were not reported in this study, mainly because
139 captured mosquitoes were too damaged for morphological identification past the genus level. There are alternatives
140 to traditional identification methods, such as barcodes targeting the COI gene (Meier et al. 2006), but those methods
141 have not yet been proven to be reliable for Arctic species. Reliable DNA databases from morphologically confirmed
142 specimens are required before using these methods.

143 We detected CSGv (JC and SSH viruses) in mosquitoes captured in Nunavut (Karrak Lake) and Nunavik
144 (Kuujuaq). However, viral detection can be affected by multiple factors. For instance, temperature is known to
145 influence vector, host, and arboviral distribution (Ciota and Keyel 2019). Since Kuujuaq is the most southern and
146 eastern site sampled (58.127277, -68.384854), its warmer summer could explain why positive pools were
147 predominantly found there. Viral detection is also closely linked to species captured (Andreadis et al. 2008). For
148 example, negative results in Hendrickson Island can simply mean that caught mosquitoes were not vectors for CSGv
149 or that vectors were not active at the sampling time. More importantly, viral detection is highly dependant on pool
150 size (Huang et al. 2001). For example, in Fairbanks, even if CSGv were present in one of the 17 mosquitoes caught,
151 it might not have been detected due to low test sensitivity. Furthermore, 2019 results were not typical for Alaska, a
152 state known for its abundance of mosquitoes. Without any baseline information about CSGv vectors in these regions,
153 our ability to extrapolate results is therefore limited.

154 For the first time in North America, we detected CSGv (JC virus) in biting flies (Simuliidae) captured in
155 Kuujuaq. To the best of our knowledge, only one other study has detected CSGv in biting flies, which was in another
156 biome, i.e., the former Czechoslovakia (Halouzka et al. 1991). Also, viral detection in biting flies (Simuliidae) does
157 not necessarily indicate vector competence. It could simply indicate the ingestion of a viremic bloodmeal. Their role
158 as potential vectors for needs further examination (Sick et al. 2019).

159 To conclude, results from this pilot year suggest that field collection of biting insects has the potential to
160 provide useful data to monitor the changing distribution and local risk associated with vector-borne zoonoses across
161 Northern regions. The sampling protocol used in this study provides a simple and cost-effective method for sampling
162 biting insects in remote Northern communities, with potential for widespread application across the Arctic. Building
163 reliable DNA databases for potential vectors as well as subsequent monitoring years will be useful to establish a
164 baseline on current species' ranges and infective status. Such studies are crucial to anticipate and track any future
165 emergence of arboviruses in the North, thereby providing key information for public health in Northern communities.

166 Acknowledgments

167 We would like to thank Mathieu Archambault (Université de Moncton), Ashley Elliott (Fisheries and Oceans
168 Canada), Camille Guillot (Université de Montréal), Robin Owsiacki and Adrián Hernández Ortiz (University of
169 Saskatchewan), Megan Wardekker (Fisheries and Oceans Canada), Jordan Bertagnolli (Government of the Northwest
170 Territories) and the Centre for Biodiversity Genomics (University of Guelph) for their help in collecting mosquitoes
171 in the field. We would like to thank Scott G. Harroun (Université de Montréal) for his help in editing this manuscript.

172 We would also like to thank Patricia Lacroix (Government of the Northwest Territories) and Malik Awan
173 (Government of Nunavut) for their help with our Wildlife Research Permit applications, as well as all of the

252 **Table 3.** Probes and primer pairs for CSG, JC and SSH viruses

Target virus	Name	Sequence
CSG viruses	CE-NC-F1	5'-GTGTTTATGATGTCGCATCA-3'
	CE-NC-R1	5'-CATATACCCTGCATCAGGATCAA-3'
	CE-NC-F2	5'-GTTTCTATGATGATGCATCC-3'
	CE-NC-R2	5'-CACAAACCCTGCATCTGGATCAA-3'
	CE-NC-FAM/MGB	5'-FAM-CAGGTGCAAATGGA-MGB-3'
JC virus	CE-NC-F2	5'-GTTTCTATGATGATGCATCC-3'
	CE-NC-R2	5'-CACAAACCCTGCATCTGGATCAA-3'
	CE-NC-FAM/MGB	5'-FAM-CAGGTGCAAATGGA-MGB-3'
SSH virus	CE-NC-F1	5'-GTGTTTATGATGTCGCATCA-3'
	CE-NC-R1	5'-CATATACCCTGCATCAGGATCAA-3'
	CE-NC-FAM/MGB	5'-FAM-CAGGTGCAAATGGA-MGB-3'
