- 15 Abstract
- The classical HLA class I genes (HLA Ia) were extensively studied because of their implication in clinical fields and anthropology. Less is known about worldwide genetic diversity and linkage disequilibrium for non-classical HLA class I genes (HLA Ib) and HLA pseudogenes. Notably, *HLA-H*, which is deleted in a fraction of the population, remains scarcely explored. The aims of this study were 1/ to get further insight into *HLA-H* genetic diversity and into how this variability potentially affects its expression and 2/ to define HLA Ib worldwide allelic diversity and linkage.
- Exome sequence data from the 1,000 Genomes Project were used to define second field HLA-A, -E, -F, -G and -H typing using PolyPheMe software. Allelic and two-loci haplotype frequencies were estimated using Gene[Rate] software both at worldwide and continental levels.
- Eleven novel *HLA-H* alleles identified in exome data were validated by NGS performed on 25 genomic DNA samples from the same cohort. Phylogenetic analysis and frequency distribution of *HLA-H* alleles revealed three clades, each predominantly represented in
- 30 Admixed American, European and East Asian populations, African populations and South
- Asian populations. Among these eleven novel alleles, two potentially encode complete transmembrane HLA proteins.
- We confirm the high LD between *HLA-H* and *-A*, and between *HLA-H* and *-G*, and show the three genes have distinct worldwide allelic distribution. Conversely, *HLA-E* and *HLA-F* both showed little LD, displayed restricted allelic diversity and practically no difference in their
- 36 distribution across the planet.
- Our work thus reveals an unexpectedly high *HLA-H* genetic diversity, with alleles highly
- 38 represented in Asia possibly encoding a functional HLA protein. Functional implication of
- these results remains to be explored, both in physiological and pathological contexts.
- 40
- 41 Keywords: genetic diversity; allele; haplotype; HLA lb; Next Generation Sequencing 42
- 43 Abbreviations: Linkage Disequilibrium: LD; Natural Killer: NK
- 44

## 1 1. Introduction

The Major Histocompatibility Complex (MHC) region is the most studied genetic region of the 2 human genome, in large part thanks to the presence of classical HLA class I (HLA-A, -B and 3 -C) and HLA class II (HLA-DR and -DQ) genes. Its huge genetic diversity is challenging 4 5 because of functional implication in many clinical fields such as transplant and graft outcome, or viral escape. However, this diversity also deeply contributed to anthropological science by 6 helping to define *Homo sapiens* evolution and the earliest worldwide migration routes [1]. 7 8 Conversely, less is known about worldwide genetic diversity and Linkage Disequilibrium (LD) of non-classical HLA class I genes (HLA-E, -F and -G) and of HLA class I pseudogenes. 9 10 Among these, HLA-E and -G are the most studied, both at genetic diversity and at functional levels [2, 3]. The 1,000 Genomes Project [4] gives the outstanding opportunity to contribute 11 12 to studying these loci [5-7].

13

Non classical HLA-E, -F and -G (HLA lb) display specific features compared to classical HLA
 class I (HLA la) such as very low genetic polymorphism and restricted pattern of antigens
 presentation. Their role is not to elicit an immune response but rather to inhibit its activation.

- HLA-E regulates natural killer cells (NK) and cytotoxic T-lymphocyte cells via its inhibitory
  receptor CD94/NKG2 [8-10]. HLA-E mRNA is expressed in most tissues [11] and HLA-E is
  mobilized at the cell surface by leader peptides of HLA Ia and HLA-G molecules. HLA-E also
  binds peptide ligands from stress proteins and viruses [12, 13]. The two main *HLA-E* alleles, *E\*01:01* and *E\*01:03*, display similar frequencies worldwide, suggesting an advantage for
  heterozygous carriers; *E\*01:03* is associated with higher expression [5, 6, 14-19].
- 24

HLA-G modulates NK and cytotoxic T-lymphocyte mediated activity as well as B-lymphocyte
proliferation and is involved in epithelial cell differentiation [9, 20, 21]. Many diseases
involving immune tolerance were studied in regards to HLA-G expression variation,
especially in pregnancy [22, 23]. Several studies associated genetic polymorphisms both at
coding level and in regulatory regions with inter-individual expression variation [23]. *HLA-G*displays five main alleles with unequal worldwide distribution [7, 14, 18, 24-28].

HLA-F mRNA is expressed in most cell types and the protein is intracellular, and is mobilized
at the cell surface of activated monocytes, NK, B-lymphocyte and T-lymphocyte [29, 30].
HLA-F, expressed in an open conformer form and whose function seems independent of
peptide loading [31, 32] is implicated in immune system regulation in pregnancy, infection,
autoimmunity and cancer, especially via its interaction with the inhibitory receptor KIR3DS1
[33, 34]. *HLA-F* displays four alleles defined at second field resolution, with *F\*01:01*representing 90% of allelic diversity [14, 26, 35, 36].

We formerly reported in a French cohort that *HLA-A* and *-G* were both in highly significant pairwise Global Linkage Disequilibrium (GLD) with the HLA-H locus (p<0.001), but displayed no exclusive association with either *HLA-E* or *HLA-F* [26].

44 *HLA-H* (formerly named *HLA-12.4* or *HLA-AR*), located at 55 Kbp away from the telomeric 45 side of *HLA-A*, is more related to HLA-A than to *HLA-B* or -C [37, 38] and together with *HLA-*46 *J* and *-G* forms a group defined as *HLA-A* related genes [39].

47

*HLA-H* has orthologs in chimpanzees, bonobos and gorillas, hence the separation between
 *HLA-H* and other *HLA-A*-related genes predates the divergence of these species [40-42]. A
 proposed model of evolution suggests the duplication of an ancestral MHC-A/H block 30
 million years ago evolving respectively into two genomic blocks containing MHC-A and MHC H/AL loci [43]. A second duplication of the MHC-H/AL-containing block generated the MHC-H
 and MHC-AL blocks seven million years later. The latter was subsequently lost in humans
 but is retained in ~50% of chimpanzees by a balancing selection process [41, 43, 44].

Similarly to *HLA-E, -F* and *-G,* limited *HLA-H* polymorphism is documented in the IPD-IMGT/HLA Database 3.33. Indeed, the 12 *HLA-H* allelic variants display less than one hundred SNPs and deletions [45]. Sequence preservation can be interpreted by strong selection of primordial biological functions, or as inactivation by deleterious mutation of genes [38].

6

Although no transcription signals could be detected upstream from the signal coding sequence in the earliest study describing one *HLA-H* allele, the authors added in their noteadded proof that in vitro transcription experiments showed a major transcript initiated upstream of the signal sequence [37]. In a recent study based on GeneChip Whole Transcript from Affymetrix, HLA-H transcriptional activity was shown [46]; these authors analyzed transcript profile modulation on breast cancer cells siRNA and drugs assays and showed a 2.3 to 2.5 fold upregulation of HLA-H, -F, -G, -E and -A.

14

15 One of the first HLA-H sequence descriptions showed that all exon/intron junctions were 16 provided with the requisite splicing signal [37]. This allele (corresponding to HLA-H\*02:06 in the IPD and IMGT/HLA database) was described to encode 362 amino-acids in the Uniprot 17 18 database (UniProtKB: P01893), whereas the HLA-H\*01:01:01:01 allele encodes 295 aminoacids. Although the peptide signal and non-cytoplasmic topological domain are encoded by 19 most HLA-H alleles described in the IPD and IMGT/HLA database, none but HLA-H\*02:06 20 displays a full length transmembrane domain. Furthermore all HLA-H alleles lack the 21 cysteine at codon 164 (amino-acid 188 including peptide signal length) critical for the 22 23 disulfide bond of the  $\alpha$ 2 domain, impairing the antigen presenting function [38]. They do, however, present three of the four critical cysteines (position 101, 203, 259) (amino-acid 125, 24 227 and 283 including peptide signal length) and the invariant glycosylation site at position 25 26 86 (amino-acid 110 including peptide signal length) [37].

*HLA-H* was thus defined as a non-functional gene, or pseudogene, reinforced by its genetic
deletion in a significant fraction of the population. This deletion of more than 50 kb between *HLA-G* and *HLA-A* loci, spanning *HLA-H*, is in LD with *HLA-A\*23/24* and *HLA-G\*01:04*alleles [15, 26, 47-49] Therefore, genetic and/or functional studies on HLA lb have paid little,
if any, attention to *HLA-H* genetic diversity.

33

27

The aims of this study were 1/ to get further insight into *HLA-H* genetic diversity and its possible implication in expression and 2/ to better define HLA Ib worldwide allelic diversity and haplotypic structure data.

#### 2. Material and methods 1

#### 2 1.1 Material

3 Analyses were performed both on exome sequence data from 2.693 individuals forming the 1.000 Genomes Project [4] and on 25 genomic DNA samples from the same cohort (Coriell 4 Institute, Camden, New Jersey, USA). 5

6 1.2 HLA allelic typing from the 1,000 Genomes Project

7 HLA-A second field allelic typing was from [50]. HLA-E, -F, -G and -H allelic assignment at the second field was performed with the PolyPheMe software v1.2 (Xegen, Gemenos, 8 France) [50] using the IPD-IMGT/HLA Database 3.33 as reference [45] .Briefly, HLA typing 9 first involved isolation of all the reads related to HLA loci using Bowtie 2 [51]. The reads thus 10 isolated were assigned to each locus targeted (HLA-E, -F, -G and -H) using an "end to end" 11 12 mapping step with Bowtie 2 [51]. The positive reference datasets included all the HLA alleles 13 of each locus investigated. The negative reference dataset included all the alleles from related loci (HLA gene and pseudogene sequences except HLA-E, -F, -G and -H). FASTQ 14 15 files containing exclusively the specific sequence reads for each locus were generated. For each locus, first field-level types were determined and resolution was then incremented to 16 second field. In this analysis, all loci with at least 300 specific reads identified were analyzed 17 and typed using all the variable positions described in the IPD-IMGT/HLA Database 3.33 18 19 [45].

- 20
- 21 22

1.3 HLA-H new allele identification and confirmation, phylogenetic analysis and putative protein prediction

HLA-H typing was not possible for many samples' exome sequence data, *i.e.* no allele from 23 the IPD-IMGT/HLA Database 3.33 corresponded to the observed SNP combination. Whole 24 sequence analysis revealed unreported SNP combinations and/or sequence variations in the 25 IPD-IMGT/HLA Database 3.33 [45]. These new alleles were thus explored in samples which 26 were hemizygous for HLA-H, i.e. displaying one allele HLA-A\*23/24 [15, 26, 47-49]. 27

28 These new HLA-H alleles identified in exome sequence data were confirmed using targeted 29 Next Generation Sequencing (NGS) of 25 genomic DNA samples hemizygous for HLA-H 30 from the 1,000 Genomes Project (Coriell Institute, Camden, New Jersey, USA). HLA-H was amplified by long-range PCR (primer sequences CAAACTCCGTGGGTGASTTT and 31 TGGCTGCTACTCTGGGTTCT, from position -483 to 4418 according to the IPD-IMGT/HLA 32 Database [45]), generating an amplicon of approximately 4,900 bp depending on alleles. 33 34 PCR fragments were sequenced as previously described [52] using a MiSeq NGS platform 35 (Illumina, Eindhoven, The Netherlands). NGS data were analyzed using PolyPheMe software 36 v1.2.

37

38 HLA-H cDNA sequences were aligned using the multiple sequence alignment tool MUSCLE in the Molecular Evolutionary Genetics Analysis (MEGA) software version X [53]. 39 Evolutionary relationships among HLA-H cDNA sequences were inferred using the Neighbor-40 41 Joining method with 1,000 bootstrap replicates. Evolutionary distances were computed using 42 the p-distance method and units were the number of base differences per site.

43

44 Putative protein prediction from HLA-H alleles was performed based on HLA-H cDNA sequences using Expasy [54]. HLA-A\*02:01:01:01, G\*01:01:01:01, H\*01:01:01:01 and 45 H\*02:06 alleles were added for reference HLA-A\*02:01:01:01, HLA-G\*01:01:01:01, HLA-46 H\*01:01:01:01 alleles were selected because of their high frequency in populations of 47 48 European descent; they are also commonly used as reference sequences, particularly in the 49 IMGT/ HLA database. HLA-H\*02:06 was selected because it encodes the protein with the longest amino-acid sequence with putative functional patterns. Peptide sequence 50 characteristics for specific domains, motifs or sites were analyzed according to Prosite 51 52 (https://prosite.expasy.org/), Uniprot (https://www.uniprot.org/) and Phobius 53 (http://phobius.sbc.su.se/). Prosite relies on documentation entries describing protein domains, families and functional sites. Uniprot uses the Basic Local Alignment Search Tool
 (BLAST) to find regions of local similarity between sequences. Phobius is used for prediction
 of transmembrane topology and signal peptides [55-57].

4 5

1.4 HLA-A, E, -F, -G and -H allelic and two-loci haplotype analysis

Allelic and two-loci haplotype frequencies were estimated based on typing results of each individual at a worldwide population level and at continental level in African populations, Admixed American populations, European populations, East Asian populations and South Asian populations (see [4] for population description). Missing data at a locus led to the exclusion of the concerned sample from further analyses. No multiple imputations were used.

Frequencies were estimated using an EM algorithm implemented in the Gene[Rate] computer tools [58]. Two-loci Linkage Disequilibrium (LD) was investigated according to locus proximity, *i.e. HLA-E~HLA-A*, *HLA-A~HLA-H*, *HLA-H~HLA-G* and *HLA-G~HLA-F*. LD was assessed by a likelihood-ratio test on the frequency estimations [58] and was provided for specific pairs of alleles as a list of standardized residuals for each observed haplotype. Values greater than |2| were considered to be a significant deviation [59].

## 3. Results

1.1 HLA-H worldwide diversity analysis identifies 11 novel alleles

Eleven *HLA-H* novel alleles identified in exome data were validated by concordance with targeted NGS performed on identical DNA samples (Table 1). *HLA-H* novel alleles, submitted to Genbank and to the IPD-IMGT /HLA Database are described in Appendice Table 1. Official names for the eleven *HLA-H* novel alleles identified in this study submitted to the IPD-IMGT /HLA Database have been officially assigned by the WHO Nomenclature Committee. This followed the agreed policy and was subject to the conditions stated in the most recent Nomenclature Report [60].

10 11

1 2

# *1.2 HLA-H* phylogenetic analysis defines three distinct groups

12 All HLA-H sequences, i.e. from the IPD-IMGT/HLA Database 3.33 and identified in this study (N=22). were aligned and evolutionary relationships among these cDNA sequences were 13 inferred using the Neighbor-Joining method. The resulting phylogenetic tree (Figure 1A) 14 15 shows three main clades. The first clade contains all the  $HLA-H^*01$  alleles and the  $H^*03:01$ 16 allele: second clade includes six HLA-H\*02 sequences (HLAthe 17  $H^{02:01/02/03/03:02/05/11}$ ; the third clade includes nine HLA-H<sup>\*02</sup> sequences, seven of 18 which are novel (*HLA-H\*02:04/06/07/08/09/10/12/13/14*). The first and third clades contain 19 sequences that were not observed in the individuals forming the 1,000 Genomes Project 20  $(H^*03:01)$  and  $H^*02:06$  alleles, respectively) and that display divergent sequences (long 21 branches). Thus, a second alignment containing all observed HLA-H sequences except the  $H^*03:01$  and  $H^*02:06$  alleles (N=20) was performed and their evolutionary relationships are 22 23 shown in Figure X (Figure 1B). This phylogenetic tree displays the same groupings as the former one, without the divergent sequences. 24

25 26

# 1.3 Two novel HLA-H alleles display all patterns of full-length HLA protein

27 Putative protein prediction from the novel HLA-H alleles based on HLA-H cDNA sequences using Expasy [54] ranged from 18 amino-acid (AA) to 362 AA (Table 2). Peptide sequence 28 analysis using Prosite, Uniprot and Phobius [55-57] are described in Table 2. Reference 29 protein sequences encoded by HLA-A\*02:01:01:01, G\*01:01:01:01 and H\*02:06 displayed all 30 patterns of full-length HLA proteins whereas those encoded by H\*01:01:01:01:01 and H\*02:04 31 32 did not show any of them. Specific patterns of transmembrane HLA protein were found in new alleles HLA-H\*02:07 and HLA-H\*02:14: a peptide signal, a non-cytoplasmic domain, a 33 transmembrane domain, a cytoplasmic domain, a glycosylation site and a disulfide bond. The 34 35 other alleles newly reported, as well as all HLA-H alleles described so far in the IPD-IMGT /HLA Database [45] lacked all or part of these critical domains and/or sites. 36

## Table 2. Putative protein prediction from new HLA-H alleles' analysis

Putative protein prediction from new *HLA-H* alleles based on *HLA-H* cDNA sequences using Expasy [54]. Specific patterns are shown according to analysis using Prosite, Uniprot and Phobius [55-57]. For Uniprot analysis, alignment of the best match is shown. Different *HLA* alleles are shown as examples (in grey: *HLA-A\*02:01:01:01, HLA-G\*01:01:01, HLA-H\*01:01:01:01:01* and *HLA-H\*02:06*). NA: Not-Applicable.

1 1.1 HLA-A, -G and -H display distinct worldwide allelic distribution conversely to 2 HLA-E and -F.

3 From the exome sequence data for 2,693 individuals forming the 1,000 Genomes Project, 4 2,160 (80%) were accurately resolved (*i.e.* defined without ambiguity at second field level) for HLA-A, -E, -H, -F and -G loci. Typing results for each sample and each locus are given in 5 6 Appendice Table 2. Their allelic frequencies are given in Tables 3A to 3E. While thirty-seven 7 second field HLA-A alleles represent over 95% of all worldwide alleles, the different populations defined at continental level display however a great disparity regarding the most 8 representative HLA-A alleles (Table 3A). For instance, HLA-A\*11:01 was barely present in 9 10 Africa, whereas it was most frequent in East Asian populations and found at intermediate 11 frequencies in European populations.

12

Five second field *HLA-E* alleles represent more than 97% of frequencies (Table 3B), in concordance with published data showing an equal distribution between *HLA-E\*01:01* and E\*01:03 [5, 6, 14-19]; E\*01:06 and E\*01:05 are respectively virtually only observed in Europe and in Africa. *HLA-E\*01:09* displays very low frequencies everywhere and was not observed in Asia.

18

Four second field *HLA-F* alleles represent more than 96% of worldwide alleles (Table 3C),  $F^{*01:01}$  was the most frequent.  $F^{*01:03}$  was observed at over 10% in all continents, except in East Asian populations.

Five second field *HLA-G* alleles are observed (Table 3D), in accordance with published data [7, 14, 18, 24-28, 61, 62]. *HLA-G\*01:06* is mostly present in South Asia and to a lesser extent in Europe, whereas *HLA-G\*01:05N* has a higher frequency in Africa.

27 Nineteen second field HLA-H alleles represent 99% of worldwide frequencies, among which 11 novel alleles (Table 3E), displaying an unreported allelic frequency. HLA-H\*01:01 is the 28 29 most frequent allele except in Africa, where HLA-H\*02:05 is more common. The deletion encompassing HLA-H (named HLA-H\*Del) is observed at over 10% in all continents and is 30 highly represented in East Asia. The new allele HLA-H\*02:07 has a higher frequency both in 31 East and South Asian populations but is absent in Africa. This is in accordance with this 32 allele, referred to as H\*02:04new and defined by a silent G>A substitution at position 368 33 compared to H\*02:04, being observed at ~9% in a French population [26]. Of note, H\*03:01 34 35 and H\*02:06 alleles, reported in early studies on HLA-H [37, 38] are not observed in the 1,000 Genomes Project panel. 36

## Table 3E

## Tables 3A, 3B, 3C, 3D and 3E. HLA-A, -E, -F, -G and -H allelic frequencies.

*HLA-A, -E, -F, -G* and *-H* allelic frequencies, observed in at least 0.2%, in worldwide populations (ALL) and in African populations (AFR), Admixed American populations (AMR), European populations (EUR), East Asian populations (EAS) and South Asian populations (SAS) (see [4] for population description). Number of individuals included in each group is given in brackets. Frequencies above 3% are in bold.

1.1 High two-loci linkage disequilibrium between HLA-H and -A, and between HLA-H and -G

Haplotypes estimated between each pair of loci and their combined frequencies are given in Tables 4A to 4D. Strong LD is observed between *HLA-A* and *-H*, and *HLA-H* and *-G* alleles, as all haplotypes with a frequency above 3% were in significant LD with very high standardized residual values.

In contrast, *HLA-E* and *-A*, and *HLA-G* and *-F* alleles display few significant associations with standardized residuals very close to the threshold value for significance; indeed the main *HLA-E* and *-F* alleles (i.e.  $E^{*01:01}$  and  $E^{*01:03}$  and  $F^{*01:01}$  and  $F^{*01:03}$ ) were not observed to be exclusively associated with *HLA-A* and *-G* alleles, with the exception of  $E^{*01:01} \sim A^{*01:01}$  in Europe and South Asia.

The tight associations found between *HLA-A* and *-H*, and *HLA-H* and *-G* are concordant with results previously observed at the scale of a French population [26] and further confirm known associations, like the deletion encompassing *HLA-H* with  $A^*23$  and  $A^*24$  alleles, but also reveal unobserved exclusive associations between *HLA-A* and *-H*, such as that between *HLA-A\*11:01* and *-H\*02:07*.

Table 4D

Tables 4A, 4B, 4C and 4D. HLA-E~HLA-A, HLA-A~HLA-H, HLA-H~HLA-G and HLA-G~HLA-F Linkage Disequilibrium (LD) and frequencies.

*HLA-E~HLA-A, HLA-A~HLA-H, HLA-H~HLA-G* and *HLA-G~HLA-F* Linkage Disequilibrium (LD) provided for pairs of alleles observed in at least 0.2% in worldwide populations (ALL) and in African populations (AFR), Admixed American populations (AMR), European populations (EUR), East Asian populations (EAS) and South Asian populations (SAS) (see [4] for population description). Number of individuals included in each group is given in brackets. Observed frequencies (obs) above 3% and standardized residuals (stdres) for each observed haplotype with values greater than |2| are in bold.

# 1 4. Discussion

The aim of this study was to investigate worldwide HLA Ib genetic diversity. To achieve this goal, we used public data from exome sequencing and confirmed novel sequences experimentally. This approach allowed to 1/ get further insight into *HLA-H* genetic diversity and how this plasticity can potentially lead to functional diversity and 2/ to analyze worldwide *HLA-E, -F* and *-G* allelic distribution and LD. Indeed, exome sequence data from the 1,000 Genomes Project [4] constitute a priceless public resource allowing genetic diversity studies [5-7].

Our main result is the description of 11 novel HLA-H alleles, and thanks to the 1,000 10 Genomes Project associated DNA collection, their confirmation using targeted NGS. We 11 show in particular that the HLA-H locus displays an unexpected diversity with 18 second field 12 alleles at worldwide level with frequency above 0.2%, with unequal distribution across the 13 14 five continents. We further confirm the high LD between HLA-H and -A, and between HLA-H 15 and -G, though at a lower extent. However, HLA-G has a greater diversity in its regulatory regions (5'URR and 3'UTR), that are structured in conserved haplotypes and in stronger LD 16 17 with HLA-H [26]. We also confirm the observation that HLA-G second field allelic distribution, like that of HLA-H and HLA-A, is different from one part of the globe to another. Conversely, 18 HLA-E and HLA-F both show little, if any, LD with their loci neighbors, display very restricted 19 allelic diversity and little difference in their worldwide distribution. 20

21

Phylogenetic analysis and frequency distribution of HLA-H alleles described in the IPD-IMGT 22 /HLA Database and newly identified here, revealed three clades, each predominantly 23 represented in Admixed American, European and East Asian populations (Clade containing 24 25  $H^*01:01$ ), African populations (Clade containing  $H^*02:05$ ) and South Asian populations (Clade containing  $H^*02:07$ ), suggesting a strong genetic drift. The genetic deletion 26 encompassing HLA-H could not be included in phylogenetic analysis but was present in at 27 least 10% of every population and above 20% in South Asian populations. Due to this 28 deletion of the HLA-H locus and to the fact that most HLA-H alleles described so far encode 29 30 truncated proteins, HLA-H is considered to be a pseudogene. Some studies however, linked its transcriptional expression with inter-individual variations in immune responsiveness [46, 31 63, 64], that might imply an activity for this locus. HLA-H allelic diversity and worldwide 32 distribution could also be due to hitchhiking with the HLA-A locus [65], reflected by their high 33 LD. The observation of the new alleles  $H^{*}02:07$  and  $H^{*}02:14$  that possibly encode a protein 34 with all the patterns of a transmembrane HLA protein, opens up new perspectives for this 35 locus. The fact that these 'complete' HLA-H sequences display three out of four cysteines 36 (lacking the one at codon 164) that are important antigen presenting function [38] whereas 37 38 HLA-E, -F and -G displayed all four of them remains to be investigated, as this cysteine was 39 not implicated in the disulfide bond predicted in all of the HLA protein sequences included in 40 this study.

41

Our results on HLA lb allelic frequencies and two-loci haplotypes estimation on worldwide 42 populations further supports the LD between HLA-A, -H and -G. Although their worldwide 43 distribution displays considerable differences, their strong LD is observed in all populations 44 investigated. Conversely, HLA-E and HLA-F, whose genetic diversity was lower at second 45 46 field resolution, displayed no LD. This difference could be an echo of their specific 47 expression and function. Indeed, whereas HLA-G is expressed in a tissue-specific manner with documented inter-individual variations and coding polymorphisms [23, 66, 67], HLA-E 48 49 and HLA-F appear to be mobilized at the cell surface upon activation [9, 33, 34, 68], and HLA-E has one high and one low expressing allele. The apparent shared function of HLA lb, 50 *i.e.* inhibition of immune activation, might thus have evolved and be regulated by two 51 independent pathways, one driven by a population genetics drift and adaptation to specific 52 53 environments, and the other led by cellular compensation mechanisms.

Furthermore, HLA lb two-loci haplotypes may be helpful in clinical fields as the involvement of HLA-G and HLA-E, both at genetic polymorphism and expression levels, has been well described in solid organ transplant and grafts. Given that HLA-A typing of recipients and donors is systematically and routinely performed in immunogenetics laboratories, our results on LD results could potentially improve transplant matching strategies.

6

7

# 5. Conclusions

8 In conclusion, our work reveals an unexpected *HLA-H* genetic diversity with alleles highly 9 represented in Asia potentially encoding a functional HLA protein. This study also contributes 10 to better define worldwide *HLA-E*, *-F* and *-G* genetic diversity, distribution and LD. Functional 11 implication of these results remains to be explored, both in physiological and pathological 12 contexts.

# 13 6. Appendices

Appendice Table 1. *HLA-H* novel alleles. Novel HLA-H alleles names, Genbank and IPD-IMGT /HLA Database submissions numbers, nearest allele and description as compared to the nearest allele.

17

# 18 Appendice Table 2. *HLA-A, -E, -H, -F and –G* second field level typing results.

HLA-A, -E, -H, -F and -G second field level typing results for 2,160 samples accurately
resolved for all locus (i.e. defined without ambiguity) from exome sequence data for 2,693
individuals forming the 1,000 Genomes Project [4].

#### 29 9. Figure

#### 30 Figures 1A and 1B. Phylogenetic relationship between *HLA-H* alleles defined at 31 second field.

32 Phylogenetic trees contain either all 22 HLA-H allelic sequences from the IPD-IMGT /HLA Database and sequences from new HLA-H alleles described in this study (Figure 1A), or 20 33 *HLA-H* allelic sequences, excluding  $H^*03:01$  and  $H^*02:06$  alleles not observed in this study 34 35 (Figure 1B). Optimal trees are shown (respectively with the sum of branch length = 0.05748059 (Figure 1A) and 0.04361905 (Figure 1B)). The percentage of replicate trees in 36 which the associated taxa clustered together in the bootstrap test (1000 replicates) are 37 38 shown next to the branches [69]. Trees are drawn to scale, with branch lengths in the same units (base differences per site) as those of the evolutionary distances used to infer the 39 40 phylogenetic tree. Evolutionary distances were computed using the Maximum Composite Likelihood method [70] and units are the number of base substitutions per site. There were a 41 42 total of 1105 positions in the final dataset. Evolutionary analyses were conducted in MEGA X 43 [53].
