9 B. & Braillard, L.: Geomorphic response to the Lateglacial-Holocene transition in high Alpine
10 regions (Sanetsch Pass, Swiss Alps)

11
12 Several palaeoclimatic archives have documented the pronounced climatic and environmental
13 change associated with the Lateglacial-Holocene transition in the European Alps. However, the
14 geomorphic response to this major environmental transition has been only punctually
15 investigated. In this study, we propose a detailed reconstruction of post-Last Glacial Maximum
16 palaeo-environmental conditions and geomorphic connectivity in the Sanetsch Pass area (2252 m
17 a.s.l., western Swiss Alps), based on a multi-method approach combining geomorphological and
18 sedimentological field investigations with quantitative sedimentology and geochronology.
19 Samples for sediment characterization (grain-size, micromorphology and X-Ray diffraction) and
20 geochronology (optically stimulated luminescence and ¹⁰Be surface exposure dating) were
21 collected from three representative landforms of the study area: a high-elevation silty deposit
22 covered by patterned ground, an alluvial fan and a hummocky moraine covered by rockfall
23 deposits. Our multi-method outcomes reveal the geomorphic history of the three deposits and

24 their connectivity through sediment cascade. These results highlight the development of rapid
25 and most probably transient landscape changes in high Alpine regions during the Lateglacial-
26 Holocene transition, with an increase in sediment flux and the establishment of paraglacial and
27 periglacial geomorphic processes.

40 High-elevation Alpine regions are active environments, where landforms are constantly re-
41 shaped by the interplay between a variety of geomorphic processes. Throughout the Quaternary,
42 the nature and dominance of these processes have been largely determined by climatic
43 oscillations between glacial and interglacial conditions. During glacial periods, glacier erosion,
44 sediment transport and deposition leave behind characteristic landforms and deposits such as U-
45 shaped valleys, glacial cirques, polished bedrock, moraines and erratic boulders (e.g. Benn &
46 Evans 2014). During or soon after glacier retreat at the glacial/interglacial transition, glacial
47 processes are gradually replaced by paraglacial and periglacial processes, which transiently
48 transform the ice-free landscape (Church & Ryder 1972; Ballantyne 2002; French 2007; Mercier
49 & Etienne 2008). Paraglacial processes involve various geomorphic agents (hillslope, fluvial,
50 aeolian) resulting in a wide range of depositional and erosional landforms (e.g. rockfall deposits,
51 debris cones, alluvial fans, gully incisions and aeolian drapes; Ballantyne 2002; Cossart *et al.*
52 2008; Borgatti & Soldati 2010; Cossart *et al.* 2013; Geilhausen *et al.* 2013; Gild *et al.* 2018).
53 Periglacial processes are also present and give origin to permafrost-related landforms like rock
54 glaciers and patterned ground (French 2007; Colombo *et al.* 2016).

55 The European Alps have been repeatedly glaciated during the Late Pleistocene, with
56 glacier expansion culminating at the Last Glacial Maximum (LGM, 26.5-19.0 ka ago; Clark *et*
57 *al.* 2009; Wirsig *et al.* 2016a). Post-LGM warming and rapid ice decay were followed by
58 episodes of glacier stillstands and readvances during the Lateglacial period (Lateglacial stadials,
59 19.0-11.6 ka ago; Ivy-Ochs *et al.* 2007; Hippe *et al.* 2014; Ivy-Ochs 2015), due to temporary
60 climate deteriorations (Schmidt *et al.* 2012). Following the Younger Dryas (YD, 12.7-11.6 ka
61 ago; Ivy-Ochs *et al.* 2007) and the Early Holocene Preboreal Oscillation cold event (11.4-11.3 ka
62 ago; Rasmussen *et al.* 2007; Schimmelpfennig *et al.* 2012), Alpine glaciers eventually retreated

63 and remained behind ice limit of the Little Ice Age (LIA, 1300-1860 CE; Hanspeter *et al.* 2005;
64 Ivy-Ochs *et al.* 2009; Steinemann *et al.* 2020), in response to Early and Middle Holocene abrupt
65 warming (Schimmelfennig *et al.* 2012).

66 Palaeoenvironmental conditions during the Lateglacial and at the Holocene transition
67 have been investigated through several palaeoclimate proxies (Heiri *et al.* 2014). However, the
68 geomorphic response to this major environmental transition has been only punctually examined,
69 focusing on specific geomorphic processes like rockfall activity (e.g. Zerathe *et al.* 2014; Ivy-
70 Ochs *et al.* 2017) or fluvial incision (e.g. Korup & Schlunegger 2007; Valla *et al.* 2010; Rolland
71 *et al.* 2017). Likewise, the timing of paraglacial activity, as well as the question of sediment
72 cascade and landscape connectivity, are still poorly understood (Mercier & Etienne 2008 and
73 references therein).

74 Our study aimed to contribute to the reconstruction of post-LGM palaeoenvironmental
75 conditions and geomorphic connectivity within high-altitude Alpine regions. We focused on the
76 Sanetsch Pass area (2252 m a.s.l., western Swiss Alps; Fig. 1) where multiple geomorphic
77 processes have left an extensive record of landforms and sediment deposits during the
78 Lateglacial and the Holocene (Fig. 2). Three landforms representative of the high Alpine
79 landscape were investigated: a silty deposit covered by patterned ground, an alluvial fan and a
80 hummocky moraine covered by rockfall deposits (Figs 1, 2, 3). These three deposits were
81 selected with the goals of (i) reconstructing their geomorphological history, (ii) investigating a
82 potential connectivity between the different records and (iii) assessing the suitability of glacial,
83 paraglacial and periglacial landforms as proxies for palaeoenvironmental reconstruction in high
84 Alpine regions. To that aim, we performed a detailed geomorphological and sedimentological

85 field investigation and collected samples for multi-methodological analyses on the different
86 landforms.

87

88 **Study area and sampling locations**

89 The study area is located next to the Sanetsch Pass (2252 m a.s.l., western Swiss Alps; Fig. 1).

90 The local bedrock is composed of Cretaceous and Paleogene sedimentary rocks belonging to the
91 Helvetic Diablerets and Wildhorn nappes (Badoux *et al.* 1959; Masson *et al.* 1980). Three
92 geological units are of particular interest for our study: calcareous shales containing ca. 20% of
93 fine detrital quartz (Palfris Formation; Föllmi *et al.* 2007) form the Arpille Ridge, siliceous
94 limestones (Helvetic Kieselkalk Formation; Föllmi *et al.* 2007) form the Arpelistock cliff, and
95 quartzose sandstones (Fruttli Member of the Klimsenhorn Formation, Menkveld-Gfeller 1997)
96 from a □ 5-m thick layer at the top of the calcareous Les Montons cliff (Fig. 2).

97 The Sanetsch Pass is currently ice free, with the nearest glacier front (Tsanfleuron
98 Glacier) □ 3 km to the southwest (Fig. 1). During the LGM, the Rhône glacier reached an
99 altitude of about 2000 m a.s.l. in the main valley above Sion (Fig. 1; Bini *et al.* 2009). The
100 Sanetsch Pass area was partly covered by ice with an estimated average thickness of □ 200 m
101 and some mountain peaks were protruding above the ice surface as nunataks (Bini *et al.* 2009).
102 The Tsanfleuron glacier was flowing both northwards and southwards from the pass, as testified
103 by lateral morainic ridges (Fig. 2; Badoux *et al.* 1959). Following the deglaciation of the Swiss
104 foreland *c.* 21 ka ago (Ivy-Ochs *et al.* 2004), the Rhône Valley became ice free *c.* 17 ka ago
105 (Hantke 1992; Hinderer 2001). The onset of sedimentation in the Pond Emines (at 2288 m a.s.l.,
106 □ 1 km southwest from the Sanetsch Pass; Fig. 2) at *c.* 12 ka ago (Berthel *et al.* 2012), and the
107 apparent post-12 ka exposure ages (Steinemann *et al.* 2020) of glacially-polished bedrock outside

108 the Tsanfleuron LIA moraine (□ 1 km west of the Sanetsch Pass; Fig. 2) imply ice-free
109 conditions at the Sanetsch Pass during or soon after the YD. Paraglacial and periglacial processes
110 following the deglaciation have resulted in a rich record of landforms reflecting the transient
111 landscape evolution (Fig. 2). Three representative landforms of the Sanetsch Pass landscape are
112 investigated in the present study (Figs 2, 3).

113 The first landform consists of a thin sediment blanket draping a bedrock platform located
114 on the southern slope of the Arpelistock peak, in contact with glacial deposit from a small local
115 glacier (ARP site, 2660-2715 m a.s.l., □ 0.23 km² in area; Fig. 3A). The surface of the ARP
116 deposit exhibits locally a polygonal patterned ground (Fig. 3B; Gobat & Guenat 2019). The
117 second landform is an alluvial fan located in the plain north of the Sanetsch Pass (CRE site,
118 2090-2130 m a.s.l., 0.14 km² in area; Fig. 3A, C). The third landform is a hummocky moraine
119 located north of the plain (SAN site, 2040-2100 m a.s.l., 0.13 km² in area; Figs. 3A, C, D). The
120 distinct hummocky morphology, with hills up to a few meters high, is partially covered by
121 rockfall deposits composed of sandstone and limestone boulders detached from the nearby
122 overhanging cliff (Les Montons peak; Figs 2, 3D).

123

124 **Methods**

125 Geomorphological and sedimentological field investigation

126 In the present study, we performed a new geomorphological mapping over an area of □ 16 km²
127 around the Sanetsch pass (Fig. 2), based on the sheet St-Léonard (1286) (Badoux *et al.* 1959) of
128 the Geological Atlas of Switzerland (1:25000). To this aim, we combined the geomorphological
129 map of Quaternary superficial deposits (Badoux *et al.* 1959) with new field investigations and
130 remote sensing mapping based on the swissALTI3D DEM and orthophotos (swisstopo).

131 Detailed stratigraphic outcrops were logged for the ARP and CRE deposits. Two
132 stratigraphic profiles (□ 40 cm-deep) were dug out in the ARP high-elevation silty deposit,
133 below the polygonal patterned ground (Fig. 3B). The CRE log was recorded from a natural
134 outcrop exposed in a gully incising the alluvial fan (4.5 m deep; Fig. 3C). Sedimentary units were
135 identified based on their grain-size range, sorting, clast shape, compaction, sedimentary
136 structures, colour and lithology. Reaction to HCl on the field and nature of contacts between
137 individual units were also recorded.

138

139 Grain-size, micromorphology and optical petrography

140 Eight bulk sediment samples were collected for grain-size analyses (G1-G6 from CRE site, G7
141 and G8 from ARP site; Figs 5 and 4, respectively), in order to understand the genesis of the ARP
142 and CRE deposits and a potential connectivity between them. Conventional grain-size
143 distribution measurements were carried out by sieving the air-dried sand and granule/pebble
144 fractions (Rivière 1977; Hadjouis 1987). Analyses of the silt and clay fractions were performed
145 using a laser Malvern MS20 diffraction system (Department of Environmental Sciences,
146 University of Basel, Switzerland). Sorting indexes (S_o) were calculated using millimetres units
147 ($S_o = (D_{75}/D_{25})^{0.5}$, where D_{25} and D_{75} are respectively the first and the third quartile of the grain-
148 size distribution), providing different sediment sorting categories: very well sorted ($S_o < 2.5$),
149 well sorted (S_o between 2.5 and 3.5), normally sorted (S_o between 3.5 and 4.5) and poorly sorted
150 ($S_o > 4.5$).

151 Three CRE undisturbed sediment samples were collected in Kubiena boxes (8x11 cm) for
152 micromorphological analyses (M1-M3; Fig. 5), with the aim to identify depositional and post-
153 depositional features in the alluvial fan sediments. The samples were first air-dried, impregnated

154 with an acetone-diluted epoxy resin and then cut with a diamond saw (Department of
155 Environmental Sciences, University of Basel, Switzerland). Two covered thin sections (4.5x4.5
156 cm) per sample were prepared (Th. Beckmann, Braunschweig, Germany) and examined optically
157 on a Leitz DM-RXP microscope, both in plane-polarized and crossed-polarized light. Bedrock
158 thin sections were additionally prepared (Department of Geosciences, University of Fribourg,
159 Switzerland) and analysed for four bedrock samples representative of the catchment lithology
160 (two from the siliceous limestone, L1 and L2, and two from the calcareous shale, S1 and S2;
161 Table S1), in order to obtain further information on the silicate fraction of the bedrock (grain
162 shape and size) and to discuss a potential connectivity between the local bedrock and the CRE
163 sediments.

164

165 X-Ray diffraction and geochemistry

166 X-Ray Diffraction (XRD) analyses were performed on a total of 22 samples, including 18 bulk
167 sediment samples from CRE and ARP sites (CRE01-CRE16, Fig. 5; ARP01 and ARP03, Fig. 4)
168 and 4 bedrock samples (L1, L2, S1, S2), to gain information on their mineral composition and
169 assess sediment provenance and potential connectivity of the ARP and CRE deposits. Bulk
170 sediments and bedrock samples were ground with a mechanical crusher, and sample powders
171 were analysed through a Rigaku Ultima IV diffractometer system using Cu-K α radiation
172 (Department of Geosciences, University of Fribourg, Switzerland). Mineral identification was
173 performed using the Rigaku's PDXL-2 software and the ICDD Powder Diffraction File 2017
174 database (International Centre for Diffraction Data). Mineral quantification was made by
175 Rietveld refinement (Rietveld 1969), with weighted residuals of the whole pattern (Rwp) and the

176 goodness of fit (GOF) considered as Rietveld fit criteria (Toby 2006). In the present refinements,
177 Rwp and GOF values range from 4.84% to 6.74% and from 1.73 to 2.90, respectively.

178 Concentrations of total carbon (TC) and total inorganic carbon (TIC) were measured on
179 the same ARP and CRE sediment samples, using a Bruker G4 Icarus elemental analyser
180 (Institute of Geology, University of Bern, Switzerland). The percentage of total organic carbon
181 (TOC) was determined from the difference between TC and TIC. These analyses and
182 calculations were performed to examine the potential presence of palaeosols in the deposits.

183

184 Geochronology

185 Portable optically stimulated luminescence. Luminescence signal intensities were measured for
186 the CRE (cre01-cre16; Fig. 5) and ARP (arp01-arp05; Fig. 4) sites, with the aim of investigating
187 potential stratigraphic variation in the luminescence response, possibly reflecting differences in
188 sediment provenance and depositional environment. Indeed, the luminescence signal of bulk
189 sediment is mainly dependent, among other factors, on the pre-deposition light exposure of
190 sediments (i.e. signal resetting or “bleaching”; King *et al.* 2014) and on the post-deposition
191 signal accumulation during burial time due to surrounding irradiation (i.e. sediment age;
192 Sanderson & Murphy 2010). Few grams of sample were collected at different depths along the
193 ARP and CRE stratigraphy, and sealed from light exposure. We quantified total photon counts
194 on two replicates of each bulk sediment sample (without chemical pre-treatment) using the
195 SUERC portable OSL reader (Sanderson & Murphy 2010), following the measurement sequence
196 of Muñoz-Salinas *et al.* (2014). The measurement sequence (150 s in total) comprises a first
197 cycle of infrared-stimulated luminescence, targeting feldspar minerals within the bulk sediment
198 (IRSL, 30 s), and a second cycle of blue-stimulated luminescence targeting quartz (hereafter

199 referred to as optically-stimulated luminescence, OSL, 60 s), separated by 10 s of dark counts.
200 Two additional periods (10 s) of dark counts bracketed each measurement sequence. Final (IRSL
201 and OSL) photon counts were obtained by averaging between the two replicate measurements of
202 each sediment sample.

203

204 Conventional optically stimulated luminescence dating. Seven fine-grain samples were collected
205 for conventional luminescence dating from the CRE alluvial fan (CRE01-CRE04; Fig. 5) and the
206 ARP high-elevation platform (ARP01-ARP03; Fig. 4), to constrain sediment deposition
207 chronology. By combining conventional and portable luminescence measurements, we
208 determined the true depositional chronology of the deposits, taking into account potential pre-
209 depositional partial bleaching or post-depositional sediment reworking (i.e. resulting in age
210 overestimation or underestimation, respectively).

211 Samples were collected with opaque plastic tubes pounded into fresh sediment surface
212 (Nelson *et al.* 2015). Under subdued laboratory illumination, samples were treated with HCl
213 (32%) and H₂O₂ (30%) to remove carbonates and organic components, respectively.
214 Sedimentation in Atterberg cylinders (based on Stokes' Law) was used to extract the 4-11 µm
215 grain-size fraction. Half of the extracted 4-11 µm fraction was additionally treated with H₂SiF₆
216 (30%) to obtain pure quartz (only ARP03 did not provide enough material for quartz
217 purification). Polymineral and quartz separates were settled on 10-mm diameter stainless steel
218 discs for subsequent luminescence analyses.

219 All conventional luminescence measurements were carried out using TL/OSL DA-20
220 Risø readers, equipped with a calibrated ⁹⁰Sr/⁹⁰Y beta source (Institute of Geology, University of
221 Bern, Switzerland). Luminescence signals were detected using an EMI 9235QA photomultiplier

222 tube, in the UV region through a 7.5 mm of Hoya U-340 transmission filter and in the blue
223 region through a Schott BG-39 and L.O.T.-Oriel D410/30nm filter combination, for quartz OSL
224 and polymineral IRSL measurements respectively.

225 OSL and/or IRSL measurements were performed according to sample mineral
226 composition. OSL equivalent dose (D_e) measurements were conducted on quartz separates of
227 two ARP samples (ARP01 and ARP02) and on all the CRE samples. A post-IR OSL protocol
228 was applied (Table S2A), which includes an IRSL stimulation at 50 °C (100 s) prior to the blue
229 OSL stimulation (at 125 °C for 100 s; Lowick *et al.* 2015). IRSL D_e measurements were
230 conducted on polymineral (non-separated) fractions for all the ARP samples using the post-IR
231 IRSL protocol of Buylaert *et al.* (2009) (this protocol targets feldspar luminescence signal only;
232 Table S2B). After a preheat treatment (250 °C for 60 s), luminescence measurement cycles of
233 this modified single-aliquot regenerative (SAR) dose protocol (Murray & Wintle 2000) consist in
234 a first IRSL stimulation at 50 °C (100 s) followed by a second IRSL stimulation at 225 °C (100
235 s). A 40s IRSL stimulation at 290 °C was added at the end of each SAR cycle in order to limit
236 signal carry-over throughout successive cycles (Wallinga *et al.* 2007). No post-IR IRSL
237 measurements were performed on CRE samples due to the absence of feldspar IRSL signal.
238 Fading rates (*g-value*; Aitken 1985) were measured on aliquots used for D_e determination,
239 following Auclair *et al.* (2003). Final fading corrected D_e values were calculated following the
240 fading correction procedure of Huntley & Lamothe (2011), using the Luminescence R package
241 (Kreutzer *et al.* 2012). Signals used for data analysis were integrated over the first 1.2-2.4 s
242 minus the following 2.6-8 s for quartz OSL measurements, and over the first 1.2-10 s minus the
243 last 90-99 s for polymineral IRSL measurements. Dose–response curves were constructed using
244 an exponential fitting. Recycling ratios within 15% of unity and recuperation within 10% of the

245 natural dose were used as acceptance criteria for the single-aliquot data. The suitability of the
246 two applied protocols was confirmed by preheat-plateau (for quartz OSL), and residual and dose-
247 recovery tests (Wintle & Murray 2006). For all the samples, residual doses <2% of the natural D_e
248 and recovered doses within 10% of the unity were measured.

249 About 200 g of bulk sediment material were collected from the surrounding of each
250 sample to determine the environmental dose rate. The material was desiccated at 60 °C to enable
251 water content quantification. U, Th and K activities were measured using high-resolution gamma
252 spectrometry (Department of Chemistry and Biochemistry, University of Bern, Switzerland;
253 Preusser & Kasper 2001) and were employed, together with the water content, as inputs for final
254 dose rate determination through the Dose Rate and Age Calculator (DRAC; Durcan *et al.* 2015).
255 Final ages were calculated using the Central Age Model (CAM; Galbraith & Roberts 2012).

256
257 ^{10}Be surface exposure dating. Three sandstone boulders rockfall-derived lying on the hummocky
258 moraine, one on a flat area, one on a hummock ridge and one in an intra-hummock hollow
259 (boulders \square 2-m wide and 1-m high, SAN site; Fig. 3C), were sampled for ^{10}Be surface-exposure
260 dating, in order to obtain a minimum age constraint for the hummocky moraine formation.
261 Samples were collected with hammer and chisel from flat surfaces on top of the boulders, with
262 evidence for minimal erosion (Gosse & Phillips 2001). Sample crushing and sieving were
263 performed to isolate the 250-400 μm grainsize fraction. Quartz was isolated using magnetic
264 separation and repeated leaching in a H_2SiF_6 -HCl mixture. Conventional chemical treatment
265 adapted from Brown *et al.* (1991) and Merchel & Herpers (1999) was followed to complete ^{10}Be
266 extraction (GTC platform, ISTERre, University Grenoble Alpes, France). $^{10}\text{Be}/^9\text{Be}$ ratios were
267 measured at ASTER French National AMS facility (CEREGE, Aix-en-Provence, France; Arnold

268 *et al.* 2010) against the in-house Be standard (Braucher *et al.* 2015), whose assumed isotope ratio
269 is 1.191×10^{11} . Correction for a full process blank ratio of $^{10}\text{Be}/^9\text{Be} = 5.4 \pm 0.6 \times 10^{-15}$ was applied.

270 Surface-exposure ages were computed with the online CREp program (Martin *et al.*
271 2017; <https://crep.otelo.univ-lorraine.fr/#/init>). Calculations were performed using a ^{10}Be
272 production rate by neutron spallation at sea level and high latitude (SLHL) of 4.16 ± 0.10 at $\text{g}^{-1} \text{a}^{-1}$
273 (Claude *et al.* 2014) scaled at the sample sites using the LSDn scaling scheme (Lifton *et al.*
274 2014). The ERA-40 reanalysis data set (Uppala *et al.* 2005) and the Lifton-VDM2016
275 geomagnetic database (Lifton 2016) were used to correct atmospheric pressure and geomagnetic
276 field fluctuations, respectively. Corrections for topographic shielding based on field
277 measurements were also applied (Dunne *et al.* 1999). For assessing the effect of potential post-
278 depositional surface covering (e.g. snow) or surface degradation processes, two end-member
279 scenarios were considered: one without any post-depositional correction and one including
280 snow-cover and surface-erosion corrections. For surface-erosion correction, an erosion rate of 1
281 mm ka^{-1} was applied, following the argument of Wirsig *et al.* (2016b). The snow-cover
282 correction factor was computed for all boulders following eq. (3.76) in Gosse & Phillips (2001),
283 considering 6 months per year persistence of a 50-cm thick snow cover (Wirsig *et al.* 2016b), a
284 snow density of 0.3 g cm^{-3} and a spallation attenuation length in snow of 109 g cm^{-2} (Delunel *et*
285 *al.* 2014).

286

287 **Results**

288 Geomorphological and sedimentological field investigation

289 We present an updated map of superficial deposits in Fig. 2, showing the Quaternary deposits
290 occurring in the study area and the location of the three study sites (ARP, CRE and SAN).

291 Sedimentological observations for ARP and CRE deposits are summarised in the
292 stratigraphic logs showed in Figs 4 and 5, respectively (detailed descriptions are given in Tables
293 S3 and S4). The stratigraphy of the ARP deposit (Fig. 4, Table S3) consists of two sediment units
294 lying on top of non-weathered siliceous-limestone bedrock. The 10-cm thick top unit (unit 1) is
295 clast-supported, with siliceous-limestone fragments in a silty matrix. The 30-cm thick basal unit
296 (unit 2) consists of a silty layer with a well-developed platy structure, containing few siliceous-
297 limestone fragments.

298 The stratigraphy of the CRE alluvial fan (Fig. 5, Table S4) displays the current soil
299 horizon (unit 1) and the recent (i.e. Holocene) coarse alluvial fan deposit (unit 2) in the first 1.5
300 m of depth. Underneath, a succession of three categories of sediment units can be observed:
301 homogenous clayey silt (units 6, 7, 9, 10, 17, called "fine layers" hereafter), silty clay or loam
302 containing weathered granules and pebbles (units 3, 4, 5, 8, 11, 12, 13, 15, 19, called
303 "heterogeneous layers" hereafter), and gravel layers clast-supported with imbricated elements
304 (units 14, 16, 18).

305

306 Grain-size and micromorphology

307 Grain-size distributions (Fig. 6) show strong similarities between the ARP silty unit (unit 2,
308 samples G7 and G8), and the CRE fine (units 6, 10, 17, samples G2, G3 and G6) and
309 heterogeneous (units 5, 12, 15, samples G1, G4 and G5) layers. Frequency curves are multi-
310 modal and characterised by one primary peak around 35 μm (coarse silt), a secondary peak
311 around 4-8 μm (fine/very fine silt), and a minor peak around 150 μm (fine sand). An additional
312 minor peak around 10^4 μm (pebble) is also visible for samples G4 (CRE site, heterogeneous
313 layer) and G8 (ARP site), which reflects the presence of some isolated clasts as observed in the

314 stratigraphy (Figs 4, 5). Median grainsize values (D_{50}) range between 11 and 16 μm (fine silt).
315 Calculated S_o vary between 2.7 and 3.4, reflecting good sorting (with the exception of G4 and
316 G8 which have a S_o of 5.5 and 4.5 respectively, but reduced to 3.3 and 2.9 if only the clayey,
317 silty and sandy fractions are considered).

318 Fig. 7 highlights the main micromorphological features observed in thin sections from the
319 CRE alluvial fan. Thin section M1 (fine unit 6; Fig. 7A) displays a moderately-developed sub-
320 angular blocky microstructure in the clayey silt, expressed by slickensides associated with
321 mottling. A low proportion (<2%) of small lithic fragments (<2 mm; not visible in Fig. 7A but
322 similar to the one shown in Fig. 7C) containing quartz grains (20 to 300 μm size) is also
323 recognized. In thin section M2 (fine unit 7; Fig. 7B) and M3 (heterogeneous unit 13), well-
324 developed horizontal laminae (1 to 5-mm thick) with normal grading are observed. In addition,
325 the lower part of thin section M2 (heterogeneous unit 8; not visible in Fig. 7B) contains a higher
326 proportion (5-10%) of weathered (partly-decarbonated) lithic fragments (2-5 mm) in a clayey-
327 silty matrix. Thin section M3 (heterogeneous units 12 and 13; only unit 13 shown in Fig. 7C)
328 shows \square 40% of weathered (partly- to completely-decarbonated) lithic fragments (3-10 mm)
329 containing quartz grains (20 to 150 μm size), which are embedded in a clayey-silty carbonated
330 matrix. These fragments present different weathering stages, but no weathering cortex on their
331 edges. Lastly, bedrock thin sections display quartz grains of 10 to 150 μm size (the main
332 population ranging between 30 and 50 μm), representing 5-15% of the siliceous limestone and
333 15-30% of the calcareous shales (Fig. 7D).

334

335 X-Ray diffraction and geochemistry

336 XRD results show four distinct average mineralogical compositions (Fig. 8). Bedrock samples
337 (samples L1-L2 and S1-S2) present similar composition, largely dominated by carbonates (55-
338 66% calcite and up to 5% dolomite). Silicates are secondary components, mainly represented by
339 quartz (23-33%) and micas (3-16%), with some chlorite appearing only in the calcareous shales
340 (S1-S2, up to 4%). ARP sediment samples (ARP01 and ARP03) are carbonate-free and contain
341 67-70% of quartz and 19% of micas as main components (with up to 8% of chlorite and 4-7% of
342 albite). For CRE samples, two main groups can be distinguished from the mineralogical
343 compositions. Nine samples (CRE02, 03, and 05 to 11) are carbonate-free and contain mainly
344 quartz (40-54%), micas (36-52%) and chlorite (1-14%). The seven other samples (CRE01, 04,
345 and 12 to 16) are characterized by variable calcite content (5-39%), in addition to quartz (32-
346 43%), micas (23-43%) and chlorite (6-11%) components. CRE04 also contains a small
347 percentage of albite (11%), as found in the ARP samples. Geochemistry analyses result in low
348 TOC percentages for all the CRE (0.3-1.2%) and ARP (0.8 and 1.2%) samples.

349

350 Geochronology

351 Portable OSL measurements. ARP and CRE depth-profiles for luminescence signal-intensity are
352 shown in Fig. 9 (samples arp01-arp05) and Fig. 10 (samples cre01-cre16), respectively
353 (luminescence counts are reported in Table S5). For ARP site (Fig. 9), both the quartz OSL and
354 feldspar IRSL intensity profiles could be measured, with more than one order of magnitude
355 difference between OSL (10^3 - 10^4 counts) and IRSL (10^1 - 10^2 counts) signals. While the IRSL
356 counts increase consistently with depth (Fig. 9B), the OSL intensity profile is more complex:
357 sample arp03 displays large uncertainty due to the significant difference between the two

358 replicate measurements, and sample arp05 deviates significantly from the increasing-signal trend
359 with depth (Fig. 9A).

360 For CRE site, the general low-feldspar content in the analysed sediments, as highlighted
361 by XRD-analyses (Fig. 8), prevented the measurement of IRSL signal along the section, and only
362 an OSL profile could be obtained (Fig. 10). The measured profile does not follow a stratigraphic
363 coherence (i.e. luminescence signal intensity increasing with depth), but alternates between two
364 signal-intensity groups characterised by low ($20\text{-}25 \times 10^3$ counts) and high ($30\text{-}50 \times 10^3$ counts)
365 OSL counts. These two groups correspond respectively to fine (low signal intensities) and
366 heterogeneous (high signal intensities) layers (Fig. 10).

367
368 Conventional OSL dating. Sample specific information and results, including D_e values, relevant
369 dose-rate data and final CAM ages (Galbraith & Roberts 2012), are shown in Tables 1 and 2, and
370 Figs 9 and 10. Both OSL and IRSL ages were obtained for two ARP samples (ARP01 and
371 ARP02; Fig. 9), while only an IRSL age was measured for sample ARP03 (due to the lack of
372 material for quartz purification). ARP final IRSL and OSL ages range between 2.5 and 7 ka, with
373 high variability between samples and signals despite sample collection at relatively similar
374 depths within unit 2 (\square 25-cm deep; Fig. 4). For both ARP01 and ARP02, the IRSL and OSL
375 ages appear to differ without any systematics (i.e. younger IRSL age for ARP01, the opposite for
376 ARP02).

377 Quartz OSL data for CRE site (Fig. 10) results in two age populations. The first age
378 population concentrates around 11 ka (weighted-average age of 10.5 ± 1.6 ka) and correspond to
379 samples CRE01 (10.0 ± 0.6 ka), CRE02 (12.3 ± 0.7 ka) and CRE04 (9.1 ± 0.6 ka). All three samples

380 have been collected from fine layers (unit 6 for samples CRE01 and CRE02, unit 17 for sample
381 CRE04). A significantly older age of 27.2 ± 1.1 ka was obtained from sample CRE03, coming
382 from a heterogeneous layer containing pebbles (unit 11). No post-IR IRSL measurements were
383 performed on CRE samples due to the absence of feldspar IRSL signal.

384

385 ^{10}Be surface exposure dating. Sample specific information, as well as measured ^{10}Be
386 concentrations and calculated exposure ages (with and without erosion and snow corrections),
387 are summarized in Table 3 and Fig. 11. A high consistency of the ^{10}Be exposure ages obtained
388 for the three SAN sandstone boulders is evident (9.3 ± 0.4 , 9.4 ± 0.4 and 9.8 ± 0.4 ka, without snow
389 and erosion corrections). The three boulder ages agree within uncertainty and yield a weighted-
390 average age estimates of 9.5 ± 0.3 ka (no snow and erosion correction) and 10.3 ± 0.3 ka (with
391 snow and erosion correction).

392

393 **Discussion**

394 Landform and sediment (post-)depositional histories

395 High-elevation platform (ARP). Field stratigraphic observations (Table S3) and the different
396 results obtained from the multi-method approach suggest (i) that the silty sediments (unit 2) from
397 the ARP high-elevation platform correspond to an aeolian deposit covered by *in situ* produced
398 cryoclasts (i.e. bedrock limestone clasts derived from freeze and thaw cycles), and (ii) that the
399 whole deposit has been reworked by recent (possibly still ongoing) cryoturbation.

400 Excluding the coarser grain-size fraction (>2 mm, most probably deriving from isolated
401 cryoclasts) from G7 and G8 grain-size analyses (Fig. 6), the good sorting indexes (2.5 and 3.3
402 respectively) and the dominance of the silty fraction ($D_{50} = 10.1$ and 11.1 μm respectively) point

403 towards loess deposit (*sensu stricto*; Pye 1987; Smalley 1995; Muhs 2013). The multi-modal
404 grain-size distributions further suggest a local deflation source, with three main modes (4-8, 35
405 and 150 μm ; Fig. 6) roughly corresponding to silicate fractions (micas and quartz) from local
406 bedrock (10-150 μm ; Fig. 7D). Observed Lateglacial aeolian deposits at low-elevations in the
407 Rhône Valley (Sion and Bex; Fig. 1) show unimodal grainsize distributions (main mode between
408 20 and 150 μm), very good sorting (1.8) and D_{50} of 35-45 μm (Guélat 2013; and pers. comm.
409 2016). We interpret the different grain-size characteristics between ARP and Rhône Valley loess
410 as the result of a mixed provenance with both local and allochthonous input for ARP deposit.

411 Several arguments allow us to exclude the hypothesis that the ARP silty sediments derive
412 from *in situ* weathering of the underlying siliceous limestone (L1-L2; Fig. 8): (i) the sharp (with
413 no weathering) contact between the base of the ARP aeolian deposit and the underlying bedrock,
414 (ii) the complete absence of carbonates, and (iii) the presence of albite in ARP samples (ARP01
415 and ARP03; Fig. 8). The albite content (4-7%) supports the hypothesis of an allochthonous
416 component within the ARP aeolian deposit, possibly related to the Rhône Valley loess at lower
417 elevations, which is dominated by quartz, micas, chlorite and feldspar mineralogy (Spaltenstein
418 1984; M. Guélat pers. comm. 2016). Such a loessic input was indeed highlighted in a nearby soil
419 profile located 1.7 km south of the Sanetsch Pass (Spaltenstein 1985). However, XRD analyses
420 alone cannot discriminate the dominant source area(s) between Alpine or more distal origin (e.g.
421 Martignier *et al.* 2015) for the ARP aeolian material. Further geochemical analyses would be
422 necessary (Újvári *et al.* 2015) to quantitatively discuss the origin of such aeolian sediments in the
423 context of atmospheric palaeo-circulations at the scale of the European Alps (e.g. Muhs *et al.*
424 2014; Rousseau *et al.* 2018).

425 Conventional luminescence dating on ARP silty sediments provides ages ranging
426 between 2 and 7 ka, with an observed discrepancy between OSL and IRSL ages and no clear
427 systematics (Fig. 9, Tables 1, 2). This mismatch is further highlighted by portable luminescence
428 measurements, with different patterns in OSL and IRSL intensity profiles (i.e. higher OSL
429 variability compared to depth-increasing IRSL signal; Fig. 9). Different luminescence signal
430 resetting rates under light exposure (i.e. bleaching) have been reported in the literature (Murray *et*
431 *al.* 2012), with quartz OSL signal bleaching more rapidly than feldspar IRSL. Our observations
432 can be explained by (i) partial bleaching of the ARP silt before deposition, which would lead to
433 overestimation of the true depositional age, and/or (ii) differential post-depositional bleaching
434 through cryoturbation, which would cause underestimation of the true depositional age. Based on
435 the sedimentology, we favour the post-depositional bleaching hypothesis: there is high
436 probability that the ARP silt was completely bleached prior to deposition, since aeolian sediment
437 transport is commonly associated with efficient sunlight exposure (Li & Wintle 1992). After
438 deposition, active cryoturbation processes resulted in both sediment reworking and formation of
439 the overlying patterned ground (unit 1; Fig. 4). Frost and thaw processes have continually
440 mobilized sediment patches from various depths (Bertran *et al.* 2019), causing light exposure of
441 reworked sediments and the (partial) resetting of their luminescence signal. Similarly,
442 stratigraphic inconsistency and large variability in luminescence ages have been observed for
443 periglacial sediment deposits, and have been attributed to post-depositional reworking due to
444 active cryoturbation processes (Bateman 2008; Andrieux *et al.* 2018). Our young OSL (2.3-4.1
445 ka) and IRSL (2.5-2.8 ka) ages are therefore probably the result of recent/ongoing post-
446 depositional bleaching through periglacial sediment reworking, while the IRSL age of sample
447 ARP02 (7.1 ± 0.7 ka) is interpreted as minimum age for the high-elevation aeolian deposit. This

448 minimum age estimate is in agreement with low-elevation loess from the Rhône Valley attributed
449 to the late YD/Early Holocene, based on luminescence dating (Guélat 2013; Parriaux *et al.*
450 2017).

451 To summarize, the high-elevation ARP deposit reflects Lateglacial to Holocene aeolian
452 dynamics in the Sanetsch area, in line with previous aeolian sediment reconstructions in the
453 Swiss Alps and foreland (Pochon 1973; Guélat 2013; Martignier *et al.* 2015). The ARP primary
454 aeolian deposit presents a mixed autochthonous (bedrock and moraine-deposit deflation) and
455 allochthonous (nearby alluvial plains such as the Rhône Valley) origin. Luminescence dating
456 suggests that deposition occurred at least *c.* 7 ka ago, however this only remains a minimum age
457 estimate due to recent/ongoing active cryoturbation and sediment reworking at the ARP site. The
458 ARP aeolian deposit may give also insights into the presence of high-elevation ice-free areas
459 (nunataks) in the Alps already during the LGM or the early Lateglacial (Bini *et al.* 2009;
460 Martignier *et al.* 2015; Gild *et al.* 2018), where aeolian sediment could accumulate, in proximity
461 of glacially-covered areas. Furthermore, luminescence analyses (both portable and conventional
462 dating) have highlighted the occurrence of (ongoing) cryoturbation processes at the ARP site,
463 providing potential palaeoclimatic proxy for the Holocene but requiring further investigation
464 (e.g. Vandenberghe 2013; Rousseau *et al.* 2018).

465
466 Alluvial fan (CRE site). Insights into the depositional history of the CRE alluvial fan and its
467 connection to the surrounding landforms and deposits also emerge from our multi-method
468 results. XRD and micromorphological analyses confirm field stratigraphic observations (Table
469 S4), revealing a local bedrock origin for the clasts contained in the heterogeneous and gravel
470 layers of the fan (Figs 5, 7, 8). This is suggested by the moderate calcite content (5-39%; Fig. 8)

471 in most of the heterogeneous CRE units, which likely relates to the presence of bedrock-derived
472 weathered granules and pebbles (55-66% calcite content in both siliceous limestone and
473 calcareous shales; Fig. 8). The absence of calcite in some heterogeneous layers can be explained
474 by clast weathering and complete decarbonation as observed in the field (very little/no reaction
475 to HCl; Table S4). Thin-section analyses further highlight mineralogical and grain-size
476 similarities between weathered clasts and bedrock (Figs 7C, D), with abundant quartz grains of
477 similar sizes (10-150 μm) in both bedrock and clasts. The absence of a developed weathering
478 cortex around the clasts suggests that weathering did not occur *in situ* (i.e. after clast deposition
479 in the alluvial fan), but is probably inherited from a previous alteration phase (e.g. within
480 morainic and/or slope parental deposits). Further support to this hypothesis is given by the low
481 TOC along the fan stratigraphy, which implies absence of paleo-soils and therefore little *in situ*
482 weathering by pedogenesis.

483 Field stratigraphic observations, grain-size and XRD analyses also show similarities
484 between the fine/heterogeneous CRE layers and the high-elevation ARP deposit. Grainsize
485 distributions closely overlap for CRE and ARP samples (G1 to G6, and G7 and G8, respectively;
486 Fig. 6), with multiple modes (4-8, 35 and 150 μm), good sorting (2.7-3.3) and silty-fraction
487 dominance (D_{50} between 10.9 and 16.5 μm). Mineralogical analyses further support this
488 observation, with the absence of calcite (except for CRE15, which probably integrates clasts
489 from overlying/underlying gravel units) and the dominance of quartz (40-54%) and micas (23-
490 43%). Stratigraphy and micromorphological analyses also show (i) fining-up sedimentary
491 sequences within some CRE units (i.e. from weathered calcareous granules and pebbles at the
492 base to silty loam at the top; Fig. 5, Table S4), (ii) a moderately-developed sub-angular blocky
493 microstructure (unit 6; Fig. 7A) and (iii) well-developed 1 to 5-mm thick horizontal laminae

494 (units 7 and 13; Fig. 7B). All together, these observations point towards an alluvial reworking of
495 aeolian sediments to form the fine units and the matrix of the heterogeneous units of the CRE
496 alluvial fan. Deposition of reworked aeolian sediments could have occurred in a lake, or possibly
497 in a pond within the alluvial fan, as suggested by the fining-up sedimentary sequences (units 3, 4
498 and 5) and the horizontal laminae (units 7 and 13). Isolated pebbles and cobbles (fine units 7, 9
499 and 10) can be interpreted as possible dropstones, and would support the lake hypothesis. Based
500 on the presence of slickensides and mottling (unit 6; Fig. 7A) as well as Fe-Mn precipitation, we
501 hypothesize ephemeral lake/pond conditions with wetting/drying cycles and low-sedimentation
502 phases, during which the original depositional microstructure (Fig. 7B) was destroyed.

503 Luminescence measurements (both portable and conventional OSL), show a general
504 alternating pattern between two populations of low-counts/young-ages and high-counts/old-age
505 along the fan stratigraphy (Fig. 10). We propose that these OSL trends reflect differences in
506 quartz provenance as well as transport processes. For the heterogeneous layers, we expect the
507 high OSL counts and old OSL age to result from the mixing and signal-averaging between grains
508 from weathered clasts carrying an inherited signal (i.e. no-light exposure during transport) with
509 well-bleached grains (i.e. full luminescence signal reset prior deposition) coming from reworked
510 loess material. Moreover, sediments from heterogeneous units were probably transported and
511 deposited during periods of high-sediment supply by sheet flow events: transportation in dense
512 and turbid flows could have prevented the complete OSL bleaching of reworked quartz grains,
513 leading therefore to higher luminescence counts and overestimated OSL age (i.e. CRE03 at
514 27.2 ± 1.1 ka). Fine layers, characterised by low OSL count and young OSL ages, may have
515 settled during periods of lower sediment supply by decantation in water, allowing
516 complete/better OSL bleaching prior to deposition. We therefore interpret OSL ages of the fine

517 CRE units (CRE01, 02 and 04; weighted-average age of 10.5 ± 1.6 ka) as more representative of
518 the true depositional age of the CRE alluvial fan. Potential incorporation of lithic fragments
519 could explain the slightly older OSL age for sample CRE02 (12.3 ± 1.6 ka, unit 6). In summary,
520 CRE fan deposition most likely occurred during or soon after the YD. This proposed chronology
521 agrees with the onset of sedimentation in Pond Emine (Fig. 2) at *c.* 12 ka ago (Berthel *et al.*
522 2012; Steinemann *et al.* 2020), implying that the Sanetsch Pass and the alluvial plain were ice
523 free during (or soon after) the YD, and that the subsequent sediment connectivity and transport
524 from the hillslopes towards the plain (CRE site) established quickly.

525

526 Hummocky moraine and rockfall boulders (SAN site). The average ^{10}Be surface exposure age
527 from the three rockfall boulders is 10.3 ± 0.3 or 9.5 ± 0.2 ka, calculated respectively with or
528 without erosion and snow corrections. For the rest of the discussion, we focus on the age
529 estimate obtained with erosion (1 mm ka^{-1} ; Wirsig *et al.* 2016b) and snow corrections (50-cm
530 snow thickness over 6 month per year; based on Wirsig *et al.* 2016b and our own field
531 observations). We however note that uncorrected age estimate differs by <10%, and would not
532 lead to any significant change in our proposed geomorphological reconstruction.

533 Dating of the rockfall boulders (*c.* 10 ka; Fig. 11) provides a minimum age constraint for
534 the hummocky moraine formation, which occurred before or at the time of the rockfall event.
535 Based on field observations of boulder distribution, we propose a scenario where the rockfall
536 occurred over stagnant ice. If the rockfall had occurred when the hummocky moraine was
537 already formed, the boulders would have been deposited mainly in the intra-hummock hollows,
538 due to gravity. Instead, the uniform distribution of rockfall boulders, placed both on hummock
539 ridges and in intra-hummock hollows, suggests that the rockfall spread over a disconnected ice

540 body, before or during the formation of the underlying hummocky morphology. We further
541 hypothesise that this stagnant ice body could have temporally dammed an ephemeral lake in the
542 plain, where the CRE alluvial fan was deposited around 10 ka ago.

543 At a regional scale, this rockfall event is contemporaneous with several other Early
544 Holocene gravitational events reported within the Alps (10-9 ka; Ivy-Ochs *et al.* 2017 and
545 reference therein), including two coeval landslides of the Rinderhorn region (Bernese Alps,
546 Switzerland; Grämiger *et al.* 2016), at only 28-km distance from the Sanetsch Pass. Glacial
547 debuitressing (Cossart *et al.* 2008) and rock stress changes associated with repeated glacial
548 fluctuations (Grämiger *et al.* 2017) were probably the trigger mechanisms behind the rockslope
549 failure.

550 The rockfall event investigated here was probably followed by a second event,
551 characterized by smaller extent (Fig. 11). Age constraint for this subsequent event is however not
552 available, but may be related to Holocene landslide/rockslide clusters observed elsewhere in the
553 European Alps (Zerathe *et al.* 2014; Ivy-Ochs *et al.* 2017).

554

555 Lateglacial to Holocene palaeoenvironmental reconstruction

556 By combining our field observations and multi-method results, we propose a
557 palaeoenvironmental reconstruction of the Sanetsch Pass area during the Lateglacial-Holocene
558 transition, with the aim to highlight the interplay between different sedimentary and geomorphic
559 processes (Fig. 12).

560 Throughout the LGM and Lateglacial periods, the area north of Sanetsch Pass was ice-
561 covered, while some peaks were protruding above the ice surface (nunataks, Fig. 12A; Bini *et al.*
562 2009), similar to the overall European Alps. These conditions may have favoured deposition of

563 aeolian drapes on nunatak platforms already at that time (Gild *et al.* 2018), with an allochthonous
564 contribution of the wind-blown material as confirmed by XRD analyses (ARP site), although
565 local *vs.* more distal sources cannot be discriminated by our multi-method approach and would
566 require further investigations. Lateral morainic ridges and glacial deposits in the Sanetsch plain
567 (Fig. 2) do not have tight chronological constraints but they are likely related to ice retreat
568 stadials during the Lateglacial (Ivy-Ochs *et al.* 2007). Several indications point towards an onset
569 of glacier retreat for the Sanetsch Pass and our investigated area at the end of the YD (Fig. 12B),
570 in close agreement with other palaeo-glacial and lacustrine chronologies in the Swiss Alps
571 (Schwander *et al.* 2000; Heiri *et al.* 2014; Schimmelpfennig *et al.* 2014). The Pond Emines (Fig.
572 2) became ice-free during the same time period (*c.* 12 ka; Berthel *et al.* 2012), when the
573 Tsanfleuron glacier finally retreated close to the most external LIA morainic ridges (\approx 1 km
574 west of the Sanetsch Pass; Fig. 2), similar to other palaeo-glaciological reconstructions in the
575 Alps (Schimmelpfennig *et al.* 2012; Kronig *et al.* 2018). A disconnected ice body, thick and
576 sediment rich, persisted at the downstream end of the Sanetsch plain until *c.* 10 ka and formed a
577 hummocky morphology overridden by rockfall deposits.

578 Glacier retreat in the Sanetsch Pass area was associated with rapid (re-)establishment of
579 paraglacial and periglacial geomorphic processes, promoting sediment connectivity and
580 transport, resulting in major landscape changes. All these processes illustrate and synthesize
581 post-glacial alpine dynamics (Church & Ryder 1972; Mercier & Etienne 2008; Fig. 12B), as
582 summarized below. Firstly, ice retreat promoted slope processes, as well as aeolian
583 remobilization of glacially-derived erosion products. Fine sediments in glacial outwash plains,
584 within the Sanetsch Pass area or other nearby valleys (e.g. the Rhône Valley), were probably
585 entrained and redeposited on mountain flanks and low-relief areas by local katabatic winds

586 and/or regional winds (Bullard & Austin 2011; Martignier *et al.* 2015). Post-YD paraglacial
587 relaxation favoured hillslope dynamics and sediment entrainment (Sanders & Ostermann, 2011),
588 with catastrophic rockfall events such as the rockslope failure of Les Montons cliff (Figs 3, 11;
589 Ivy-Ochs *et al.* 2017). The alluvial fan (CRE site) was deposited at the downstream end of the
590 fluvioglacial plain, probably within an ephemeral ice-dammed lake contemporary to the
591 hummocky moraine formation. Exposed catchment-slope deposits (i.e. aeolian, glacial and talus)
592 were remobilized and transported downhill into the plain, where they were redeposited to form a
593 stratigraphic succession of coarse and fine layers within the CRE alluvial fan (Beaudoin & King
594 1994). We propose that the aeolian deposit identified on the high-elevation plateau (ARP site) is
595 a remnant of a broader aeolian drape. The ARP aeolian sediments have been preserved due to the
596 low connectivity between the platform and the downstream hillslopes (Figs 2, 3), but this
597 potentially more-extensive deposit has been eroded elsewhere in the Sanetsch Pass area, with the
598 reworked fine sediments being eventually incorporated in the alluvial fan downslope.

599 Based on our OSL chronology, we hypothesize that short-lived sedimentation in the CRE
600 alluvial fan stopped or slowed down already during/soon after the YD, resulting from a drastic
601 change in base-level and sedimentation dynamics due to the melting of the ice-dam. Since then,
602 landscape dynamics around the Sanetsch Pass seem to have been dominated by (i) hillslope
603 denudation and localized stream incision within bedrock and glacial/alluvial sediments (Figs 2,
604 3C) at low elevations, and (ii) active periglacial processes at high elevations, with aeolian-
605 sediment cryoturbation (ARP site) and rock glaciers within scree deposits (Fig. 2).

606

607 **Conclusions**

608 Based on a combined approach of geomorphological and sedimentological field investigations
609 together with different analytical methods, we proposed a detailed reconstruction of post-LGM
610 palaeoenvironmental conditions and geomorphic connectivity in the Sanetsch Pass area (western
611 Swiss Alps). Our study brings quantitative constraints on the high-altitude landscape response to
612 ice retreat and climate changes during the Lateglacial-Holocene transition. Our multi-method
613 results show that silty sediments from the high-elevation platform are primary aeolian sediments,
614 deposited on ice-free areas before or at the post-YD glacier retreat and then reworked by
615 cryoturbation. Post-YD ice retreat was also associated with slope relaxation and aeolian/glacial
616 sediment remobilization. This is evidenced by the contemporary occurrence of hummocky
617 moraine formation, rockfall event and alluvial fan deposition within an ephemeral ice-dammed
618 lake, all taking place at *c.* 10-12 ka. Altogether, our results highlight the development of rapid
619 and most probably transient landscape changes in high Alpine regions during the Lateglacial-
620 Holocene transition, with an increase in sediment flux following glacier retreat and the
621 establishment of paraglacial and periglacial geomorphic processes.

622 Several palaeoclimatic archives, mainly from lacustrine and peat records, have
623 documented the pronounced climatic and environmental change associated with the end of the
624 YD in the European Alps. In this study, we have shown that landscape dynamics and
625 connectivity between geomorphic markers can also be used as quantitative proxies to constrain
626 the environmental response to such climatic transition.

627

628 Acknowledgements. The authors thank M. Gobat for sharing his intuition of a possible aeolian
629 deposit on the Arpille plateau, and N. Diaz, P. Pérez Cutillas and B. Lehmann for help during
630 field investigations. S. Lane (University of Lausanne) is warmly thanked for access to the

631 portable luminescence reader. P. Renzel and T. Beckmann are thanked for the grainsize analyses
632 and micromorphological thin-section preparation. M. Guélat is thanked for sharing unpublished
633 mineralogical and grainsize data from aeolian deposits of the Rhône Valley. J. Krbanjevic is
634 thanked for support during geochemistry analyses. The authors warmly thank the ASTER team
635 (D. Bourlès, G. Aumaitre, K. Keddadouche, and R. Braucher) for the measurements performed at
636 the ASTER AMS facility (CEREGE, Aix-en-Provence). I. Schimmelpfening, one anonymous
637 reviewer, and the editor J. Piotrowski are thanked for constructive reviews and manuscript
638 corrections. This study was supported by the Swiss National Science Foundation SNSF (Grant
639 PP00P2_170559) and the French ANR-PIA programme (ANR-18- MPGA-0006). All data are
640 available in tables in the main text and online supporting information.

641

642 Author contributions. LB, PGV, and RD designed the study; ES, LB, PGV, and RD
643 performed field investigations and sample collection. ES performed luminescence analysis
644 (with NG and PGV), grainsize and micromorphology (with LB), XRD analysis (with BG),
645 and ^{10}Be cosmogenic analysis (with JC and PGV). ES wrote the manuscript with input
646 from all co-authors.

889 **List of Figures**

890 **Figure 1.** Location of the study area (swissALTI3D DEM from swisstopo, authorization
891 5701367467/000010). Present-day glaciers, main peaks around the Sanetsch Pass and the Rhône
892 River are marked. The yellow box indicates the extent of the geomorphological map presented in
893 Fig. 2. Inset shows location of the Sanetsch Pass (red box) within Switzerland and the European
894 Alps, with the LGM ice extent (Ehlers & Gibbard 2004).

895

896 **Figure 2.** Detailed map of the Quaternary deposits occurring in the study area (swissALTI3D
897 DEM from swisstopo, authorization 5701367467/000010). The different Quaternary deposits and
898 the three study sites are shown: high-elevation platform covered by patterned ground (ARP),
899 alluvial fan (CRE) and hummocky moraine and rockfall deposits (SAN). The hillshade area
900 corresponds to bedrock (mainly limestones, as well as shales for the Arpille ridge, see text for
901 details).

902

903 **Figure 3.** Field photographs. **A.** General view of the three study sites (see Fig. 2 for locations)
904 looking from the South (orthophoto and swissALTI3D DEM from swisstopo, authorization
905 5701367467/000010). **B.** High-elevation platform covered by sorted polygonal patterned ground
906 (ARP site), on the southern slope of the Arpelistock peak. Arrows indicate the locations of the
907 two stratigraphic sections and the ARP samples. **C.** View from the Arpille ridge on the Sanetsch
908 valley, with arrows indicating the location of the alluvial-fan log (CRE site) and the hummocky
909 moraine with overlying rockfall deposits (SAN site), in contact with the Sanetsch artificial lake.
910 **D.** Hummocky moraine (SAN site) partially covered by rockfall boulders derived from Les
911 Montons cliff.

912

913 **Figure 4.** Stratigraphy of the ARP site (left: photograph, right: log). Sedimentological units and
914 samples collected for the different analyses are represented: XRD (ARP01 and ARP03, red
915 crossed circles), grain size (G7 and G8, black circles), conventional OSL (ARP01-ARP03, red
916 crossed circles) and portable OSL (arp01-arp05, blue boxes). Unit colours refer to the
917 stratigraphic description in Table S3. The deposit lies on top of non-weathered siliceous-
918 limestone bedrock.

919

920 **Figure 5.** Stratigraphy of the CRE site (left: photograph, right: log). Sedimentological units and
921 samples collected for the different analyses are shown: XRD (CRE01-CRE16, blue boxes), grain
922 size (G1-G6, black circles), micromorphology (M1-M3, black rectangles), conventional OSL
923 (CRE01-CRE04, red crossed circles) and portable OSL (cre01-cre16, blue boxes). Red dashed
924 lines show the extent of the photograph in proportion to the log. Unit colours refer to the
925 stratigraphic description in Table S4.

926

927 **Figure 6.** Grain-size distributions of ARP (G7 and G8, in red) and CRE (G1-G6, in blue)
928 samples. Individual cumulative (top) and frequency (bottom) curves show strong similarities
929 between ARP and CRE sites. The distribution curves of G4 (CRE) and G8 (ARP) are slightly
930 different because of the presence of small clasts within the samples (see individual peak at $\square 10^4$
931 μm). Grain-size distribution data are reported in Table S6.

932

933 **Figure 7.** Main micromorphological features observed in CRE fine and heterogeneous units (A-
934 C) and bedrock thin section D). **A.** Thin section M1 (unit 6), shows a blocky microstructure

935 developed in the silty sediments expressed by slickensides associated with mottling (reddish
936 zones pointed by yellow arrows). **B.** Detail of thin section M2 showing the well-developed
937 horizontal parallel lamination present within unit 7. **C.** Detail of thin section M3 with weathered,
938 decarbonated lithic fragments containing quartz grains (greyish grains, examples highlighted by
939 yellow arrows), in a clayey-silty carbonated matrix (unit 13). **D.** Bedrock thin section (calcareous
940 shales S1) showing abundant quartz grains (greyish grains, examples highlighted by yellow
941 arrows). xpl = crossed polarized light; ppl = plane polarized light.

942

943 **Figure 8.** XRD bulk mineralogical compositions of CRE (CRE01-CRE16), ARP (ARP01 and
944 ARP03) and bedrock (L1-L2: siliceous limestone, S1-S2: calcareous shale) samples. Cumulative
945 mineral percentages are reported in Table S7.

946

947 **Figure 9.** Portable and conventional luminescence measurements for the ARP site. **A.** OSL
948 signal intensity profile and quartz OSL ages. **B.** IRSL signal intensity profile and polymineral
949 IRSL ages. See Fig. 4 for the legend of the stratigraphic column.

950

951 **Figure 10.** Portable and conventional luminescence measurements for the CRE site. OSL signal
952 intensity profile and quartz OSL ages are shown. See Fig. 5 for the legend of the stratigraphic
953 column.

954

955 **Figure 11.** ^{10}Be surface exposure ages from rock-fall sandstone boulders lying on the hummocky
956 moraine (SAN site, modified orthophoto from swisstopo, authorization 5701367467/000010).
957 ^{10}Be surface exposure ages calculated with snow and erosion corrections are shown. See Table 3

958 for the ages obtained without applying any correction. The blue dashed-line delimits the extent
959 of a younger rockfall deposit than the one dated in the present study. Inset shows probability
960 density plots of the individual and weighted-average ^{10}Be surface exposure ages, after snow and
961 erosion corrections.

962

963 **Figure 12.** Schematic palaeoenvironmental reconstruction of the study area. **A.** Glacier extent
964 with subglacial sediment deposition, and aeolian drapes deposition on nunatak platforms, during
965 the LGM and Lateglacial periods. **B.** Paraglacial (alluvial, colluvial, lacustrine, aeolian) and
966 periglacial (cryoturbation) geomorphic processes during/soon after glacier retreat, at the
967 Lateglacial-Holocene transition. The three landforms investigated in the study are indicated
968 (ARP, CRE, SAN).

969

970 **List of Tables**

971 Table 1. Sample luminescence details and corresponding quartz OSL dating results. For
972 analytical details about the measurement protocol, see Table S2A. CAM = Central Age Model;
973 OD = Over Dispersion (Galbraith & Roberts 2012).

974

975 Table 2. Sample luminescence details and corresponding polymineral IRSL dating results. See
976 Table 1 (ARP samples) for radionuclides concentration and water content. For analytical details
977 about the measurement protocol, see Table S2B. CAM = Central Age Model; OD = Over
978 Dispersion (Galbraith & Roberts 2012).

979

980 Table 3. Details on cosmogenic ^{10}Be samples, concentrations and exposure ages. Samples
981 thickness and density are 2.5 cm and 2.65 g cm^{-3} , respectively.

982

983 **Supporting information**

984 Table S1. Samples locations, corresponding geomorphic units and conducted analyses.

985

986 Table S2. Luminescence protocols. A. Post-IR OSL protocol, after Murray & Wintle (2000),
987 applied on quartz separates from CRE and ARP sample (except for sample ARP03, which did
988 not provide enough material for quartz purification). B. Post-IR IRSL protocol, after Buylaert *et*
989 *al.* (2009), applied on polymineral ARP samples. No post-IR IRSL measurements were
990 performed on CRE samples due to the absence of feldspar IRSL signal.

991

992 Table S3. Stratigraphic description and field interpretation of the sedimentological units forming
993 the ARP high-elevation platform deposit. The thickness of the units is given in Fig. 4. *Reaction
994 to HCl on the field: no (-), little (-/+), strong (+), very strong (++) reaction.

995

996 Table S4. Stratigraphic description and field interpretation of the sedimentological units forming
997 the upper 4.5 m of the CRE alluvial fan. The thickness of the units is given in Fig. 5. *Reaction
998 to HCl on the field: no (-), little (-/+), strong (+), very strong (++) reaction.

999

1000 Table S5. Luminescence signal intensities measured for CRE and ARP sites using the SUERC
1001 portable OSL reader (Sanderson & Murphy 2010), and following the measurement sequence of
1002 Muñoz-Salinas *et al.* (2014). IRSL counts are the total photon counts obtained after the first 30 s

1003 of IRSL stimulation. OSL counts are the total photon counts obtained after the 60 s of OSL
1004 stimulation. The counts and respective errors were obtained by averaging between two replicate
1005 measurements of each bulk sediment sample. Dim IRSL counts were measured along the CRE
1006 section, due to the low-feldspar content in the analysed sediments. For this reason, only the OSL
1007 signal intensity profile is represented in Fig. 10.

1008

1009 Table S6. Grain-size distributions of CRE (G1-G6; S6A) and ARP (G7 and G8; S6B) samples.
1010 Individual cumulative and frequency percentages of the different grain sizes are reported. Details
1011 about grain-size distribution measurements are given in the main text.

1012 Table S6A. Grain-size distributions of CRE samples.

1013 Table S6B. Grain-size distributions of ARP samples.

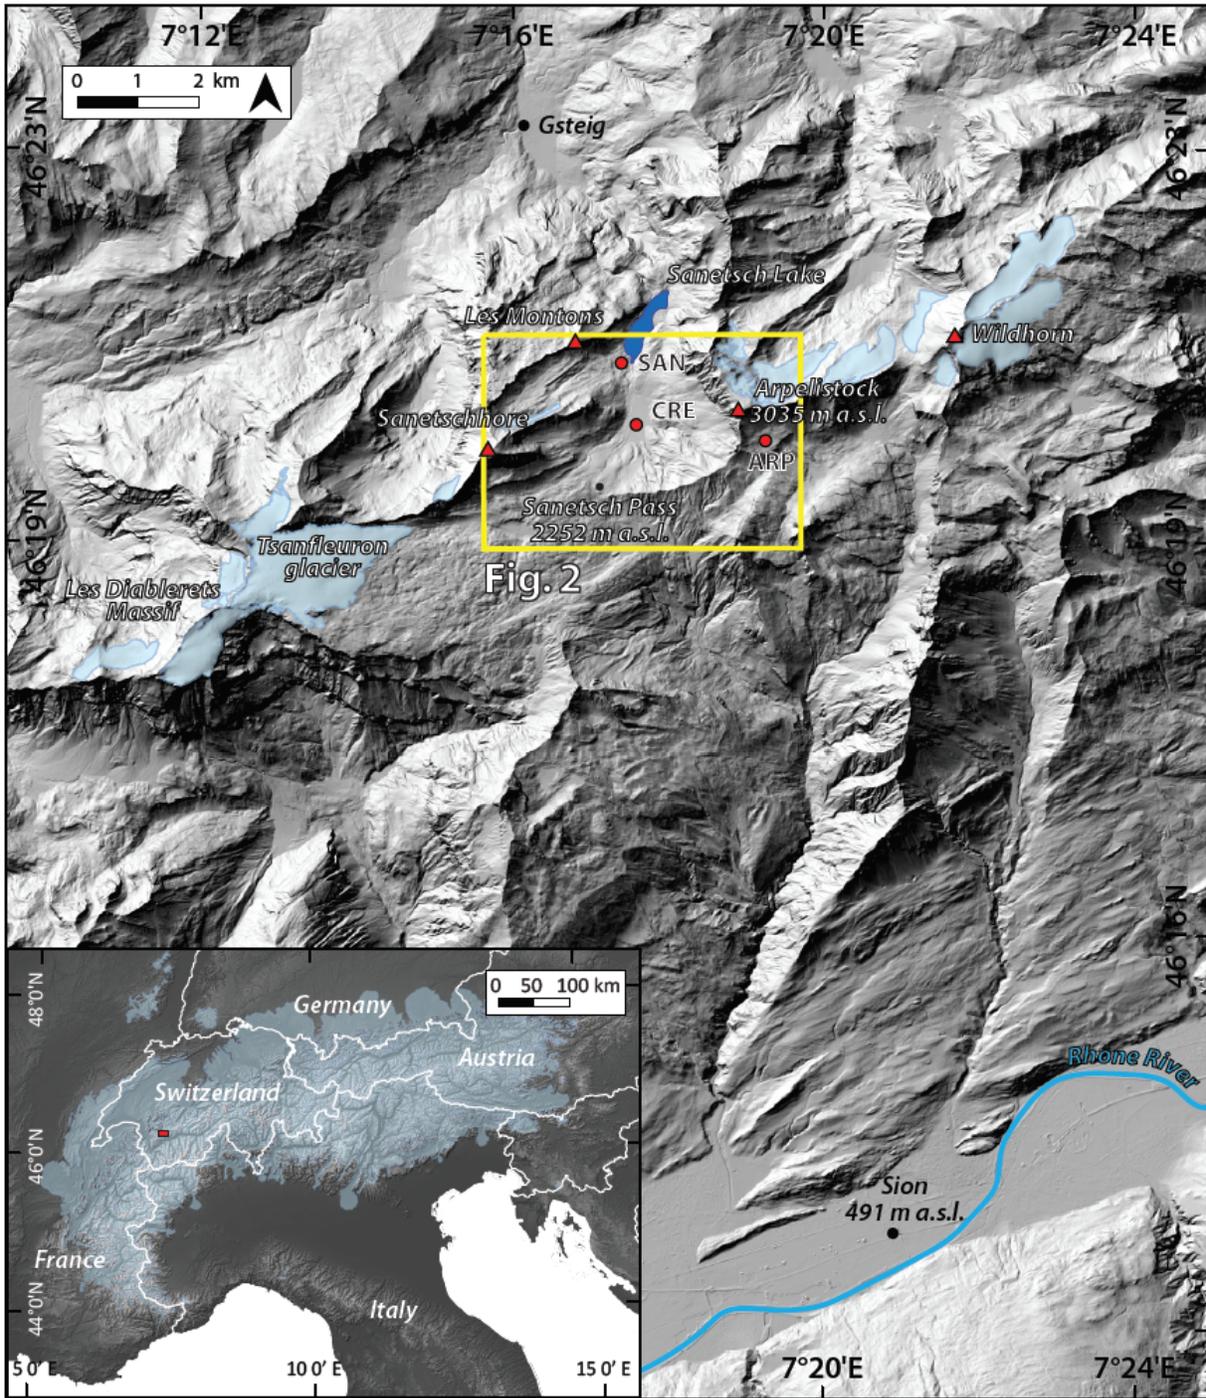

1014

1015 Table S7. XRD bulk mineralogical compositions of CRE (CRE01-CRE16), ARP (ARP01
1016 and ARP03) and bedrock (L1-L2: siliceous limestone, S1-S2: calcareous shale) samples.
1017 Cumulative mineral percentages are reported. Details about XRD analyses are given in the main
1018 text.

1 List of Figures

2
3 **Figure 1.** Location of the study area (DEM from swisstopo, authorization 5701367467/000010).
4 Present-day glaciers, main peaks around the Sanetsch Pass and the Rhône River are mapped. The

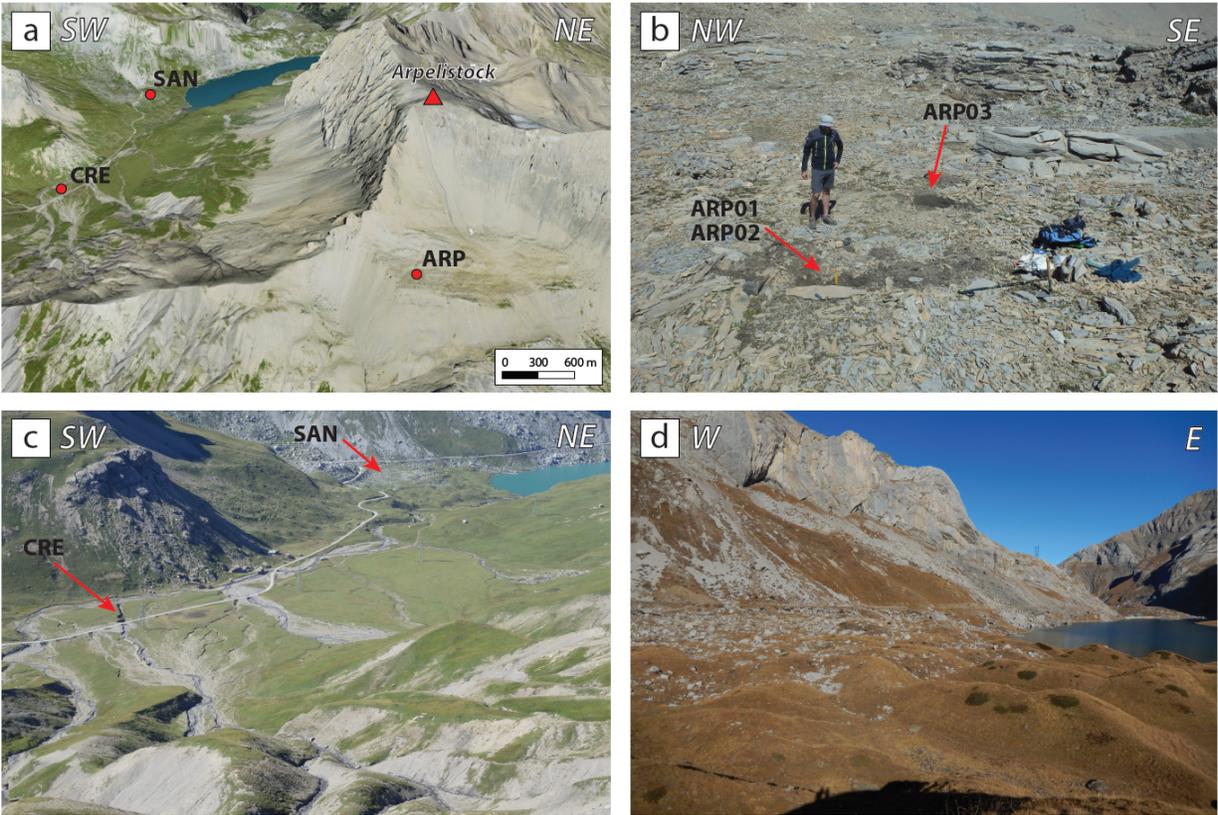

5 yellow box indicates the extent of the geomorphological map represented in Figure 2. Inset
 6 shows location of the Sanetsch Pass (red box) within Switzerland and the European Alps, with
 7 the LGM ice extent (Ehlers and Gibbard, 2004).

8

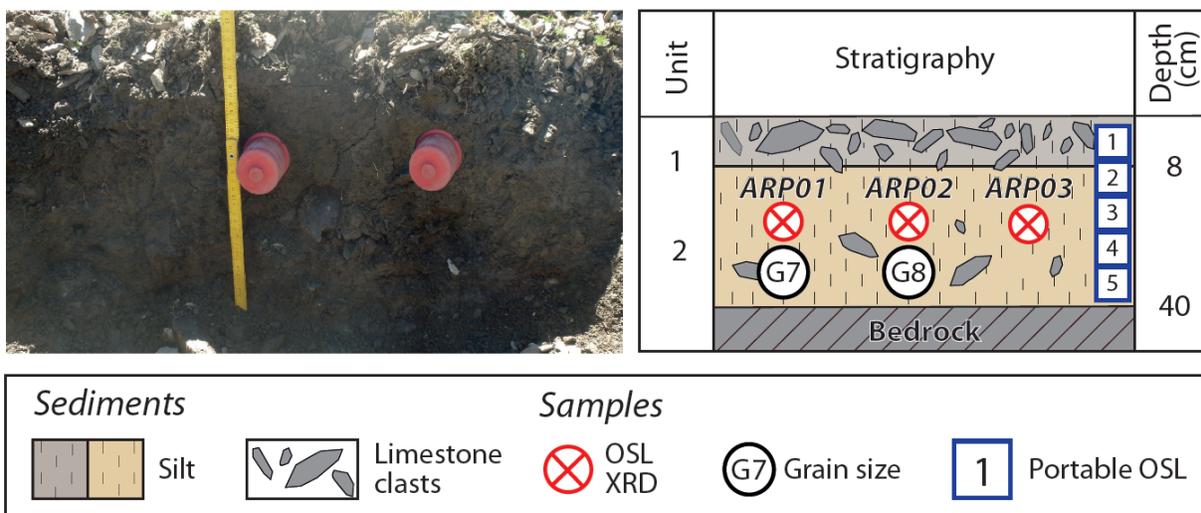

9

10 **Figure 2.** Detailed map of the Quaternary superficial deposits occurring in the study area
 11 (swissALTI3D DEM from swisstopo, authorization 5701367467/000010). The different
 12 Quaternary deposits and the three study sites are represented: high-elevation platform covered by
 13 patterned ground (ARP), alluvial fan (CRE) and hummocky moraine and rockfall deposits
 14 (SAN). The hillshade area corresponds to bedrock (mainly limestones, as well as shales for the
 15 Arpille ridge, see text for details).

16

17 **Figure 3.** Field photographs. **a)** General view of the three study sites (see Figure 2 for locations)
 18 looking from the South (orthophoto and swissALTI3D DEM from swisstopo, authorization
 19 5701367467/000010). **b)** High-elevation platform covered by sorted polygonal patterned ground
 20 (ARP site), on the southern slope of the Arpelistock peak. Arrows indicate the locations of the
 21 two stratigraphic sections and the three ARP samples. **c)** View from the Arpille ridge on the
 22 Sanetsch valley, with arrows indicating the location of the alluvial-fan log (CRE site) and the
 23 hummocky moraine with overlying rockfall deposits (SAN site), in contact with the Sanetsch
 24 artificial lake. **d)** Hummocky moraine (SAN site) partially covered by rockfall boulders derived
 25 from Les Montons cliff.

26

27 **Figure 4.** Stratigraphy of the ARP site (left: photograph, right: log). Sedimentological units and

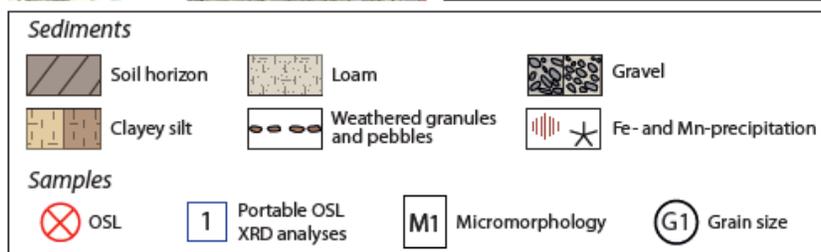

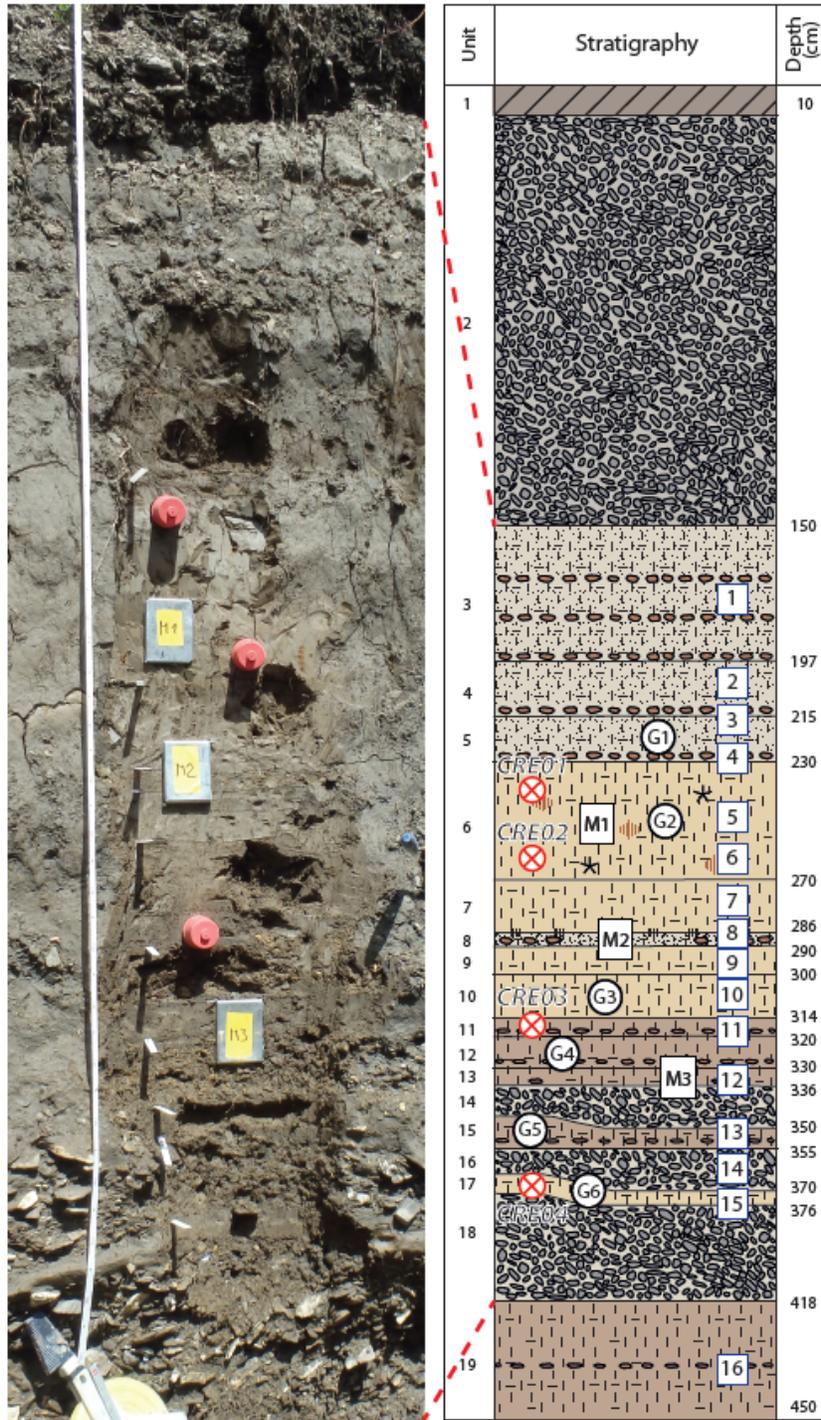

28 samples collected for the different analyses are represented: XRD (ARP01 and ARP03, red

29 crossed circles), grain size (G7 and G8, black circles), conventional OSL (ARP01-ARP03, red

30 crossed circles) and portable OSL (arp01-arp05, blue boxes). Unit colours refer to the

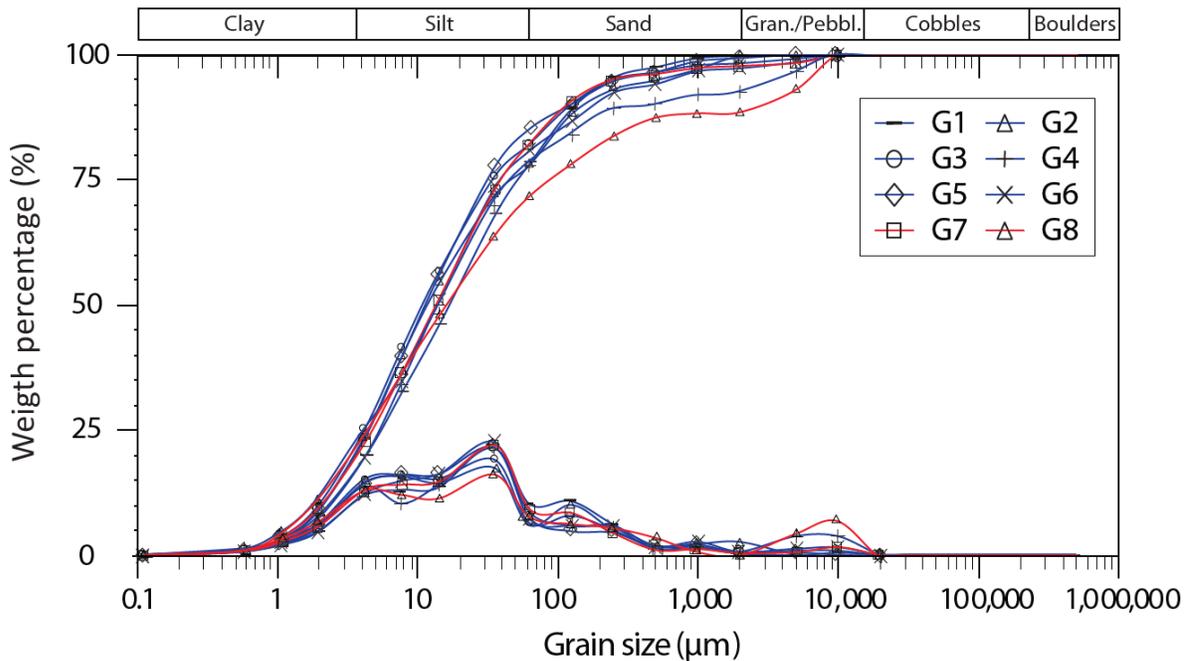

31 stratigraphic description in Table S3. The deposit lies on top of non-weathered siliceous-

32 limestone bedrock.

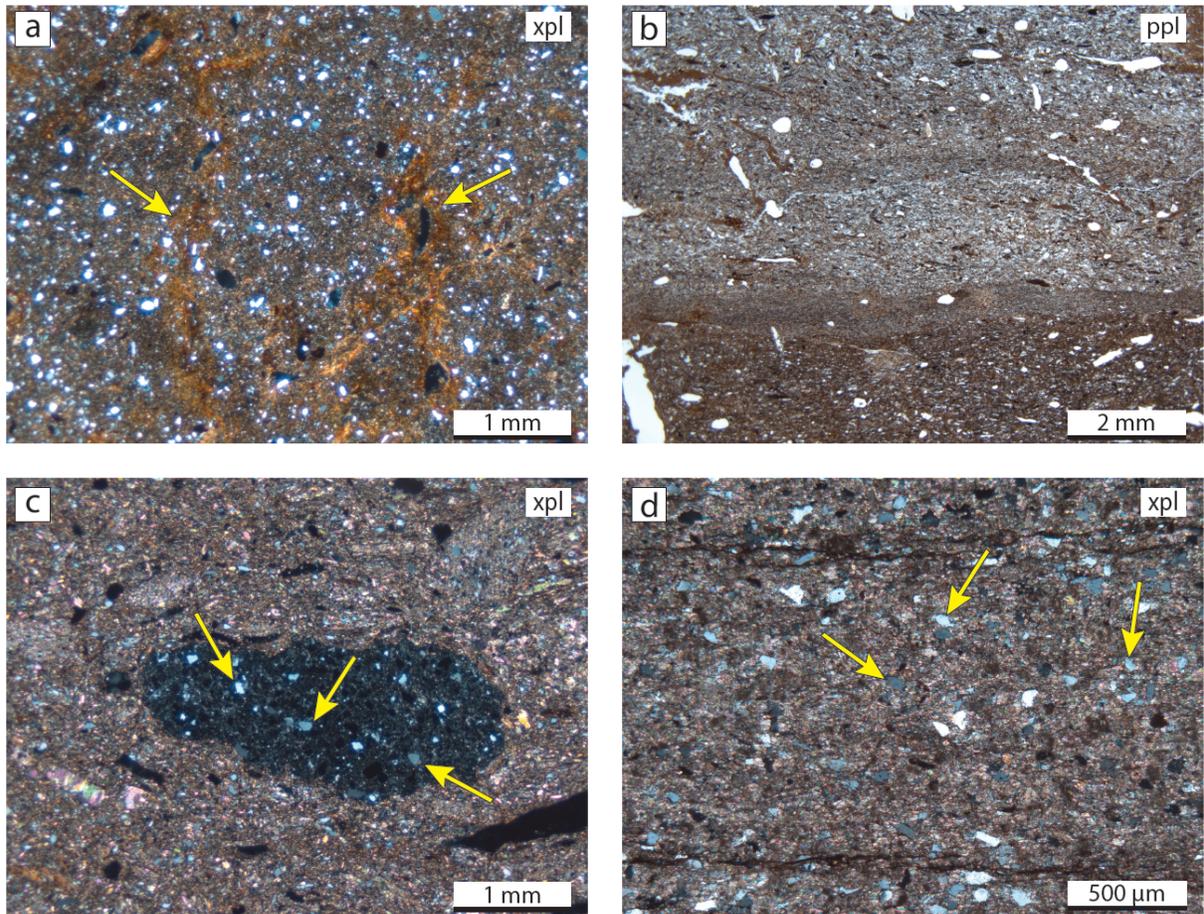

34 **Figure 5.** Stratigraphy of the CRE site (left: photograph, right: log). Sedimentological units and
 35 samples collected for the different analyses are shown: XRD (CRE01-CRE16, blue boxes), grain
 36 size (G1-G6, black circles), micromorphology (M1-M3, black rectangles), conventional OSL
 37 (CRE01-CRE04, red crossed circles) and portable OSL (cre01-cre16, blue boxes). Red dashed
 38 lines show the extent of the picture in proportion to the log. Unit colours refer to the stratigraphic
 39 description in Table S4.

40
 41

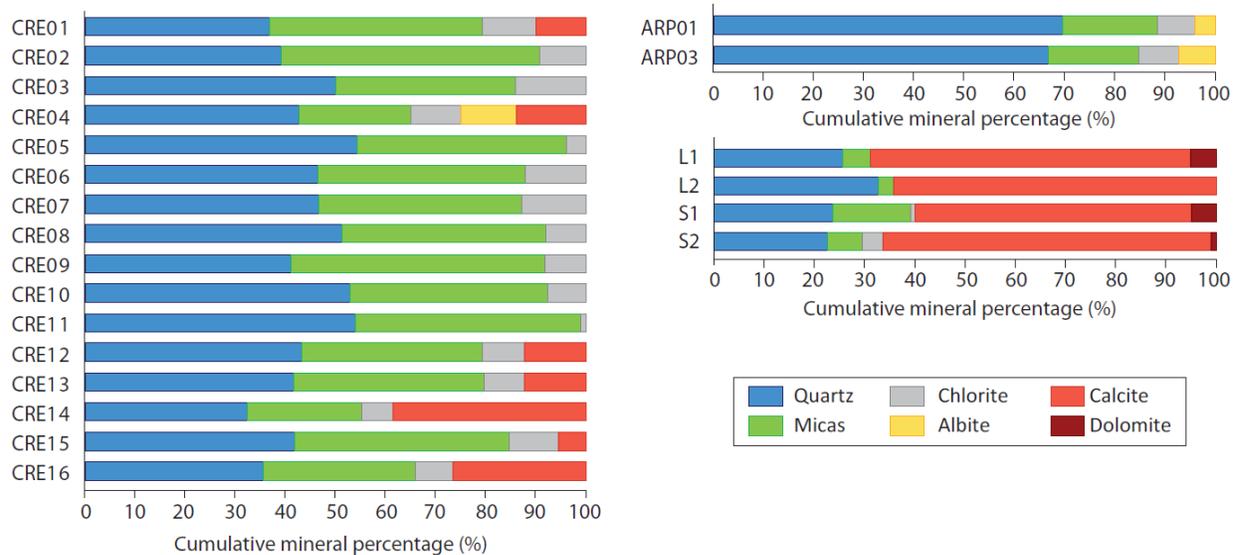

42
 43 **Figure 6.** Grain-size distributions of ARP (G7 and G8, in red) and CRE (G1-G6, in blue)
 44 samples. Individual cumulative (top) and frequency (bottom) curves are plotted, and show strong
 45 similarities between ARP and CRE sites. The distribution curves of G4 (CRE) and G8 (ARP) are
 46 slightly different because of the presence of small clasts within the samples (see individual peak
 47 at ca. $10^4 \mu\text{m}$).

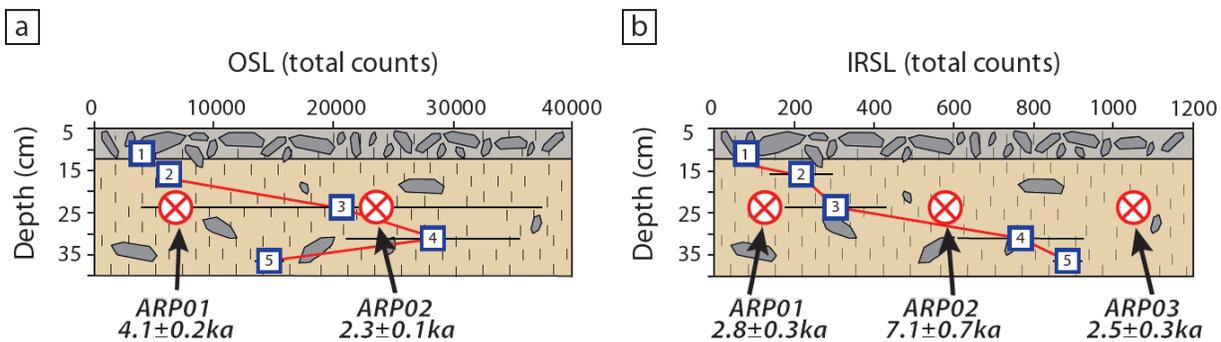

48

1 **Table S1.** Samples locations, corresponding geomorphic units and conducted analyses.

Sample Name	Location WGS84 (°N/°E)	Altitude (m a.s.l.)	Geomorphic unit	Analysis
G1 - G6	46.34091/ 7.29049	2100	Alluvial fan (CRE)	Grain-size
G7, G8	46.33703/ 7.31810	2712	High-elevation platform (ARP)	Grain-size
M1 - M3	46.34091/ 7.29049	2100	Alluvial fan (CRE)	Micromorphology
L1, L2; S1, S2	46.33715/ 7.31815; 46.33380/ 7.30790	2712; 2650	Bedrock (limestone; shale)	Petrographic thin section
CRE01 - CRE16	46.34091/ 7.29049	2100	Alluvial fan (CRE)	XRD and Geochemistry
ARP01, ARP03	46.33703/ 7.31810	2712	High-elevation platform (ARP)	XRD and Geochemistry
L1, L2; S1, S2	46.33715/ 7.31815; 46.33380/ 7.30790	2712; 2650	Bedrock (limestone; shale)	XRD
cre01 - cre16	46.34091/ 7.29049	2100	Alluvial fan (CRE)	Portable OSL
arp01 - arp05	46.33703/ 7.31810	2712	High-elevation platform (ARP)	Portable OSL
CRE01 - CRE04	46.34091/ 7.29049	2100	Alluvial fan (CRE)	OSL burial dating
ARP01 - ARP03	46.33703/ 7.31810	2712	High-elevation platform (ARP)	OSL burial dating
SAN01	46.35111/ 7.28751	2055	Rockfall deposit (SAN)	¹⁰ Be exposure dating
SAN02	46.35117/ 7.28900	2056	Rockfall deposit (SAN)	¹⁰ Be exposure dating
SAN03	46.35137/ 7.28874	2054	Rockfall deposit (SAN)	¹⁰ Be exposure dating

2 **Table S2.** Luminescence protocols. **A.** Post-IR OSL protocol, after Murray & Wintle (2000),
 3 applied on quartz separates from CRE and ARP sample (except for sample ARP03, which did
 4 not provide enough material for quartz purification). **B.** Post-IR IRSL protocol, after Buylaert *et*
 5 *al.* (2009), applied on polymineral ARP samples. No post-IR IRSL measurements were
 6 performed on CRE samples due to the absence of feldspar IRSL signal.

7 **Table S2A**

Step	Treatment	
1	Natural/regenerative dose	9
2	Preheat	200°C, 60 s
3	IRSL	50°C, 100 s
4	OSL	125°C, 100 s
5	Test dose	500 s
6	Preheat	200°C, 60 s
7	IRSL	50°C, 100 s
8	OSL	125°C, 100 s
9	Return to step 1	13

16 **Table S3.** Stratigraphic description and field interpretation of the sedimentological units forming the ARP high-elevation platform
 17 deposit. The thickness of the units is given in Fig. 4. *Reaction to HCl on the field: no (-), little (-/+), strong (+), very strong (++)
 18 reaction.

Unit	Description	HCl*	Field interpretation
1	Angular platy fragments of grey siliceous limestones (60%) in a greyish brown silty matrix (40%). Clast-supported, no preferred orientation of elements. Well-developed forms of sorted polygonal patterned grounds on the surface.	-	<i>In situ</i> cryoclasts bedrock derived, reworked by frost and thaw processes.
2	Light yellowish brown silt containing few limestone angular fragments. Well-developed platy structure.	++	Aeolian deposit.

20 **Table S4.** Stratigraphic description and field interpretation of the sedimentological units forming the upper 4.5 m of the CRE alluvial
 21 fan. The thickness of the units is given in Fig. 5. *Reaction to HCl on the field: no (-), little (-/+), strong (+), very strong (++) reaction.

Unit	Description	HCl*	Field interpretation
1	Dark brown humic loam containing platy fragments of shale. Granular structure.	-	Current A horizon of a soil developed under an alpine meadow.
2	Platy subangular fragments (mean diameter 5-10 cm, max. 30 cm) of slightly weathered shale (ca. 70%) in a greyish brown loamy matrix (ca. 30%). Clast-supported with imbricated elements.	++	Coarse alluvial fan deposit.
3	Three sub-units each composed of slightly weathered granules and pebbles (shale and limestone) at the base and yellowish to grayish brown silty loam at the top.	++	Alluvial fining-up sedimentary sequences possibly deposited in a lake.
4, 5	Orange strongly weathered (almost decarbonated) pebbles (shale and limestone) at the base, light yellowish to grayish brown silty loam at the top.	-/+	Alluvial fining-up sedimentary sequences possibly deposited in a lake (affected by pre- or post-depositional weathering).
6	Light yellowish brown clayey silt with black and red mottles (Fe-Mn hydromorphism) especially at the base. Massive structure.	-	Aeolian sediments (in situ deposited or reworked by fluvial transport).
7, 9, 10, 17	Yellowish to grayish brown clayey silt. Massive structure, less consistent than unit 6. Laterally, presence of isolated pebbles and cobbles in units 7, 9 and 10.	-	Aeolian sediments possibly deposited or reworked in a lake, with possible dropstones (10-15 cm).
8	Yellowish brown sandy loam containing orange weathered calcareous granules.	-/+	Alluvial input (affected by pre- or post-depositional weathering).

11, 12, 13	Greyish brown silty clay with strongly weathered (decarbonated) granules and pebbles at the base. Massive structure, very low consistency.	-/+	
15, 19	Similar to above but with little weathering of the pebbles.	++	Alluvial input.
14, 16, 18	Grey calcareous pebbles and granules (ca 60%) in a yellowish brown loamy matrix (40%). Clast-supported sediment with weathered imbricated elements.	++	

Table S5. Luminescence signal intensities measured for CRE and ARP sites using the SUERC portable OSL reader (Sanderson & Murphy 2010), and following the measurement sequence of Muñoz-Salinas *et al.* (2014). IRSL counts are the total photon counts obtained after the first 30 s of IRSL stimulation. OSL counts are the total photon counts obtained after the 60 s of OSL stimulation. The counts and respective errors were obtained by averaging between two replicate measurements of each bulk sediment sample. Dim IRSL counts were measured along the CRE section, due to the low-feldspar content in the analysed sediments. For this reason, only the OSL signal intensity profile is represented in Fig. 10.

Sample	Depth (cm)	IRSL (counts)	OSL (counts)
cre01	175	79±24	22697±154
cre02	205	68±24	22062±2674
