HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Clinical phenotype and outcomes of pneumococcal versus meningococcal purpura fulminans: a multicenter retrospective cohort study

Damien Contou^{1*} and Nicolas de Prost² on behalf of the HOPEFUL Study group

Keywords: Purpura fulminans, Neisseria meningitidis, Streptococcus pneumoniae, Septic shock, Meningitis

were excluded.

Purpura fulminans (PF) is a rare cause of septic shock characterized by the association of a sudden and extensive purpuric rash together with an acute circulatory failure [1] leading to high rates of intensive care unit (ICU) mortality [1, 2] and long-term sequelae [3]. Clinical presentation of patients with PF differs from that of patients with meningitis since PF patients are commonly admitted to the ICU for hemodynamic impairment exposing them to early death from refractory circulatory failure, as opposed to patients with meningitis who are usually admitted to the ICU for neurological impairment. Among adult patients, Neisseria meningitidis and Streptococcus pneumoniae are the most commonly involved microorganisms accounting for more than 80% of PF [1] and meningitis [4]. While clinical features and outcomes widely differ between adult patients with pneumococcal and meningococcal meningitis [4], it remains unclear whether pneumococcal (pPF) and meningococcal (mPF) PF exhibit different clinical phenotypes and outcomes, although pPF was previously shown to predominantly occur in asplenic patients [5] and carries a higher risk of limb amputation [1]. We therefore compared the clinical, biological presentations and outcome of adult patients with pPF and mPF.

with pPF were included. As compared to patients with mPF, those with pPF were older and had higher ICU severity scores. Chronic alcoholism and asplenia were more frequent in pPF, while the proportion of patients without previous comorbid conditions was lower. The time elapsed between disease onset and ICU admission was longer and purpura was less often noticed before ICU admission in pPF than in mPF. pPF patients also had lower platelet counts, higher serum urea and creatinine levels, and more frequent bacteremia. pPF patients needed more frequent invasive mechanical ventilation support, renal replacement therapy, plasma and plate-

We performed an ancillary analysis of a 17-year multicenter retrospective study conducted in 55 cent-

ers in France, which included all consecutive patients

 $(\geq 18 \text{ years})$ admitted to the ICU for an infectious PF

(2000–2016) [1]. Patients with non-microbiologically

documented PF or a bacterial documentation other than

Neisseria meningitidis and Streptococcus pneumoniae

During the study period, 195 patients with mPF and 67

The Kaplan–Meier survival analysis did not show significant difference between pPF and mPF patients (p = 0.80 by the log-rank test, Fig. 1).

lets transfusions and had higher durations of invasive

mechanical ventilation and vasopressor support. ICU

mortality and rate of limb amputation were higher in

patients with pPF (Table 1).

Limb amputation	19 (10)	21 (31)	< 0.001
Limb amputation among ICU survivors	18/125 (14)	19/32 (59)	< 0.001
Death in ICU	70 (36)	35 (52)	0.027
Duration of ICU stay, days	5 [2–11]	14 [3–35]	< 0.001
Duration of hospital stay, days	12 [2–23]	23 [3–78]	0.003

Continuous variables are reported as median [Interquartile range] and compared between groups using the Student t-test. Categorical variables are reported as numbers (percentages) and compared using χ^2 test. A p value < 0.05 was considered significant

ICU intensive care unit; IMV Invasive Mechanical Ventilation, ECMO Extracorporeal membrane oxygenation, LVEF Left ventricular ejection fraction, SAPSII Simplified Acute Physiology Score, SOFA Sequential Organ Failure Assessment

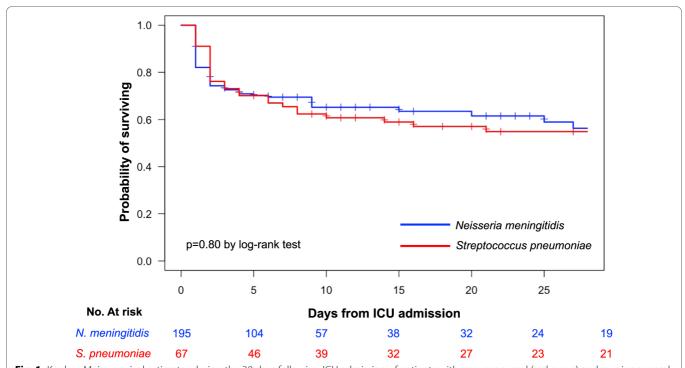

Fig. 1 Kaplan–Meier survival estimates during the 30 days following ICU admission of patients with pneumococcal (red curve) and meningococcal (blue curve) purpura fulminans

By multiple logistic regression adjusting on age, SOFA score, administration of β -lactam antibiotic therapy before ICU admission, platelet counts and arterial lactate levels, pPF was not associated with ICU mortality (adjusted Odds Ratio = 1.15 95% CI 0.45–2.89, p = 0.77).

As already reported in adults patients with bacterial meningitis [4], this study confirms that significant differences exist between mPF and pPF, regarding both the clinical presentation at ICU admission and outcomes. Patients with pPF showed a different clinical phenotype,

with less frequent purpura possibly leading to less frequent antibiotic treatment, more comorbidities with a more severe presentation at ICU admission, resulting in a higher rate of organ failures during ICU stay. Whether this more severe presentation should be ascribed to the level of virulence of the causative pathogen or to host-related characteristics is unsettled.

Our study has several limitations including its retrospective design and its long recruitment period with a high number of centers implying ICU procedures being inevitably heterogeneous. Nevertheless, the clinical presentation as well as the course in the ICU of patients with PF seem to differ according to the causative bacterium. This clinical observation should encourage researchers to better study the pathophysiology of pPF in order to develop targeted innovative therapies as being done for mPF [6].

Abbreviations

ICU: Intensive care unit; mPF: Meningococcal purpura fulminans; pPF: Pneumococcal purpura fulminans; SOFA: Sequential Organ Failure Assessment.
