## Highlights

- ESMO recommends the use of tumour multigene NGS in NSCLC, cholangiocarcinoma, prostate and ovarian cancers.
- It is recommended to test TMB in well- and moderately-differentiated NETs, cervical, salivary, thyroid and vulvar cancers.

- Academic research centres should perform multigene NGS as part of their missions to enable access to innovative treatments.
- A large panel of genes could be ordered, considering the benefit for the patient and the cost for the public healthcare system.

## **Abstract**

Next-generation sequencing (NGS) allows sequencing a high number of nucleotides in a short time frame at an affordable cost. While this technology has been widely implemented, there are no recommendations from scientific societies about their use in oncology practice. The European Society for Medical Oncology (ESMO) is proposing three levels of recommendations for the use of NGS. Based on the current evidence, ESMO recommends routine use of NGS on tumour samples in advanced non-squamous NSCLC, prostate cancers, ovarian cancers and cholangiocarcinoma. In these tumours, large multigene panels could be used if they add acceptable extra cost compared to small panels. In colon cancers, NGS could be an alternative to polymerase chain reaction (PCR). In addition, based on KN158 trial and considering that patients with endometrial and small cell lung cancers should have broad access to anti-PD1 antibodies, it is recommended to test tumour mutational burden (TMB) in cervical cancers, well- and moderately-differentiated neuroendocrine tumours, salivary cancers, thyroid and vulvar cancers, as TMB-high predicted response to pembrolizumab in these cancers.

Outside the indications of multigene panels, and considering that the use of large panel of genes could lead to few clinically meaningful responders, ESMO acknowledges that a patient and a doctor could decide together to order a large panel of genes, pending no extra cost for the public healthcare system and if the patients is informed about the low likelihood of benefit. ESMO recommends that the use of off-label drugs matched to genomics is done only if an access programme and a procedure of decision has been developed at the national or regional level. Finally, ESMO recommends that clinical research centres develop multigene sequencing as a tool to screen patients eligible for clinical trials and to accelerate drug development, and prospectively capture the data that could further inform how to optimise the use of this technology.

**Keywords:** Next-generation sequencing (NGS), genomic alterations, metastatic cancers

## Introduction

Next-generation sequencing (NGS) allows sequencing of a high number of nucleotides in a short timeframe and at an affordable cost per patient (1–3). In this document, we will discuss the clinical utility of using NGS as a technology, and how this technology should be used (small *versus* large panels) in frequent diseases. The recommendations will be done at three levels: from public health perspective, from the perspective of academic clinical research centres, and the level of each individual patient. NGS has recently moved into the clinics with the aim of sequencing long and complex genes and/or multiple genes per tumour sample, in order to identify driver and/or targetable alterations. Pioneering studies have shown that NGS presents a good analytical validity to detect clonally dominant alterations (4). Based on this observation, several companies and academic centres have implemented NGS assays to guide treatment decisions. While this technology has been widely implemented, there are no recommendations from scientific societies about their use in daily clinical practice. Several prospective trials have reported outcome associated with the use of multigene sequencing. In the SHIVA trial, the use of multigene sequencing did not improve outcome in patients with metastatic hard-to-treat cancers in comparison to unmatched therapies (5). In the single-arm MOSCATO trial the use of multigene sequencing and comparative genomic hybridisation (CGH) arrays was associated with an improved progression-free survival (PFS) in 30% of patients and an objective response rate (ORR) of 11% (6). Several other studies have consistently reported ORRs ranged between 10-30% in patients whose tumours harboured actionable alterations (7–10). One of the major issues with most of prospective trials testing multigene sequencing is the exclusion of patients whose tumours present a genomic alteration that matches an approved drug. Aside large prospective trials, several cases have been reported to present an outlier sensitivity to a drug given based on an unforeseen, non-recurrent, somatic genomic alteration (11,12). In the present article, we present the ESMO recommendations about whether and how tumour multigene NGS could be used to profile metastatic cancers.

## Method

The ESMO Precision Medicine Working Group has set a group of experts in the field of clinical cancer genomics in order to address the following questions:

Should NGS be used in daily practice?

If so, should large panel of genes be used?

These questions should be addressed from the perspective of public health, academic clinical research centres and from the perspective of the individual patients.

In order to address these questions, the group developed the method summarised in Figure 1. The general strategy was to determine whether NGS can substitute complex or multiple testings. First, all recurrent genomic alterations were identified in the eight cancers that are associated with highest number of deaths in the world (13). The ESMO Scale for Clinical Actionability of molecular Targets (ESCAT) ranking was then determined for each alteration. ESCAT is a framework that ranks a match between drug and genomic alterations, according to their actionability (14). ESCAT level I means that the match of an alteration and a drug has been validated in clinical trials, and should drive treatment decision in daily practice. A level II means that a drug that matches the alteration has been associated with responses in phase I/II or in retrospective analyses of randomised trials. ESCAT level III includes alterations that are validated in another cancer, but not in the disease-to-treat. ESCAT level IV are hypothetically targetable alterations based on preclinical data. ESCAT ranking was generated for each alteration by medical oncologists with an expertise in genomics, then validated by two external experts, and by the Working Group. From the ESCAT ranking and prevalence of alterations for each tumour type, we calculated the number of patients to test with NGS, to identify one patient that can be matched to an effective drug in daily practice (ESCAT level I). The main document reports these numbers with the hypothesis that NGS has a perfect analytical validity, while supplementary tables report these numbers taking hypothesis of 99% and 95% sensitivity/specificity (15). We assume that there is no proven impact in terms of public health of detecting level II-IV actionable alterations. Finally, in addition to ESCAT ranking, the group integrated the results of the KN158 study (16) in the recommendations. KN158 study evaluated the efficacy of pembrolizumab single agent according to tumour mutational burden (TMB) in 10 different diseases.

## **Multigene sequencing: Prerequisites from the technical side**

*In vitro* diagnostic (IVD) tests, such as NGS assays, can be broadly separated into two main categories. On one hand, there are manufactured products (reagents, instruments, kits) which have been cleared or approved by the respective authorities (e.g. US Food and Drug Administration [FDA]) and are sold to clinical laboratories for subsequent use. There are numerous instances where there are unmet analytical or clinical needs, not uncommonly due to the lack of approved and commercially available assays; in these cases, laboratory-developed tests (LDTs) are being designed by and deployed for clinical decision-making within a single clinical, often academic, laboratory. In the dynamic and fast-moving field of cancer precision medicine and molecular pathology, LDTs play a central role as they are often driving diagnostic innovation at times when no approved options exist. Regardless of the IVD category that is being used in a clinical lab, an environment that continuously assures and monitors assay quality and performance is critical as inadequate validation and use of assays could place patients at risk. Whilst the assessment of test characteristics and quality assurance schemes are governed by country-specific legislation and different regulatory models, technical parameters, including modality of sequencing, sequencing depth, fraction of on target reads, alignment quality, read quality, error rates, types of sources of DNA (ctDNA, frozen, FFPE), minimal tumour cell content are essential and combined under the umbrella of 'analytical validity'. Once the analytical validity and the robustness of the assay is ascertained, its clinical validity and clinical utility need to be considered. Professional groups have endeavored to provide guidelines for the standardisation of the parameters of sequencing, data analysis and interpretation of the findings, and are listed in Table 1.

In fact, a framework that includes standardised validation protocols and reflects the concepts of i) analytical validity (i.e. the ability of a test to accurately measure the analyte of interest as e.g. defined by the parameters: accuracy, precision, sensitivity, specificity, positive and negative predictive values), ii) clinical validity (i.e. the accuracy with which a genetic test identifies a particular clinical condition with respect to a diagnostic, prognostic or predictive category) and iii) clinical utility (i.e. whether the test and any subsequent interventions result in an improved health outcome among people with a positive test result and the risks that occur as a result of the test being performed) should be universally considered and applied. ESMO recommends that genomic reports include the ranking of the genomic alterations either by ESCAT or OncoKb (17).

## Recommendations

### *General frame*

Recommendations for NGS (summarized in Table 2) are done at three levels.

1. Recommendations for daily practice (ESCAT level I) aim to reflect the impact of the use of tumour multigene NGS on public health.
2. Recommendations for clinical research centers aim to determine whether performing multigene sequencing could increase access to innovation, accelerate drug development and could therefore be a mission of clinical research centres.
3. Patient-centric recommendations.

### *Health Economics evidence*

From a payer perspective, evidence of the cost-effectiveness of the use of multigene sequencing in daily practice is weak (18–21). We identified two economic studies in NSCLC. The first one has compared the performance of targeted NGS panels with traditional assays in an *EGFR*-mutant predominant population (22). The second one has studied the cost-effectiveness of multigene panel sequencing compared to single-marker testing (23). These studies suggest that multigene sequencing in NSCLC is moderately cost-effective. Moreover, implementation of multigene sequencing in daily practice requires investments that have to be considered, especially regarding sequencing and bioinformatics workflows in order to deliver results to clinicians in a timely manner (24). ***Finally, from a public health perspective, it must also be considered that the results of NGS panels could lead to recommend expensive drugs outside of their approved indications (25). There is a need to regulate the volumes of NGS procedures at the national level.***

### **Genomic alterations in advanced non-squamous non-small cell lung cancer (NSCLC) classified according to ESCAT**

*EGFR* mutations represent the first driver alterations identified in advanced non-squamous NSCLC (26). Most of them are in frame activating deletions in exon 19 and point hotspot activating mutations in exon 21 (*L858R*), followed by acquired resistant mutations in exon 20 (*T790M*). Several randomised, phase III trials have shown that *EGFR* tyrosine kinase inhibitors (TKIs) improve outcome in patients with *EGFR*-

mutated NSCLC (27–30). Based on these data, these specific *EGFR* mutations reach the highest level in the ESCAT. Point mutations or duplications in exons 18–21 (*G719X* in exon 18, *L861Q* in exon 21, *S768I* in exon 20), are unusual *EGFR* mutations. Efficacy of afatinib and osimertinib were assessed in prospective, non-randomised trials, reporting a high ORR and improving PFS (31,32). In addition, in patients with exon 20 insertions of *EGFR*, poziotinib (selective TKI inhibitor) presented a limited therapeutic efficacy, also evaluated in prospective studies (33,34). Another predictive biomarker that reaches a high position in the ESCAT is *ALK* fusion. In randomised trials, *ALK* inhibitors confirmed an improvement of clinical outcomes across patients with *ALK*-rearranged NSCLC (35–39). Some other alterations like *MET* exon 14 skipping, *BRAF*<sup>V600E</sup> mutations, and *ROS1* fusions have been identified (40). A significant ORR and clinical meaningful benefit have been shown in phase I/II studies in patients with NSCLC with *MET*<sub>ex14</sub> mutations treated with *MET* TKI such as crizotinib, capmatinib or tepotinib, with *BRAF*<sup>V600E</sup> mutations that received dabrafenib-vemurafenib, and with *ROS1* fusions treated with crizotinib, ceritinib or entrectinib (41–47). No randomised trials were developed for these aberrations. Based on these results crizotinib obtained the Breakthrough Designation from the FDA for *MET*<sub>ex14</sub>-mutated NSCLC, entrectinib for *ROS1*-positive NSCLC by FDA, and dabrafenib-vemurafenib was approved for NSCLC with *BRAF*<sup>V600E</sup> mutation by both FDA and European Medicines Agency (EMA). Fusions involving neurotrophic tyrosine receptor kinase genes (*NTRK1-3*) occur with a low prevalence across different cancer types. *TRK* inhibitors (larotrectinib, entrectinib) have demonstrated durable responses in *NTRK*-fusion positive tumours including NSCLC (48–50), leading to agnostic drug approvals by the EMA and FDA. In addition, LOXO-292 showed efficacy in phase I/II studies in patients with *RET* fusion-positive NSCLC, receiving the FDA Breakthrough Designation (51). Several other drivers with therapeutic potential have been identified including *MET* amplifications, *KRAS*<sup>G12C</sup> mutations (AMG510), and *ERBB2* mutations and amplifications (52–57). Although it has been suggested that TMB-high ( $\geq 10$  mut/Mb) could be a potential predictive biomarker for immune checkpoint inhibitors (ICIs), this data is not mature enough to drive decisions in NSCLC (58). Finally, some alterations validated in other tumour types can be found in patients with NSCLC, but no evidence for drug efficacy has been reported yet (Table 3A) (59–63). In the Table 3B we have described the main molecular variations classified by ESCAT in advanced squamous NSCLC.

***Summary of recommendations: It is recommended that a tumor (or plasma) sample from a patient with advanced non-squamous NSCLC is profiled using NGS technology, in order to detect level I alterations. Considering the high frequency of fusions, RNA-based NGS, or DNA-based NGS designed to capture such fusions, are the preferred options. There is no evidence that panels detecting genes with lower level of evidence brings additional value from a public health perspective. They could be used***

***only if the report ranks genomic alterations according to valid ranking systems (e.g. ESCAT, OncoKB) and on the basis of specific agreements with payers taking into account the overall cost of the strategy (including off-label use of drugs) as compared to small panels. Regarding this later point, ESMO does not recommend the use of off-labels drugs matched to genomic alterations, except if an access programme and a procedure of decision has been developed at the national or regional level, as illustrated by the DRUP programme (64). It is recommended that hospitals who run drug development programmes and clinical trials run multigene sequencing in the context of molecular screening programmes since lung cancer presents some level II-IV alterations.***

### **Genomic alterations in metastatic breast cancer (mBC) classified according to ESCAT**

*ERBB2* amplifications are predictive of clinical benefit of anti-HER2 therapies, which yield an improvement of overall survival (OS) and PFS (65–69), while neratinib (irreversible pan-HER TKI) has been associated with responses in patients with *ERBB2* mutations (55). Phase III studies reported a significant improvement of PFS with poly ADP ribose polymerase (PARP) inhibitors in patients with germline *BRCA1/2*-mutated mBC (70,71). It is currently estimated that a somatic multigene sequencing cannot substitute germline testing for *BRCA1/2* status. Alpelisib, an  $\alpha$ -selective phosphatidylinositol 3-kinase (PI3K) inhibitor, improves PFS in patients with HR+/HER2- mBC that harbour *PIK3CA* hotspot mutations, and is approved in this group of patients (72). Drugs targeting rare alterations found in different solid tumours, like microsatellite instability-high (MSI-H) and *NTRK* fusions obtained approvals across tumour types (50,73). Nevertheless, *NTRK* fusions highly correlate with secretory phenotype and MSI-high tumours are enriched in triple negative breast cancers (TNBCs), where anti-PDL1 antibodies are approved. *ESR1* mutations occur in around 20% of patients previously treated with aromatase inhibitors and are associated with response to selective oestrogen receptor degrader (74). Nevertheless, these data are preliminary and cannot be used in daily practice. Other promising targets in mBC are *PTEN* loss of function mutations and/or homozygous deletions (TNBCs) and *AKT1*<sup>E17K</sup> mutations, which in retrospective and prospective analyses, respectively, showed a clinical benefit and increased responsiveness to AKT inhibitors. Nevertheless, no results are available from practice changing trials yet (75,76). In addition, *NF1* mutations were identified as a mechanism of endocrine resistance, but there is no yet targeted therapy available in this genomic segment (77). Lastly, there are some alterations with no major impact in mBC that are validated in other malignances (Table 4) (55,63,78).

***Summary of recommendations: Considering that somatic sequencing cannot fully substitute germline BRCA testing, that PIK3CA status can be determined by PCR on the three hotspots, and pending that HER2 testing is accurately done by immunohistochemistry (IHC) in the local centre, there is currently no need to perform tumour multigene NGS for patients with mBC in the context of daily practice. From the perspective of clinical research centres, and considering the high number of level II alterations, it is important to include mBC patients in molecular screening programmes and include them in trials testing targeted therapies matched to genomic alterations (AKT1<sup>E17K</sup>, PTEN, ERBB2 mutations, ESR1 and NF1 mutations).***

### **Genomic alterations in metastatic colorectal (mCRC) classified according to ESCAT**

Pivotal randomised trials and meta-analysis highlighted that hotspot RAS mutations (K-RAS and N-RAS) predict resistance to EGFR monoclonal antibodies (mAbs) in the metastatic setting (79–81). The addition of encorafenib (BRAF inhibitor) to cetuximab was associated with a significant survival benefit in a recent phase III trial in patients presenting a BRAF<sup>V600E</sup> mutation (82). Alterations in mismatch repair proteins (MLH1, MSH2, MSH6, and PMS2) can be identified by IHC and MSI-H by PCR to detect smaller length DNA fragments. Testing for MSI-H is of great clinical interest in mCRC because it predicts the efficacy of pembrolizumab and nivolumab in this setting (83,84). As mentioned before, tropomyosin receptor kinase (TRK) inhibitors showed high efficacy in multi-histology trials in NTRK fusion-positive tumours (50,85); and mCRC with ERBB2 amplifications/overexpression (detected with fluorescence in-situ hybridisation or IHC) presented significant responses with dual HER2 therapy in prospective studies (86,87). In Table 5 we mention the main driver alterations categorised according to ESCAT, including those with lack of clinical data in mCRC, but with impact in other tumours (76,88–94).

***Summary of recommendations: Since most level I alterations are hotspot mutations in KRAS, NRAS and BRAF, and considering that MSI status is determined by IHC or PCR, there is no need to test samples using multigene NGS in the context of daily practice. Nevertheless, multigene NGS can be an alternative to PCR tests only if it does not generate extra cost compared to standard techniques already implemented in routine. This would allow detection of ERBB2 amplifications, and, in some panels, detect MSI status with high accuracy. If large panel NGS is performed, it should include detection of NTRK fusions. As for mBC patients, patients with mCRC can present oncogenic alterations for which drugs are being developed and it is therefore recommended for clinical research centres to***

***include patients in molecular screening programmes to propose access to innovative agents in clinical trials.***

### **Genomic alterations in advanced prostate cancer classified according to ESCAT**

Metastatic castration-resistant prostate cancer (mCRPC) presents aberrations in DNA repair genes with a high frequency (20-30%). Poly ADP ribose polymerase inhibitors (PARPi) improved outcomes from patients with different DNA repair gene alterations in a randomised phase III trial; however, exploratory per-gene analysis suggested that most of the benefit was obtained from patients with *BRCA1/2* somatic mutations (93). This is supported by multiple phase II trials, where patients with *BRCA1/2* alterations achieved the higher response rates. Data about *PALB2*, *RAD50*, *RAD51* or *BRIP1* mutations is promising but sparse due to low frequency of these aberrations (93,95). Other genes involved in DNA repair, like *MLH1/MSH2/MSH6* lead to MSI-H when mutated. Therapy with ICIs demonstrated effectiveness in multi-histology basket studies, although in advanced prostate cancer have shown minimal activity (96–98). *PTEN* alterations are found very frequently in mCRPC (99), and AKT inhibitors in combination with abiraterone showed antitumour activity in a retrospective analysis of a randomised phase II trial (100). Preliminary results of IPATential 150, a phase III randomised trial which evaluated ipatasertib (AKT inhibitor) with abiraterone and prednisone compared to standard therapy, showed an improvement of radiographic PFS (co-primary end point) in patients with *PTEN* loss and mCRPC but not in the overall population (101). Some alterations ranked level I/II in other diseases are observed in prostate cancer, but are not yet validated (102) (see Table 6).

***Summary of recommendations: In countries where poly ADP ribose polymerase inhibitors (PARPi) are accessible for patients with prostate cancer, it is recommended to perform NGS on tumour sample to assess mutational status of, at least, BRCA1/2. According to the preliminary results of the phase III with AKT inhibitors in patients with PTEN alterations, this gene could be added to the panel.***

***Given that they are unlikely to be cost-effective in these cases, larger panels can be used only on the basis of specific agreements with payers taking into account the overall cost of the strategy (including off-label use of drugs) and pending a ranking of additional alterations using a valid ranking system. These panels should include DNA repair genes and MSI signature.***

### **Genomic alterations in metastatic gastric cancer (mGC) classified according to ESCAT**

*ERBB2* amplifications are observed in around 15% of gastric cancers (103). In these patients, trastuzumab demonstrated a significant improvement of OS in randomised trials (104). According to basket trials, patients with MSI-H and *NTRK* fusion-positive tumours treated with ICIs and TRK inhibitors are expected to provide benefit (48,73). Some limited responses were observed in patients with *EGFR* and *MET*-amplified mGC treated with cetuximab and crizotinib in prospective analysis (105,106). These findings require further investigation. In addition, many other level I/II aberrations of other cancer types are observed in gastric cancer, but not validated in this latter disease (46,55,63,90,107–111). All these alterations are described in Table 7.

***Summary of recommendations: There is no current need to perform tumour multigene NGS in patients with mGC in daily practice. Detection of MSI and NTRK fusions should be done using cheap standard methods.***

### **Genomic alterations in advanced pancreatic ductal adenocarcinoma (PDAC) classified according to ESCAT**

Patients with germline *BRCA1/2*-mutated advanced PDAC presented a longer PFS with maintenance olaparib (112,113). In advanced PDAC with somatic *BRCA1/2* mutations an increased response with PARP inhibitors has been reported in few patients included in a prospective trial (114). The panel therefore considered that somatic *BRCA1/2* alterations are not yet validated in advanced PDAC. As we mentioned for other tumours, patients with MSI-H and *NTRK*-fusion-positive tumours presented meaningful clinical benefit with matched therapies in multi-histology studies (50,97,115,116). Several additional alterations are classified at high-level according to ESCAT in other tumours, but have not shown yet significant impact in pancreatic cancer like *KRAS*, *PIK3CA*, *BRAF*<sup>V600E</sup> mutations, *MDM2*, *ERBB2* amplifications, and *NRG1*, *ALK*, *RET*, *ROS1* fusions (55,91,117–126). The main drivers of PDAC and their classification are described in Table 8.

***Summary of recommendations: It is not currently recommended to perform tumour multigene NGS in patients with advanced PDAC in daily practice. Considering the unmet medical needs and the high number of alterations ranked as level II-IV, ESMO considers it is the mission of clinical research centres and their networks to propose multigene sequencing to patients with advanced PDAC in the context of***

***molecular screening programmes in order for patients to get access to innovative drugs. If multigene sequencing is not performed, detection of MSI and NTRK fusions should be done using cheaper standard methods, pending drugs are approved and reimbursed.***

#### **Genomic alterations in advanced hepatocellular carcinoma (HCC) classified according to ESCAT**

While numerous aberrations are being evaluated, very few targets currently have impact on clinical decisions (127). As we described for the majority of cancers, due to their clinical benefit larotrectinib and ICIs were approved for patients with *NTRK*-fusion positive and MSI-H solid tumours respectively, who have no alternative treatments, (48,97). There are also other alterations with strong benefit across different tumour types like *PIK3CA*, *RAS* mutations and *MET* amplifications (72,128,129), and no clinical evidence in this disease (Table 9).

***Summary of recommendations: It is not currently recommended to perform tumour multigene NGS in patients with advanced HCC in daily practice. Considering the unmet medical needs and the number of alterations ranked as level II-IV, ESMO considers it is the mission of clinical research centres to propose multigene sequencing to patients with advanced HCC in the context of molecular screening programmes. If multigene sequencing is not performed, detection of MSI and NTRK fusions should be done using cheaper standard methods, pending drugs are approved and reimbursed.***

#### **Genomic alterations in advanced cholangiocarcinoma (CC) classified according to ESCAT**

*IDH1* mutations are ranked level I in ESCAT (IA) (130). In addition, pemigatinib, a selective FGFR1,2,3 inhibitor, led to a 35% ORR in patients with advanced *FGFR2*-fusion-positive CC in a prospective phase II trial (131), getting the accelerated approval by the FDA. As we mentioned previously, patients with MSI-H and *NTRK*-fusion positive tumours presented clinically meaningful benefit with ICIs and TRK inhibitors in basket studies (50,132). Finally, RAF/MEK inhibitors were associated with 42% OR in patients with advanced CC and *BRAF*<sup>V600E</sup> mutations (133) (Table 10). In Table 10 are also described some alterations with efficacy in other tumours but not yet validated in this disease (52,72,93,134).

***Summary of recommendations: Tumour multigene NGS could be used to detect level I actionable alterations in cholangiocarcinoma. Given that they are unlikely to be cost-effective in these cases, larger panels can be used only on the basis of specific agreements with payers taking into account the***

**overall cost of the strategy (including off-label use of drugs) and pending a ranking of additional alterations using a valid ranking system.**

**Other tumour types:** While the systematic ranking of genomic alterations was done exclusively for the eight more frequent killers, we also assessed the frequency of level I alterations in other tumour types. In ovarian cancers, where *BRCA1/2* somatic mutations have been associated with increased benefit to PARPi (135), the use of multigene NGS is justified. Larger panels can be used only on the basis of specific agreements with payers taking into account the overall cost of the strategy (including off-label use of drugs) and pending appropriate method of reporting. While there is no level I evidence, multigene sequencing could also be used in carcinoma of unknown primary (136).

#### **Specific situations:**

**Tumour mutational burden and KN158 study:** KN158 has evaluated the efficacy of pembrolizumab according to TMB in 10 cancers (anal cancer, cervical cancer, endometrial cancer, small cell lung cancer (SCLC), salivary cancer, thyroid cancers, well-to-moderately differentiated NETs, biliary cancers, vulvar cancer, mesothelioma). Response rates were 27% and 7% in patients with TMB-high (MSI-low) or TMB-low cancers. There was no TMB-high detected in biliary cancers, and the percentage of response was lower in TMB-high in anal cancer and mesothelioma. We can classify TMB as level IIA according to ESCAT. If we consider that indications of anti-PD(L)1 antibodies are broad in endometrial cancers and SCLC, the **TMB should be determined only in cervical cancer, NET, salivary cancers, vulvar cancers, thyroid cancers. Considering that the study was not agnostic, but limited to few cancers, the group thinks that additional studies are needed before implementing TMB in all cancers where anti-PD(L)1 antibodies are not approved.**

**NTRK fusions:** TRK inhibitors have been shown to be effective in broad range of cancers. *NTRK* fusions occur in <1% of cancers. Incidence of *NTRK* fusions is very high in mammary analogue secretory carcinoma of salivary glands and in secretory breast cancers. A high incidence is also observed in sarcoma and thyroid cancers. **Considering the very low incidence, the group recommends using NGS to detect NTRK fusions only in cancers where this technology is recommended otherwise. In cancers where there is no need for multigene sequencing, it was considered that the detection of NTRK fusion**

*is not an argument per se to recommend NGS since alternative, cheaper, diagnostic methods exist. Such alternative, cheaper methods should be prioritised to screen patients for NTRK fusions, in countries where TRK inhibitors are available.*

**Conclusion:** ESMO recommends using tumour multigene NGS in patients presenting with advanced non-squamous NSCLC, prostate, ovarian cancers and cholangiocarcinoma. Large panels of genes can be used if they generate only an acceptable increase in the overall cost, drugs included. In addition, based on KN158, it is recommended to determine TMB in cervical cancer, salivary cancer, thyroid cancers, well-to-moderately differentiated neuroendocrine tumours, vulvar cancer, pending drug access. In colorectal cancers, NGS can be an alternative to PCR-based tests, if it is not associated with extra cost. ESMO strongly recommends that clinical research centres perform multigene sequencing as part of their missions to accelerate cancer research and drug development through clinical trials, provide access to innovation to patients and to collect data. In addition, economic evaluations alongside clinical trials should also be implemented to foster evidence in this field. Outside the indications mentioned before, and considering that the use of large panel of genes could lead to identification of few exceptional responders, ESMO acknowledges that a patient and a doctor could decide together to order a large panel of genes, pending no extra cost for the public healthcare system, and if the patient is informed about the low likelihood of benefit.

These recommendations will need to be updated on a regular basis as new data emerges for novel therapies across tumour types.

### **Acknowledgment**

This is a project initiated by the ESMO Translational Research and Precision Medicine Working Group.

We would also like to thank ESMO leadership for their support in this manuscript.

### **Funding**

It is a project funded by European Society for Medical Oncology (no grant number applies).

## Disclosures

JR: Advisory: MSD, Boehringer, BMS, AstraZeneca, Roche; Speaker's bureau: Pfizer; Travel support: OSE Immunotherapeutics SA, BMS, AstraZeneca, Roche.

JM: Advisory board : Amgen, AstraZeneca, Clovis Oncology, Janssen, MSD and Roche-Foundation Medicine; Research funding: AstraZeneca and Pfizer Oncology; PI of several industry sponsored clinical trials.

CBW: Personal and speakers' fees, reimbursement for travel and accommodation and honoraria for participation in advisory boards from Bayer, Celgene, Ipsen, MedScape, Rafael Pharmaceuticals, RedHill, Roche, Servier, Shire/Baxalta and Taiho; scientific grant support by Roche.

FB: Personal fees from AstraZeneca, Bayer, Bristol-Myers Squibb, Boehringer–Ingelheim, Eli Lilly Oncology, F. Hoffmann–La Roche Ltd, Novartis, Merck, MSD, Pierre Fabre, Pfizer and Takeda.

MPL: Research grants (to hospital): MSD, Astellas, JnJ, Sanofi; Advice: Roche, Bayer, Amgen, JnJ, Sanofi, Servier, Pfizer, Incyte.

NN: Speaker's fee and/or advisory boards: Amgen, AstraZeneca, Bayer, Biocartis, BMS, Boehringer Ingelheim, Eli Lilly, Illumina, Incyte, MERCK, MSD, Qiagen, Roche, Thermofisher, Sanofi; Institutional financial interests (financial support to research projects): AstraZeneca, Biocartis, BMS, Illumina, Merck, Qiagen, Roche, Sysmex, Thermofisher; non-financial interests: President of the International Quality Network for Pathology (IQN Path); President of the Italian Cancer Society (SIC).

ASc: Speakers bureau: Ipsen, Astra Zeneca, Amgen, MSD, GSK; Consulting: INCYTE Biosciences.

FM-B: Consulting: Aduro BioTech Inc., Alkermes, DebioPharm, eFFECTOR Therapeutics, F. Hoffman-La Roche Ltd., Genentech Inc., IBM Watson, Jackson Laboratory, Kolon Life Science, OrigiMed, PACT Pharma, Parexel International, Pfizer Inc., Samsung Bioepis, Seattle Genetics Inc., Tyra Biosciences, Xencor, Zymeworks; Advisory Committee: Immunomedics, Inflection Biosciences, Mersana Therapeutics, Puma Biotechnology Inc., Seattle Genetics, Silverback Therapeutics, Spectrum Pharmaceuticals, Zentalis; Sponsored Research: Aileron Therapeutics, Inc. AstraZeneca, Bayer Healthcare Pharmaceutical, Calithera Biosciences Inc., Curis Inc., CytomX Therapeutics Inc., Daiichi Sankyo Co. Ltd., Debiopharm International, eFFECTOR Therapeutics, Genentech Inc., Guardant Health Inc., Millennium Pharmaceuticals Inc., Novartis, Puma Biotechnology Inc., Taiho Pharmaceutical Co.; Honoraria: Chugai Biopharmaceuticals, Mayo Clinic, Rutgers Cancer Institute of New Jersey; Other (Travel Related): Beth Israel Deaconess Medical Center.

NW: research grant from Puma Biotechnology; scientific advisory board and stockholder for Relay Therapeutics; advisor to Eli Lilly.

ASt: Advisory Board/Speakers Bureau: Astra Zeneca, Eli Lilly, Bayer, BMS, Illumina, Janssen, MSD, Pfizer, Roche, Seattle Genetics, Thermo Fisher; Grants: Bayer, BMS, Chugai.

JB: Travel support: BMS; Consulting fees: BMS, MSD, Astellas. SM: Statistical advice: IDDI and Janssen Cilag; Independent Data Monitoring Committee member: Hexal, Steba, IQVIA, Roche, Sensorion, Biophytis, Servier, Yuhan.

FA: research grants and talks/advisory boards compensate to the hospital: Roche, Pfizer, Novartis, AstraZeneca, Daiichi Sankyo, Lilly.

**Table 2.** Summary recommendations

Tumour types	General recommendations for daily practice	Recommendation for clinical research centers	Special considerations for patients
Lung adenocarcinoma	Tumour multigene NGS to assess level I alterations. Larger panels can be used only on the basis of specific agreements with payers taking into account the overall cost of the strategy (drug included*) and if they report accurate ranking of alterations. NGS can either be done on RNA or DNA, if it includes level I fusions in the panel.	It is highly recommended that clinical research centres perform multigene sequencing in the context of molecular screening programmes in order to increase access to innovative drugs and to speed-up clinical research. This is particularly relevant in breast, pancreatic and hepatocellular cancers where level II-IV alterations are numerous.	Using large panel of genes could lead to few clinically meaningful responders, not detected by small panels or standard testings. In this context and outside the diseases where large panels of genes are recommended, ESMO acknowledges that a patient and a doctor could decide together to order a large panel of genes, pending no extracost for the public healthcare system, and if the patients is informed about the low likelihood of benefit.
Squamous cell lung cancers	No current indication for tumour multigene NGS		
Breast cancers	No current indication for tumour multigene NGS		
Colon cancers	Multigene tumour NGS can be an alternative option to PCR if it does not result in additional cost.		
Prostate cancers	Multigene tumour NGS to assess level I alterations. Larger panels can be used only on the basis of specific agreements with payers taking into account the overall cost of the strategy and if they report accurate ranking of alterations.		
Gastric cancers	No current indication for tumour multigene NGS		
Pancreatic cancers	No current indication for tumour multigene NGS		
Hepatocellular carcinoma	No current indication for tumour multigene NGS		
Cholangiocarcinoma	Multigene tumour NGS could be recommended to assess level I alterations. Larger panels can be used only on the basis of specific agreements with payers taking into account the overall cost of the strategy		

	(drug included*) and if they report accurate ranking of alterations. RNA-based NGS can be used.		
Others	<p>Tumour multigene NGS can be used in ovarian cancers to determine somatic <i>BRCA1/2</i> mutations. In this latter case, larger panels can be used only on the basis of specific agreements with payers taking into account the overall cost of the strategy (drug included*) and if they report accurate ranking of alterations.</p> <p>Large panel NGS can be used in carcinoma of unknown primary.</p> <p>It is recommended to determine TMB in cervical cancer, salivary cancer, thyroid cancers, well-to-moderately differentiated neuroendocrine tumours, vulvar cancer, pending drug access (and in TMB-high endometrial and SCL cancers if anti-PD1 antibody is not available otherwise).</p>		

\*ESMO recommends using off-label drugs matched to genomics only if an access programme and a procedure of decision have been developed at the national or regional level, as illustrated by the DRUP programme.
