HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

SYMPOSIUM ON THE GLOBAL GOVERNANCE IMPLICATIONS OF BLOCKCHAIN

BLOCKCHAIN IN OUTER SPACE

*Primavera De Filippi** and *Andrea Leiter***

Blockchain technology has spurred the emergence of powerful narratives to promote new ways of governing outer space. The list of proposed uses for blockchain applications in outer space is endless—from property registries for asteroid mining, to supply chain management systems, or interplanetary cryptocurrencies for the space economy—along with Elon Musk claiming that “SpaceX is going to put a literal Dogecoin on the literal moon.”¹ Yet, thus far, none of these projects have gone beyond simple declarations or white papers, mostly due to the inherent limitations on the effective enforcement of blockchain-based rules outside of their own technical framework. In this essay, we argue that blockchain technology is relevant for outer space because it fosters novel narratives² advancing possible futures characterized by new modes of governance. The strongest and most prominent of these narratives is the crypto-libertarian one, which draws heavily on the absence of a state, the sanctity of property, and the primacy of private ordering through decentralized markets. But there are other narratives proposed by relevant actors in the blockchain space that are dedicated to other modes of governance.³ By focusing on alternative narratives for blockchain technology, we illustrate how the possible applications of blockchain technology in outer space may extend beyond the current libertarian dreams, to support a more commons-based approach to outer space governance.

International Legal Framework of Outer Space Governance and the Commercial Space Industry

Outer space governance was established through a series of international treaties, enacted during the Cold War period. The Outer Space Treaty of 1967 (OST) is the most significant piece of legislation in this regard. It establishes an international legal framework for outer space, intended to preserve outer space as a *global commons*—i.e.,

IN SOC'Y* 101284 (2020).

46 a “province of [hu]man kind” that shall remain free for exploration by all states, and that should not be subject to
47 national appropriation by any means (Article II).

48 At the time of drafting of these treaties, outer space exploration was primarily an affair of national governments,
49 which was principally undertaken for geopolitical purposes. With the exception of a few private efforts, sovereign
50 powers were the main source of investment for space exploration, and—while it was predicted that private actors
51 would eventually engage in outer space activities—it was considered preferable that state actors remain responsible
52 for outer space governance.

53 Today, however, space activities are increasingly dominated by private actors.⁴ The global space economy grew
54 from 200 billion USD in 2005 to 450 billion USD in 2021, with 80 percent of the revenue generated by private
55 companies, mostly driven by U.S.-based entrepreneurs.⁵ Corporations such as SpaceX, Blue Origin, and Virgin
56 Galactic have already announced the dawn of the “commercial space age.”⁶ While the geopolitical underpinnings
57 cannot be ignored, these companies are participating in the race for space exploration mostly for commercial
58 reasons.⁷

59 As private entities, these companies are not *directly* subject to the provisions of these international treaties; yet,
60 they are *indirectly* affected by them, to the extent that they are expected to respect the laws of the country in which
61 they operate, which are subject to the treaties’ provisions. As a result, it is generally understood that—just like
62 national governments—private companies cannot claim sovereignty over any celestial body in outer spaces.
63 Yet, the wording of the relevant treaties is sufficiently ambiguous as to allow for the commodification of outer
64 space resources by private parties.⁸ Indeed, if the OST framework for the governance of outer space was aimed at
65 preventing national appropriation, it never excluded the possibility of extracting resources from outer space,⁹ pro-
66 vided that the extraction is undertaken “for the benefit and in the interest of all humankind” (Article 1).¹⁰

67 Accordingly, in recent years, some countries—such as the United States,¹¹ Luxembourg,¹² the United Arab
68 Emirates,¹³ and Japan¹⁴—have enacted laws enabling private entities to claim ownership over the resources
69 they extract from outer space, provided that this does not entail or presuppose claims of national sovereignty.¹⁵
70 These countries are interpreting the provisions of the OST in such a way as to allow for the private appropriation
71 of resources in outer space, despite the explicit prohibition of national appropriation of celestial bodies.¹⁶ This
72 interpretation is explicitly recognized in Section 10 of the Artemis Accords of October 2020, stipulating that

91 “the extraction of space resources does not inherently constitute national appropriation under Article II of the
92 Outer Space Treaty.”¹⁷

93 This increase of commercial activity and its support in national legislation builds on the presumed distinction
94 between the national appropriation of celestial bodies (through a claim of sovereignty) and the private appropri-
95 ation of celestial resources (through private property claims). This distinction is grounded on the alleged separa-
96 tion of roles and jurisdictions between the state and the market,¹⁸ mostly supported by liberal and libertarian
97 visions of society.¹⁹ Although these visions recognize the complementarity between the market and the state,
98 they consider that resource allocation is generally best achieved through a decentralized market, only involving
99 a minimal state²⁰ in charge of protecting private property rights.²¹

100 *Blockchain Narratives for Outer Space*

101 It is in this alleged separation between the state and the market that blockchain technology enters into play,
102 bringing a new set of narratives for private ordering²² based on the myth of an autonomous and decentralized
103 market order.²³ In particular, blockchain narratives of transnationality (i.e., spanning across multiple jurisdic-
104 tions)²⁴, alegality (i.e., existing beyond the purview of the law),²⁵ and self-sovereignty (i.e., operating independently
105 of any sovereign authority)²⁶ can be regarded as relevant catalysts for some of the emerging practices of private
106 ordering in outer space.

107 The decentralized character of blockchain technology facilitates coordination between multiple parties, with no
108 centralized control. The transparency and tamper-resistance of the technology makes it possible for anyone with
109 an Internet connection and a blockchain wallet to record information in a secure and immutable manner, provid-
110 ing a secure audit trail of *who has done what when*. Finally, the automation inherent in smart contract-based systems
111 enables operations to be carried out automatically by the underlying blockchain network, without any third-party
112 intervention.

113 While the legal validity and enforceability of these smart contract provisions ultimately depend on the laws of
114 national jurisdictions, blockchain technology enables the creation of an alternative regime to traditional property

136 and contract law, whose enforceability does not depend on the laws of any given country, but rather on the tech-
137 nological rules embedded into a particular blockchain infrastructure. In other words, blockchain technology could
138 be considered as a “new means of securing legal protections” in outer space, despite the lack of an “international
139 consensus on the sovereignty-property relation.”²⁷

140 In light of these above-described features, blockchain technology has come to be regarded as a promising vehicle for
141 advancing decentralized markets that operate independently from any governmental authority.²⁸ This narrative of block-
142 chain technology has also been leveraged for raising funds for outer space projects. One of the most well-known exam-
143 ples comes again from Elon Musk, who announced in May 2021 that a SpaceX mission to the Moon with an estimated
144 cost of 62 million USD would allegedly be entirely funded in Dogecoins. There are many other initiatives that advertise
145 blockchain-based fundraising for space ventures (such as Space Decentral²⁹ or ConsenSys Space³⁰)—although it
146 remains to be seen if the money raised will indeed be used for commercial undertakings in outer space.

147 The problem with these blockchain-based initiatives is that they fail to acknowledge that enforcement cannot be
148 achieved by blockchain technology alone when interacting with non-digital assets. Indeed, while blockchain tech-
149 nology and smart contracts are often said to be self-enforcing or self-executing, this only applies to digital contracts
150 or digital assets that subsist exclusively on the blockchain. As soon as a blockchain-based infrastructure needs to
151 interact with a non-blockchain-based structure, the trustless and self-executing features of the technology fall
152 short—with regard to both collecting *inputs* and enforcing *outputs* outside of the blockchain infrastructure.

153 Whether a blockchain is used as a land-registry for outer space;³¹ as a distributed platform to negotiate and
154 record orbital positions and mining licenses;³² as a traffic management system for the identification and the local-
155 ization of satellites and space debris;³³ as a supply chain management system for space-related activities; or even as
156 a smart contract framework to control the operations of physical devices³⁴—all of these applications require, on
157 the one hand, a trusted set of “oracles” that can feed the blockchain-based system with external information, and,
158 on the other hand, a third-party enforcement authority that can intervene in case of a dispute. These issues are not
159 specific to outer space; they apply to every application of blockchain technology that needs to interface with a non-
160 blockchain-based structure.

161 Blockchain-based systems are thus not an effective work-around for the general dependence of private ordering
162 on third-party enforcement institutions. While the Artemis Accords indicate that state-based legislation still has a
163 considerable role to play despite the increased presence of private entities in outer space, how enforcement will be
164 facilitated in outer space—and by whom—is still up for debate.

166 *Alternative Blockchain Narratives for Outer Space*

167 If the currently proposed applications for blockchain in outer space are inherently flawed—due to their depen-
168 dence on external actors for access to information and for the enforcement of outcomes in the physical world—is
169 there room for blockchain technology to make another potential contribution in the field of outer space?

Beyond the libertarian ideology, blockchain technology has enabled other narratives that could contribute to promoting better governance in outer space fostering a more distributed and participatory framework for decision making. Collectives of researchers, activists, and developers are already experimenting with blockchain technology for the governance of the commons.³⁵ They believe this technology brings a long-missing piece to the commons' governance puzzle through the affordances it offers—e.g., reducing free-riding and enabling the collective management of funds.³⁶ Blockchain technology thus appeals to many grassroots communities³⁷ and decentralization advocates,³⁸ who see in this technology new opportunities for distributed and participatory governance.

Beyond grassroots communities, the technology could also serve the interests of both public and private space actors in enhancing institutional trust, not by relying on automated enforcement but rather by enhancing transparency and accountability. Indeed, blockchain technology is particularly well-suited for the governance of poly-centric systems, where a variety of actors—often with diverging economic and political interests—need to come to a consensus about a particular course of action, without reliance on a centralized authority to coordinate their actions. Accordingly, many of the attempts at designing new distributed governance structures in the context of blockchain applications could potentially be transposed to the outer space field. A blockchain could be used, for instance, to support international cooperation and facilitate the reconciliation of transactions amongst multiple interacting actors through a shared database that is held in common by all relevant stakeholders. This is currently being done by the Space 4.0 initiative of the European Space Agency,³⁹ leveraging smart contracts to guarantee accurate payments, procurement, supplier agreements, and automated transactions. Besides, blockchain technology could help improve the governance of shared resources and distribute the proceeds of outer space resource extraction, thanks to the ability to manage funds in a transparent and decentralized fashion, with no reliance on any intermediary authority.⁴⁰

Conclusion

Blockchain technologies are a powerful force of innovation with the potential to bring transformation in existing modes of governance. Yet, to date, most of the innovation facilitated by blockchain technology is driven by a particular set of libertarian narratives. These narratives have inspired a variety of applications in outer space, aimed at replacing sovereign rules with private ordering and market-based dynamics that could allegedly operate without the need for any governmental structure or trusted intermediary. Indeed, given the prohibition of national appropriation of celestial bodies, private ordering has become a popular mechanism to negotiate the allocation and exploitation of celestial resources. Yet, as we discussed in this essay, these applications are limited to the extent that they assume enforcement capabilities that the technology does not afford. Nevertheless, while the

226 crypto-libertarian narrative may be the most noticeable one, blockchain technology has generated other narratives,
227 providing new opportunities to experiment with more inclusive and participative commons-based or trust-based
228 governance models. Those propositions have the potential to contribute to the governance of outer space as a
229 global commons.
