(Received 26 May 1994; accepted 29 September 1994)

Abstract—Air oxidation of $[\text{PPh}_4][\text{Mo}_3\text{I}_{12}]$ produces $[\text{PPh}_4][\text{MoOI}_4]$, a rare example of an iodide-containing molybdenum(V) complex, whose structure has been determined by X-ray crystallography. This structural determination completes the $[\text{MoOX}_4]^-$ ($\text{X} = \text{Cl}, \text{Br}, \text{I}$) series. The structural parameters are compared with those of the other halide analogues and with those of crystallographically characterized base adducts, $[\text{MoOI}_4(\text{L})]^-$ ($\text{L} = \text{H}_2\text{O}, \text{THF}$). Also, a comparison between the donor power of O^{2-} vs the pentamethylcyclopentadienyl anion for molybdenum(V) is made possible by comparing $[\text{MoOI}_4]^-$ with the non-existent $(\eta\text{-C}_5\text{Me}_5)\text{MoI}_4$.

Oxomolybdenum(V) derivatives are a well-investigated class of compounds, both mononuclear and dinuclear compounds being well represented.¹ Most of these compounds have chloride ligands making up the valence and a smaller number of them have bromides. Rare examples of iodide-containing oxomolybdenum(V) complexes are the $[\text{MoOI}_4(\text{L})]^-$ ions ($\text{L} = \text{H}_2\text{O}, \text{THF}$),² which may be considered as base adducts of the well-known class of oxohalide complexes $[\text{MoOX}_4]^-$, of which both the chloro³ and bromo⁴ derivatives have been well characterized. The iodo member of this series has not been reported before. We report here the structure of the base-free $[\text{MoOI}_4]^-$ ion and discuss the structural trends of the entire $[\text{MoOX}_4]^-$ series, as well as the structural changes upon base coordination.

EXPERIMENTAL

$[\text{PPh}_4][\text{Mo}_3\text{I}_{12}]$ was prepared *in situ* as described elsewhere⁵ from $\text{MoI}_3(\text{THF})_3$ (225 mg, 0.325 mmol)

and $[\text{PPh}_4]\text{I}$ (155 mg, 0.33 mmol) in CH_2Cl_2 (10 cm^3) under dinitrogen. The resulting solution was then reacted with dry air at room temperature under constant magnetic stirring. After *ca* 5 h, the purple precipitate that had formed was filtered off and dried *in vacuo*. Yield 156 mg, 50.1%. Found: C, 30.9; H, 2.2. Calc. for $\text{C}_{24}\text{H}_{20}\text{I}_4\text{MoP}$: C, 31.1; H, 2.2%. IR (Nujol mull, cm^{-1}): 970.3 ($\text{Mo}=\text{O}$). The compound is only sparingly soluble in CH_2Cl_2 . Single crystals of the product were grown in two independent ways: (i) by dissolving 144 mg of the crude product in CH_2Cl_2 (25 cm^3) and cooling the resulting solution to -20°C ; (ii) by slowly diffusing air into a still solution of $[\text{PPh}_4][\text{Mo}_3\text{I}_{12}]$ in CH_2Cl_2 . Both crystals gave the same unit cell parameters within experimental error.

A red crystal having approximate dimensions of $0.30 \times 0.28 \times 0.22$ mm was mounted in a glass capillary in a random orientation. Cell constants and an orientation matrix for data collection were obtained from least-squares refinement, using the setting angles of 25 reflections in the range $18 < \theta < 22^\circ$, measured by the computer-controlled diagonal slit method of centring. As a measure of crystal quality, omega scans of several intense reflections were mea-

* Author to whom correspondence should be addressed.

sured; the width at half-height was 1.01° with a take-off angle of 3.0° , indicating poor crystal quality. From the systematic absences in the $hk0$ layer of $h+k \neq 2n$ and from subsequent least-squares refinement, the space group was determined to be $P4/n$ (No. 85). Periodic monitoring of three stan-

dard reflections did not show a significant variation in intensity, thus a decay correction was not applied. Lorentz and polarization correction were applied to the data, and an empirical absorption correction based on the method of Walker and Stuart was also applied.⁶ Intensities of equivalent reflections were averaged. Sixty-four reflections were rejected from the averaging process because their intensities differed significantly from the average. The agreement factors for the averaging of the 22 observed and accepted reflections was 3.3% based on intensity and 2.4% based on F_0 .

The structure was solved using the structure solution program SHELXS-86.⁷ The remaining atoms were located in succeeding difference Fourier syntheses. Hydrogen atoms were located and added to the structure factor calculations but their positions were not refined. Crystal data are collected in Table 1 and selected bond distance and angles are reported in Table 2 in comparison with those of other $[\text{MoOX}_4]^-$ ions and with those of $[\text{MoOI}_4(\text{L})]^-$ ($\text{L} = \text{H}_2\text{O}$, THF).

The atomic coordinates have been deposited with the Cambridge Crystallographic Data Centre.

RESULTS AND DISCUSSION

The title compound forms as a purple microcrystalline solid by air oxidation of the trinuclear face-shared trioctahedral $[\text{Mo}_3\text{I}_{12}]^{3-}$ species⁵ in dry CH_2Cl_2 . The reaction formally entails the addition of an oxygen atom to each molybdenum centre in the trinuclear anion which is fragmented into mononuclear species. The compound shows the characteristic $\text{Mo}=\text{O}$ stretching vibration at 970 cm^{-1} , which is to be compared with 1005 cm^{-1} for $[\text{MoOBr}_4]^-$ ⁴ and 1015 cm^{-1} for $[\text{MoOCl}_4]^-$.^{3c} This trend correlates with the decreased electronegativity on going from chlorine to bromine to iodine. Prolonged exposure to air of solutions and

suspensions of the purple $[\text{MoOI}_4]^-$ salt yields a brown insoluble material which also shows a strong $\text{Mo}=\text{O}$ stretch in the IR spectrum at 970 cm^{-1} . This decomposition product has a much lower carbon, hydrogen analysis, indicating a PPh_4^+ salt of an oligonuclear $\text{Mo}-\text{O}-\text{I}$ anion, but the material has not been further characterized.

$[\text{PPh}_4][\text{MoOI}_4]$ crystallizes in the tetragonal space group $P4/n$ with the cation located on a 4 site and the anion on a 4 site. The structure is isomorphous with those reported previously for the $[\text{AsPh}_4][\text{MoOCl}_4]^{3a,b}$ and $[\text{PPh}_4][\text{MoOBr}_4]^4$ salts. The cation is unexceptional and will not be discussed further. A view of the anion is shown in Fig. 1 and the bond distances and angles are collected in Table 2 and compared with those of the analogous $[\text{MoOX}_4]^-$ ($\text{X} = \text{Cl}, \text{Br}$) ions and with those of the base adducts $[\text{MoOI}_4(\text{L})]^-$ ($\text{L} = \text{H}_2\text{O}, \text{THF}$). As for the analogous $[\text{MoOX}_4]^-$ ($\text{X} = \text{Cl}, \text{Br}$) ions, the geometry can be described as a square pyramid with the oxo ligand occupying the apical position and the four iodides identifying the square base. The geometry of the base adducts, on the other hand, is pseudo-octahedral with the neutral base located *trans* with respect to the oxo ligand. Thus, coordination of the base perturbs only slightly the geometry of the base-free anion.

The $\text{Mo}-\text{I}$ distance for the title compound is near the short end of the reported range for such a parameter, being slightly shorter than the $\text{Mo}-\text{I}$ bonds in the cationic molybdenum(IV) complex $[\text{CpMoI}_2(\text{PMe}_3)_2]^+$, e.g. $2.721(2)$ and $2.742(2)\text{ \AA}$,⁸ but slightly longer than the terminal $\text{Mo}-\text{I}$ distance reported for the class of $\text{Mo}_3\text{HI}_7\text{L}_3$ clusters [$\text{L} = \text{THF}$, $2.688(3)$ and $2.692(4)\text{ \AA}$; MeCN , $2.710(5)\text{ \AA}$; PhCN , $2.673(4)\text{ \AA}$].⁹ In comparison with the $[\text{MoOI}_4(\text{H}_2\text{O})]^-$ and $[\text{MoOI}_4(\text{THF})]^-$ structures (see Table 2), the $\text{Mo}-\text{I}$ distance is shorter by *ca* 0.04 \AA . The lengthening upon coordination of the axial base is expected as a result of a greater electron density on the metal centre. For the chloro and bromo systems, the $\text{Mo}-\text{X}$ lengths experience an analogous lengthening as a result

of base coordination (0.04 \AA on going from $[\text{MoOCl}_4]^-$ to $[\text{MoOCl}_4(\text{H}_2\text{O})]^-$,¹⁰ and 0.05 \AA on going from $[\text{MoOBr}_4]^-$ to $[\text{MoOBr}_4(\text{H}_2\text{O})]^-$).^{2a} For the same reason, the $\text{Mo}=\text{O}$ distance is significantly shorter in the base-free complex. The introduction of an axial base causes an expected opening of the MoI_4 umbrella, with the $\text{O}=\text{Mo}-\text{I}$ angles being $6-8^\circ$ larger and the *trans*- $\text{I}-\text{Mo}-\text{I}$ correspondingly $12-16^\circ$ smaller in the base-free complex (see Table 2).

A comparison between the structural parameters of the different $[\text{MoOX}_4]^-$ ions is rather interesting. There are unexpected discrepancies between the $\text{Mo}-\text{O}$ distances in different ions (see Table 2) and even between two separate structural determinations for the same compound, i.e. $[\text{AsPh}_4][\text{MoOCl}_4]$ (the two crystals being isomorphous but with significantly different volumes). For the two different $[\text{MoOCl}_4]^-$ determinations,^{3a,b} the $\text{Mo}-\text{O}$ distance varies by as much as 0.1 \AA , the other parameters varying to a much lesser extent. Concerning the other two ions, $[\text{MoOBr}_4]^-$ shows a long $\text{Mo}-\text{O}$ distance, similar to that of the $[\text{MoOCl}_4]^-$ ion with the longer $\text{Mo}-\text{O}$ bond, and also quite different angular parameters corresponding to a flatter MoBr_4 plane. The $\text{Mo}-\text{O}$ distance in $[\text{MoOI}_4]^-$, on the other hand, is close to that of the $[\text{MoOCl}_4]^-$ ion with the shorter $\text{Mo}-\text{O}$ bond, and the other geometric parameters compare quite well with those of both determinations of the chloro species. It is not clear what may cause such an unexpected variation in geometric parameters. An artificially longer $\text{Mo}-\text{O}$ bond could result from compositional disorder with a co-crystallized impurity such as a square pyramidal $[\text{MoX}_5]^-$ ion, although the existence of such a species seems doubtful.¹¹ The $\text{Mo}-\text{O}$ distances around 1.7 \AA do not appear reasonable, because a lengthening of this distance is expected upon coordination of an axial base, and the $\text{Mo}-\text{O}$ distances in *trans*- $[\text{MoOX}_4(\text{H}_2\text{O})]^-$ are $1.66(1)$,¹⁰ $1.65(1)$ ^{2a} and $1.65(1)\text{ \AA}$ ^{2a} for $\text{X} = \text{Cl}, \text{Br}$ and I , respectively, i.e. more in accord with the distances around 1.6 \AA for $\text{Mo}-\text{O}$ in the base-free $[\text{MoOX}_4]^-$ ions. Other relevant $\text{Mo}-\text{O}$ distances are $1.641(4)\text{ \AA}$ in $[\text{Me}_2\text{C}=\text{NH}_2][\text{MoOCl}_4]$, where the anions are arranged pairwise to yield weak axial $\text{O}=\text{Mo}\cdots\text{Cl}$ interactions,^{3d} and $1.65(1)\text{ \AA}$ in $[\text{AsPh}_4]_2[\text{MoOCl}_4][\text{MoOCl}_4(\text{MeCN})]$ (same distance found in the base-free ion and in its acetonitrile adduct).^{3c}

Finally, we would like to remark that the $[\text{MoOI}_4]^-$ ion and its base adducts are rare examples of iodide-containing molybdenum(V) species. Iodide is usually not compatible with high oxidation state metals because it can be easily oxidized by them to afford polyiodide salts of the metal

Fig. 1. An ORTEP view of the $[\text{MoOI}_4]^-$ ion.

in a lower oxidation state through an internal redox process. Thus, although chloride and bromide support the oxidation states V and IV for molybdenum in MoCl_5 and MoBr_4 , respectively, the highest oxidation state homoleptic molybdenum iodide known is MoI_3 .¹² A way to render the metal less oxidizing is to increase its electron density through donation from the ligand system. Oxygen is a very strong π -donor and serves well for this purpose. It is interesting to make a comparison between $[\text{MoOI}_4]^-$ and another system recently reported by us, namely $[\text{Cp}^*\text{MoI}_4]^-$, which shows an identical square pyramidal coordination geometry with the Cp^* ligand in the apical position.¹³ The latter is a molybdenum(IV) complex, and a cyclic voltammetric investigation was carried out to probe for the possible oxidation to a neutral Cp^*MoI_4 complex of molybdenum(V). It was found, however, that the first observed oxidation process involves the I^- ligands to afford I_3^- , thereby proving the internal redox instability of a hypothetical neutral Cp^*MoI_4 complex of molybdenum(V). It is pertinent to mention here that the corresponding $[\text{Cp}^*\text{MoX}_4]^-$ ($\text{X} = \text{Cl}, \text{Br}$) undergo reversible electrochemical oxidations to the corresponding square pyramidal neutral complexes of molybdenum(V), which are stable and isolable species.¹³ Therefore, the molybdenum centre is less oxidizing (electron richer) in $[\text{MoOI}_4]^-$ (**I**) than in Cp^*MoI_4 (**II**), meaning that O^{2-} is overall a stronger electron donor than Cp^{*-} for molybdenum(V). We point out here that the oxo ligand, when it can make use of both lone pairs for π -bonding, is a six-electron donor just like Cp^{*-} , justifying the formalism used in structures **I** and **II**.
