CLIPS OPERATION BETWEEN TYPE II AND TYPE III O(3)-SUBGROUPS WITH APPLICATION TO PIEZOELECTRICITY

P. AZZI AND M. OLIVE

Abstract. Clips is a binary operation between conjugacy classes of closed subgroups of a compact group, which has been introduced to obtain the isotropy classes of a direct sum of representations \( E_1 \oplus E_2 \), if the isotropy classes are known for each factor \( E_1, E_2 \). This allows, in particular, to compute the isotropy classes of any reducible representation, once one knows the decomposition into irreducible factors and the symmetry classes for the irreducible factors.

In the specific case of the three dimensional orthogonal group O(3), clips between some types of subgroups of O(3) have already been calculated. However, until now, clips between type II and type III subgroups were missing. Those are encountered in 3D coupled constitutive laws. In this paper, we complete the clips tables by computing the missing clips. As an application, we obtain 25 isotropy classes for the standard O(3) representation on the full 3D Piezoelectric law, which involves the three Elasticity, Piezoelectricity and Permittivity constitutive tensors.

1. Introduction

Given a linear representation \((V, \rho)\) of a compact group \(G\), the symmetry classes (or isotropy classes) are defined as the sets of conjugacy classes of the symmetry subgroups of \(G\) (see [1], for more details). Finding explicitly the isotropy classes of a given representation has always been a difficult task, but it is known that there exists only a finite number of them. This fact was first conjectured by Montgomery [5, problem 45] and proved by Mostow in the case of the action of a compact Lie group on a compact manifold [19] using the result of Floyd [7].

The explicit calculation of isotropy classes is an interesting problem not only in mathematics but also in mechanics because the symmetry classes are connected to material symmetries. The problem of classifying materials according to their symmetries goes back to the work of Lord Kelvin [13]. Since then, many authors devoted a great effort to formulate the problem especially for SO(3) and O(3) tensorial representations (used to model constitutive laws in mechanics). Surprisingly, it was only in 1996 that Forte and Vianello [8] solved definitively the problem for the Elasticity tensor (a fourth-order tensor). In that case, eight isotropy classes were found. Based on this method, the problem was solved for other constitutive laws. For instance, 16 isotropy
classes were obtained for the Piezoelectricity tensor (a third-order tensor) [21, 30, 29, 20, 31]. Similar results were obtained for other constitutive tensor spaces [9, 15].

However, the Forte-Vianello approach requires rather fine calculations and reasoning to establish the classification. This complexity makes difficult its application to more involved situations, such as constitutive tensors of order greater than 4 or coupled constitutive laws involving a family of tensors [12, 6]. A systematic way to calculate the isotropy classes was proposed by Cho-
sat and Guyard in [3] using a binary operation between conjugacy classes. This operation was named the clips operation in [23, 24, 22, 25], where it was generalized and used to determine isotropy classes for reducible representations.

Clips tables for SO(3)-subgroups were obtained first in [3]. The problem is more complicated for O(3)-subgroups, since there exist three types of subgroups (see Appendix A), where type I corresponds to SO(3)-subgroups. Clips tables for O(3)-subgroups were calculated in [22], except the ones between type II and type III subgroups. In this paper, we complete these results by providing these missing tables, which have never been obtained before. The clips tables 1 and 2 given in this paper, together with the tables provided in [22], furnish an exhaustive list of clips tables between O(3)-subgroups. Since the isotropy classes are known for the irreducible representations of O(3) [10, 4], this allows, in practice, to determine the isotropy classes of any reducible representation of O(3). As an original application, we used these results to determine the 25 isotropy classes of the full 3D Piezoelectricity law, in which three constitutive tensors are involved: the Elasticity, the Piezoelectricity and the Permittivity tensors.

Organization of the paper. The paper is organized as follows. In section 2, we recall basic material on symmetry classes and we introduce the clips operation. In section 3, we provide (in tables 1 and 2) the list of clips between O(3)-subgroups of type II and III. The proofs and calculations for these clips are given in section 4. The application to the full Piezoelectricity law is detailed in section 5, where 25 symmetry classes are found. To be self-contained, the classification of closed O(3)-subgroups, up to conjugacy, is recalled in Appendix A.

2. ISOTROPY CLASSES AND CLIPS OPERATION

In this section, we recall the notions of isotropy groups and isotropy classes of a group representation and we introduce clips operation for sets of conjugacy classes. We consider a linear representation \((V,G,\rho)\) of a group \(G\) on a finite dimensional vector space \(V\), i.e., a group morphism

\[ \rho : G \rightarrow \text{GL}(V) \]

with \(\text{GL}(V)\), the group of invertible linear mappings of \(V\) into itself.

The *isotropy (or symmetry) group* of \(v \in V\) is defined as

\[ G_v := \{ g \in G; \rho(g)v = v \}, \]

and the *isotropy (or symmetry) class* of \(v\) is the conjugacy class \([G_v]\) of its isotropy group

\[ [G_v] := \{ gG_vg^{-1}; g \in G \}. \]

For a given subgroup \(H \subset G\), the conjugacy class \([H]\) is an *isotropy class* of the linear representation \((V,G,\rho)\) if \(H\) is conjugate to some isotropy group \(G_v\). Let us then define \(\mathcal{J}(V)\) to be the set of all isotropy classes of the representation \(V\)

\[ \mathcal{J}(V) := \{ [G_v]; v \in V \}. \]

As mentioned in the introduction, the finiteness of \(\mathcal{J}(V)\) is proven when \(G\) is a compact Lie group and \(V\) is a compact manifold (see, for instance, [19], [1], [16]). The result for a linear representation of a compact Lie group on a vector space follows immediately, since, then, an invariant scalar product exists and the restriction of the representation to the unit sphere, which is a compact manifold, has the same isotropy classes as the full representation.

**Theorem 2.1.** Let \((V,G)\) be a linear representation of a compact Lie group \(G\) on a vector space \(V\). Then there exists a finite number of isotropy classes

\[ \mathcal{J}(V) = \{ [H_1], \ldots, [H_n] \}. \]
Remark 2.2. The set of conjugacy classes \([H]\) of closed subgroups of a compact group is endowed with a partial order relation (see \([2]\)), given by

\[
[H] \preceq [K] \iff \exists g \in G, \ gHg^{-1} \subset K.
\]

Given this finiteness result, it is important to explicitly calculate the isotropy classes of a given representation. In the specific case of \(SO(3)\) linear representations, Michel \([18]\) obtained the isotropy classes for the irreducible representations and the ones for \(O(3)\) irreducible representations were obtained by Ihrig and Golubitsky \([11]\). Thereafter, Chossat and Guyard \([3]\) get the isotropy classes of a direct sum of two irreducible \(SO(3)\) representations. To do so, they introduced a binary operations on conjugate \(SO(3)\)-subgroups that allows one to compute the set of isotropy classes \(J(V)\) of a direct sum \(V = V_1 \oplus V_2\) of linear representations of a group \(G\), if we know the isotropy classes for each individual irreducible representations. Such an operation is generalized to a binary operation on all conjugacy classes of subgroups of a given group \(G\) and is defined as follows

**Definition 2.3.** For two subgroups \(H_1\) and \(H_2\) of a group \(G\), we define the clips operation of the conjugacy classes \([H_1]\) and \([H_2]\) as the subset of conjugacy classes

\[
[H_1] \odot [H_2] := \{[H_1 \cap gH_2g^{-1}] : g \in G\}.
\]

This definition immediately extends to two families (finite or infinite) \(\mathcal{F}_1\) and \(\mathcal{F}_2\) of conjugacy classes

\[
\mathcal{F}_1 \odot \mathcal{F}_2 = \bigcup_{[H_i] \in \mathcal{F}_1} [H_1] \odot [H_2].
\]

The following lemma states a central result that is useful to find the isotropy classes of a reducible representation once we know the isotropy classes of irreducible ones (see \([22]\) for a proof).

**Lemma 2.4.** Let \(V_1\) and \(V_2\) be two linear representations of \(G\). Then the set \(J(V_1 \oplus V_2)\) of isotropy classes of the diagonal representation of \(G\) on \(V_1 \oplus V_2\) is given by

\[
J(V_1 \oplus V_2) = J(V_1) \odot J(V_2).
\]

Using this result, one can find the isotropy classes of any representation \(V\) provided we know

1. a stable decomposition \(V = W_1 \oplus \cdots \oplus W_r\);
2. the isotropy classes of each representations \(W_k\);
3. the clips table of \([H_1] \odot [H_2]\) for all subgroups of \(G\).

Lemma 2.4 has already been applied to find the isotropy classes of some \(O(3)\) reducible representations, which are essentially the standard \(O(3)\) representations on odd order tensor spaces on \(\mathbb{R}^3\) (see \([24, 22]\)). To extend these results to all reducible \(O(3)\) representations, new clips table of closed \(O(3)\)-subgroups have to be calculated.

3. CLIPS OPERATION BETWEEN CLOSED O(3)-SUBGROUPS

The clips tables have already been established for two type I subgroups in \([3, \text{table 1}]\) and \([22, \text{Table 1}]\) (see remark 3.2. As for two type III subgroups, the clips have already been calculated in [22, Table 2]). The clips operation between a type I and a type III subgroup is deduced from [22, Lemma 5.4]. The clips between a type I and a type II subgroup or two type II subgroups are deduced from the clips between two type I subgroups, see remark 1.

As recalled in Appendix A (see also [11] for details), any closed \(O(3)\)-subgroup is either of type I, type II or type III. More specifically

- Every type I closed \(O(3)\)-subgroup is conjugate to one of the following list

  (1) \(SO(3)\), \(O(2)\), \(SO(2)\), \(D_n\), \(Z_n\), \(T\), \(O\), \(I\), or \(1\).

- Every type II closed \(O(3)\)-subgroup is conjugate to \(H \oplus \mathbb{Z}_2^c\) where \(H\) is a type I subgroup and \(\mathbb{Z}_2^c := \{-\text{Id}, \text{Id}\}\).
• Every type III closed O(3)-subgroup is conjugate to one of the following list:

\[ Z_{2n}, \ D_n^0, \ D_{2n}^d, \ O^-, \ O(2)^-. \]

Each closed subgroups from the lists (1) and (2) is defined in Appendix A.

**Remark 3.1.** Every type III subgroup of O(3) is constructed from a pair of SO(3) subgroups \((\Gamma_+, \Gamma)\) of index 2, where \(\Gamma_+ = \Gamma \cap \text{SO}(3)\), such that \(\Gamma = \Gamma_+ \cup -\gamma \Gamma_+; \quad \gamma \in \tilde{\Gamma} \setminus \Gamma_+\).

Note that \(\tilde{\Gamma} = \Gamma_+ \cup \gamma \Gamma_+\).

Five subgroups of type III can be deduced

\[ Z_{2n}^- = Z_n \cup (-r(e_3, \pi/n))Z_n \quad \forall n \geq 1. \]

\[ D_n^0 = Z_n \cup (-r(e_1, \pi))Z_n \quad \forall n \geq 2. \]

\[ D_{2n}^d = D_n \cup (-r(e_3, \pi/n))D_n \quad \forall n \geq 1. \]

\[ O^- = T \cup (-r(e_3, \pi/2))T. \]

\[ O(2)^- = \text{SO}(2) \cup (-r(e_1, \pi))\text{SO}(2). \]

The notation \(r(n, \theta)\), with \(\theta \in [0; 2\pi]\) and \(n = (n_x, n_y, n_z)\), a unit vector, denotes the Rodrigues formula to represent a rotation by angle \(\theta\) around \(n\), which is given by

\[ r(n, \theta) = \exp(\theta j(n)) = \text{Id} + j(n) \sin(\theta) + j(n)^2(1 - \cos(\theta)) \]

where \(j(n)\) denotes the antisymmetric matrix with entries

\[ j(n) = \begin{pmatrix} 0 & -n_z & n_y \\ n_z & 0 & -n_x \\ -n_y & n_x & 0 \end{pmatrix}. \]

As said before, the clips tables for two type I subgroups can be found in [3, table 1] and [22, Table 1]. However, these two tables differ in some cases. In the following remark, we point out the differences between the two references and we recalculate the disputed clips.

**Remark 3.2.** The two tables regrouping the clips between two SO(3)-subgroups provided in [3, table 1] and [22, Table 1] differ in the following cases:

- Clips between \([D_n]\) and \([O(2)]\) (see equations (23) and (29) for details on these subgroups): the table given by Chossat [3] is the correct one in this case

\[ [D_n] \oplus [O(2)] = \{ [1], [D_n], [D_2] \text{if } n \text{ is even}, [Z_2] \} \]

while Olive [22] has \([D_2]\) if \(n\) is odd. Indeed, the following intersection

\[ D_n \cap gO(2)g^{-1} = \left\{ r \left( e_3, \frac{2k\pi}{n} \right), r(b_i, \pi) \right\} \cap \{ r(ge_3, \theta), r(gb, \pi) \} \]

gives \([D_2]\) only if \(n\) is even (take for instance \(g = r \left( e_2, \frac{\pi}{7} \right)\)).

- Clips between \([T]\) and \([T]\): the table of Olive [22, table 1] is the correct one for this case

\[ [T] \oplus [T] = \{ [1], [Z_2], [D_2], [Z_3], [T] \} \]

since Chossat [3, table 1] omits the conjugacy class \([D_2]\). Indeed, \([D_2] \in [T] \oplus [T]\) since the intersection

\[ T \cap gTg^{-1}, \quad \text{for } T = \bigcup_{i=1}^{3} Z_{e_i}^2 \cup \bigcup_{j=1}^{4} Z_{3j}^s (24), \]

gives \([D_2]\) for \(g = r \left( e_2, \frac{\pi}{7} \right)\) for example.
Remark 3.4. In tables we have used the conventions

\[ [Z_1] := [1], \quad [D_1] = [Z_2], \quad [D_1^+] = [Z_2^-], \quad [D_2^+] = [D_2^-]. \]

Remark 3.5. Note that in [22, figure 3] it was stated that \( D_2^+ \subset D_{2n}^d \) only when \( n \) is odd. However, this is true for all \( n \).

</table>

Table 1. Clips between type II and III O(3)-subgroups (part 1)
Indeed, as we have reason, we use a characterization of these conjugacy classes making use of the clips between sometimes and we risk to not cover all the groups resulting from this intersection. For this intersection $\Gamma = \Gamma + \Gamma$ of index 2, where $\Gamma = \Gamma \cap \text{SO}(3)$, such that

\[ \Gamma = \Gamma + \Gamma \cup -\gamma \Gamma_+; \quad \gamma \in \Gamma \setminus \Gamma_+. \]

Note that $\Gamma = \Gamma_+ \cup \Gamma_-$ be a subgroup of type III and $H$ a subgroup of $\text{SO}(3)$. By definition, the clips operation between a type II and a type III subgroups $[\Gamma] \oplus [H \oplus \mathbb{Z}_2]$ is given by the intersection $\Gamma \cap (gHg^{-1} \oplus \mathbb{Z}_2)$ which can be reduced to

\[ \Gamma \cap (gHg^{-1} \oplus \mathbb{Z}_2) = (\Gamma_+ \cap (gHg^{-1})) \cup (-\gamma \Gamma_+ \cap (gHg^{-1})), \quad -\gamma \in \Gamma \setminus \Gamma_+ \]

Indeed, as we have $H \oplus \mathbb{Z}_2 = H \cup (-H)$ we deduce that

\[ \Gamma \cap (H \oplus \mathbb{Z}_2) = (\Gamma_+ \cup (-\gamma \Gamma_+)) \cap (H \cup (-H)) \]

\[ = (\Gamma_+ \cap H) \cup (\Gamma_+ \cap (-H)) \cup (-\gamma \Gamma_+ \cap H) \cup (-\gamma \Gamma_+ \cap (-H)) \]

\[ = (\Gamma_+ \cap H) \cup ((\gamma \Gamma_+) \cap H) \]

In the following, we prove a theorem which describes the possible conjugacy classes belonging to the clips between a type II and type III subgroups of $\text{O}(3)$. The computation of such classes can be complicated since it involves intersection of groups of type III which can be tricky sometimes and we risk to not cover all the groups resulting from this intersection. For this reason, we use a characterization of these conjugacy classes making use of the clips between

Table 2. Clips between type II and III $\text{O}(3)$-subgroups (part 2)
type I subgroups that have already been calculated before. But, before, a preparatory lemma is needed.

**Lemma 4.1.** Let \((K_+, \tilde{K})\) be a pair of subgroups of a group \(G\) of index 2 and \(H\) be a subgroup of \(G\). Then, either

\[
K_+ \cap H = \tilde{K} \cap H, \text{ or the pair } (K_+ \cap H, \tilde{K} \cap H) \text{ is of index } 2.
\]

**Proof.** Consider the following exact sequence

\[
1 \to K_+ \xrightarrow{\iota} \tilde{K} \xrightarrow{p} \tilde{K}/K_+ \cong \mathbb{Z}_2 \to 1
\]

Then \(p(\tilde{K} \cap H)\) is a subgroup of \(\mathbb{Z}_2\). Therefore, either \(p(\tilde{K} \cap H) = \mathbb{Z}_2\) and in this case \((K_+ \cap H, \tilde{K} \cap H)\) is a pair of index 2 (considering the exact sequence \(1 \to K_+ \cap H \to \tilde{K} \cap H \to \mathbb{Z}_2\)) or \(p(\tilde{K} \cap H) = 1\) and then \(\tilde{K} \cap H = K_+ \cap H\). \(\square\)

**Theorem 4.2.** Let \(\Gamma\) be a type III subgroup of \(O(3)\), built from the pair of \(SO(3)\) subgroups \((\Gamma_+, \tilde{\Gamma})\) of index 2 and let \(H\) be a subgroup of \(SO(3)\). Let \(L\) be a subgroup of \(O(3)\) such that \([L] \in [\Gamma] \otimes [H \oplus \mathbb{Z}_2]\) then, either

1. \(L\) is of type I and \([L] \in ([\Gamma_+] \otimes [H]) \cap ([\tilde{\Gamma}] \otimes [H])\),
2. Or \(L\) is of type III built from a pair \((L_+, \tilde{L})\) of index 2 such that \([L_+] \in [\Gamma_+][H]\) and \([\tilde{L}] \in [\tilde{\Gamma}] \otimes [H]\).

**Proof.** First remark that \(-\text{Id}\) doesn’t belong to the intersection between a type II and a type III subgroups and hence if \([L] \in [\Gamma] \otimes [H \oplus \mathbb{Z}_2]\) then \(L\) is either of type I or type III. Let \([L] \in [\Gamma] \otimes [H \oplus \mathbb{Z}_2]\) then \(L\) is given by the union (8)

\[
L = \Gamma_+ \cap gHg^{-1} \cup (-\gamma \Gamma_+ \cap gHg^{-1}) \quad g \in SO(3), \quad \gamma \in \Gamma \setminus \Gamma_+.
\]

If \(\gamma \Gamma_+ \cap gHg^{-1} = \emptyset\) then \(L\) is of type I and \(L = \Gamma_+ \cap gHg^{-1} = \tilde{\Gamma} \cap gHg^{-1}\). Hence, \([L] \in ([\Gamma_+] \otimes [H]) \cap ([\tilde{\Gamma}] \otimes [H])\).

If \(\gamma \Gamma_+ \cap gHg^{-1} \neq \emptyset\) then \(L\) is of type III and \(\Gamma_+ \cap gHg^{-1} \neq \tilde{\Gamma} \cap gHg^{-1}\). Since \((\Gamma_+, \tilde{\Gamma})\) is a pair of index 2 then, by lemma 4.1, the pair \((\Gamma_+ \cap gHg^{-1}, \tilde{\Gamma} \cap gHg^{-1})\) is of index 2. Hence, there exists \(\sigma \in \tilde{\Gamma} \cap gHg^{-1} \setminus (\Gamma_+ \cap gHg^{-1})\) such that

\[
L = \Gamma_+ \cap gHg^{-1} \cup (-\sigma(\Gamma_+ \cap gHg^{-1}))
\]

Hence, the result. \(\square\)

In the next subsections, we compute the clips operation between type II and type III subgroups of \(O(3)\) using theorem 4.2 which involves clips between type I \(O(3)\)-subgroups that have already been calculated in previous works ([3, 22], see also remark 3.2). Indeed, the classes for the clips operation between a subgroup \(H \oplus \mathbb{Z}_2\) of type II and a subgroup \(\Gamma\) of type III are deduced from the knowledge of the tables of the clips \([\Gamma_+] \otimes [H]\) and \([\tilde{\Gamma}] \otimes [H]\). By eliminating the classes that can’t be realised by any \(g \in SO(3)\), we deduce the clips operation between \([\Gamma]\) and \([H \oplus \mathbb{Z}_2]\).

4.1. **Clips with \(\mathbb{Z}_n^-\).** First, let us recall that \(\mathbb{Z}_n^-\) is built from the couple \((\mathbb{Z}_n, \mathbb{Z}_{2n})\), where \(\mathbb{Z}_n\) is given by (22), as in the equation (16) of appendix A

\[
\mathbb{Z}_{2n}^- = \mathbb{Z}_n \cup (-\gamma \mathbb{Z}_n), \quad \gamma = \pi \left( e_3, \frac{\pi}{n} \right)
\]

where we note \(\mathbb{Z}_1 := \{\text{Id}\}\) when \(n = 1\).

**Lemma 4.3.** Let \(n \geq 1\) and \(m \geq 2\) be two integers and \(d = \gcd(m, n)\). Then

\[
[Z_{2n}] \otimes [Z_m \oplus \mathbb{Z}_2] = \begin{cases} 
\{[\text{Id}], [Z_{2n}]\} & \text{if } \frac{m}{d} \text{ even} \\
\{[\text{Id}], [Z_d]\} & \text{else} 
\end{cases}
\]

**Proof.** We deduce from (8) that

\[
\mathbb{Z}_{2n}^- \cap (g\mathbb{Z}_m g^{-1} \oplus \mathbb{Z}_2) = (\mathbb{Z}_n \cap g\mathbb{Z}_m g^{-1}) \cup (-\gamma \mathbb{Z}_n \cap g\mathbb{Z}_m g^{-1}), \quad \gamma = \pi \left( e_3, \frac{\pi}{n} \right).
\]
In the case when \( ge_3 \) and \( e_3 \) are not colinear, such group reduces to \( I \), so we suppose now that \( ge_3 = ± e_3 \). We thus have to consider

\[
(Z_n ∩ Z_m) ∪ (−(γ Z_n ∩ Z_m))
\]

where \( Z_n ∩ Z_m = Z_d \) and \( γ Z_n ∩ Z_m \) is obtained by solving the equations of unknown \( k_1, k_2 \in \mathbb{Z} \)

\[
\frac{2k_1 + 1}{n} = \frac{2k_2}{m} \iff (2k_1 + 1)dn_1 = 2k_2dn_1, \quad \gcd(m_1, n_1) = 1.
\]

We get solutions only if \( m_1 = \frac{m}{d} \) is even. By replacing \( m_1 \) by \( 2p \) we get that \( p \) devides \( k_2 \) hence \( k_2 = pk' \) with \( k' \) odd. On one hand, \( \frac{2k_1 + 1}{n} = \frac{k'}{2pm} \) and on the other hand, \( \frac{2k_1 + 1}{n} = \frac{k'}{dm_1} \). We deduce that

\[
γ Z_n ∩ Z_m = \left\{ r \left( e_3, \frac{(2k + 1)π}{d} \right) \right\}
\]

\( □ \)

In the following, recall that

\[
Z(n) := Z_{2n}^- ⊕ (Z_2 ⊕ Z_2^c) = \begin{cases} [Z_2] & \text{if } n \text{ even} \\ [Z_2^-] & \text{else} \end{cases}
\]

**Lemma 4.4.** Let \( n ≥ 1 \) and \( m ≥ 2 \) be two integers and \( d = \gcd(m, n) \). Then

\[
[Z_{2n}^-] ⊕ [D_m] ⊕ [Z_2^c] = \begin{cases} \{(1), [Z_{2d}], Z(n)\} & \text{if } \frac{m}{d} \text{ even} \\ \{(1), [Z_d], Z(n)\} & \text{else} \end{cases}
\]

**Proof.** Recall from (23) that

\[
D_m = Z_m \cup_{i=1}^{m} \mathbb{Z}_2 \mathbb{b}_i, \quad Z_2 \mathbb{b}_i := \{ e, r(\mathbb{b}_i, π) \}
\]

where \( \mathbb{b}_i \) are called the secondary axes of the subgroup \( D_m \), with

\[
\mathbb{b}_1 = e_1, \quad \mathbb{b}_k = r\left( e_3, \frac{π}{m} \right) \mathbb{b}_{k-1}, \quad k = 2, \ldots, m.
\]

We have

\[
Z_{2n}^- ∩ (gD_mg^{-1} ⊕ Z_2^c) = (Z_n ∩ gD_mg^{-1}) \bigcup (−(γ Z_n ∩ (gD_mg^{-1}))).
\]

The non trivial cases take place for \( ge_3 = ± e_3 \) and the union is deduced from Lemma 4.3, and for \( gb_i = ± e_3 \) in which case we get \( Z(n) \), so we can conclude. \( □ \)

**Lemma 4.5.** Let \( d_3 = \gcd(3, n) \) and \( d_5 = \gcd(5, n) \). We have

\[
[Z_{2n}^-] ⊕ [T] ⊕ [Z_2^c] = \{(1), [Z_{d_3}], Z(n)\}, \quad [Z_{2n}^-] ⊕ [I] ⊕ [Z_2^c] = \{(1), Z(n), [Z_{d_3}], [Z_{d_5}]\}.
\]

\[
[Z_{2n}^-] ⊕ [O] ⊕ [Z_2^c] = \begin{cases} \{(1), [Z_2], [Z_{d_3}], [Z_4]\} & \text{if } n \text{ is even and } 4|n \\ \{(1), [Z_2], [Z_{d_3}], [Z_4]\} & \text{if } n \text{ is even but } 4 \nmid n \end{cases}
\]

**Proof.** By (8), we have to consider

\[
(Z_n ∩ (gHg^{-1})) \cup (−(γ Z_n ∩ (gHg^{-1}))) \text{ for } H = T, O, I.
\]

Let us consider decomposition (24) of the group \( T \). Then the only non trivial cases are obtained for \( ge_3 = ± e_3 \) in which case we get \( Z(n) \) and for \( gs_{t_j} = ± e_3 \) and we get \( Z_{d_3} \). For the group \( O \) given in (25), the only non trivial cases are for \( ga_{k_i} = ± e_3 \) and \( gs_{t_j} = ± e_3 \) which have been calculated in the case of \( T \) and for \( ge_3 = ± e_3 \) in which case we get \( Z_4 \) if \( 4 \mid n \), \( Z_4 \) if \( n \) is even but \( 4 \nmid n \) and \( Z_2^- \) otherwise.

For the group \( I \), we consider the decomposition (27) and we deduce the result following the same reasoning. \( □ \)

Finally, for the subgroups \( SO(2) \) and \( O(2) \) given in (28) and (29) and as a direct consequence of (8),
Lemma 4.6. For any integer \( n \geq 1 \) we have:

\[
[Z_{2n}] \circ [SO(2) \oplus \mathbb{Z}_2] = \{[1], [Z_{2n}]\}, \quad [Z_{2n}] \circ [O(2) \oplus \mathbb{Z}_2] = \{[1], Z(n), [Z_{2n}]\}
\]

with \( Z(n) \) given by (9).

4.2. Clips with \( \mathbb{D}_n^* \). As explained in Appendix A, the subgroup \( \mathbb{D}_n^* \) is obtained for \( -\gamma = -r(e_1, \pi) \), so that

\[
\mathbb{D}_n^* = Z_n \cup -\gamma Z_n = Z_n \cup \{-r(b_1, \pi), \ldots, -r(b_n, \pi)\}, \quad b_1 = e_1, \quad b_k = r\left(e_3, \frac{\pi}{n}\right)b_{k-1}
\]

where \( \{b_i\} \) are called secondary axes of the dihedral subgroup \( \mathbb{D}_n \) (see [22, Appendix A]).

Lemma 4.7. Let \( m, n \geq 2 \) be two integers and \( d = \text{gcd}(m, n) \). Then

\[
[D_n^*] \circ [Z_m \oplus \mathbb{Z}_2^*] = \begin{cases} 
\{[1], [Z_d]\} & \text{if } m \text{ is odd} \\
\{[1], [Z_d^*], [Z_d]\} & \text{if } m \text{ is even} 
\end{cases}
\]

Proof. From (8) we have to consider

\[
\mathbb{D}_n^* \cap (gZ_m g^{-1} \oplus \mathbb{Z}_2^*) = (Z_n \cap gZ_m g^{-1}) \cup (-\gamma Z_n \cap gZ_m g^{-1}), \quad \gamma = r(e_1, \pi),
\]

where \( \gamma Z_n = \{r(b_1, \pi), \ldots, r(b_n, \pi)\} \). Here, the only non–trivial cases are obtained when \( gZ_m g^{-1} = Z_n \) (see lemma 4.3) or \( Z_{2k}^* \), which leads directly to the result.

Lemma 4.8. Let \( m, n \geq 2 \) be two integers and \( d = \text{gcd}(m, n) \) and \( d_2 = \text{gcd}(2, n) \). Then

\[
[D_n^*] \circ [D_m \oplus \mathbb{Z}_2^*] = \begin{cases} 
\{[1], [Z_d], [Z_d], [Z_d^*], [D_d^*], [D_d]\} & \text{if } m \text{ is even} \\
\{[1], [Z_d], [Z_d], [Z_d^*], [D_d^*]\} & \text{if } m \text{ is odd} 
\end{cases}
\]

Proof. We apply theorem 4.2 with \( \Gamma_p = Z_n \) and \( \Gamma = \mathbb{D}_n \). We have from [22, table 1]

\[
[Z_n] \circ [D_m] = \{[1], [Z_{d_2}], [Z_d]\} \quad \text{and} \quad [D_n] \circ [D_m] = \{[1], [Z_d], [D_d]\} \text{ (if } m \text{ and } n \text{ even), } [Z_d], [D_d]\}
\]

Hence, the classes of \( [D_n^*] \circ [D_m \oplus \mathbb{Z}_2^*] \), corresponding to type I subgroups, are among the following list

\[
([\Gamma_p] \circ [H]) \cap ([\Gamma] \circ [H]) = \{[1], [Z_{d_2}], [Z_d]\}
\]

and the classes corresponding to type III subgroups are among

\[
\{[Z_d^*], [D_{d_2}^*]\} \text{ (if } m \text{ is even), } [D_d^*]\}.
\]

We can check that all the possibilities can occur by using (8):

\[
(Z_n \cap gD_m g^{-1}) \cup (-\gamma Z_n \cap gD_m g^{-1})
\]

where \( \gamma Z_n \) is obtained for \( \{r(b_i, \pi), i = 1, \ldots, n\} \) and \( \mathbb{D}_m = Z_m \cup m \cup Z_{2k}^* \), we get

- \( [Z_{d_2}] \) for a rotation \( g \) such that \( gb_j = e_3 \) for \( j = 1, \ldots, m \) (take for instance \( g = r(e_3, \frac{\pi}{2}) \circ r(e_2, \frac{\pi}{2}) \) that turns only \( e_1 \) to \( e_3 \) and nothing else);
- \( [Z_d] \) for a rotation \( g \) such that \( ge_3 = e_3 \) (for instance \( g = r(e_3, \frac{\pi}{2}) \));
- \( [Z_d^*] \) for a rotation \( g \) such that \( gb_j = b_i \) for \( i = 1, \ldots, n \) and \( j = 1, \ldots, m \) (for instance \( g = r(e_1, \frac{\pi}{2}) \));
- \( [D_d^*] \) for the identity rotation for instance;
- \( [D_{d_2}^*] \) if \( m \) is even and in this case we can take \( g = r(e_2, \frac{\pi}{2}) \) for instance so we have \( ge_3 = e_1 = b_1 \) and \( gb_2 = b_2 = e_2 \).

Lemma 4.9. Let \( n \geq 2 \) be an integer, \( d_2 = \text{gcd}(2, n) \) and \( d_3 = \text{gcd}(3, n) \). We have

\[
[D_n^*] \circ [T \oplus \mathbb{Z}_2^*] = \{[1], [Z_d^*], [Z_{d_2}], [Z_{d_3}], [D_{d_2}^*]\}.
\]
Proof. We deduce from [22, table 1] and theorem 4.2 that the classes in $[D_n^2] \oplus [T \oplus Z_2^h]$, corresponding to type I subgroups, are among the following list
\[
([Z_n] \oplus [T]) \cap ([D_n] \oplus [T]) = \{ [1], [Z_{d_2}], [Z_{d_3}] \}
\]
and the classes corresponding to type III subgroups are among
\[
\{ [Z_2^{-}], [D_{d_2}] \}.
\]
We can check that all the possibilities can occur by using (8):
\[
(Z_n \cap gTg^{-1}) \cup (-\gamma Z_n \cap gTg^{-1})
\]
where $\gamma Z_n = \{ r(b_i, \pi), i = 1, \ldots, n \}$ and $T = \bigcup_{i=1}^{3} Z_2^i \bigcup_{j=1}^{2} Z_3^{2j} (24)$, we get
- $[Z_2^{-}]$ for a rotation $g$ such that $ge_1 = b_i$ for $i = 1, \ldots, n$ (take for instance $g = r(e_1, \pi)$);
- $[Z_{d_2}]$ for a rotation $g$ such that $ge_i = e_3$ for $i = 1, \ldots, 3$ (take for instance $g = r(e_3, \pi/3)$);
- $[Z_{d_3}]$ for a rotation $g$ such that $gs_i = e_3$;
- $[D_{d_2}]$ for a rotation $g$ such that $ge_i = e_3$ for $i = 1, 2, 3$ and the two remaining $e_i$ turn to two orthogonal $b_i$ (exists for $n$ even).

\[\Box\]

Lemma 4.10. Let $n \geq 2$ be an integer, $d_2 = \gcd(2, n)$, $d_3 = \gcd(3, n)$ and $d_4 = \gcd(4, n)$. We have
\[
[D_n^2] \oplus [O \oplus Z_2^h] = \{ [1], [Z_{d_2}], [Z_{d_3}], [Z_{d_4}], [Z_2^{-}], [D_{d_2}], [D_{d_3}], [D_{d_4}] \}.
\]
Proof. We deduce from [22, table 1] and theorem 4.2 that the classes in $[D_n^2] \oplus [O \oplus Z_2^h]$, corresponding to type I subgroups, are among the following list
\[
([Z_n] \oplus [O]) \cap ([D_n] \oplus [O]) = \{ [1], [Z_{d_2}], [Z_{d_3}], [Z_{d_4}] \}
\]
and the classes corresponding to type III subgroups are among
\[
\{ [Z_2^{-}], [D_{d_2}^{-}], [D_{d_3}^{-}], [D_{d_4}^{-}] \}.
\]
We can check that all the possibilities can occur by using (8):
\[
(Z_n \cap gOg^{-1}) \cup (-\gamma Z_n \cap gOg^{-1})
\]
where $O = \bigcup_{i=1}^{3} Z_2^i \bigcup_{j=1}^{4} Z_3^{4j} \bigcup_{k=1}^{6} Z_2^{6k} (25)$, we get
- $[Z_2^{-}]$ for a rotation $g$ such that $ga_{d_2} = b_i$ for $i = 1, \ldots, n$ and $k = 1, \ldots, 6$ (for instance take $g = r(e_1, \pi/3) \circ r(e_3, \pi/2)$ that turns only $a_{c_1}$ to $e_1$);
- $[Z_{d_2}]$ for a rotation $g$ such that $ga_{d_3} = e_3$ for $k = 1, \ldots, 6$;
- $[Z_{d_3}]$ for a rotation $g$ such that $gs_i = e_3$;
- $[Z_{d_4}]$ for a rotation $g$ such that $ge_i = e_3$ for $i = 1, \ldots, 3$ (take for instance $g = r(e_3, \pi/3) \circ r(e_1, \pi/4)$);
- $[D_{d_2}^{-}]$ for a rotation $g$ such that $ga_{c_2} = e_3$ and two other edge axes $a_{c_2}$ turn to two orthogonal axes $\pm b_i$ for $i = 1, \ldots, n$ (exists for $n$ even);
- $[D_{d_3}^{-}]$ for a rotation $g$ such that $ga_{c_3} = e_3$ and three other edge axes $a_{c_3}$ (for instance $a_{c_1}, a_{c_3}$ and $a_{c_5}$ are three coplanar edge axes separated by an angle of $\pi$) turn to three $b_i$;
- $[D_{d_4}^{-}]$ for $g = r(e_3, \pi/4)$ for example.

\[\Box\]

Lemma 4.11. Let $n \geq 2$ be an integer, $d_2 = \gcd(2, n)$, $d_3 = \gcd(3, n)$ and $d_5 = \gcd(5, n)$. We have
\[
[D_n^2] \oplus [I \oplus Z_2^h] = \{ [1], [Z_{d_2}], [Z_{d_3}], [Z_{d_5}], [Z_2^{-}], [D_{d_2}] \}.
\]
Proof. We deduce from [22, table 1] and theorem 4.2 that the classes in $[D_n^2] \oplus [I \oplus Z_2^h]$, corresponding to type I subgroups, are among the following list
\[
([Z_n] \oplus [I]) \cap ([D_n] \oplus [I]) = \{ [1], [Z_{d_2}], [Z_{d_3}], [Z_{d_5}] \}
\]
and the classes corresponding to type III subgroups are among
\[ \{ [Z_2^-], [D_{d_2}], [D_{d_2'}], [D_{d_5}] \} . \]

We can check that all the possibilities can occur, except \([D_{d_2}^+]\) and \([D_{d_5}^+]\), by using (8):
\[ (Z_n \cap gIg^{-1}) \cup (-\gamma Z_n \cap gIg^{-1}) \]
where \( I = \bigcup_{i=1}^{6} Z_{3}^{v_i} \bigcup_{j=1}^{10} Z_{3}^{v_j} \bigcup_{k=1}^{15} Z_{2}^{v_k} \) (27), we get

- \([Z_2^-]\) for a rotation \(g\) such that \(gw_k = b_i\) for \(i = 1, \ldots, n\) and \(k = 1, \ldots, 15\);
- \([Z_{d_2}]\) for a rotation \(g\) such that \(gw_k = e_3\) for \(k = 1, \ldots, 15\);
- \([Z_{d_3}]\) for a rotation \(g\) such that \(gv_j = e_3\) for \(j = 1, \ldots, 10\);
- \([Z_{d_5}]\) for a rotation \(g\) such that \(gu_i = e_3\) for \(i = 1, \ldots, 6\);
- \([D_{d_2}^+]\) for a rotation \(g\) such that \(gw_k = e_3\) and two other axes \(w_k\) turn to two orthogonal axes \(b_i\) for \(i = 1, \ldots, n\) (exists for \(n\) even) (the identity rotation works as well since \(w_4\), \(w_10, w_{12}\) are colinear to \(e_1, e_2, e_3\) (\(e_2 = b_i\) for some \(i\) for \(n\) even));
- \([D_{d_3}^+]\) for a rotation \(g\) such that \(gv_j = e_3\) and three other axes \(w_j\) turn to three \(b_i\). However, there is no three coplanar \(w_k\) separated by an angle of \(\frac{\pi}{3}\);
- \([D_{d_5}^+]\) for a rotation \(g\) such that \(ge_i = e_3\) and five axes \(w_i\) turn to five \(b_i\). However, there is no five coplanar \(w_k\) separated by angle of \(\frac{\pi}{5}\).

\[ \square \]

**Lemma 4.12.** For any integer \(n \geq 2\), we have
\[ [D_{d_2}^+] \otimes [SO(2) \otimes Z_2^n] = \{ [1], [Z_2^-], [Z_n] \} \]
\[ [D_{d_2}^+] \otimes [O(2) \otimes Z_2^n] = \{ [1], [Z_2^-], [D_{d_2}], [D_{d_5}] \} \]

*Proof.* By theorem 4.2 we deduce that the classes in the clips \([D_{d_2}^+] \otimes [SO(2) \otimes Z_2^n]\) are among the following list
\[ \{ [1], [Z_2^-], [Z_n] \} . \]

All the classes of the above list can be realized by a rotation \(g\) using the union \(Z_n \cap gSO(2)g^{-1} \cup (-\gamma Z_n \cap gSO(2)g^{-1})\) (8) where \(SO(2)\) consists of all the rotations around \(e_3\). Indeed, we get:

- \([Z_2^-]\) for a rotation \(g\) such that \(ge_3 = b_i\) for \(i = 1, \ldots, n\),
- \([Z_n]\) for the identity rotation for instance.

As for the classes in \([D_{d_2}^+] \otimes [O(2) \otimes Z_2^n]\), by theorem 4.2 we know that such classes are among the following list
\[ \{ [1], [Z_{d_2}], [Z_2^-], [D_{d_2}], [D_{d_5}] \} . \]

By the same reasoning, the above classes can be all realized except for \([Z_{d_2}]\) using (8)
\[ (Z_n \cap gO(2)g^{-1} \cup (-\gamma Z_n \cap gO(2)g^{-1})) \]
where \(\gamma Z_n = \{ r(b_i, \pi), i = 1, \ldots, n \} \) and \(gO(2)g^{-1} = \{ r(ge_3, \theta), r(gb, \pi), b \in (xy) \text{ plan} \} \). Indeed, we get

- \([Z_2^-]\) for a rotation \(g\) such that \(gb = b_i\) for \(i = 1, \ldots, n\) (take for instance \(g = r(e_3, \frac{\pi}{n}) \circ r(e_1, \frac{\pi}{n})\) that turns only \(e_2\) to \(e_1\));
- \([D_{d_2}^+]\) for \(g = r(e_2, \frac{\pi}{n})\) for example;
- \([D_{d_5}^+]\) for the identity rotation for example;

\[ \square \]

**4.3. Clips with \(D_{2n}^d\).** First we have (see Appendix A)
\[ D_{2n}^d = D_n \cup (-\gamma D_n), \quad \gamma = r(e_3, \frac{\pi}{n}) \]
Proof. We can check that all the possibilities can occur by using (11):

where we can write

\[
\mathbb{D}_n = \left\{ \mathbf{r} \left( \frac{2k_1 \pi}{n} \right), \mathbf{r}(b_{2l+1}, \pi); \quad k_1 = 0, \ldots, n - 1 \right\}
\]

\[
-\gamma \mathbb{D}_n = \left\{ -\mathbf{r} \left( \frac{2k_2 + 1 \pi}{n} \right), -\mathbf{r}(b_{2l}, \pi); \quad k_2 = 0, \ldots, n - 1 \right\}
\]

with

\[
b_1 = e_1 \quad \text{and} \quad b_l = r \left( \frac{\pi}{n} \right) b_{l-1}.
\]

**Lemma 4.13.** Let \( m, n \geq 2 \) be two integers and \( d = \gcd(m, n) \). Then

\[
[\mathbb{D}_m^d] \cap [Z_m \oplus Z_2^d] = \begin{cases} \{ [I], [Z_2], [Z_2^d], [Z_2^{-d}] \} & \text{if } \frac{m}{d} \text{ even} \\ \{ [I], [Z_2], [Z_2^{-d}], [Z_2^d], [Z_d], [D_2^d] \} & \text{if } \frac{m}{d} \text{ odd and } m \text{ is even} \\ \{ [I], [Z_2], [Z_d], [D_d], [D_2^d] \} & \text{else} \end{cases}
\]

Proof. From (8) we have to consider intersection

\[
\mathbb{D}_m^d \cap (gZ_m g^{-1} \oplus Z_2^d) = (\mathbb{D}_n \cap gZ_m g^{-1}) \cup (-\gamma \mathbb{D}_n \cap gZ_m g^{-1}) = \gamma = r \left( \frac{\pi}{n} \right)
\]

which can always reduces to 1. Otherwise we have only to consider three cases:

- \( ge_3 = \pm e_3 \) and we deduce intersection from lemma 4.3;
- \( ge_3 = \pm b_{2k} \) for some \( k \) and intersection reduces to \( Z_2 \) for \( m \) even;
- \( ge_3 = \pm b_{2k+1} \) for some \( k \) and intersection reduces to \( Z_2 \) for \( m \) even, and we can conclude the proof.

\[
\square
\]

**Lemma 4.14.** Let \( m, n \geq 2 \) be two integers, \( d = \gcd(m, n) \) and \( d_2 = \gcd(2, n) \). Then

\[
[\mathbb{D}_2^d] \cap [D_m \oplus Z_2^d] = \begin{cases} \{ [I], [Z_2], [D_2], [Z_2^{-d}], [Z_2^d], [D_2^d] \} & \text{if } \frac{m}{d} \text{ is even} \\ \{ [I], [Z_2], [D_2], [Z_2^{-d}], [Z_2^d], [D_2^d], [D_d], [D_2^d] \} & \text{if } \frac{m}{d} \text{ is odd and } m \text{ is even} \\ \{ [I], [Z_2], [D_d], [D_2^d] \} & \text{else} \end{cases}
\]

Proof. We apply theorem 4.2 with \( \Gamma = \mathbb{D}_n \) and \( \tilde{\Gamma} = \mathbb{D}_2^d \). We deduce from [22, table 1]

\[
[\mathbb{D}_n] \cap [D_m] = \{ [I], [Z_2], [D_2] \} \text{ (if } m \text{ and } n \text{ even), } [Z_d], [D_d] \}
\]

and

\[
[\mathbb{D}_2^d] \cap [D_m] = \begin{cases} \{ [I], [Z_2], [D_2], [Z_2^{-d}], [D_2^d] \} & \text{if } \frac{m}{d} \text{ even} \\ \{ [I], [Z_2], [D_2], [Z_d], [D_d] \} & \text{if } m \text{ even and } \frac{m}{d} \text{ odd} \\ \{ [I], [Z_2], [D_d], [D_2^d] \} & \text{if } m \text{ odd} \end{cases}
\]

Hence, the classes in \([\mathbb{D}_2^d] \cap [D_m] \), corresponding to type I subgroups, are among the following list

\[
([\mathbb{D}_n] \cap [D_m]) \cap ([\mathbb{D}_2^d] \cap [D_m]) = \begin{cases} \{ [I], [Z_2], [D_2] \} & \text{if } \frac{m}{d} \text{ even} \\ \{ [I], [Z_2], [D_2], [Z_d], [D_d] \} & \text{if } m \text{ even and } \frac{m}{d} \text{ odd} \\ \{ [I], [Z_2], [D_d], [D_2^d] \} & \text{if } m \text{ odd} \end{cases}
\]

and the classes corresponding to type III subgroups are among

\[
\begin{cases} \{ [Z_2], [D_2], [Z_2^{-d}], [D_2^d] \} & \text{if } \frac{m}{d} \text{ even} \\ \{ [Z_2], [D_2], [Z_d], [D_d] \} & \text{if } m \text{ even and } \frac{m}{d} \text{ odd} \\ \{ [Z_2], [D_d], [D_2^d] \} & \text{if } m \text{ odd} \end{cases}
\]

We can check that all the possibilities can occur by using (8):

\[
(\mathbb{D}_n \cap gD_m g^{-1}) \cup (-\gamma \mathbb{D}_n \cap gD_m g^{-1})
\]

where \( \mathbb{D}_n \) and \( \gamma \mathbb{D}_n \) are given in (23) and (11). We obtain
• $[\mathbb{D}_d^d]$ if $m/d$ is even and $[\mathbb{D}_d]$ otherwise for a rotation $g$ such that $ge_3 = e_3$ and $gb_i = \pm b_{2l+1}$ for some $l$;

• $[\mathbb{D}_d^d]$ if $m/d$ is even and $[\mathbb{D}_d^z]$ otherwise for a rotation $g$ such that $ge_3 = e_3$ and $gb_i = \pm b_{2l}$ for some $l$;

• $[\mathbb{Z}_2]$ if $m/d$ is even and $[\mathbb{Z}_d]$ otherwise for a rotation $g$ such that $ge_3 = e_3$ only;

$$
\begin{cases}
[\mathbb{D}_2] & \text{if } m \text{ and } n \text{ even} \\
[\mathbb{D}_2^z] & \text{if } m \text{ even and } n \text{ odd} \\
[\mathbb{Z}_2] & \text{if } m \text{ odd and } n \text{ even} \\
[\mathbb{Z}_2] & \text{if } m \text{ and } n \text{ odds}
\end{cases}
$$

• $[\mathbb{Z}_2]$ for a rotation $g$ such that $ge_3 = \pm b_{2l+1}$ for some $l$;

• $[\mathbb{Z}_2]$ if $m$ is even for a rotation $g$ such that $ge_3 = b_{2l}$.

\[\square\]

Lemma 4.15. For any integer $n \geq 2$ and $d_k = \gcd(n, k)$ for $k = 2, 3$, we have

$$
[\mathbb{D}_d^d] \oplus [T \oplus \mathbb{Z}_2^d] = \{[\mathbb{I}], [\mathbb{Z}_2], [\mathbb{Z}_d], [\mathbb{D}_d], [\mathbb{Z}_2^*], [\mathbb{D}_2^z]\}.
$$

Proof. We deduce from [22, table 1] and theorem 4.2 that the classes in $[\mathbb{D}_d^d] \oplus [T \oplus \mathbb{Z}_2^d]$, corresponding to type I subgroups, are among the following list

\[(\mathbb{D}_n \oplus [T]) \cap ([\mathbb{D}_2n] \oplus [T]) = \{[\mathbb{I}], [\mathbb{Z}_2], [\mathbb{Z}_d], [\mathbb{D}_d]\}\]

and the classes corresponding to type III subgroups are among

\{[\mathbb{Z}_2^*], [\mathbb{D}_2^z]\}.

We can check that all the possibilities can occur by using (8):

\[(\mathbb{D}_n \cap gT g^{-1}) \cup (- (\mathbb{D}_n \cap gT g^{-1})) ,
\]

where $\mathbb{D}_n$ and $\gamma \mathbb{D}_n$ are given in (23) and (11) and $T$ in (24). We get

• $[\mathbb{Z}_d]$ for a rotation $g$ such that $gs_{i_l} = \pm e_3$;

• $[\mathbb{Z}_2]$ for a rotation $g$ such that $ge_i = b_{2l+1}$ for $i = 1, \ldots, 3$ (take for instance $g = r(e_1, \frac{\pi}{3}) \circ r(e_3, \frac{\pi}{3})$);

• $[\mathbb{Z}_2^*]$ for a rotation $g$ such that $ge_i = b_{2l}$ for $i = 1, \ldots, 3$;

• $[\mathbb{D}_d]$ for a rotation $g$ such that $ge_i = e_3$ for $i = 1, 2, 3$ and the two remaining $e_i$ turn to two $b_{2l+1}$ for some $l$;

• $[\mathbb{D}_d^z]$ for a rotation $g$ such that $ge_i = e_3$ for $i = 1, 2, 3$ and the two remaining $e_i$ turn to two $b_{2l}$ for some $l$.

\[\square\]

Lemma 4.16. Let $n$ be any integer and $d_k = \gcd(n, k)$ for $k = 2, 3$, we have

$$
[\mathbb{D}_d^d] \oplus [O \oplus \mathbb{Z}_2^d] = \begin{cases}
\{L_0, [\mathbb{Z}_d^*], [\mathbb{Z}_4], [\mathbb{D}_4], [\mathbb{D}_4^z]\} & \text{if } 4 \mid n \\
\{L_0, [\mathbb{Z}_d^*], [\mathbb{D}_4^d]\} & \text{if } n \text{ is even and } 4 \n div n \\
\{L_0\} & \text{if } n \text{ is odd}
\end{cases}
$$

$L_0 := [\mathbb{I}], [\mathbb{Z}_2], [\mathbb{D}_d], [\mathbb{Z}_2^*], [\mathbb{D}_2^z], [\mathbb{Z}_d], [\mathbb{D}_d], [\mathbb{D}_d^z], [\mathbb{D}_d^3]$

Proof. We deduce from [22, table 1]

$$
[\mathbb{D}_d] \oplus [O] = \{[\mathbb{I}], [\mathbb{Z}_2], [\mathbb{Z}_d], [\mathbb{D}_d], [\mathbb{D}_d], [\mathbb{D}_d^3]\}
$$
where \( d_4 = \gcd(4, n) \) and
\[
[D_{2n}] \otimes [O] = \{ [I], [Z_2], [Z_{d_4}], [Z_{2d_4}], [D_2], [D_{d_4}], [D_{2d_4}] \}.
\]
We deduce, by theorem 4.2, that the classes in \([D_{2n}] \otimes [\mathbb{O} \oplus Z_2]^c\), corresponding to type I subgroups, are among the following list
\[
([D_{2n}] \otimes [O]) \cap ([D_{2n}] \otimes [O]) = \{ [I], [Z_2], [Z_{d_4}], [D_{d_4}], [D_{2d_4}], [Z_4] \} \quad (\text{if } 4 \mid n), \quad [D_4] \quad (\text{if } 4 \nmid n)
\]
and the classes corresponding to type III subgroups are among
\[
\{ [Z_2^2], [Z_2^-] \} \quad (\text{if } n \text{ is even}), \quad [D_2^2], [D_{d_4}^2], [D_{2d_4}^2] \quad (\text{if } 4 \mid n), \quad [D_4^2] \quad (\text{if } n \text{ is even and } 4 \nmid n)
\].

We can check that all the possibilities can occur by using (8):
\[
(D_n \cap g\mathbb{O}g^{-1}) \cup (-\gamma D_n \cap g\mathbb{O}g^{-1})
\]
where \( D_n \) and \( \gamma D_n \) are given in (23) and (11) and \( O \) in (25). We get
- \([Z_2]\) for a rotation \( g \) such that \( ga_{ck} = b_{2l+1} \) for \( i = 1, \ldots, n \);  
- \([D_{d_4}^c]\) for a rotation \( g \) such that \( ga_{ck} = e_3 \) and two other edge axes \( a_{ck} \) turn to two orthogonal axes \( b_{2l+1} \) (exists for \( n \) even) for some \( l \);  
- \([Z_2^-]\) for a rotation \( g \) such that \( ga_{ck} = b_2 \);  
- \([D_2^2]\) for a rotation \( g \) such that \( ga_{ck} = b_{2l+1} \) and two other edge axes \( a_{ck} \) turn to two orthogonal axes \( b_{2l} \) for some \( l \);  
- \([Z_{d_4}^2]\) for a rotation \( g \) such that \( gs_{i} = e_3 \);  
- \([D_{d_4}^2]\) or \([D_{2d_4}^2]\) for a rotation \( g \) such that \( gs_{i} = e_3 \) and three other edge axes \( a_{ck} \) turn to three secondary axis of \( D_n \) (either three \( b_{2l+1} \) or three \( b_{2l} \)) (one can take for instance \( g = r(e_3, \frac{\pi}{2}) \circ r(<1,-1,0,0>) \) to get \( D_{d_4} \));  
- \([Z_4]\) for a rotation \( g \) such that \( ge_i = e_3 \) for \( i = 1, \ldots, 3 \) (when \( 4 \mid n \));  
- \([Z_4^-]\) for a rotation \( g \) such that \( ge_i = e_3 \) for \( i = 1, \ldots, 3 \) (when \( n \) is even and \( 4 \nmid n \));  
- \([D_4]\) or \([D_{d_4}^-]\) for a rotation \( g \) such that \( ge_i = e_3 \) with \( 4 \mid n \) and two edge axes \( a_{ck} \) together with the remaining two \( e_i \) turn to four secondary axis of \( D_n \) (either four \( b_{2l+1} \) or four \( b_{2l} \));  
- \([D_{2d_4}^2]\) for the identity rotation for instance.

\[\square\]

**Lemma 4.17.** For any integer \( n \geq 2 \) and \( d_k = \gcd(n, k) \) for \( k = 2, 3, 5 \), we have
\[
[D_{2n}^d] \otimes [I \oplus Z_2^c] = \{ [I], [Z_2], [Z_{d_k}], [D_{d_k}], [D_{2d_k}], [Z_{d_k}], [D_{2d_k}] \}
\]

**Proof.** We deduce from [22, table 1] and theorem 4.2 that the classes in \([D_{2n}^d] \otimes [I \oplus Z_2^c]\), corresponding to type I subgroups, are among the following list
\[
([D_{2n}] \otimes [I]) \cap ([D_{2n}] \otimes [I]) = \{ [I], [Z_2], [D_{d_k}], [D_{2d_k}], [Z_{d_k}], [D_{2d_k}] \}
\]
and the classes corresponding to type III subgroups are among
\[
\{ [Z_2], [D_2^2], [D_{d_k}^2], [D_{2d_k}^2] \}.
\]
We can check that all the possibilities can occur except \([D_{d_k}], [D_{2d_k}], [D_{2d_k}^2]\) for the same argument as in lemma 4.11 by using (8):
\[
(D_n \cap g\mathbb{I}g^{-1}) \cup (-\gamma D_n \cap g\mathbb{I}g^{-1})
\]
where \( D_n \) and \( \gamma D_n \) are given in (23) and (11) and \( I \) in (27). We get
- \([Z_2]\) for a rotation \( g \) such that \( gw_k = b_{2l} \) for \( k = 1, \ldots, 15 \);  
- \([Z_2]\) for a rotation \( g \) such that \( gw_k = b_{2l+1} \) for \( k = 1, \ldots, 15 \);  
- \([D_{d_k}^c]\) for a rotation \( g \) such that \( gw_k = e_3 \) and two other axes \( w_k \) turn to two orthogonal axes \( b_{2l+1} \);  
- \([D_{2d_k}^c]\) for a rotation \( g \) such that \( gw_k = e_3 \) and two other axes \( w_k \) turn to two orthogonal axes \( b_{2l} \);  
- \([Z_{d_k}]\) for a rotation \( g \) such that \( gw_j = e_3 \) for \( j = 1, \ldots, 10 \);  
- \([Z_{d_k}]\) for a rotation \( g \) such that \( gw_i = e_3 \) for \( i = 1, \ldots, 6 \).
Finally, we have

Lemma 4.18. For any integer \( n \geq 2 \) we have

\[
[D_{2n}] \oplus [SO(2) \oplus \mathbb{Z}_2^\gamma] = \{[1], [Z_2], [Z_2^\gamma], [Z_{2n}]\}
\]
\[
[D_{2n}^2] \oplus [O(2) \oplus \mathbb{Z}_2^\gamma] = \{[1], [Z_2], [Z_2^\gamma], [D_{d_2}], [D_2^2], [D_{2n}^2]\}.
\]

Proof. By theorem 4.2 we deduce that the classes in the clips \([D_{2n}] \oplus [SO(2) \oplus \mathbb{Z}_2^\gamma]\) are among the following list

\[
\{[1], [Z_2], [Z_2^\gamma], [Z_{2n}]\}.
\]

All the classes of the above list can be realized by a rotation \( g \) using the union

\[
\mathbb{D}_n \cap gSO(2)g^{-1} \cup (-\gamma \mathbb{D}_n \cap gSO(2)g^{-1})(8).
\]

Indeed, we get:

- \([Z_2]\) for a rotation \( g \) such that \( ge_3 = b_{2l+1} \);
- \([Z_2^\gamma]\) for a rotation \( g \) such that \( ge_3 = b_{2l} \);
- \([Z_{2n}]\) for the identity rotation for instance.

As for the classes in \([D_{2n}^2] \oplus [O(2) \oplus \mathbb{Z}_2^\gamma]\), by theorem 4.2 we know that such classes are among the following list

\[
\{[1], [Z_2], [Z_2^\gamma], [D_{d_2}], [D_{2n}^2], [D_2^2]\}.
\]

By the same reasoning, the above classes can all be realized by a rotation \( g \) using (8)

\[
\mathbb{D}_n \cap gO(2)g^{-1} \cup (-\gamma \mathbb{D}_n \cap gO(2)g^{-1})
\]

where \( gO(2)g^{-1} = \{r(ge_3, \theta), r(ge_3, \pi), b \in xy \text{ plane}\} \). We get,

- \([Z_2]\) for a rotation \( g \) such that \( g = r(e_1, \frac{\pi}{2}) \) or \( r(e_2, \frac{\pi}{2}) \) that turns only \( e_3 \) to \( e_1 \) for instance;
- \([Z_2^\gamma]\) for a rotation \( g \) such that \( gb = b_{2k} \) for some \( k \) and some \( b \in (xy)-\text{plane} \) and that doesn’t turn \( e_3 \) to the other axes of \( \mathbb{D}_{2n} \) (take for instance \( g = r(b_{2k}, \frac{\pi}{2}) \) or \( r(e_3, \alpha) \) where \( \alpha \) is the angle between \( b \) and \( b_{2k} \);
- \([D_{d_2}]\) for a rotation \( g = r(e_2, \frac{\pi}{2}) \) for instance (for \( n \) even there exists \( k \) such that \( b_{2k+1} = e_2 \);
- \([D_{2n}^2]\) for a rotation \( g = r(v, \frac{\pi}{2}) \) where \( v \) is a secondary axis of \( \mathbb{D}_{2n} \) orthogonal to \( e_3 \) and \( b_{2k} \) for instance;
- \([D_{2n}^2]\) for the identity rotation for example.

\[\square\]

4.4. Clips with \( \mathbb{O}^- \). First, we introduce a useful decomposition of the subgroup \( \mathbb{O}^- \) (see Appendix A), constructed from the couple of index 2 \((T, \mathbb{O})\)

\[
\mathbb{O}^- = T \cup (-\gamma T), \quad \gamma = r(e_1, \frac{\pi}{2})
\]

where

\[
T = \bigcup_{i=1}^{3} \bigcup_{j=1}^{4} \mathbb{Z}_2^{a_{c_k}},
\]

\[
\gamma T = \left\{ r(a_{c_k}, \pi), r(e_1, \frac{\pi}{2}), r(e_2, \frac{3\pi}{2}) \right\}.
\]

Lemma 4.19. Let \( m \geq 2 \) be an integer and \( d_k^m = \gcd(k, m) \) \((k = 2, 3)\). Then we have

\[
[\mathbb{O}^-] \oplus [\mathbb{Z}_m] = \left\{ \begin{array}{ll}
[1], [Z_2], [Z_{d_2}], [Z_{4}], \\
[1], [Z_{d_2}], [Z_{d_2}], [Z_4]
\end{array} \right\}
\]

if \( 4|m \)

\[
[\mathbb{O}^-] \oplus [\mathbb{Z}_m] = \left\{ \begin{array}{ll}
[1], [Z_2], [Z_{d_2}], [Z_{4}], \\
[1], [Z_{d_2}], [Z_{d_2}], [Z_4]
\end{array} \right\}
\]

otherwise.
Proof. From (8) we have to consider intersection
\[ \mathbb{O}^- \cap \left( gZ_m g^{-1} \oplus \mathbb{Z}^2_2 \right) = (\mathbb{T} \cap gZ_m g^{-1}) \cup \left( -\left( \gamma \mathbb{T} \cap gZ_m g^{-1} \right) \right) \gamma = r \left( e_1, \frac{\pi}{n} \right) \]
which can always reduces to 1. Otherwise we have only to consider three cases:
- \( e_3 = \pm e_i \) and we get \([Z_{2}^-]\) if 4 \( \mid \) m and \([Z_{2}^\prime] \) if not;
- \( e_3 = \pm s_j \) and we get \([Z_{2}^\prime] \);
- \( e_3 = \pm a_c \) and we get \([Z_{2}^\prime] \).

\[ \square \]

Lemma 4.20. Let \( m \geq 2 \) be an integer. We have
\[ \mathbb{O}^- \cap \mathbb{D}_m \oplus \mathbb{Z}^2_2 = \left\{ \left\{ [1], [Z_2], [Z_2^\prime], [Z_{d_1}^\prime], [Z_{d_2}], [D_{d_2}^\prime], [D_{d_2}^\prime z], [D_{d_2}^z] \right\} \right. \]
if 4 \( \mid \) m
\[ \left\{ \left\{ [1], [Z_2], [Z_2^\prime], [Z_{d_1}^\prime], [D_{d_2}], [D_{d_2}^\prime], [D_{d_2}^z] \right\} \right. \]
if m is even and 4 \( \nmid \) m.
\[ \left\{ \left\{ [1], [Z_2^\prime], [Z_{d_1}^\prime], [D_{d_2}] \right\} \right. \]
if m is odd.

Proof. We apply theorem 4.2 with \( \Gamma = \mathbb{T} \) and \( \tilde{\Gamma} = \mathbb{O} \). We deduce from [22, table 1]
\[ [\mathbb{T}] \cap [\mathbb{D}_m] = \left\{ \left\{ [1], [Z_2], [Z_{d_1}^\prime], [D_{d_2}] \right\} \right. \]
and
\[ \left\{ [\mathbb{O}] \cap [\mathbb{D}_m] \right\} = \left\{ \left\{ [1], [Z_2], [Z_{d_1}], [D_{d_2}] \right\} \right. \}
Hence, the classes in \([\mathbb{O}^-] \cap [\mathbb{D}_m \oplus \mathbb{Z}^2_2] \), corresponding to type I subgroups, are among the following list
\[ ([\mathbb{T}] \cap [\mathbb{D}_m]) \cap ([\mathbb{O}] \cap [\mathbb{D}_m]) = \left\{ \left\{ [1], [Z_2], [Z_{d_1}], [D_{d_2}] \right\} \right. \]
and the classes corresponding to type III subgroups are among
\[ \left\{ \left\{ [Z_2^\prime], [D_{d_1}^z], [Z_{d_2}] \right\} \right. \]
if 4 \( \mid \) m
\[ \left\{ \left\{ [Z_2^\prime], [D_{d_2}], [D_{d_2}^z] \right\} \right. \]
if m even and 4 \( \nmid \) m.
\[ \left\{ \left\{ [Z_2^{\prime z}], [D_{d_2}^z] \right\} \right. \]
if m odd.
We can check that all the possibilities can occur by using (8), except \([D_2] \) when 4 \( \mid \) m since it becomes \( D_{d_2}^z \) in this case. Consider
\[ (\mathbb{T} \cap g\mathbb{D}_m g^{-1}) \cup \left( -\left( \gamma \mathbb{T} \cap g\mathbb{D}_m g^{-1} \right) \right) \]
where \( \gamma \mathbb{T} \) is given by (14). We obtain
- \([Z_2] \) for a rotation \( g_b \) such that \( g_b e_i = e_j \) for \( i = 1, \ldots, m \) and \( j = 1, \ldots, 3 \) (take for instance \( g = r \left( e_2, \frac{\pi}{2} \right) \circ r \left( e_3, \frac{\pi}{2} \right) \));
- \([Z_2^-] \) for a rotation \( g_b \) such that \( g_b e_i = a_{c_k} \) for \( i = 1, \ldots, m \) (take for instance \( g = r \left( a_{c_k}, \frac{\pi}{2} \right) \circ r \left( e_3, \frac{\pi}{2} \right) \));
- \([Z_{d_1}] \) for a rotation \( g_b \) such that \( g_b e_i = s_j \);
- \([D_{d_1}^z] \) for a rotation \( g_b \) such that \( g_b e_i = s_j \) and three secondary axis \( b_i \) of \( \mathbb{D}_m \) turn to three \( a_{c_k} \);
- \([D_2] \) for a rotation \( g_b \) such that \( g_b e_i = e_i \) and two orthogonal secondary axis of \( \mathbb{D}_m \) turn to the two remaining \( e_i \) and that is possible when \( m \) is even and 4 \( \nmid \) m since if 4 \( \mid \) m we get \([D_2] \);
- \([D_5] \) for a rotation \( g_b \) such that \( g_b e_i = e_i \) and two orthogonal secondary axis of \( \mathbb{D}_m \) turn to orthogonal \( a_{c_k} \) and this is possible if \( m \) is even;
- \([Z_{4}^-] \) for a rotation \( g_b \) such that \( g_b e_i = e_i \) for \( i = 1, \ldots, 3 \) and if 4 \( \mid \) m.

\[ \square \]

Lemma 4.21. We have
\[ [\mathbb{O}^-] \cap [\mathbb{T} \oplus \mathbb{Z}^2_2] = \left\{ \left\{ [1], [Z_2], [Z_2^-], [D_2], [D_5], [Z_3], [T] \right\} \right. \]
Proof. We deduce from [22, table 1] and theorem 4.2 that the classes in \([O^-] \oplus [T \oplus Z_2^8]\), corresponding to type I subgroups, are among the following list

\[(T \oplus [T]) \cap ([O] \oplus [T]) = \{[1], [Z_2], [Z_3], [D_2], [T]\}\]

and the classes corresponding to type III subgroups are among

\[\{[Z_2^-], [D_2^+]\}\]

We can check that all the possibilities can occur by using (8):

\[(T \cap gTg^{-1}) \cup (-\gamma T \cap gTg^{-1})\]

where \(\gamma T\) is given by (14) and \(T\) in (24). We get

- \([Z_3]\) for a rotation \(g\) such that \(g s_{t_j} = s_{t_i}\);
- \([D_2]\) for a rotation \(g = r(e_2, \frac{\pi}{2})\) for instance;
- \([Z_2^-]\) for a rotation \(g = r(e_3, \frac{\pi}{3}) \oplus r(e_2, \frac{\pi}{2})\) for instance;
- \([D_2^+]\) for a rotation \(g\) such that \(g e_i = e_j\) for \(i = 1, \ldots, 3\) and the two remaining \(e_i\) turn to two \(a_{c_k}\) (for instance \(g = r(e_3, \frac{\pi}{2})\));
- \([Z_2^-]\) for a rotation \(g\) such that \(g e_i = a_{c_k}\) for \(i = 1, \ldots, 3\) (for instance \(g = r(a_{c_1}, \frac{\pi}{2}) \oplus r(e_3, \frac{\pi}{3})\));
- \([T]\) for the identity rotation for instance.

\[\square\]

Lemma 4.22. We have

\[\{O^-\} \oplus [O \oplus Z_2^8] = \{[1], [Z_2], [Z_2^-], [Z_3], [Z_4^-], [D_2], [D_2^+], [D_4^-], [O^-]\}\]

Proof. We deduce, by theorem 4.2, that the classes in \([O^-] \oplus [O \oplus Z_2^8]\), corresponding to type I subgroups, are among the following list

\[(T \oplus [O]) \cap ([O] \oplus [O]) = \{[1], [Z_2], [Z_3], [D_2], [T]\}\]

and the classes corresponding to type III subgroups are among

\[\{[Z_2^-, [Z_4^-, [D_2^+, [D_4^+], [O^-]\}\]

We can check that all the possibilities can occur by using (8) except \([D_2]\) since to get \([D_2]\) we need a rotation \(g\) such that \(g a_{c_k} = e_i\) and \(g e_i = e_i\) which will give \([Z_4^-]\). We have

\[(T \cap gOg^{-1}) \cup (-\gamma T \cap gOg^{-1})\]

where \(\gamma T\) is given by (14) and \(O\) in (25):

- \([Z_2]\) for a rotation \(g\) such that \(g a_{c_k} = e_i\) for \(i = 1, \ldots, 3\) (take for instance \(g = r(e_1, \frac{\pi}{3}) \oplus r(e_3, -\frac{\pi}{2})\));
- \([Z_2^-]\) for a rotation \(g = r(a_{c_1}, \frac{\pi}{2}) \oplus r(e_3, \frac{\pi}{2})\);
- \([D_2^+]\) for a rotation \(g = r(e_3, \frac{\pi}{2})\) for example;
- \([Z_3]\) for a rotation \(g\) such that \(g s_{t_j} = s_{t_i}\);
- \([D_2^+]\) for a rotation \(g\) such that \(g s_{t_j} = s_{t_k}\) and three edge axes \(a_{c_k}\) turn to three \(a_{c_k}\);
- \([Z_4^-]\) for a rotation \(g\) such that \(g e_i = e_j\) for some \(i, j = 1, \ldots, 3\) (take for instance \(g = r(e_3, \frac{\pi}{3})\));
- \([D_4^-]\) for a rotation \(g = r(e_3, \frac{\pi}{2})\) for example;
- \([O^-]\) for the identity rotation for instance.

\[\square\]

Lemma 4.23. We have

\[\{O^-\} \oplus [I \oplus Z_2^8] = \{[1], [Z_2], [Z_2^-], [Z_3], [D_2], [T]\}\]
Proof. We deduce from [22, table 1] and theorem 4.2 that the classes in $[O^-] \oplus [I \oplus Z_2^r]$, corresponding to type I subgroups, are among the following list

$$(\{T\} \oplus \{I\}) \cap ([O] \oplus \{I\}) = \{[1], [Z_2], [Z_3], [T]\}$$

and the classes corresponding to type III subgroups are among

$$\{[Z_2^-], [D_2^z], [D_2^z]\}.$$ We can check that all the possibilities can occur except $[D_2^z]$ (same argument as in lemma 4.11) by using (8):

$$(T \cap gIg^{-1}) \cup (-\gamma T \cap gIg^{-1})$$

where $\gamma T$ is given by (14) and $I$ in (27). Hence, we get

- $[Z_2]$ for a rotation $g$ such that $gw_k = e_i$ for $k = 1, \ldots, 15$ and $i = 1, \ldots, 3$;
- $[Z_2^-]$ for a rotation $g$ such that $gw_k = a_{ck}$;
- $[D_2^z]$ for a rotation $g$ such that $gw_k = e_i$ and two other axes $w_k$ turn to two orthogonal axes $a_{ck}$ (take for instance $g = r(e_3, \pm \frac{\pi}{4})$);
- $[Z_3]$ for a rotation $g$ such that $gv_j = s_{ij}$;
- $[T]$ for the identity rotation for instance.

Lemma 4.24. We have

$$[O^-] \oplus [SO(2) \oplus Z_2^r] = \{[1], [Z_2], [Z_2^-], [Z_4^-]\}.$$ Proof. By theorem 4.2 we deduce that the classes in the clips $[O^-] \oplus [SO(2) \oplus Z_2^r]$ are among the following list

$$\{[1], [Z_2], [Z_3], [Z_2^-], [Z_4^-]\}.$$ All the classes of the above list can be realized by a rotation $g$ using the union $T \cap gSO(2)g^{-1} \cup (-\gamma T \cap gSO(2)g^{-1})$ (8) except $[Z_2]$. Indeed, we get:

- $[Z_3]$ for a rotation $g$ such that $ge_3 = s_{ij}$;
- $[Z_2^-]$ for a rotation $g$ such that $ge_3 = a_{ck}$;
- $[Z_4^-]$ for the identity rotation for instance.

Lemma 4.25. We have

$$[O^-] \oplus [O(2) \oplus Z_2^r] = \{[1], [Z_2], [D_2^z], [D_2^z], [D_3^z], [D_4^z]\}. $$

Proof. By theorem 4.2 we deduce that the classes in the clips $[O^-] \oplus [O(2) \oplus Z_2^r]$ are among the following list

$$\{[1], [Z_2], [D_2], [Z_2^-], [D_2^z], [D_3^z], [D_4^z]\}.$$ Using the union $T \cap gO(2)g^{-1} \cup (-\gamma T \cap gO(2)g^{-1})$ (8) where

$$gO(2)g^{-1} = \{r(ge_3, \theta), r(gb, \pi), b \in xy \text{ plan}\},$$

we deduce the classes that can be realized by a rotation $g$:

- $[Z_2]$ for a rotation $g$ such that $ge_3 = a_{ck}$;
- $[D_2^z]$ for a rotation $g$ such that $ge_3 = s_{ij}$ and three axes $b$ of the $(xy)$-plane turn to $a_{ck}$ (take for instance $g = r(< -1, 1, 0 >, \arccos(1/\sqrt{3}))$);
- $[D_4^z]$ for the identity rotation for instance.
4.5. **Clips with \(O(2)^-\).** We construct \(O(2)^-\) as follows

\[
O(2)^- = SO(2) \cup - (\gamma SO(2)) \quad \text{where} \quad \gamma = r(e_1, \pi)
\]

\[
= \{ r(e_3, \theta), \theta \in [0, 2\pi], -r(b, \pi) \}.
\]

where \(r(b, \pi)\) represent the symmetry with respect to all the axes in the \(xy\) plane.

**Lemma 4.26.** Let \(m \geq 2\) be an integer and \(d'_2 = \gcd(2, m)\). We have

\[
[O(2)^-] \otimes [\mathbb{Z}_m \oplus \mathbb{Z}_2] = \left\{ [\mathbb{I}], [\mathbb{Z}_m], [\mathbb{D}_m^z] \right\}
\]

**Proof.** We get the result by considering the following intersection (from (8))

\[
O(2)^- \cap (g\mathbb{Z}_m g^{-1} \oplus \mathbb{Z}_2) = (SO(2) \cap g\mathbb{Z}_m g^{-1}) \cup (-\gamma SO(2) \cap g\mathbb{Z}_m g^{-1})
\]

where \(\gamma = r(e_1, \pi)\) and \(\gamma SO(2) = \{ r(b, \pi) \}\). □

The proof of the following lemma is similar to the proof of lemma 4.8.

**Lemma 4.27.** For any integer \(m \geq 2\), we have

\[
[O(2)^-] \otimes [\mathbb{D}_m] = \left\{ [\mathbb{I}], [\mathbb{Z}_2], [\mathbb{D}_m^z], [\mathbb{D}_m^z] \right\} \quad \text{if} \quad m \text{ is even}
\]

\[
[O(2)^-] \otimes [\mathbb{D}_m] = \left\{ [\mathbb{I}], [\mathbb{Z}_2], [\mathbb{D}_m^z] \right\} \quad \text{if} \quad m \text{ is odd}
\]

**Proof.** We apply theorem 4.2 with \(\Gamma_+ = SO(2)\) and \(\tilde{\Gamma} = O(2)\). We deduce from [22, table 1]

\[
[SO(2)] \otimes [\mathbb{D}_m] = \{ [\mathbb{I}], [\mathbb{Z}_2], [\mathbb{Z}_m] \}
\]

and

\[
[O(2)] \otimes [\mathbb{D}_m] = \{ [\mathbb{I}], [\mathbb{Z}_2], [\mathbb{D}_m^z], [\mathbb{D}_m] \}
\]

Hence, the classes in \([O(2)^-] \otimes [\mathbb{D}_m] \oplus [\mathbb{Z}_2]\), corresponding to type I subgroups, are among the following list

\[
([SO(2)] \otimes [\mathbb{D}_m]) \cap ([O(2)] \otimes [\mathbb{D}_m]) = \{ [\mathbb{I}], [\mathbb{Z}_2] \}
\]

and the classes corresponding to type III subgroups are among

\[
\{ [\mathbb{Z}_2^z], [\mathbb{D}_m^z], [\mathbb{D}_m^z] \},
\]

We can check that all the possibilities can occur by using (8), except \([\mathbb{D}_2]\) when \(4 \mid m\) since it becomes \(\mathbb{D}_4^z\) in this case. Consider

\[
(SO(2) \cap g\mathbb{D}_m g^{-1}) \cup (-\gamma SO(2) \cap g\mathbb{D}_m g^{-1})
\]

where \(\gamma SO(2) = \{ r(b, \pi) \}, \quad b \in xy \text{ plane}\). We obtain

- \([\mathbb{Z}_2]\) for a rotation \(g\) such that \(gb_1 = e_3\) (possible only if \(m\) is odd since if \(m\) is even the second part of the intersection won’t be empty);
- \([\mathbb{Z}_2^z]\) for a rotation \(g\) such that \(gb_1 = b\) for some \(b\) in the \(xy\) plane;
- \([\mathbb{D}_m^z]\) for a rotation \(g = r(e_2, \frac{\pi}{2})\) for example;
- \([\mathbb{D}_m^z]\) for the identity rotation for instance.

The argumentation for the calculation of the clips with \(O(2)^-\) is very similar to the ones for \(\mathbb{D}_4^z\) exposed in subsection 4.2.

**Lemma 4.28.** We have

\[
[O(2)^-] \otimes [T \oplus \mathbb{Z}_2^z] = \{ [\mathbb{I}], [\mathbb{Z}_2], [\mathbb{Z}_4], [\mathbb{Z}_2^z], [\mathbb{D}_2^z] \}
\]

\[
[O(2)^-] \otimes [O \oplus \mathbb{Z}_2^z] = \{ [\mathbb{I}], [\mathbb{Z}_2], [\mathbb{Z}_2^z], [\mathbb{D}_2^z], [\mathbb{D}_3^z], [\mathbb{D}_4^z] \}
\]

\[
[O(2)^-] \otimes [I \oplus \mathbb{Z}_2^z] = \{ [\mathbb{I}], [\mathbb{Z}_2], [\mathbb{Z}_2^z], [\mathbb{D}_2^z] \}
\]

And finally we deduce the clips with \(SO(2) \oplus \mathbb{Z}_2^z\) and \(O(2) \oplus \mathbb{Z}_2^z\) in the same way as in lemma 4.12.
Lemma 4.29. We have
\[ [O(2)^{-} \bigodot [SO(2) \oplus \mathbb{Z}_2^2] = \{ [1], [Z_2], [SO(2)] \}. \]
\[ [O(2)^{-} \bigodot [O(2) \oplus \mathbb{Z}_2^2] = \{ [D_2^2], [O(2)^{-}] \}. \]

5. Application to Piezoelectricity

We propose here to apply clips operation to the specific case of the Piezoelectricity law. We introduce the space of constitutive tensors occurring in the mechanical description of Piezoelectricity, which describes the electrical behavior of a material subject to mechanical stress. It is defined by a triplet of tensors given by an elasticity tensor, a Piezoelectricity tensor and a permittivity tensor. Such a space is naturally endowed with an O(3) representation, and the finite set of isotropy classes is obtained in theorem 5.1 below.

We recall now the Piezoelectricity law, while details can be found in [28, 14, 27, 17]. First, the mechanical state of a material is characterized by two fields of symmetric second order tensors: the stress tensor $\boldsymbol{\sigma}$ and the strain tensor $\boldsymbol{\varepsilon}$. The relation between these two fields forms the constitutive law that describes the mechanical behavior of a specific material. In linear elasticity, the relation is linear, given by
\[ \boldsymbol{\sigma} = E : \boldsymbol{\varepsilon} \]
which is known as the generalized Hooke’s law. Such fourth order elasticity tensor $E$ have the index symmetries
\[ E_{ijkl} = E_{jikl} = E_{ijlk} = E_{klij} \]
and we define the associated space of elasticity tensors $\mathbb{E}_{la}$, which is a 21 dimensional vector space.

Similarly to the mechanical state, the electrical state of a material is described by two vector fields: the electric displacement field $\mathbf{d}$ and the electric field $\mathbf{e}$. These two fields are related and the relation between them forms the constitutive law that describes the electrical behavior of a material. In the linear case, it is given by
\[ \mathbf{d} = S : \mathbf{e} \]
where the second order symmetric tensor $S$ is the permittivity tensor. We define $S$ to be the vector space of the permittivity tensors, which is of dimension 6.

Finally, the Piezoelectricity law is given by the coupled law
\[ \begin{cases} \boldsymbol{\sigma} = E : \boldsymbol{\varepsilon} - \mathbf{e} : \mathbf{P} \\ \mathbf{d} = \mathbf{P} : \boldsymbol{\sigma} + S : \mathbf{e} \end{cases} \]
which involves a third order tensor $\mathbf{P}$ called the Piezoelectricity tensor, satisfying the index symmetry
\[ P_{ijk} = P_{kij} \]
The vector space of Piezoelectricity tensors is an 18 dimensional vector space, noted $\mathbb{P}_{iez}$.

As a consequence, the linear electromechanical behavior of any homogeneous material is defined by a triplet $\mathcal{P}$ of constitutive tensors
\[ \mathcal{P} := (E, P, S) \in \mathbb{E}_{la} \oplus \mathbb{P}_{iez} \oplus S \]
and we define $\mathcal{P}_{iez}$ to be the space of Piezoelectricity constitutive tensors:
\[ \mathcal{P}_{iez} = \mathbb{E}_{la} \oplus \mathbb{P}_{iez} \oplus S. \]

The natural O(3) representation on $(E, P, S) \in \mathcal{P}_{iez}$ is given in any orthonormal basis by
\[ (\rho(g)E)_{ijkl} := g_{ip} g_{jq} g_{kr} g_{ls} E_{pqrs}, \quad (\rho(g)P)_{ijk} := g_{ip} g_{jq} g_{kr} P_{pqr}, \quad (\rho(g)S)_{ij} := g_{ip} g_{jq} S_{pq} \]
where $g \in O(3)$.

As a consequence of lemma 2.4, the isotropy classes $\mathcal{J}(\mathcal{P}_{iez})$ can be deduced from isotropy classes $\mathcal{E}_{la}, \mathcal{P}_{iez}$ and $S$:
\[ \mathcal{J}(\mathcal{P}_{iez}) = (\mathcal{J}(\mathcal{E}_{la}) \odot \mathcal{J}(\mathcal{P}_{iez})) \odot \mathcal{J}(S). \]
Recall from [25] the isotropy classes of Piez (the notations and definitions of $O(3)$-subgroups have been moved to Appendix A)

$$\mathcal{J}(\text{Piez}) = \left\{ [1], [Z_2], [Z_3], [D_2], [D_3], [D_4], [D_5], [D_6], [SO(2)], [O(2)], [O(2)^-], [O^-], [O(3)], \right\}. $$

The symmetry classes for $O(3)$ representation on Ela and $S$ are the same as the symmetry classes for $SO(3)$ representation which can be found in [9] and [26], except that each type I subgroup occurring in the list of isotropy classes has to be replaced by the corresponding type II subgroup (see Appendix A). Indeed, $-\text{Id}$ acts trivially on Ela and $S$, and we have

$$\mathcal{J}(\text{Ela}) = \left\{ [1], [Z_2 + Z_3^2], [D_2 + Z_3^2], [D_3 + Z_2^2], [D_4 + Z_2^2], [O + Z_3^2], [O(2) + Z_3^2], [SO(3) + Z_2^2] \right\},$$

and

$$\mathcal{J}(S) = \left\{ [D_2 + Z_2^2], [O(2) + Z_3^2], [SO(3) + Z_2^2] \right\}. $$

We deduce the isotropy classes of the Piezoelectricity law $\text{Piez} = \text{Ela} \oplus \text{Piez} \oplus S$ from lemma 2.4 by calculating the clips operations between the isotropy classes of Ela, Piez and $S$ (see Table 1 and Table 2 for clips between type II and III $O(3)$-subgroups and [22, table 1] for clips between two type I and remark 3.1 (1) for type I with type II and two type II).

**Theorem 5.1.** There exists 25 isotropy classes for the Piezoelectricity law $\text{Ela} \oplus \text{Piez} \oplus S$ given by

$$\mathcal{J}(\text{Piez}) = \left\{ [1], [Z_2 + Z_3^2], [D_2 + Z_3^2], [D_3 + Z_2^2], [D_4 + Z_2^2], [O + Z_3^2], [O(2) + Z_3^2], [SO(3) + Z_2^2] \right\}.$$
We propose in Table 3 generators of type I and type III closed O(3)-subgroups.

Table 3. Generators of closed O(3)-subgroups

We give now some useful decompositions of subgroups \( T, \mathbb{O} \) and \( I \). To do so, first introduce subgroups

\[
(21) \quad \mathbb{Z}_n^u := \left\{ r\left(\mathbf{u}, \frac{2\pi}{n}\right) \right\}, \quad \mathbb{D}_n^u,v := \left\{ r\left(\mathbf{u}, \frac{2\pi}{n}\right), r(\mathbf{v}, \pi) \right\}
\]

where \( \mathbf{u}, \mathbf{v} \) are a non–zero orthogonal vectors. In such notations, the axis \( \langle \mathbf{u} \rangle \) generated by \( \mathbf{u} \) is said to be the primary axis of \( \mathbb{Z}_n^u \) and \( \mathbb{D}_n^{u,v} \), while \( \langle \mathbf{v} \rangle \) is said to be a secondary axis of \( \mathbb{D}_n^{u,v} \). In fact we have

\[
\mathbb{Z}_n = \mathbb{Z}^{e_3}_{n}, \quad \mathbb{D}_n = \mathbb{D}^{e_3,e_1}_{n}
\]

and for any \( g \in SO(3) \)

\[
g\mathbb{Z}_n g^{-1} = \mathbb{Z}^{e_3}_{n}, \quad g\mathbb{D}_n g^{-1} = \mathbb{D}^{e_3,e_1}_{n}
\]

In particular, \( \mathbb{Z}_n \) is given by

\[
(22) \quad \mathbb{Z}_n = \left\{ r\left(\mathbf{e}_3, \frac{2k\pi}{n}\right), k = 0, \ldots, n - 1 \right\}
\]

And \( \mathbb{D}_n \) by

\[
(23) \quad \mathbb{D}_n = \left\{ r\left(\mathbf{e}_3, \frac{2k\pi}{n}\right), r(\mathbf{b}_i, \pi); \quad k = 0, \ldots, n - 1, \quad i = 1, \ldots, n \right\}
\]
with \( b_i \) being the secondary axis of \( \mathbb{D}_n \) in the \((xy)\)-plane such that \( b_1 = e_1 \) and \( b_i = r (e_3, \frac{2}{n}) b_{i-1} \), for \( i \geq 2 \). We propose now details on compositions of the subgroups \( T \), \( O \) and \( I \), with explicit axes for all cyclic and dihedral subgroups they contain.

First we have (see [11] for instance)

\[
T = \bigcup_{i=1}^{3} \mathbb{Z}_2^{e_i} \cup \bigcup_{j=1}^{4} \mathbb{Z}_3^{s_{ij}}
\]

with

\[
s_{t_1} = e_1 + e_2 + e_3, \quad s_{t_2} = e_1 - e_2 - e_3, \quad s_{t_3} = -e_1 + e_2 - e_3, \quad s_{t_4} = -e_1 - e_2 + e_3.
\]

For the cubic group we have

\[
O = \bigcup_{i=1}^{3} \mathbb{Z}_4^{e_i} \cup \bigcup_{j=1}^{4} \mathbb{Z}_3^{s_{ij}} \cup \bigcup_{k=1}^{6} \mathbb{Z}_2^{a_{ij}}
\]

with vectors \( a_k \) given by

\[
a_{c_1} = e_1 + e_2, \quad a_{c_2} = e_1 - e_2, \quad a_{c_3} = e_1 + e_3
\]

\[
a_{c_4} = e_1 - e_3, \quad a_{c_5} = e_2 + e_3, \quad a_{c_6} = e_2 - e_3.
\]

Finally we have

\[
I = \bigcup_{i=1}^{6} \mathbb{Z}_5^{u_i} \cup \bigcup_{j=1}^{10} \mathbb{Z}_3^{v_i} \cup \bigcup_{k=1}^{15} \mathbb{Z}_2^{w_k}
\]

Taking \( \phi := (1 + \sqrt{5})/2 \) to be the golden ratio, vectors \( u_i \) are obtained as centers of icosahedron faces (see [22, Figure 11]):

\[
u_1 := (1 + 3\phi)e_1 + (2 + \phi)e_3, \quad u_2 := (2 + \phi)e_1 + (1 + 3\phi)e_2, \quad u_3 := (2 + \phi)e_2 - (1 + 3\phi)e_3
\]

\[
u_4 := -(2 + \phi)e_2 - (1 + 3\phi)e_3, \quad u_5 := (1 + 3\phi)e_1 - (2 + \phi)e_3, \quad u_6 := (2 + \phi)e_1 - (1 + 3\phi)e_2.
\]

Then vectors \( v_j \) are obtained from vertices of icosahedron:

\[
v_1 := e_1 + e_2 + e_3, \quad v_2 := \phi e_1 + \frac{1}{\phi} e_2, \quad v_3 := e_1 + e_2 - e_3, \quad v_4 := \phi e_2 - \frac{1}{\phi} e_3
\]

\[
v_5 := \phi e_2 + \frac{1}{\phi} e_3, \quad v_6 := -e_1 + e_2 + e_3, \quad v_7 := -\phi e_1 + \frac{1}{\phi} e_2, \quad v_8 := -e_1 + e_2 - e_3
\]

\[
v_9 := -\frac{1}{\phi} e_1 - \phi e_3, \quad v_{10} := \frac{1}{\phi} e_1 - \phi e_3
\]

while vectors \( w_k \) are obtained from its edges:

\[
w_1 := e_1 + (\phi + 1)e_2 + \left(1 + \frac{1}{\phi}\right)e_3, \quad w_2 := \left(1 + \frac{1}{\phi}\right)e_1 + e_2 + (\phi + 1)e_3
\]

\[
w_3 := (\phi + 1)e_1 + \left(1 + \frac{1}{\phi}\right)e_2 + e_3, \quad w_4 := \phi e_1, \quad w_5 := (\phi + 1)e_1 + \left(1 + \frac{1}{\phi}\right)e_2 - e_3
\]

\[
w_6 := (\phi + 1)e_1 - \left(1 + \frac{1}{\phi}\right)e_2 + e_3, \quad w_7 := \left(1 + \frac{1}{\phi}\right)e_1 - e_2 + (\phi + 1)e_3,
\]

\[
w_8 := (\phi + 1)e_1 - \left(1 + \frac{1}{\phi}\right)e_2 - e_3, \quad w_9 := e_1 + (\phi + 1)e_2 - \left(1 + \frac{1}{\phi}\right)e_3
\]

\[
w_{10} := \phi e_2, \quad w_{11} := -e_1 + (\phi + 1)e_2 + \left(1 + \frac{1}{\phi}\right)e_3, \quad w_{12} := \phi e_3
\]

\[
w_{13} := -\left(1 + \frac{1}{\phi}\right)e_1 + e_2 + (\phi + 1)e_3, \quad w_{14} := -e_1 + (\phi + 1)e_2 - \left(1 + \frac{1}{\phi}\right)e_3,
\]

\[
w_{15} := -\left(1 + \frac{1}{\phi}\right)e_1 - e_2 + (\phi + 1)e_3.
\]
Finally, the subgroups $SO(2)$ and $O(2)$ are given by

\begin{equation}
SO(2) = \{ r(e_3, \theta), \theta \in [0, 2\pi] \}
\end{equation}

and

\begin{equation}
O(2) = \{ r(e_3, \theta), r(b, \pi), \theta \in [0, 2\pi], b \in (xy) - \text{plane} \}.
\end{equation}
