## **GETTING IN TOUCH WITH THE EU**

### **In person**

All over the European Union there are hundreds of Europe Direct information centres. You can find the address of the centre nearest you at: [https://europa.eu/european-union/contact\\_en](https://europa.eu/european-union/contact_en)

### **On the phone or by email**

Europe Direct is a service that answers your questions about the European Union. You can contact this service:

- by freephone: 00 800 6 7 8 9 10 11 (certain operators may charge for these calls),
- at the following standard number: +32 22999696 or
- by email via: [https://europa.eu/european-union/contact\\_en](https://europa.eu/european-union/contact_en)

## **FINDING INFORMATION ABOUT THE EU**

### **Online**

Information about the European Union in all the official languages of the EU is available on the Europa website at: [https://europa.eu/european-union/index\\_en](https://europa.eu/european-union/index_en)

### **EU publications**

You can download or order free and priced EU publications at: <https://op.europa.eu/en/publications>. Multiple copies of free publications may be obtained by contacting Europe Direct or your local information centre (see [https://europa.eu/european-union/contact\\_en](https://europa.eu/european-union/contact_en)).

### **EU law and related documents**

For access to legal information from the EU, including all EU law since 1952 in all the official language versions, go to EUR-Lex at: <http://eur-lex.europa.eu>

### **Open data from the EU**

The EU Open Data Portal (<http://data.europa.eu/euodp/en>) provides access to datasets from the EU. Data can be downloaded and reused for free, for both commercial and non-commercial purposes.

Annexes (see next page)	

There are 28 annexes to this report:

- Eight new Risk Assessments (Annex 1a-8a)
- Eight new documents on measures and their implementation cost and cost-effectiveness for these eight species (Annex 1b-8b)
- Twelve revisions of existing Risk Assessments (Annex 9-20).

Annex 1a: Risk assessment for *Bipalium kewense* (Kew Flatworm)

Annex 1b: Evidence on measures and their implementation cost and cost-effectiveness for *Bipalium kewense* (Kew Flatworm)

Annex 2a: Risk assessment for *Cervus nippon* (Sika Deer)

Annex 2b: Evidence on measures and their implementation cost and cost-effectiveness for *Cervus nippon* (Sika Deer)

Annex 3a: Risk assessment for *Cherax destructor* (Common Yabby)

Annex 3b: Evidence on measures and their implementation cost and cost-effectiveness for *Cherax destructor* (Common Yabby)

Annex 4a: Risk assessment for *Delairea odorata* (Cape Ivy)

Annex 4b: Evidence on measures and their implementation cost and cost-effectiveness for *Delairea odorata* (Cape Ivy)

Annex 5a: Risk assessment for *Marisa cornuarietis* (Colombian Ramshorn Apple Snail)

Annex 5b: Evidence on measures and their implementation cost and cost-effectiveness for *Marisa cornuarietis* (Colombian Ramshorn Apple Snail)

Annex 6a: Risk assessment for *Mulinia lateralis* (Dwarf Surf Clam)

Annex 6b: Evidence on measures and their implementation cost and cost-effectiveness for *Mulinia lateralis* (Dwarf Surf Clam)

Annex 7a: Risk assessment for *Obama nungara* (Obama Flatworm)

Annex 7b: Evidence on measures and their implementation cost and cost-effectiveness for *Obama nungara* (Obama Flatworm)

Annex 8a: Risk assessment for *Pycnonotus jocosus* (Red-whiskered Bulbul)

Annex 8b: Evidence on measures and their implementation cost and cost-effectiveness for *Pycnonotus jocosus* (Red-whiskered Bulbul)

Revised Risk Assessments on

Annex 9: *Asterias amurensis* (North Pacific Sea Star)

Annex 10: *Axis axis* (Axis Deer)

Annex 11: *Broussonetia papyrifera* (Paper Mulberry)

Annex 12: *Callinectes sapidus* (Atlantic Blue Crab)

Annex 13: *Castor canadensis* (North American Beaver)

Annex 14: *Celastrus orbiculatus* (Staff-vine)

Annex 15: *Cortaderia selloana* (Pampas Grass)

Annex 16: *Faxonius immunis* (Calico Crayfish)

Annex 17: *Misgurnus anguillicaudatus* (Oriental Weatherfish)

Annex 18: *Pycnonotus cafer* (Red-vented Bulbul)

Annex 19: *Vespa mandarinia* (Asian Giant Hornet)

Annex 20: *Xenopus laevis* (African Clawed Frog)

**Study on Invasive Alien Species – Development of risk assessments to tackle priority species and enhance prevention**

## Abstract

Providing evidence-based and scientifically robust risk assessments, as foreseen under Article 5 of the Regulation (EU) 1143/2014 on the prevention and management of the introduction and spread of invasive alien species (IAS), is one step in the process of developing the list of IAS of Union concern. The aim of the current study is to develop such risk assessments alongside evidence on management measures and their implementation cost and cost-effectiveness to help inform policies and prioritise actions.

This study includes eight new risk assessments and associated management annexes, for the following species: *Bipalium kewense* (Kew Flatworm), *Cervus nippon* (Sika Deer), *Cherax destructor* (Common Yabby), *Delairea odorata* (Cape Ivy), *Marisa cornuarietis* (Colombian Ramshorn Apple Snail), *Mulinia lateralis* (Dwarf Surf Clam), *Obama nungara* (Obama Flatworm), and *Pycnonotus jocosus* (Red-whiskered Bulbul).

This study further includes ten risk assessments from previous contracts, revised according to the comments from the Scientific Forum and other stakeholders, concerning the following species: *Asterias amurensis* (North Pacific Seastar), *Axis axis* (Axis Deer), *Broussonetia papyrifera* (Paper Mulberry), *Callinectes sapidus* (Atlantic Blue Crab), *Cortaderia selloana* (Pampas Grass), *Faxonius immunis* (Calico Crayfish), *Misgurnus anguillicaudatus* (Oriental Weatherfish), *Pycnonotus cafer* (Red-vented Bulbul), *Vespa mandarinia* (Asian Giant Hornet), and *Xenopus laevis* (African Clawed Frog). In addition, two risk assessments submitted by a Member State were revised in this contract: *Castor canadensis* (North American Beaver) and *Celastrus orbiculatus* (Staff-vine).

## Résumé

Comme le prévoit l'article 5 du règlement (UE) n° 1143/2014 sur la prévention et la gestion de l'introduction et de la propagation des espèces exotiques envahissantes (EEE), la production d'évaluations de risques sur base d'éléments probants et solides scientifiquement est une étape dans le processus d'élaboration de la liste des EEE préoccupantes pour l'Union. L'objectif de la présente étude est d'élaborer de telles évaluations de risques, ainsi que des informations probantes sur les mesures de gestion, leur coût de mise en œuvre et le rapport coût-efficacité pour informer les politiques et définir les priorités d'action.

Cette étude comprend huit nouvelles évaluations des risques et les annexes de gestion associées, pour les espèces suivantes: *Bipalium kewense* (Vers plat à tête de marteau), *Cervus nippon* (Cerf sika), *Cherax destructor* (Ecrevisse de Murray), *Delairea odorata* (Lierre d'Allemagne), *Marisa cornuarietis* (Marise corne-de-bélier), *Mulinia lateralis* (Palourde naine), *Obama nungara* (Vers plat Obama), et *Pycnonotus jocosus* (Bulbul orphée).

Cette étude comprend également dix évaluations de risques issues des contrats précédents et révisées sur base des commentaires du Forum scientifique et des autres parties prenantes. Elles portent sur les espèces suivantes: *Asterias amurensis* (Etoile de mer du Pacifique Nord), *Axis axis* (Cerf axis), *Broussonetia papyrifera* (Mûrier à papier), *Callinectes sapidus* (Crabe bleu de l'Atlantique), *Cortaderia selloana* (Herbe de la Pampa), *Faxonius immunis* (Ecrevisse calicot), *Misgurnus anguillicaudatus* (Loche asiatique), *Pycnonotus cafer* (Bulbul à ventre rouge), *Vespa mandarinia* (Frelon géant), et *Xenopus laevis* (Xénope lisse). En outre, deux évaluations des risques proposées par un Etat membre ont été révisées dans ce contrat: *Castor canadensis* (Castor nord américain) et *Celastrus orbiculatus* (Bourreau des arbres).

## Executive Summary

**Disclaimer:** “*The information and views set out in this study are those of the authors and do not necessarily reflect the official opinion of the Commission. The Commission does not guarantee the accuracy of the data included in this study. Neither the Commission nor any person acting on the Commission’s behalf may be held responsible for the use which may be made of the information contained therein.*”

On 1 January 2015 the Regulation (EU) 1143/2014 on the prevention and management of the introduction and spread of invasive alien species (IAS) entered into force. The center piece of the Regulation is a list of IAS of Union concern (the Union list), for which different measures must be taken, depending on presence/absence/distribution in the EU Member States. Providing evidence-based and scientifically robust risk assessments, as foreseen under Article 5 of the Regulation, is one step in the process of developing the Union list. The aim of the current project is to provide such risk assessments and further information that then can inform whether the IAS should be considered for inclusion on the list of IAS of Union concern.

This Final Report is part of the fulfilment of the contract “Study on invasive alien species – Development of risk assessments to tackle priority species and enhance prevention” 07.0202/2020/834529/ETU/ENV.D.2 (1<sup>st</sup> renewal of contract 07.0202/2019/812602/ETU/ENV.D.2). It includes all deliverables and further information on the background and processes within the project tasks completed since the Kick-off Meeting on the 12<sup>th</sup> November 2020, which was held online (Zoom). Specifically, it includes eight new Risk Assessments and Risk Management Notes along with a documentation of the peer-review process before, during and after the Quality Assurance Workshop held online on the 15<sup>th</sup> and 17<sup>th</sup> September 2021, as well as ten revised Risk Assessments from a previous contract of the wider project team and two revised Risk Assessments from a third party. The results of the study are presented according to the five tasks defined in the contract:

Task 1: Revision of existing Risk Assessments

Task 2: Selection of new species to be assessed

Task 3: Preparation of new Risk Assessments

Task 4: Preparation of new Risk Management Notes (Evidence on measures and their implementation cost and cost-effectiveness)

Task 5: Quality assurance workshop

A few minor corrections have been made in the templates for the Risk Assessments and the Risk Management Notes from the version used in the first year of the contract 07.0202/2019/812602/ETU/ENV.D2, based on discussions within the project team and the Commission. Modifications include *inter alia* the correction of typographical errors, an update of one hyperlink that was not functional anymore, clarifications regarding the risk assessment area after Brexit, the abstinence of providing a response and confidence score in case of “no information has been found” and that a higher potential future impact score due to climate change needs an explicit justification in the provided comment. More specifically:

1) Whenever the instructions state that In the case of lack of information the assessors are requested to use a standardized answer: “No information has been found.” it is suggested to add the following clarification: In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable).

2) In Qu. 4.3, it is suggested to add the following clarification to the instructions: A potential increase in the distribution range due to climate change does not per se justify a higher impact score. A reference to this is also added to Qu. 4.5 and 4.20.

The current versions of both documents are provided as supplements at the end of this report.

Task 1: The Commission provided twelve Risk Assessments for revision that have been developed under previous contracts by the wider project team or by a Member State. These revisions consider comments from the Scientific Forum (representatives of Member States) and stakeholders and generated updated versions of the documents, which are included here as Annexes 9-20 to this Final Report.

The twelve species are:

#	Group	Scientific Name	Common Name
1	Marine	<i>Asterias amurensis</i>	North Pacific Sea Star
2	Vertebrates	<i>Axis axis</i>	Axis Deer
3	Plants	<i>Broussonetia papyrifera</i>	Paper Mulberry
4	Marine	<i>Callinectes sapidus</i>	Atlantic Blue Crab
5	Vertebrates	* <i>Castor canadensis</i>	North American beaver
6	Plants	* <i>Celastrus orbiculatus</i>	Staff-vine
7	Plants	<i>Cortaderia selloana</i>	Pampas Grass
8	Freshwater	<i>Faxonius immunis</i>	Calico Crayfish
9	Freshwater	<i>Misgurnus anguillicaudatus</i>	Oriental Weatherfish
10	Vertebrates	<i>Pycnonotus cafer</i>	Red-vented Bulbul
11	Invertebrates	<i>Vespa mandarinia</i>	Asian Giant Hornet
12	Vertebrates	<i>Xenopus laevis</i>	African Clawed Frog

\*Risk Assessment submitted by a Member State

Task 2: The objective of this task was to agree on a selection of priority species for subsequent Risk Assessments in task 3 and development of Risk Management Notes in task 4. The project team was divided into five expert thematic groups: Freshwater animals, Marine species, Plants (including freshwater), Terrestrial invertebrates and Vertebrates. Proposals from the team, and the Commission, were subsequently discussed before and during the online Kick-off Meeting on the 12<sup>th</sup> November 2020. Emphasis was placed on IAS that are not yet present in the European Union (or have a limited distribution) and have the potential to have an adverse impact on biodiversity. From this consultation process, the following eight species were selected:

#	Group	Scientific Name	Common Name
1	Invertebrates	<i>Bipalium kewense</i>	Kew Flatworm
2	Vertebrates	<i>Cervus nippon</i>	Sika Deer
3	Freshwater	<i>Cherax destructor</i>	Common Yabby
4	Plants	<i>Delairea odorata</i>	Cape Ivy
5	Freshwater	<i>Marisa cornuarietis</i>	Colombian Ramshorn Apple Snail
6	Marine	<i>Mulinia lateralis</i>	Dwarf Surf Clam
7	Invertebrates	<i>Obama nungara</i>	Obama Flatworm
8	Vertebrates	<i>Pycnonotus jocosus</i>	Red-whiskered Bulbul

Task 3: The Risk Assessments were developed by experts from the project team, along with additional experts acting as lead authors, co-authors and/or peer-reviewers. For all eight species dedicated new species distribution models were developed to provide a more robust knowledge base (acknowledging the caveats of such models) for the relevant questions in the Risk Assessments. All Risk Assessments were subject to an internal quality control review, an external peer-review by at least two independent experts according to the requirements of COM Delegated Regulation (EU) 2018/968 and a Quality Assurance Workshop (task 5). The final Risk Assessments of the eight species are included as Annex 1a-8a to this Final Report.

Task 4: The Risk Management Notes were developed in parallel with the risk assessments by experts from the project team, along with additional experts as lead authors, co-authors and/or peer-reviewers for the eight species. All Risk Management

Notes, as for the Risk Assessments, were subject to an internal quality control review, an external peer-review by at least two independent experts and were discussed at the Quality Assurance Workshop (task 5). The final Risk Management Notes of the eight species are included as Annex 1b-8b to this Final Report.

Task 5: Due to the on-going COVID-19 situation the Quality Assurance Workshop was organized as an online meeting on 15<sup>th</sup> & 17<sup>th</sup> September 2021. The aim of the workshop was to provide authors, peer-reviewers and the Commission the opportunity to discuss any unclarified issues, eliminate remaining uncertainties as far as possible, and assure the highest possible quality of the Risk Assessments and Risk Management Notes. In preparation for the workshop, authors have considered and incorporated comments from the peer-reviewers before the workshop. At the workshop, authors presented their work in plenary sessions, while open questions were discussed in virtual breakout groups. The comments from the peer-reviewers and the considerations from the authors are included in this Final Report. After the workshop, authors finalized the Risk Assessments and Risk Management Notes for this Final Report.

This Final Report outlines the work achieved for each task in detail. It is accompanied by 28 Annexes: eight new Risk Assessments (Annex 1a-8a), eight new Risk Management Notes (Annex 1b-8b), and twelve revised Risk Assessments (Annex 9-20).

## Résumé exécutif

**Avertissement:** "Les informations et les opinions présentées dans cette étude sont celles des auteurs et ne reflètent pas nécessairement l'opinion officielle de la Commission. La Commission ne garantit pas l'exactitude des données contenues dans cette étude. Ni la Commission ni aucune personne agissant au nom de la Commission ne peuvent être tenues responsables de l'utilisation qui pourrait être faite des informations contenues dans cette étude. "

Le 1er janvier 2015, le règlement (UE) 1143/2014 sur la prévention et la gestion de l'introduction et de la propagation des espèces exotiques envahissantes (EEE) est entré en vigueur. La pièce maîtresse du règlement est une liste d'EEE qui préoccupent l'Union (la liste de l'Union), pour lesquelles différentes mesures doivent être prises, en fonction de leur présence/absence/distribution dans les États membres de l'UE. Comme prévu à l'article 5 du règlement, la production d'évaluations de risques sur base d'éléments probants et solides scientifiquement est une étape du processus d'élaboration de la liste de l'Union. L'objectif du projet actuel est de fournir de telles évaluations des risques et d'autres informations qui pourront ensuite indiquer si on doit envisager d'inclure ces EEE dans la liste des EEE de préoccupation européenne.

Ce rapport final s'inscrit dans le cadre de l'exécution du contrat " Étude sur les espèces exotiques envahissantes - Développement d'évaluations des risques pour lutter contre les espèces prioritaires et renforcer la prévention " 07.0202/2020/834529/ETU/ENV.D.2 (1er renouvellement du contrat 07.0202/2019/812602/ETU/ ENV.D.2). Il comprend tous les livrables et des informations supplémentaires sur le contexte et les processus dans le cadre des tâches du projet réalisées depuis la réunion de lancement du 12 novembre 2020, qui s'est tenue en ligne (Zoom). Plus précisément, il comprend huit nouvelles évaluations des risques et notes de gestion des risques ainsi qu'une documentation sur le processus d'examen par les pairs avant, pendant et après le workshop portant sur l'assurance qualité qui s'est tenu en ligne les 15 et 17 septembre 2021, ainsi que dix évaluations des risques révisées provenant d'un contrat précédent de l'équipe de projet élargie et deux évaluations des risques révisées provenant d'un tiers. Les résultats de l'étude sont présentés en fonction des cinq tâches définies dans le contrat:

Tâche 1: Révision des évaluations de risques existantes

Tâche 2: Sélection de nouvelles espèces à évaluer

Tâche 3: Préparation des nouvelles évaluations de risque

Tâche 4: Préparation de nouvelles notes relatives à la gestion de risque (Données probantes sur les mesures, leur coût d'implémentation et leur rapport coût-efficacité).

Tâche 5: Workshop portant sur l'assurance qualité

Quelques corrections mineures ont été apportées aux modèles pour les évaluations des risques et les notes de gestion des risques par rapport à la version utilisée au cours de la première année du contrat 07.0202/2019/812602/ETU/ENV.D2, sur la base des discussions au sein de l'équipe de projet et de la Commission. Les modifications comprennent notamment la correction d'erreurs typographiques, la mise à jour d'un lien hypertexte qui n'était plus fonctionnel, des clarifications concernant le domaine d'évaluation des risques après le Brexit, l'abstention de fournir une réponse et un score de confiance en cas de « aucune information n'a été trouvée » et le fait que le score d'impact potentiel futur plus élevée en cas de changement climatique nécessite une justification explicite dans le commentaire fourni. Plus précisément:

1) Lorsque les instructions indiquent qu'en cas de manque d'information, les évaluateurs sont invités à utiliser une réponse standardisée: "Aucune information n'a été trouvée", il est suggéré d'ajouter la précision suivante: Dans ce cas, aucun score et aucune confiance ne doivent être donnés et le "score" standardisé est N/A (non applicable).

2) Au point Qu. 4.3, il est suggéré d'ajouter la clarification suivante aux instructions: Une augmentation potentielle de l'aire de répartition due au changement climatique ne justifie pas en soi un score d'impact plus élevé. Une référence à ce point est également ajoutée aux questions 4.5 et 4.20.

Les versions actuelles des deux documents sont fournies comme suppléments à la fin de ce rapport.

Tâche 1: La Commission a fourni douze évaluations de risques pour révision qui ont été développées sous des contrats précédents par l'équipe de projet plus large ou par un État membre. Ces révisions prennent en compte les commentaires du Forum scientifique (représentants des États membres) et des parties prenantes et ont généré des versions mises à jour des documents, qui sont incluses ici en tant qu'annexes 9-20 au présent rapport final.

Les douze espèces sont:

#	Groupe	Nom scientifique	Nom vernaculaire
1	Marines	<i>Asterias amurensis</i>	Etoile de mer du Pacifique Nord
2	Vertébrés	<i>Axis axis</i>	Cerf axis
3	Plantes	<i>Broussonetia papyrifera</i>	Mûrier à papier
4	Marines	<i>Callinectes sapidus</i>	Crabe bleu de l'Atlantique
5	Vertébrés	* <i>Castor canadensis</i>	Castor nord américain
6	Plantes	* <i>Celastrus orbiculatus</i>	Bourreau des arbres
7	Plantes	<i>Cortaderia selloana</i>	Herbe de la Pampa
8	D'eau douce	<i>Faxonius immunis</i>	Ecrevisse calicot
9	D'eau douce	<i>Misgurnus anguillicaudatus</i>	Loche asiatique
10	Vertébrés	<i>Pycnonotus cafer</i>	Bulbul à ventre rouge
11	Invertébrés	<i>Vespa mandarinia</i>	Frelon géant
12	Vertébré	Xénope lisse	Xénope lisse

\*Évaluation de risques produite par un Etat membre

Tâche 2: L'objectif de cette tâche était de convenir d'une sélection d'espèces prioritaires pour les évaluations de risques ultérieures de la tâche 3 et le développement de notes de gestion des risques de la tâche 4. L'équipe de projet a été divisée en cinq groupes thématiques d'experts: animaux d'eau douce, espèces marines, plantes (y compris d'eau douce), Invertébrés terrestres et Vertébrés. Les propositions de l'équipe et de la Commission, ont ensuite été discutées avant et pendant la réunion de lancement en ligne du 12 novembre 2020. L'accent a été mis sur les EEE qui ne sont pas encore présentes dans l'Union européenne (ou dont la distribution est limitée) et qui ont le potentiel d'avoir un impact négatif sur la biodiversité. Sur base de ce processus de consultation, les huit espèces suivantes ont été sélectionnées:

#	Groupe	Nom scientifique	Nom vernaculaire
1	Invertébrés	<i>Bipalium kewense</i>	Vers plat à tête de marteau
2	Vertébrés	<i>Cervus nippon</i>	Cerf sika
3	D'eau douce	<i>Cherax destructor</i>	Ecrevisse de Murray
4	Plantes	<i>Delawarea odorata</i>	Lierre d'Allemagne
5	D'eau douce	<i>Marisa cornuarietis</i>	Marise corne-de-bélier
6	Marines	<i>Mulinia lateralis</i>	Palourde naine
7	Invertébrés	<i>Obama nungara</i>	Vers plat Obama
8	Vertébrés	<i>Pycnonotus jocosus</i>	Bulbul orphée

Tâche 3: Les évaluations des risques ont été élaborées par des experts de l'équipe du projet, ainsi que par d'autres experts agissant en tant qu'auteurs principaux, co-auteurs et/ou réviseurs. Pour les huit espèces, de nouveaux modèles de distribution ont été développés afin de fournir une base de connaissances plus solide (tout en reconnaissant les limites de ces modèles) pour les questions pertinentes des évaluations des risques. Toutes les évaluations des risques ont fait l'objet d'un examen de contrôle de qualité interne, d'une révision externe par au moins deux experts indépendants conformément aux exigences du règlement délégué (UE) 2018/968 de la COM et d'un workshop d'assurance qualité (tâche 5). Les évaluations finales des risques des huit espèces figurent à l'annexe 1a-8a du présent rapport final.

Tâche 4: Les notes de gestion des risques ont été élaborées parallèlement aux évaluations des risques par des experts de l'équipe de projet, ainsi que par d'autres experts en tant qu'auteurs principaux, co-auteurs et/ou pairs pour les huit espèces. Toutes les notes sur la gestion des risques, comme pour les évaluations des risques, ont fait l'objet d'un contrôle de qualité interne, d'une révision externe par au moins deux experts indépendants et ont été discutées lors de l'atelier sur l'assurance qualité (tâche 5). Les notes finales de gestion des risques des huit espèces sont incluses dans l'annexe 1b-8b de ce rapport final.

Tâche 5: En raison de la situation COVID-19 toujours en cours, le workshop d'assurance qualité a été organisé sous forme de réunion en ligne les 15 et 17 septembre 2021. L'objectif était de fournir aux auteurs, aux pairs examinateurs et à la Commission l'opportunité de discuter de tous les problèmes non clarifiés, d'éliminer les incertitudes restantes autant que possible, et d'assurer la meilleure qualité possible des évaluations des risques et des notes de gestion des risques. En préparation de l'atelier, les auteurs ont pris en compte et intégré les commentaires des pairs examinateurs avant l'atelier. Lors de l'atelier, les auteurs ont présenté leurs travaux lors de sessions plénières, tandis que les questions ouvertes ont été discutées dans des groupes de discussion virtuels. Les commentaires des évaluateurs et les considérations des auteurs sont inclus dans ce rapport final. Après l'atelier, les auteurs ont finalisé les évaluations des risques et les notes de gestion des risques pour ce rapport final.

Le présent rapport final décrit en détail le travail accompli pour chaque tâche. Il est accompagné de 28 annexes: huit nouvelles évaluations des risques (annexe 1a-8a), huit nouvelles notes de gestion des risques (annexe 1b-8b) et douze évaluations des risques révisées (annexe 9-20).

## Overview of Tasks

### Task 1: Revision of existing Risk Assessments

Task lead: Wolfgang Rabitsch

Over the project period, the Commission selected and provided twelve existing risk assessments of species for revision that had been developed under previous contracts or submitted by a Member State. The aim of these revisions was to consider and incorporate – if appropriate – comments from the Scientific Forum and stakeholders and subsequently generate updated versions of the risk assessments along with a documentation of the revisions. The twelve species identified for this task are:

Annex	Group	Scientific Name	Common Name	Delivery date
Annex 9	Marine	<i>Asterias amurensis</i>	North Pacific Sea Star	October 15
Annex 10	Vertebrates	<i>Axis axis</i>	Axis Deer	March 4
Annex 11	Plants	<i>Broussonetia papyrifera</i>	Paper Mulberry	October 15
Annex 12	Marine	<i>Callinectes sapidus</i>	Atlantic Blue Crab	October 15
Annex 13	Vertebrates	* <i>Castor canadensis</i>	North American beaver	January 14
Annex 14	Plants	* <i>Celastrus orbiculatus</i>	Staff-vine	January 14
Annex 15	Plants	<i>Cortaderia selloana</i>	Pampas Grass	October 15
Annex 16	Freshwater	<i>Faxonius immunis</i>	Calico Crayfish	October 15
Annex 17	Freshwater	<i>Misgurnus anguillicaudatus</i>	Oriental Weatherfish	October 15
Annex 18	Vertebrates	<i>Pycnonotus cafer</i>	Red-vented Bulbul	March 4
Annex 19	Invertebrates	<i>Vespa mandarinia</i>	Asian Giant Hornet	October 15
Annex 20	Vertebrates	<i>Xenopus laevis</i>	African Clawed Frog	March 4

\*Risk Assessment submitted by a Member State

According to the Terms of Reference, the delivery of up to ten revised risk assessments is part of the Progress Report. Due to the delayed submission of such documents to the project team, it was approved by the Commission to decouple the revisions from the Progress Report and deliver these with the Final Report, due by October 2021.

Following discussions in the context of the COVID19-pandemic approval was given by the Commission to organize the Quality Assurance Workshop as an online meeting (see Task 5). To compensate for the reduced costs (for T&S), it was discussed and approved that the project team will revise two additional existing Risk Assessments from previous contracts, i.e. twelve revisions in total.

Comments from the Scientific Forum and stakeholders have been received and addressed by the project team in relation to two Risk Assessments submitted by a Member State. In these cases, a separate, stand-alone document with the suggested amendments and clarifications was produced (Annex 13 & 14). For the other Risk Assessments, a clean and track-changes version together with a cover note addressing the changes made were returned to the Commission within the given deadlines.

## Task 2: Selection of new species to be assessed

Task lead: Alan Stewart, Jodey Peyton

The objective of this task was to agree on a selection of priority species for subsequent risk assessments in task 3 and development of risk management notes in task 4. As in previous contracts, groups of experts were convened with expertise in five taxonomic/ecological groupings. The membership of these groups was as follows (group co-leaders in bold):

Freshwater animals: **Frances Lucy, Elena Tricarico**, Hugo Verreycken

Marine species: **Marika Galanidi, Jack Sewell**, Argyro Zenetos, Paraskevi Karachle

Plants (including freshwater): **Rob Tanner**, Jodey Peyton, Helmut Kudrnovsky

Terrestrial invertebrates: **Marc Kenis, Richard Shaw**, Wolfgang Rabitsch, Alan Stewart, Helen Roy

Vertebrates: **Riccardo Scalera, Tim Adriaens**, Peter Robinson, Yasmine Verzelen

The Commission was sent a draft list of priority species in advance of the kick-off meeting, with indications of the species of highest priority for Risk Assessments according to the views of the project team. The Commission also provided species to be considered. The species were discussed and reconciled at the kick-off meeting on 12th November 2020.

The following working procedure was adopted:

Leaders of each expert group were asked to propose four species per group. This resulted in 20 species to put forward, from which to select the eight to suggest to the Commission for formal Risk Assessment. Experts were requested to prepare a single paragraph for each species explaining why it is being proposed (Annex II). The instructions for Task 2 in the project tender were also circulated among the experts, along with the Excel spreadsheet to be used as the starting point for discussion within each group. The above mentioned Excel spreadsheet (the same that was used for the selection during the previous contract year) included a sheet with the list of species arising from the 2015 horizon scanning exercise, and separate sheets for each of the groups. Experts were invited to add new species as appropriate. As in previous years, the following criteria were considered:

- Not yet arrived in EU or very small populations
- Likely to arrive in next 10 years
- Likely to impact on:
  - Biodiversity
  - Economy
  - Human health & wellbeing
- Practicality of management, probability of success, cost

Once experts from each group had suggested their species, Task 2 co-leaders combined them into a single list of 20 species from which they selected 2 top priority species for each group (Figure 1) in consultation with other members of the team. This list was sent to the Commission on 3 November 2020, in advance of the kick-off meeting.

After preliminary feedback from the Commission, the plant and marine groups added two more species for further discussions (Fig. 1).

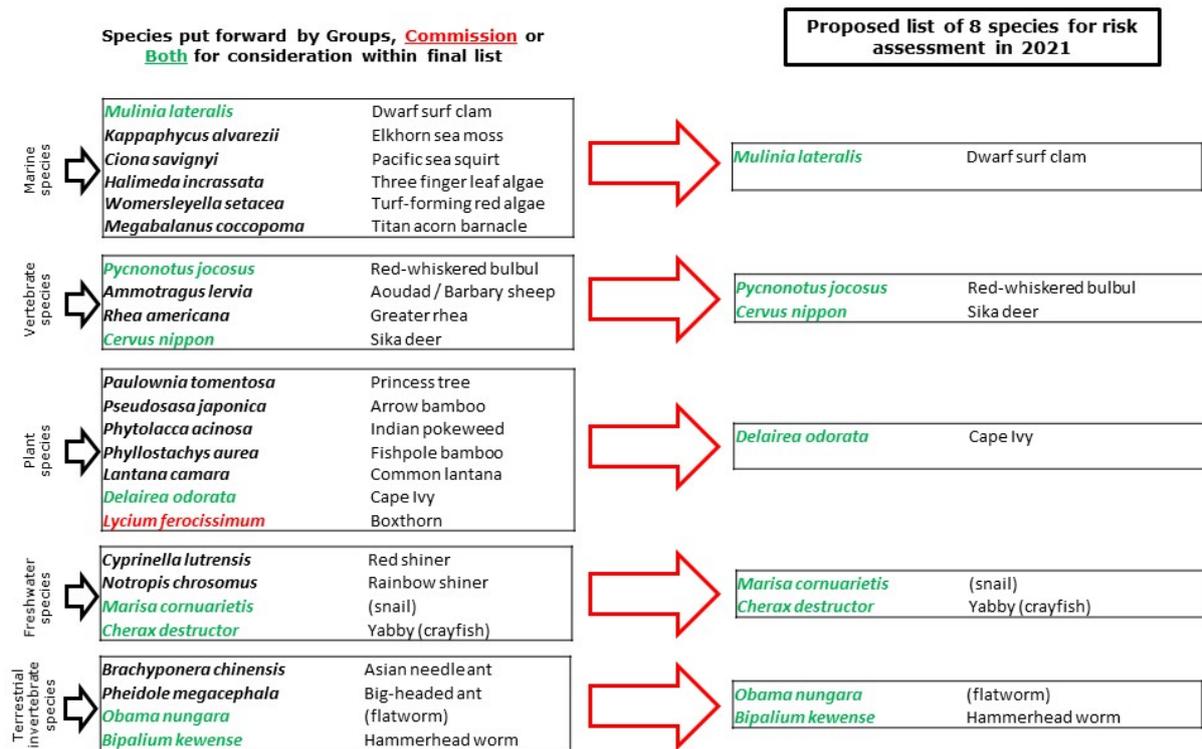

Figure 1. Process of selection of species for risk assessments in 2021 (Suggestions by both Expert Groups and European Commission in green, suggestions by European Commission in red).

All species proposed by the project team were presented and discussed at the kick-off meeting, from which a final list of 8 species was agreed for risk assessments in Task 3 and management notes in Task 4 (Table 1).

For *Mulinia lateralis*, the Commission remarked that they were hesitant but tried to give at least one species per group and this one seemed the most interesting marine species of those proposed.

For the plants, the Commission pointed out that although the plant experts insisted on *Paulownia* they were not convinced that anything could be done about it in the framework of the IAS Regulation (since beyond horticulture that is mentioned in the summary, it is widely used in plantations for timber). It was also mentioned, however, that the species will be re-assessed next year.

The bamboos seemed problematic as these genera have 20–60 species each and potential listing would be impossible to implement. The *Phytolacca* would be interesting but at the previous round the experts dismissed it. In the final report of 2019 under task 2 it is indeed mentioned that “there is very little available information on its current or potential impacts”.

Table 1: Final list of eight species for risk assessment in 2021, agreed following the kick-off meeting with the European Commission and leading author(s) from the project team.

#	Group	Scientific Name	Common Name	Leading Author(s)
1	Invertebrates	<i>Bipalium kewense</i>	Kew Flatworm	Leigh Winsor
2	Vertebrates	<i>Cervus nippon</i>	Sika Deer	Riccardo Scalera
3	Freshwater	<i>Cherax destructor</i>	Common Yabby	Elena Tricarico
4	Plants	<i>Delairea odorata</i>	Cape Ivy	Rob Tanner
5	Freshwater	<i>Marisa cornuarietis</i>	Colombian Ramshorn Apple Snail	Frances Lucy
6	Marine	<i>Mulinia lateralis</i>	Dwarf Surf Clam	Christine Wood
7	Invertebrates	<i>Obama nungara</i>	Obama flatworm	Archie Murchie
8	Vertebrates	<i>Pycnonotus jocosus</i>	Red-whiskered Bulbul	Tim Adriaens

With respect to other species discussed for inclusion, it was concluded to keep the African boxthorn, *Lycium ferocissimum*, and the green macroalgae *Halimeda incrassata* for further discussions next year.

### Task 3: Preparation of new Risk Assessments

Task lead: Riccardo Scalera

Before the external peer-review an internal quality check was made by the task 3 and 4 leaders and the project lead, with the aim to ensure that all questions were addressed in line with the template guidelines and instructions, and that all Risk Assessments and Risk Management Notes were consistent between and across the documents.

The "Checklist for peer-review", which was developed in the first year of the contract (see Final Report 2020) to support a coherent summary of the reviewing process, was distributed to the peer-reviewers with information on the guidelines and the criteria for each score. Peer-reviewers were specifically asked to consider these elements within their assessment.

Contact was made with designated peer-reviewers, explaining the rules of procedure and expected deadlines. Table 2 provides an overview of the peer-reviewers. Risk Assessments and Risk Management Notes were distributed to the peer-reviewers along with the before mentioned checklist with a deadline of four weeks for execution of the peer-review. For each risk assessment, it was ensured that the author(s) and the peer-reviewers are not affiliated to the same institution, as required under Article 2(9) of the Delegated Regulation 2018/968 on risk assessments.

Table 2: Peer-reviewers for the eight Risk Assessments and Risk Management Notes.

#	Scientific Name	Common Name	Peer-Reviewers
1	<i>Bipalium kewense</i>	Kew flatworm	Brian Boag Richard Shaw
2	<i>Cervus nippon</i>	Sika deer	Wojtek Solarz Alastair Ward
3	<i>Cherax destructor</i>	Common yabby	Antonin Kouba Francisco Oficialdegui
4	<i>Delairea odorata</i>	Cape ivy	Giuseppe Brundu Johan van Valkenburg
5	<i>Marisa cornuarietis</i>	Colombian ramshorn apple snail	Elena Tricarico Hugo Verreycken
6	<i>Mulinia lateralis</i>	Dwarf surf clam	Francis Kerckhof Argyro Zenetos
7	<i>Obama nungara</i>	Obama flatworm	Brian Boag Richard Shaw
8	<i>Pycnonotus jocosus</i>	Red-whiskered bulbul	Thomas Evans Enrique Murgui

In addition to the "Checklist for Peer-Review", the authors were provided with the short "Checklist after Peer-Review", which was also developed in the first year of the contract (see Final Report 2020). The purpose of this Checklist is to streamline and document any substantial changes from the peer-review, which is requested according to Commission Delegated Regulation (EU) 2018/968 of 30 April 2018 and forms an integral part of this Final Report. Commission Delegated Regulation (EU) 2018/968 of 30 April 2018 requests in Art. 2(7) that "A quality control process shall be an integral part of the risk assessment and shall include at least a review of the risk assessment by two peer reviewers. The risk assessment shall include a description of the quality control process."

## EU IAS risk assessments 2020/21: Summary of modelling approach

Björn Beckmann & Dan Chapman

Species Distribution Models (SDMs) were created for all eight species for which risk assessments were conducted this year: *Delairea odorata*, *Bipalium kewense*, *Obama nungara*, *Mulinia lateralis*, *Marisa cornuarietis*, *Cherax destructor*, *Pycnonotus jocosus* and *Cervus nippon*. No recent models with a suitable geographical scope existed for these species, and we considered that sufficient information was available to build models in terms of distribution data, and information about ecological and ecophysiological requirements of the species.

Species distribution records were obtained from eight large online databases – the Global Biodiversity Information Facility (GBIF), the Biodiversity Information Serving Our Nation database (BISON), iNaturalist, the Berkeley Ecoinformatics Engine database, the VertNet databases, the Integrated Digitized Biocollections (iDigBio), the Ocean Biogeographic Information System (OBIS), and the Atlas of Living Australia. Additional records were supplied for several species by the respective risk assessment teams, for example museum records and records extracted from publications. For all species, records were scrutinised and any removed which did not refer to populations established outdoors (e.g. captive records), as were those where the georeferencing was too imprecise (e.g. records referenced to a country or island centroid).

A presence-background (presence-only) ensemble modelling strategy was employed using the BIOMOD2 R package version 3.4.6 (Thuiller et al. 2009, 2020). These models contrast the environment at the species' occurrence locations against a random sample of the global background environmental conditions (often termed 'pseudo-absences') in order to characterise and project suitability for occurrence. This approach has been developed for distributions that are in equilibrium with the environment. Because invasive species' distributions are not at equilibrium and subject to dispersal constraints at a global scale, we took care to minimise the inclusion of locations suitable for the species but where it has not been able to disperse to (Chapman et al. 2019). Therefore the background sampling region included:

- Regions where we have an a priori expectation of high unsuitability for the species so that absence is assumed irrespective of dispersal constraints; AND
- The area accessible by native populations, in which the species is likely to have had sufficient time to disperse to all locations; AND
- The area accessible to non-native populations, defined as a buffer around the non-native occurrences, encompassing regions likely to have had high propagule pressure for introduction by humans and/or dispersal of the species.

Within the "unsuitable" background region, 10 samples of 5000 randomly places pseudo-absences were obtained. In the "accessible" background regions, 10 samples of the same number of pseudo-absences were taken as there were occurrence points, weighting the sampling by recording effort (reflecting a higher confidence in the absence of the focal species in better-surveyed regions). We used the density of records held by GBIF for the higher taxonomic group of each species as a proxy for recording effort.

Climate data for modelling terrestrial species were selected from the 'Bioclim' variables contained within the WorldClim database (Hijmans et al. 2005), and for marine species from the 'Bio-ORACLE' set of GIS rasters providing geophysical, biotic and environmental data for surface and benthic marine realms (Tyberghein et al. 2012, Assis et al. 2017). For *Mulinia lateralis*, climatic data were supplemented by a "Growing Degree Days" measure (a sum of biologically useful warmth) calculated from MARSPEC monthly sea surface temperature data (Sbrocco & Barber 2013). For species where climatic moisture availability was considered important, a Climatic moisture index (CMI) was calculated as the ratio of mean annual precipitation to potential evapotranspiration by estimating

monthly potential evapotranspirations from the WorldClim monthly temperature data and solar radiation using the simple method of Zomer et al. (2008) which is based on the Hargreaves evapotranspiration equation (Hargreaves 1994). For *Cervus nippon*, as a proxy for potential depth and duration of snow cover, the inverse of the mean temperature of the coldest quarter (Bio11) was multiplied with mean precipitation of the coldest quarter (Bio19), to produce a number that is greatest in areas where winters are both cold and have high precipitation. The numbers were scaled to values between 0 and 1.

To estimate the effect of climate change on the potential distribution, equivalent modelled future climate conditions for the 2070s under the Representative Concentration Pathways (RCP) 2.6 and 4.5 were also obtained. These represent low and medium emissions scenarios, respectively.

Additional non-climatic predictor layers were used for several species where these were considered relevant: Tree cover, estimated from the MODerate-resolution Imaging Spectroradiometer (MODIS) satellite continuous tree cover raster product, produced by the Global Land Cover Facility (<http://glcf.umd.edu/data/vcf/>), and a Human influence index (HII), since many non-native invasive species associate with anthropogenically disturbed habitats. We used the Global Human Influence Index Dataset of the Last of the Wild Project (Wildlife Conservation Society & Center for International Earth Science Information Network, Columbia University, 2005), which is developed from nine global data layers covering human population pressure (population density), human land use and infrastructure (built-up areas, night-time lights, land use/land cover) and human access (coastlines, roads, railroads, navigable rivers). For *Mulinia lateralis*, the distance to the nearest large river mouth was used as a proxy for presence of brackish water (in addition to the Bio-Oracle salinity layer mentioned above). The location of rivers and their average discharge was taken from the "HydroRIVERS" dataset, version 1.0 (Lehner et al. 2008). Point locations of river mouths were "rasterized" to the model grid, summing discharge per 0.25 x 0.25 degree grid cell in case there were several river mouths per cell. Endorheic rivers (not flowing into the oceans) were excluded. For each model grid cell, distance-by-sea (in meters) to the nearest cell with average discharge > 10 m<sup>3</sup>/s was then calculated using "gridDistance" in the R package "raster", version 3.4.5 (Hijmans 2020). For *Delawarea odorata*, we calculated distance to the sea as a proxy for oceanic climate; values were ln+1 transformed for modelling to improve normality.

Each dataset (i.e. combination of the presences and the individual background samples) was randomly split into 80% for model training and 20% for model evaluation. With each training dataset, seven statistical algorithms were fitted with the default BIOMOD2 settings (Generalised linear model, Generalised boosting model, Generalised additive model with a maximum of four degrees of freedom per smoothing spline, Artificial neural network, Multivariate adaptive regression splines, Random forest, and Maxent). Since background samples tended to be larger than the number of occurrences, prevalence fitting weights were applied to give equal overall importance to the occurrences and the background. Normalised variable importance was assessed and variable response functions were produced using BIOMOD2's default procedure.

Model predictive performance was assessed by the following three measures: AUC, the area under the receiver operating characteristic curve (Fielding & Bell 1997, Manel et al. 2001), Cohen's Kappa (Cohen 1960), and TSS, the true skill statistic (Allouche et al. 2006). Ensemble models were created by first rejecting poorly performing algorithms with relatively extreme low AUC values and then averaging the predictions of the remaining algorithms, weighted by their AUC.

Projections were classified into suitable and unsuitable regions using a "lowest presence threshold" (Pearson et al. 2007), setting the cut-off as the lowest value at which 98% of all presence records are classified correctly under the current climate. In order to express the sensitivity of classifications to the choice of this threshold, thresholds at which 95% and 99% of records are classified correctly were used in the calculation of error bars in

the figures illustrating suitability per bioregion and country, in addition to taking account of uncertainty in the projections themselves.

We also produced limiting factor maps for Europe following Elith et al. (2010). For this, projections were made separately with each individual variable fixed at a near-optimal value. These were chosen as the median values at the occurrence grid cells. Then, the most strongly limiting factors were identified as the one resulting in the highest increase in suitability in each grid cell.

Finally, we calculated the proportion of the area of each EU member state and the UK, and of each Biogeographical region of Europe, projected to be suitable for establishment of each terrestrial species, both for the current climate and for projected climate for the 2070s under the two climate change scenarios mentioned above. For marine species, we calculated the proportion of the areas projected to be suitable of the coastal territorial waters of European Union countries and the UK, and of the marine subregions of Europe.

## The peer-review

The comments of the peer reviewers have been taken into account in the documents discussed during the workshop and any pending issue was further discussed before the finalization of the documents. As such, the final versions of the risk assessments and risk management notes represent the consensus reached between authors and peer reviewers. A summary of key points in response to the peer-reviewer comments and the discussions at the quality assurance workshop is provided below by the authors of the assessments. Also, authors were invited to provide pending research needs that would improve the knowledge base for the species.

### ***Bipalium kewense* (Kew flatworm)**

Both the internal and external reviews were most helpful, and the reviewers are thanked for their comments, suggestions, and advice, all of which were greatly appreciated. There were no substantial disagreements with the reviewers, and their valuable suggestions to clarify and to expand on certain topics were adopted. Some additional useful information was supplied by the reviewers regarding the outdoor establishment of the species. Following discussions at the Workshop the Risk Management Notes were expanded slightly to ensure inclusion of health, safety, and environmental precautions where relevant, and an indication of a time line for remedial action upon the discovery of the species.

Where the reviewers suggested amending scores, this was only one stage up or down, and was done to ensure consistency of approach across all the risk assessments, especially in the "Impacts" section. Also, where responses to a question were "No information has been found on this issue", and the responses scored as N/A, they were checked to ensure that a confidence level was NOT provided. In all cases, scores were amended without disagreement, and were justified to provide clarity to the response.

*Have there been substantial changes to the scores of the probabilities of introduction, entry, establishment, and spread or the magnitude of impacts?*

No substantial changes. Some scores were amended but only one step up or down to be consistent with other risk assessments.

*Have there been substantial changes to the scores in the risk summary and the conclusion of the risk assessment (overall risk)?*

As above, no substantial changes.

*Have there been substantial changes to the levels of confidence?*

As above, no substantial changes.

*Have there been important additional references and other sources of information included that were previously missing?*

Yes. Some additional references supporting statements in those sections that were expanded or clarified subsequent to the advice from the reviewers.

*Have there been clarifications to the content that improved readability and understanding?*

Yes. The reviewers provided many queries to the risk assessment to improve clarity and understanding. In some cases, they suggested alternative wording or asked for

certain topics to be expanded. They also checked the text to make sure that conclusions were consistent with the evidence supplied.

### ***Identified data gaps and research needs***

As an experimental animal regarded as an example of a triclad flatworm, *Bipalium kewense* has been the subject of numerous scientific studies. However, the few ecological studies conducted on the species were largely concerned with the seasonal occurrence and survival of the species. Although *B. kewense* is solely vermivorous, there are no studies concerned with the impact of the flatworm upon earthworm populations in the urban situations worldwide in which the flatworm is encountered outside its natural distribution. Possibly the presence and behaviour of *B. kewense* in urban gardens and parks, in contrast say, to *Arthurdendyus triangulatus*, the New Zealand flatworm, has not been such so as to raise concerns by gardeners and horticulturalists over its possible impacts on the garden environment that might otherwise have led to further investigations. As is the situation with other alien species of flatworms, little is known about how to specifically control *B. kewense*. Rather, incursions of all land planarians are likely to be controlled in much the same way as they all share a similar biology.

The evidence gaps with respect to the Risk Assessment are therefore:

- What are the food preferences of *B. kewense* for various species of earthworms?
- What is the impact of *B. kewense* upon urban populations of earthworms?
- Depending upon the results of the foregoing two points, what risk does the flatworm pose to native / other earthworm populations should it become established outside of urban situations?
- What is the effectiveness of hot-water treatment against flatworm zooids (fragments), adults and egg capsules, and also
- What is the possible cost-effectiveness of such treatment?

### ***Cervus nippon (Sika Deer)***

*Have there been substantial changes to the scores of the probabilities of introduction, entry, establishment, and spread or the magnitude of impacts?*

No. Following the peer-review and the discussion held during the workshop, only some changes on the level of confidence were made (see below).

*Have there been substantial changes to the scores in the risk summary and the conclusion of the risk assessment (overall risk)?*

No. In general peer-reviewers agreed with the scoring and relevant justifications. Scores were double checked during the workshop for many points throughout the document, but only a few changes were made, i.e. Qu. 1.6a, 1.6d, 3.12, and on some small remark to the comments (but they did not affect the final result). In particular, a discussion was held on whether a "major" score on impact to biodiversity was sufficiently justified, and this reached general consensus given the impact of the species due to the risk of hybridisation with the native red deer.

*Have there been substantial changes to the levels of confidence?*

The levels of confidence were double checked for many points throughout the document to ensure they correctly reflect a proper interpretation/understanding of the current knowledge on the relevant issues (some minor changes were made following agreement by all authors during the workshop). However, in general this did not lead to any substantial changes to the overall assessment.

*Have there been important additional references and other sources of information included that were previously missing?*

A few references were added, e.g. Dvořák and Palyzová 2016, González-Suárez et al 2015, Goodman et al. 1999, Liu et al. 2020, Osterholm et al. 2019, Polaina et al. 2021, Wyman et al. 2016 , but in general the assessment was already well covered and supported by all key literature.

*Have there been clarifications to the content that improved readability and understanding?*

Yes. Some minor changes were made to the text throughout the document, based on the correct interpretation of the available literature and the knowledge on the issue (thanks to the specific skills of the peer-reviewers). In many cases, the points raised by the peer reviewers, and preliminarily addressed by the authors, were (re)discussed (and relevant justification fine tuned, if needed), so to achieve consensus among co-authors and peer-reviewers. Among the other things, the importance of the occurrence of hybrids was extensively discussed. It was decided that hybrids must be explicitly addressed by the RA, and that while it is not clear whether the species has to be considered established in countries where only hybrids are present, all relevant information has to be clearly reported/discussed in the replies. Also, the need to consider more clearly both introduction and entry was stressed, particularly in relation to the issue of detection. In general, it was agreed that any information that would appear too generic or speculative, e.g. based on the knowledge of other cervids, would be not included, unless strictly necessary because of evident knowledge gaps for the target species. The SDM did not require any revisions as it was considered by the peer-reviewers of very good quality already.

### ***Cherax destructor (Common Yabby)***

The SDM has been recalculated after discussion at the workshop, based on new records provided for France and Ireland. The model results are similar to before, but the projected suitabilities are larger for some bioregions and countries, with north-western France now considered suitable, and Ireland very nearly suitable under current climate, and with large suitable areas under future climates.

*Have there been substantial changes to the scores of the probabilities of introduction, entry, establishment, and spread or the magnitude of impacts?*

No substantial changes to the scores of probabilities of introduction, entry, establishment, and spread or the magnitude of impacts. Some minor adjustments based upon by additional information and references provided by the reviewers.

*Have there been substantial changes to the scores in the risk summary and the conclusion of the risk assessment (overall risk)?*

No substantial change to the scores in the risk summary and the conclusion of the risk assessment (overall risk).

*Have there been substantial changes to the levels of confidence?*

No substantial changes to the levels of confidence. Some minor adjustments based upon additional information and references provided by the reviewers.

*Have there been important additional references and other sources of information included that were previously missing?*

Some additional references were added for the new records used in the model, for better illustrating the interspecific crayfish species interactions and the other diseases potentially carried by the species.

*Have there been clarifications to the content that improved readability and understanding?*

Some minor clarifications in order to improve readability and understanding. The issue of alien American crayfish possible acting as a barrier for the species has been better explained.

### ***Delairea odorata (Cape Ivy)***

*Have there been substantial changes to the scores of the probabilities of introduction, entry, establishment, and spread or the magnitude of impacts?*

No. Only some editorial changes were made to the text.

*Have there been substantial changes to the scores in the risk summary and the conclusion of the risk assessment (overall risk)?*

No. Only some editorial changes were made to the text.

*Have there been substantial changes to the levels of confidence?*

No. though additional text has been added for some questions to further justify the confidence level.

*Have there been important additional references and other sources of information included that were previously missing?*

The reviewers did supply some additional references that have been included in the risk assessment.

*Have there been clarifications to the content that improved readability and understanding?*

Yes, some text has been amended to further clarify answers. In particular, the reviewers suggested the removal of the pathway 'Landscape/flora/fauna important in the wild' as the species is generally described as growing poorly in full sunlight, and there is no evidence that the species has been used for this purpose. In the risk assessment, it is stated that the pathway was considered but not evaluated further due to the points above.

### ***Marisa cornuarietis (Colombian Ramshorn Apple Snail)***

There were no substantial disagreements with the reviewers on the Risk Assessment document. There were valuable suggestions for clarification and to expand on certain topics. For example, two extra pathways of spread suggested by one reviewer were added to the Risk Assessment. Some additional clarifications and references were also sought. The keypoint, with regard to availability of references, was that in some cases the response changed, for example for economic cost, the response was changed to, 'No information has been found on the issue'. The Risk Management Notes were expanded at the reviewers' request to more clearly address the questions asked in the guidelines, for example those relating to acceptability, cost and potential environmental damage of

any control measures. Where the reviewers suggested amending response scores, they were amended without disagreement. At the workshop one member state record on the distribution map was questioned and after discussion, was removed. The model was subsequently recreated and the new version added to the risk assessment.

*Have there been substantial changes to the scores of the probabilities of introduction, entry, establishment, and spread or the magnitude of impacts?*

No.

*Have there been substantial changes to the scores in the risk summary and the conclusion of the risk assessment (overall risk)?*

No.

*Have there been substantial changes to the levels of confidence?*

No.

*Have there been important additional references and other sources of information included that were previously missing?*

Yes. Some important references were included in both the RA and the Management Annex. The reassessed model was included, but did not change the predicted spread to new member states or regions.

*Have there been clarifications to the content that improved readability and understanding?*

Yes, in some cases copy-editing improved the quality and comprehension of the document.

### ***Mulinia lateralis* (Dwarf Surf Clam)**

*Have there been substantial changes to the scores of the probabilities of introduction, entry, establishment, and spread or the magnitude of impacts?*

Following the peer-review and the discussion held during the workshop, some reductions of a single level, were made to the scores. These changes primarily related to the probability of spread via ballast water. In addition, the possible points of introduction score was changed from widespread to isolated. These changes followed a discussion as to whether the habitat surrounding major transshipment ports in the Mediterranean would be suitable for establishment of *M. lateralis*. As there is no good evidence available either way, it was agreed to adopt the lower score and the relevant confidence levels were reduced.

*Have there been substantial changes to the scores in the risk summary and the conclusion of the risk assessment (overall risk)?*

Only a reduction in the probable rate of spread from rapidly to moderately.

*Have there been substantial changes to the levels of confidence?*

Some changes to the levels of confidence were made as mentioned above, and to provide consistency across the assessment.

*Have there been important additional references and other sources of information included that were previously missing?*

No. One reviewer provided details of additional evidence of establishment and predator behaviour resulting from personal observations, which was included.

*Have there been clarifications to the content that improved readability and understanding?*

Some minor changes were made to the text to provide clarification.

### **Identified data gaps and research needs**

- Research on the presence of *Mulinia lateralis* in ballast water and sediments
- Research on non-native species (including *M. lateralis*) present in dredging waste, in hopper water, and on dredging equipment
- Data on international dredging activities including: number of operational vessels, dredging locations, transit points, current biosecurity measures, any current legislation in member states
- Research on the presence of *Mulinia lateralis* in bivalve transfers in the Greater North sea
- Research on the presence of *Perkinsus chesapeaki* in the Greater North Sea clam population
- Research on its impact on native species, including species it interacts with through competition and predation

### **Obama nungara (Obama flatworm)**

The input provided by both the internal and external reviewers was positive and very valuable. There were no major disagreements and virtually all suggestions were accepted. The only suggestion not incorporated in the RA was a request to include more pathways for spread (e.g. as a 'contaminant of plants'), as suggested in the internal review. We did not add this in as the existing evidence for spread was via the pathways 'contaminant nursery stock' and 'transportation of habitat material'. Therefore, with limited data and to avoid duplication and speculation, we discussed the 'contaminant of plants' pathway in the section introduction rather than as a full section. The risk management notes were expanded on the reviewers' recommendations to include more assessment of stakeholder/consumer acceptance, environmental impact and health and safety implications of any management measures.

*Have there been substantial changes to the scores of the probabilities of introduction, entry, establishment, and spread or the magnitude of impacts?*

No, there were no substantial changes for the majority of the scores, with only a one step amendment in some cases to keep uniformity with other RAs. There was discussion about the impact score of *Obama nungara* and the lack of data to substantiate a 'major' score. This was discussed in detail with the reviewers and at the workshop. It was agreed that 'absence of evidence' was not 'evidence of absence' and the purpose of the RA was to be proactive in preventing damage caused by invasive alien species. Since the flatworm is a relatively recent introduction to Europe, clear evidence of impact may take time to be seen and there are no studies to date. However, delaying scoring until evidence of damaging impact is apparent would be a strategic management mistake. Therefore, scoring was done on the basis of the

biological similarities of *O. nungara* with other invasive terrestrial flatworms and the damaging impact caused by them.

*Have there been substantial changes to the scores in the risk summary and the conclusion of the risk assessment (overall risk)?*

No, there were no substantial changes bearing in mind the above.

*Have there been substantial changes to the levels of confidence?*

No substantial changes. For the impact of *O. nungara*, confidence levels were rated low due to its recent introduction to Europe and lack of data.

*Have there been important additional references and other sources of information included that were previously missing?*

The reviewers supplied additional records that became available during the period of the risk assessment exercise.

*Have there been clarifications to the content that improved readability and understanding?*

Yes, there were several instances where the experience of the reviewers assisted in making the text clearer and more understandable to non-specialists.

### **Identified data gaps and research needs**

*Obama nungara* is established and spreading in Europe. There is an urgent need to assess the impact of this predatory flatworm on prey species. First, the prey species range in Europe needs to be clarified. Second, the impact of *O. nungara* predation on said prey populations needs to be investigated. Without these data, confidence in assessing the impact of *O. nungara* will remain low. For detection of flatworms in general, eDNA techniques need to be investigated. Similarly, for control of alien terrestrial flatworms, phytosanitation using hot water treatments needs to be trialled.

### ***Pycnonotus jocosus* (Red-whiskered Bulbul)**

*Have there been substantial changes to the scores of the probabilities of introduction, entry, establishment, and spread or the magnitude of impacts?*

No. Apart from some small changes in confidence levels (e.g. Qu 4.1) that were flagged during the review process, there were no substantial changes in scores across the different modules. At the workshop however, all suggestions for alternative scores raised by the two reviewers were collectively discussed until consensus was reached on the scores:

The likelihood of introduction and entry into the RA area under current (Q1.9) and future (Q1.10) climate was scored as very likely with high confidence. Likewise, the likelihood of establishment in the RA area under current (Q2.9) and future (Q2.10) climate was scored as very likely with high confidence. The score for introduction/entry was challenged on the basis of the EU bird ban which reduced the number of wild birds kept in captivity as pets and therefore one introduction per year could probably be too much. Likewise, the score for establishment was challenged arguing that in 20 years only one population managed to establish in the RA area and therefore this would correspond with a score of likely (1 in 10 years) or lower. The decision was to stick to the scoring guidance for introduction/entry and establishment,

which stipulates a score of very likely should be given for already introduced and established species.

There was some discussion on raising the score for impact outside the RA area to massive, considering the documented extinction and declines in *Nephila* spiders and native bulbul respectively. Revisiting the scoring ranges for biodiversity impact, the group decided to stick with major impact. The report on the Mauritius spider extinction is not presenting spider population monitoring data and most probably other factors contributed to the extinction (e.g. habitat loss). This is certainly also the case for Nicobar bulbul (cf. Birdlife factsheet information). Therefore, the group considered the criterion "widespread impact" not fulfilled and we agreed on major impact.

4.3 future impact in the RA area. Although the landscape matrix around the currently established population in Valencia might not provide perfect bulbul habitat, there is scope for the bulbul to spread to the adjacent natural park which is a pretty vast area (~3000ha + the city of Valencia). Second, we should not consider the current case of invasion as the sole representative model for other invasion events (e.g. on Mediterranean islands). Kept current score.

Concerns were raised by one of the reviewers about potentially over-scoring the current and potential economic impact of the species (Q 4.9, 4.11, 4.12), making parallels with overstated damages to orchards and agricultural assets in the Valencia area done by native species like thrushes and starlings. It was however noted that agricultural assets vary greatly across the risk assessment area therefore solely considering the area of current establishment is not representative for a potential future invasion scenario. Also, there is direct evidence outside the RA area of agricultural damages on a variety of crops (e.g. California, Hawaii), although there is a lack of quantified studies of production losses. This is already mentioned in the argumentation and reflected in low confidence. The group decided to reiterate these arguments in the relevant questions with direct reference to the monetary impact scale. It is noted that actually a conservative approach was taken but still a score of moderate (>100,000 euros) is easily reached even in case of small agricultural damages across the entire RA area.

Revisit confidence scores across the impact section of the PRA (quite a few times a score of low while overall the confidence was scored medium). After discussion, the current confidence scores stand except for 4.1 (impact outside RA area). Here, the confidence score was increased to high considering the direct observational evidence and the relatively good body of evidence of impacts across the non-native range - impact is not inferred from other species but there is direct evidence for the species itself. As a consequence, the overall confidence on impact is more balanced but it was noted that in principle, the overall confidence has no direct link with the composite questions.

*Have there been substantial changes to the scores in the risk summary and the conclusion of the risk assessment (overall risk)?*

No. There was a discussion on one reviewer comment suggesting lowering the score for impact and for overall risk (from major to moderate and high to moderate respectively). However, after having reviewed scoring ranges and impact information, it was concluded that a high risk score was justified, especially considering the presence of sensitive island biota, documented ecosystem-level effects and competitive exclusions and local extinctions of native species.

*Have there been substantial changes to the levels of confidence?*

Some minor changes to confidence levels were made following agreement by all authors and reviewers present at the workshop. Most of these were upgrades of the level of confidence, for instance because impacts were not derived from other species

but based on actual evidence for *P. jocosus*. The changes in confidence did not lead to any substantial changes to the risk assessment.

*Have there been important additional references and other sources of information included that were previously missing?*

Yes. At the suggestion of the reviewers some additional references were included. Most notably, some relevant literature on factors explaining invasion success in birds related to specific species traits were included that helped justify scores for establishment and spread (e.g. Callaghan et al. 2019, Cassey et al. 2004, Sol et al. 2002). Also the atlas of breeding and wintering birds of Valencia was in press and is now properly referenced. A few extra references were added on prayer release. Additionally, it was decided not to cite the red-vented bulbul risk assessment but to refer to primary references.

*Have there been clarifications to the content that improved readability and understanding?*

Yes, there were several clarifications throughout the PRA suggested by the reviewers and discussed at the workshop. Minor changes were made throughout, based on reviewer's knowledge on the issue, one particular area for instance concerns the situation with the Valencia population where clarifications and additions were provided about landscape context, conservation value, other species present in the area and details on invasion history.

The relevance of inclusion of the pathway "prayer release" (CBD: Other intentional releases) was discussed at the workshop. Although it is widely practiced in buddhist cultures in the native range, and there is growing concern reported worldwide in the literature about the conservation implications of this phenomenon, it is probably quite unlikely this is an issue in the RA area with birds (there are however examples in other taxa e.g. lobsters, butterflies). As there are documented cases in western countries (e.g. UK, Canada), it cannot be excluded. Evidence however reports that the chances of birds surviving these releases are low. Decision is to keep it in as a pathway, as very unlikely, also to be consistent with the red-vented bulbul PRA which mentions it.

One particular issue was discussion around the concept of "detectability" (how likely is the species to be introduced/enter the environment undetected). Reviewers raised the issue that it is not clear who is concerned in this detection. For introduction, this should refer to official control and inspection services, for (post-border) entry this is more related to the public (naturalists, landowners, gardeners, etc.). The group's decision was to consider introduction and entry separately in the score argumentation but not to go for a "confounded" average score to keep the focus on the pathway and how it is controlled in line with the nature of the question. The group also decided that a lower likelihood (to become detected) for the pet pathway, as opposed to zoo escapes, was justified, even if probably there are a lot of facilities that are not up standard with respect to housing and do represent a risk of escapes of a similar level as pets kept by private people. Additional information on reporting obligations for zoos in the framework of the Zoo Directive was provided by the Commission and was included in the RA. There is formal reporting of the number of birds kept in -zoos, therefore any birds missing could be noticed, even if zoos may have more birds. In case of private collections, there is no such mechanism and the likelihood of escapes not being detected is higher. As for entry into the environment, the species is conspicuous and would most probably be reported by the birding community fairly rapidly.

The species distribution model was discussed following comments from one reviewer who had particular concerns with counterintuitive results of the model for Iberia, identifying some areas (e.g. Galicia, Extremadura and Andalucia) which are probably

less suitable for the species because of harsh winters or unsuitable landscape context, as relatively higher risk than the area where the species is currently established in Iberia. In part, this may be due to the lack of a detailed habitat layer. The group decided to try including this layer and explore whether the model results are any better, and to point to the limitations of the model in relevant questions. It is also noted that the response curves of some of the models in the ensemble deviate for bio6 (minimum temperature of the coldest month) which might be an important variable, it is unclear where this is coming from. In response to the workshop discussion, a new version of the model was produced by Bjorn Beckmann (October 2021, version 6) which included a habitat layer and removed predictors with little influence in the model and/or correlated with others. More specifically, forest cover, which had minimal influence in the model was removed and instead a "modified Enhanced Vegetation Index", was used in the model. However, this still only had a marginal influence in the model (2%). As the projected suitability was similar to the current version (slightly higher in the Atlantic and Mediterranean regions) and had similar uncertainties, in line with a decision at the workshop, we stick to the original model and better outline uncertainties on model predictions in some areas.

A few small reviewer comments were taken into account for the risk management annex, notably additional information on public acceptance of management was included in the document.

### ***Identified data gaps and research needs***

The following knowledge gaps were identified: data on the size and geographic spread of captive populations in the RA area, the suitability of (semi)natural habitats in the RA area, studies on the current biodiversity impact of the species in the RA area and quantified data on production losses caused by the species.

#### Task 4: Preparation of new Risk Management Notes (evidence on measures and their implementation cost and cost-effectiveness)

Task lead: Peter Robertson

Task 4 uses a template for data collection based on the requirements from the Commission. This requires the collection of information in relation to management techniques and their costs. This is compiled as a separate Annex to each of the Risk Assessments and provides information that would help inform management decisions. The format of these templates was reviewed at the onset of the project, including opportunities to increase the level of structured detail required for completion, and to provide a summary assessment of the availability of methods suitable for different management objectives. A new section requiring details of monitoring and surveillance methods was introduced in the previous year of the contract.

The Annex describes methods for prevention, eradication and management, and supporting methods for monitoring and surveillance. These include a description of the method, evidence for its cost and cost-effectiveness, a measure for the confidence in the available information in each case and a list of bibliographic references.

For the eight species assessed under this study, there was increased emphasis on the inclusion of quantitative information on the costs of management and the maximum areas (in m<sup>2</sup>, km<sup>2</sup>, ha) over which successful management, particularly eradications, have been conducted. These were considered to be particularly useful to inform possible management decisions, however, it was accepted that the availability of published information on these topics, for selected species or their close relatives, was often limited. In cases where there are no methods available to meet a particular objective, or the available methods are only useful in limited circumstances, this should be clearly highlighted in the summary and in the text.

First drafts were produced by authors of the risk assessments and/or members of the project team, followed by an internal quality review and then external peer review. Revised drafts were then discussed at the Quality Assurance Workshop (task 5). This included a check on completeness, a simple analysis of content, and whether this was of a quantitative or qualitative nature. This highlighted a short-list of issues to consider in relation to the individual species accounts in subsequent break-out sessions. Following this, final drafts were produced and these are included as Annex 1b-8b to this Final Report.

## Task 5: Quality Assurance Workshop

Task lead: Helen Roy

As a consequence of the COVID19-pandemic it was approved by the Commission to organize the Quality Assurance Workshop on 15 and 17 September 2021 as an online meeting. The aim of the workshop was to provide authors, peer-reviewers and the Commission the opportunity to discuss any unclarified issues, eliminate remaining uncertainties as far as possible, and assure the highest possible quality of the Risk Assessments and Risk Management Notes.

In preparation for the workshop, authors considered and incorporated comments from the peer-reviewers submitted in advance of the workshop. The comments from the peer-reviewers and the considerations from the authors are also documented within this report (see Task 3). At the workshop, all lead authors presented a summary of their work and open questions were discussed in virtual breakout groups and in the plenary. After the workshop, authors finalized the Risk Assessments and Risk Management Notes taking into account also further comments provided by the Commission.

The Agenda of the meeting was adjusted to the shorter duration compared to previous physical meetings in Brussels. After a short introduction and overview of the project by Wolfgang Rabitsch (Project lead), Björn Beckmann provided an overview of the species distribution modelling approach, followed by Pete Robertson providing an overview of the Management Annex. Then, lead authors of four of the eight Risk Assessments gave short summaries of the major sections and overall assessments of their species and explained any peculiarities and difficulties of the work. On the second day, the remaining four Risk Assessments were presented as on the first day.

Agenda of the virtual Quality Assurance Workshop:

<b>Day 1 (15th September)</b>		
<b>Time</b>	<b>Agenda Item</b>	<b>Lead</b>
0930	Registration / Log-in Zoom	
0945	Welcome and introduction	EC
1000	Overview of the project	Wolfgang Rabitsch
1015	Overview of modelling approaches	Björn Beckmann
1030	Overview of RMN	Pete Robertson
1045	Overview of selected (4) RA+RMN (10 minutes talk + 5 minutes general discussion per assessment)	RA lead authors
	<i>Bipalium kewense</i> (Kew Flatworm)	Leigh Winsor
	<i>Cervus nippon</i> (Sika Deer)	Riccardo Scalera
	<i>Cherax destructor</i> (Common Yabby)	Elena Tricarico
	<i>Mulinia lateralis</i> (Dwarf Surf Clam)	Christine Wood
1145	Break	
1200	Breakout groups to finalise RA+RMN	Groups

1330	Feedback from breakout groups including general discussion	
1415	Wrap-up and End of Day 1	Wolfgang Rabitsch

## Day 2 (17th September)

Time	Agenda Item	Lead
0930	Registration / Log-in Zoom	
0945	Welcome	Wolfgang Rabitsch
0950	Overview of selected (5) RA+RMN (10 minutes talk + 5 minutes general discussion per assessment)	RA lead authors
	<i>Delairea odorata</i> (Cape Ivy)	Rob Tanner
	<i>Marisa cornuarietis</i> (Colombian Ramshorn Apple Snail)	Frances Lucy
	<i>Obama nungara</i> (Obama Flatworm)	Archie Murchie
	<i>Pycnonotus jocosus</i> (Red-whiskered Bulbul)	Tim Adriaens
1100	Breakout groups to finalise RA+RMN	Groups
1145	Break	
1200	Breakout groups to finalise RA+RMN (cont.)	Groups
1245	Feedback from breakout groups including general discussion	
1330	Wrap-up and End of Workshop	Wolfgang Rabitsch

### Attendees of the Workshop:

Tim	Adriaens
Björn	Beckmann
Giuseppe	Brundu
Bram	D'Hondt
Siobhan	Edney
Thomas	Evans
Marika	Galanidi
Darren	Garland
Jean-Lou	Justine
Francis	Kerckhof
Antonin	Kouba
Helmut	Kudrnovsky
Frances	Lucy

Leonardo	Mazza
Archie	Murchie
Francisco	Oficialdegui
Juan	Perez-Lorenzo
Jodey	Peyton
Wolfgang	Rabitsch
Peter Andrew	Robertson
Riccardo	Scalera
Richard	Shaw
Wojtek	Solarz
Alan John	Stewart
Anthony	
Robert Anton	Tanner
Elena	Tricarico
Johan	Van Valkenburg
Hugo	Verreycken
Alastair	Ward
Leigh	Winsor
Christine	Wood

## Conclusions

A few modifications were made to the Risk Assessment and Risk Management Note templates, but essentially they remained the same as in the first year of the contract.

The level of detail and consistency across the eight Risk Assessment and Risk Management Annexes has benefitted from the internal quality control and this feedback loop will be applied again in the third year of the project. Also, the use of structured “checklists” for peer-reviewers and authors after peer-review supported an effective and structured approach for collecting the necessary information for this Final Report and will be continued in the third year of the project.

Of the eight species assessed in this year of the project, four were deemed to constitute an overall “High risk”, three with “Medium” and one with “High” confidence. The overall risk for the four other species was deemed to be “Moderate”, with “Medium” and “Low” confidence for two species each (Tab. 3).

Table 3: Compilation of the responses (High, Moderate, Low) and confidence (High, Medium, Low) assigned within the conclusion of the risk assessments

#	Scientific Name	Common Name	Overall Risk	Confidence
1	<i>Bipalium kewense</i>	Kew flatworm	Moderate	Low
2	<i>Cervus nippon</i>	Sika deer	High	High
3	<i>Cherax destructor</i>	Common yabby	High	Medium
4	<i>Delairea odorata</i>	Cape ivy	Moderate	Low
5	<i>Marisa cornuarietis</i>	Colombian ramshorn apple snail	Moderate	Medium
6	<i>Mulinia lateralis</i>	Dwarf surf clam	Moderate	Medium
7	<i>Obama nungara</i>	Obama flatworm	High	Medium
8	<i>Pycnonotus jocosus</i>	Red-whiskered bulbul	High	Medium

## Supplement Risk Assessment Template

**Risk assessment template developed under the "Study on Invasive Alien Species – Development of risk assessments to tackle priority species and enhance prevention" Contract No 07.0202/2020/834529/ETU/ENV.D.2<sup>1</sup>**

**Name of organism:**

**Author(s) of the assessment:** *name, affiliation, city, country*

**Risk Assessment Area:** The risk assessment area is the territory of the European Union 27 and the United Kingdom, excluding the EU-outermost regions.

**Peer review 1:** *name, affiliation, city, country*

**Peer review 2:** *name, affiliation, city, country*

### Document version history:

Version	Date	File Name	Author(s)	Status and description
0.1				First draft for internal review
1.0				First draft for peer-review
1.1				Draft for Workshop
2.0				Final RA within project year for submission to Scientific Forum
2.1				Updated version after comments from Scientific Forum and Stakeholders
3.0				Final RA for submission to Committee

---

<sup>1</sup> This template is based on the Great Britain non-native species risk assessment scheme (GBNNRA). A number of amendments have been introduced to ensure compliance with Regulation (EU) 1143/2014 on IAS and relevant legislation, including the Delegated Regulation (EU) 2018/968 of 30 April 2018, supplementing Regulation (EU) No 1143/2014 of the European Parliament and of the Council with regard to risk assessments in relation to invasive alien species (see <https://eur-lex.europa.eu/legal-content/en/TXT/?uri=CELEX%3A32018R0968> ).

## **General instructions:**

- Completing risk assessments can be time consuming. Risk assessors and peer reviewers should read all questions before completing each assessment to determine where most detail needs to be provided.
- Responses and justifying comments should be concise and directly answer the question being asked.
- The risk assessment shall be based on the most reliable scientific information available, including the most recent results of international research, supported by references to peer reviewed scientific publications. In cases where there are no peer reviewed scientific publications or where the information provided by such publications is insufficient, or to supplement the information collected, the scientific evidence may also include other publications, expert opinions, information collected by Member States' authorities, official notifications and information from databases, including information collected through citizen science. All sources shall be acknowledged and referenced.
- All responses in the risk assessment shall be backed up by primary references. However, as the risk assessment is not a comprehensive review of the biology or ecology of the species but rather needs to assess the relevant information, references to major monographic reviews are acceptable for these points.
- The scoring of the magnitude of impacts (see Annex II) is not identical with the scoring of other risk assessment protocols. For example, the score “Major” in EICAT has a different meaning than “Major” in the present template. Assessors should not copy-paste scores from other protocols without explanations, specifically with regard to the assessment area, and follow the definitions as given in Annex II (see Qu. A.3).
- Questions in the risk assessment should be answered even where there is little information to support a response, with uncertainty in the response clearly discussed. Where there is such a lack of information, the assessor shall state this explicitly.
- The scoring of impacts does not take possible management actions into account.
- Certain questions are not accompanied by specific instructions or explanatory comments as these are sufficiently self-explanatory. Authors should not consider any such questions as less important. In case of doubt or uncertainty, authors may contact [wolfgang.rabitsch@umweltbundesamt.at](mailto:wolfgang.rabitsch@umweltbundesamt.at) for clarification.
- Each answer provided in the risk assessment shall include an assessment of the level of confidence attached to that answer, reflecting the possibility that information needed for the answer is not available or is insufficient or the fact that the available evidence is conflicting. See Annex III for the documented method.
- The author(s) of the risk assessment and the peer reviewers shall not be affiliated to the same institution.

## **SECTION A – ORGANISM INFORMATION AND SCREENING**

**A1. Identify the organism. Is it clearly a single taxonomic entity and can it be adequately distinguished from other entities of the same rank?**

including the following elements:

- the taxonomic family, order and class to which the species belongs;
- the scientific name and author of the species, as well as a list of the most common synonym names;
- names used in commerce (if any)
- a list of the most common subspecies, lower taxa, varieties, breeds or hybrids

As a general rule, one risk assessment should be developed for a single species. However, there may be cases where it may be justified to develop one risk assessment covering more than one species (e.g. species belonging to the same genus with comparable or identical features and impact). It shall be clearly stated if the risk assessment covers more than one species, or if it excludes or only includes certain subspecies, lower taxa, hybrids, varieties or breeds (and if so, which subspecies, lower taxa, hybrids, varieties or breeds). Any such choice must be properly justified.

Response:

**A2. Provide information on the existence of other species that look very similar [that may be detected in the risk assessment area, either in the environment, in confinement or associated with a pathway of introduction]**

Include both native and non-native species that could be confused with the species being assessed, including the following elements:

- other alien species with similar invasive characteristics, to be avoided as substitute species (in this case preparing a risk assessment for more than one species together may be considered);
- other alien species without similar invasive characteristics, potential substitute species;
- native species, potential misidentification and mis-targeting

Response:

**A3. Does a relevant earlier risk assessment exist? Give details of any previous risk assessment, including the final scores and its validity in relation to the risk assessment area.**

Response:

**A4. Where is the organism native?**

including the following elements:

- an indication of the continent or part of a continent, climatic zone and habitat where the species is naturally occurring
- if applicable, indicate whether the species could naturally spread into the risk assessment area

Response:

**A5. What is the global non-native distribution of the organism outside the risk assessment area?**

Response:

**A6. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species been recorded and where is it established? The information needs to be given separately for recorded (including casual or transient occurrences) and established occurrences. “Established” means the process of an alien species successfully producing viable offspring with the likelihood of continued survival<sup>2</sup>.**

**A6a. Recorded: List regions**

**A6b. Established: List regions**

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

- Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea.

Comment on the sources of information on which the response is based and discuss any uncertainty in the response.

For delimitation of EU biogeographical regions please refer to <https://www.eea.europa.eu/data-and-maps/figures/biogeographical-regions-in-europe-2> (see

---

<sup>2</sup> Convention on Biological Diversity, Decision VI/23

also Annex VI).

For delimitation of EU marine regions and subregions consider the Marine Strategy Framework Directive areas; please refer to <https://www.eea.europa.eu/data-and-maps/data/msfd-regions-and-subregions/technical-document/pdf> (see also Annex VI).

Response (6a):

Response (6b):

**A7. In which biogeographic region(s) or marine subregion(s) in the risk assessment area could the species establish in the future under current climate and under foreseeable climate change? The information needs be given separately for current climate and under foreseeable climate change conditions.**

**A7a. Current climate: List regions**

**A7b. Future climate: List regions**

With regard to EU biogeographic and marine (sub)regions, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

Response (7a):

Response (7b):

**A8. In which EU Member States has the species been recorded and in which EU Member States has it established? List them with an indication of the timeline of observations. The information needs be given separately for recorded and established occurrences.**

**A8a. Recorded: List Member States**

**A8b. Established: List Member States**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland,

France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden; provide information for the United Kingdom if relevant

The description of the invasion history of the species shall include information on countries invaded and an indication of the timeline of the first observations, establishment and spread.

Response (8a):

Response (8b):

**A9. In which EU Member States could the species establish in the future under current climate and under foreseeable climate change? The information needs be given separately for current climate and under foreseeable climate change conditions.**

**A9a. Current climate: List Member States**

**A9b. Future climate: List Member States**

With regard to EU Member States, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

Response (9a):

Response (9b):

**A10. Is the organism known to be invasive (i.e. to threaten or adversely impact upon biodiversity and related ecosystem services) anywhere outside the risk assessment area?**

Response:

**A11. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea

Response:

**A12. In which EU Member States has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden; provide information for the United Kingdom if relevant

Response:

**A13. Describe any known socio-economic benefits of the organism.**

including the following elements:

- Description of known uses for the species, including a list and description of known uses in the risk assessment area and third countries, if relevant.
- Description of social and economic benefits deriving from those uses, including a description of the environmental, social and economic relevance of each of those uses and an indication of associated beneficiaries, quantitatively and/or qualitatively depending on what information is available.

If the information available is not sufficient to provide a description of those benefits for the entire risk assessment area, qualitative data or different case studies from across the risk assessment area or third countries shall be used, if available.

Response:

## SECTION B – DETAILED ASSESSMENT

### Important instructions:

- In the case of lack of information the assessors are requested to use a standardized answer: “No information has been found.” In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable).
- With regard to the scoring of the likelihood of events or the magnitude of impacts see Annexes I and II.
- With regard to the confidence levels, see Annex III.
- Highlight the selected response score and confidence level in **bold** but keep the other scores in normal text (so that the selected score is evident in the final document).

## 1 PROBABILITY OF INTRODUCTION AND ENTRY

### Important instructions:

- **Introduction** is the movement of the species into the risk assessment area (it may be either in captive conditions and/or in the environment, depending on the relevant pathways).
- **Entry** is the release/escape/arrival in the environment, i.e. occurrence in the wild
- Introduction and entry may coincide for species entering through pathways such as “corridor” or “unaided”, but it also may differ. If different, please consider all relevant pathways, both for the introduction into the risk assessment area and the entry in the environment.
- The classification of pathways developed by the Convention of Biological Diversity (CBD) should be used (see Annex IV). For detailed explanations of the CBD pathway classification scheme consult the IUCN/CEH guidance document<sup>3</sup> and the provided key to pathways<sup>4</sup>.
- For organisms which are already present (recorded or established) in the risk assessment area, the likelihood of introduction and entry should be scored as “very likely” by default.
- Repeated (independent) introductions and entries at separate locations in the risk assessment area should be considered here (see Qu. 1.7).

**Qu. 1.1. List relevant pathways through which the organism could be introduced into the risk assessment area and/or enter into the environment. Where possible give details about the specific origins and end points of the pathways as well as a description of any associated commodities.**

For each pathway answer questions 1.2 to 1.8 (copy and paste additional rows at the end of

<sup>3</sup> <https://circabc.europa.eu/sd/a/7e5f0bd4-34e8-4719-a2f7-c0cd7ec6a86e/2020-CBD-pathways-interpretation.pdf>

<sup>4</sup> <https://circabc.europa.eu/sd/a/0aeba7f1-c8c2-45a1-9ba3-bcb91a9f039d/TSSR-2016-010%20CBD%20pathways%20key%20full%20only.pdf>

this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 1.2a, 1.3a, etc. and then 1.2b, 1.3b etc. for the next pathway.

In this context a pathway is the route or mechanism of introduction and/or entry of the species.

The description of commodities with which the introduction of the species is generally associated shall include a list and description of commodities with an indication of associated risks (e.g. the volume of trade; the likelihood of a commodity being contaminated or acting as vector).

If there are no active pathways or potential future pathways this should be stated explicitly here, and there is no need to answer the questions 1.2-1.9.

Pathway name:

**Qu. 1.2a. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	intentional	<b>CONFIDENCE</b>	low
	unintentional		medium
			high

Response:

**Qu. 1.3a. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
	unlikely		medium
	moderately likely		high
	likely		

	very likely		
--	-------------	--	--

Response:

**Qu. 1.4a. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response:

**Qu. 1.5a. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response:

**Qu. 1.6a. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response:

**Qu. 1.7a. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated widespread ubiquitous	<b>CONFIDENCE</b>	low medium high
-----------------	--------------------------------------	-------------------	-----------------------

Response:

**Qu. 1.8a. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response:

*End of pathway assessment, repeat Qu. 1.3 to 1.8 as necessary using separate identifier.*

**Qu. 1.9. Estimate the overall likelihood of introduction into the risk assessment area or entry into the environment based on all pathways and specify if different in relevant biogeographical regions in current conditions.**

Provide a thorough assessment of the risk of introduction in relevant biogeographical regions in current conditions: providing insight in to the risk of introduction into the risk assessment area.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response:

**Qu. 1.10. Estimate the overall likelihood of introduction into the risk assessment area or entry into the environment based on all pathways in foreseeable climate change conditions?**

Thorough assessment of the risk of introduction in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of introduction (e.g. change in trade or user preferences)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely introduction within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response:

## 2 PROBABILITY OF ESTABLISHMENT

### Important instructions:

- For organisms which are already established in parts of the risk assessment area or have previously been eradicated, the likelihood of establishment should be scored as “very likely” by default.
- Discuss the risk also for those parts of the risk assessment area, where the species is not yet established.

**Qu. 2.1. How likely is it that the organism will be able to establish in the risk assessment area based on similarity of climatic and abiotic conditions in its distribution elsewhere in the world?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response:

**Qu. 2.2. How widespread are habitats or species necessary for the survival, development and multiplication of the organism in the risk assessment area? Consider if the organism specifically requires another species to complete its life cycle.**

<b>RESPONSE</b>	very isolated isolated moderately widespread widespread ubiquitous	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response:

**Qu. 2.3. How likely is it that establishment will occur despite competition from existing species in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely	<b>CONFIDENCE</b>	low medium high
-----------------	--	-------------------	-----------------------

	likely very likely		
--	-----------------------	--	--

Response:

**Qu. 2.4. How likely is it that establishment will occur despite predators, parasites or pathogens already present in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response:

**Qu. 2.5. How likely is the organism to establish despite existing management practices in the risk assessment area? Explain if existing management practices could facilitate establishment.**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response:

**Qu. 2.6. How likely is it that biological properties of the organism would allow it to survive eradication campaigns in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response:

**Qu. 2.7. How likely are the biological characteristics of the organism to facilitate its establishment in the risk assessment area?**

including the following elements:

- a list and description of the reproduction mechanisms of the species in relation to the environmental conditions in the risk assessment area
- an indication of the propagule pressure of the species (e.g. number of gametes, seeds, eggs or propagules, number of reproductive cycles per year) of each of those reproduction mechanisms in relation to the environmental conditions in the risk assessment area.
- If relevant, comment on the likelihood of establishment based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in establishment whereas for others high propagule pressure (many thousands of individuals) may not.
- If relevant, comment on the adaptability of the organism to facilitate its establishment and if low genetic diversity in the founder population would have an influence on establishment.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response:

**Qu. 2.8. If the organism does not establish, then how likely is it that casual populations will continue to occur?**

Consider, for example, a species which cannot reproduce in the risk assessment area, because of unsuitable climatic conditions or host plants, but is present because of recurring introduction, entry and release events. This may also apply for long-living organisms.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response:

**Qu. 2.9. Estimate the overall likelihood of establishment in the risk assessment area under current climatic conditions. In addition, details of the likelihood of establishment**

**in relevant biogeographical regions under current climatic conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in current conditions: providing insight in the risk of establishment in (new areas in) the risk assessment area.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response:

**Qu. 2.10. Estimate the overall likelihood of establishment in the risk assessment area under foreseeable climate change conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under foreseeable climate change conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of establishment (e.g. increase in average winter temperature, increase in drought periods)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely establishment within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response:

### 3 PROBABILITY OF SPREAD

**Important instructions:**

- Spread is defined as the expansion of the geographical distribution of an alien species within the risk assessment area.
- Repeated releases at separate locations do not represent continuous spread and should be considered in the probability of introduction and entry section (Qu. 1.7).

**Qu. 3.1. How important is the expected spread of this organism within the risk assessment area by natural means? (List and comment on each of the mechanisms for natural spread.)**

including the following elements:

- a list and description of the natural spread mechanisms of the species in relation to the environmental conditions in the risk assessment area.
- an indication of the rate of spread discussed in relation to the species biology and the environmental conditions in the risk assessment area.

The description of spread patterns here refers to the CBD pathway category “Unaided (Natural Spread)”. It should include elements of the species life history and behavioural traits able to explain its ability to spread, including: reproduction or growth strategy, dispersal capacity, longevity, dietary requirements, environmental and climatic requirements, specialist or generalist characteristics.

<b>RESPONSE</b>	minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	--	-------------------	-----------------------

Response:

**Qu. 3.2a. List and describe relevant pathways of spread other than "unaided". For each pathway answer questions 3.3 to 3.9 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 3.3a, 3.4a, etc. and then 3.3b, 3.4b etc. for the next pathway.**

including the following elements:

- a list and description of pathways of spread with an indication of their importance and associated risks (e.g. the likelihood of spread in the risk assessment area, based on these pathways; likelihood of survival, or reproduction, or increase during transport and storage; ability and likelihood of transfer from the pathway to a suitable habitat or host) in relation to the environmental conditions in the risk assessment area.
- an indication of the rate of spread for each pathway discussed in relation to the species biology and the environmental conditions in the risk assessment area.
- All relevant pathways of spread (except “Unaided (Natural Spread)”, which is

assessed in Qu. 3.1) should be considered. The classification of pathways developed by the Convention of Biological Diversity shall be used (see Annex IV).

Pathway name:

**Qu. 3.3a. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional	<b>CONFIDENCE</b>	low
	unintentional		medium
			high

Response:

**Qu. 3.4a. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

Response:

## 4 MAGNITUDE OF IMPACT

Important instructions:

- Questions 4.1-4.5 relate to biodiversity and ecosystem impacts, 4.6-4.8 to impacts on ecosystem services, 4.9-4.13 to economic impact, 4.14-4.15 to social and human health impact, and 4.16-4.18 to other impacts. These impacts can be interlinked, for example, a disease may cause impacts on biodiversity and/or ecosystem functioning that leads to impacts on ecosystem services and finally economic impacts. In such cases the assessor should try to note the different impacts where most appropriate, cross-referencing between questions when needed.
- Each set of questions starts with the impact elsewhere in the world, then considers impacts in the risk assessment area (=EU excluding outermost regions) separating known impacts to date (i.e. past and current impacts) from potential future impacts (including foreseeable climate change).
- Only negative impacts are considered in this section (socio-economic benefits are considered in Qu. A.7)
- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable).

### Biodiversity and ecosystem impacts

**Qu. 4.1. How important is the impact of the organism on biodiversity at all levels of organisation caused by the organism in its non-native range excluding the risk assessment area?**

including the following elements:

- Biodiversity means the variability among living organisms from all sources, including terrestrial, marine and other aquatic ecosystems and the ecological complexes of which they are part; this includes diversity within species, between species and of ecosystems
- impacted chemical, physical or structural characteristics and functioning of ecosystems

<b>RESPONSE</b>	minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	--	-------------------	-----------------------

Response:

**Qu. 4.2. How important is the current known impact of the organism on biodiversity at all levels of organisation (e.g. decline in native species, changes in native species communities, hybridisation) in the risk assessment area (include any past impact in your response)?**

Discuss impacts that are currently occurring or are likely occurring or have occurred in the past in the risk assessment area. Where there is no direct evidence of impact in the risk assessment area (for example no studies have been conducted), evidence from outside of the risk assessment area can be used to infer impacts within the risk assessment area.

<b>RESPONSE</b>	minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	--	-------------------	-----------------------

Response:

**Qu. 4.3. How important is the potential future impact of the organism on biodiversity at all levels of organisation likely to be in the risk assessment area?**

See comment above. The potential future impact shall be assessed only for the risk assessment area. A potential increase in the distribution range due to climate change does not *per se* justify a higher impact score.

<b>RESPONSE</b>	minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	--	-------------------	-----------------------

Response:

Response:

## **Economic impacts**

**Qu. 4.9. How great is the overall economic cost caused by the organism within its current area of distribution (excluding the risk assessment area), including both costs of / loss due to damage and the cost of current management.**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the world these should be reported here. The assessment of the potential costs of / loss due to damage shall describe those costs quantitatively and/or qualitatively depending on what information is available. Cost of / loss due to damage within different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage. As far as possible, it would be useful to separate costs of / loss due to the organism from costs of current management.

<b>RESPONSE</b>	minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	--	-------------------	-----------------------

Response:

**Qu. 4.10. How great is the economic cost of / loss due to damage (excluding costs of management) of the organism currently in the risk assessment area (include any past costs in your response)?**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the EU these should be reported here. Assessment of the potential costs of damage on human health, safety, and the economy, including the cost of non-action. A full economic assessment at EU scale might not be possible, but qualitative data or different case studies from across the EU (or third countries if relevant) may provide useful information to inform decision making. In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable). Cost of / loss due to damage within different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

### **Social and human health impacts**

**Qu. 4.14. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism for the risk assessment area and for third countries, if relevant (e.g. with similar eco-climatic conditions).**

The description of the known impact and the assessment of potential future impact on human

health, safety and the economy, shall, if relevant, include information on

- illnesses, allergies or other affections to humans that may derive directly or indirectly from a species;
- damages provoked directly or indirectly by a species with consequences for the safety of people, property or infrastructure;
- direct or indirect disruption of, or other consequences for, an economic or social activity due to the presence of a species.

Social and human health impacts can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>	minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high

Response:

<b>RISK SUMMARIES</b>			
	<b>RESPONSE</b>	<b>CONFIDENCE</b>	<b>COMMENT</b>
<b>Summarise Introduction and Entry*</b>	very unlikely unlikely moderately likely likely very likely	low medium high	Provide a comprehensive short summary of your response to Questions 1.8-1.9.
<b>Summarise Establishment*</b>	very unlikely unlikely moderately likely likely very likely	low medium high	Provide a comprehensive short summary of your response to Questions 3.13-3.14.
<b>Summarise Spread*</b>	very slowly slowly moderately rapidly very rapidly	low medium high	Provide a comprehensive short summary of your response to Questions 4.11-4.12.
<b>Summarise Impact*</b>	minimal minor moderate major massive	low medium high	Provide a comprehensive short summary of your response to Question 5.19-5.20.
<b>Conclusion of the risk assessment (overall risk)</b>	low moderate high	low medium high	The combination of specific elements (scores) of a risk assessment into a final overall score is difficult. There is no accepted or agreed (or correct) formula or decision protocol for this final step. This risk assessment template uses many different sources of information to deliver assessment scores along the invasion continuum (introduction, entry, establishment, spread, impact), which are not necessarily equal. The conclusion of the risk assessment, however, needs to match the scores of the specific elements in a consistent and sensible way and requires justification of the overall risk.

\*in current climate conditions and in foreseeable future climate conditions

## **ANNEX I Scoring of Likelihoods of Events**

(taken from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

<b>Score</b>	<b>Description</b>	<b>Frequency</b>
Very unlikely	This sort of event is theoretically possible, but is never known to have occurred and is not expected to occur	1 in 10,000 years
Unlikely	This sort of event has occurred somewhere at least once in the last millenium	1 in 1,000 years
Moderately Likely	This sort of event has occurred somewhere at least once in the last century	1 in 100 years
Likely	This sort of event has happened on several occasions elsewhere, or on at least once in the last decade	1 in 10 years
Very likely	This sort of event happens continually and would be expected to occur	Once a year

## **ANNEX II Scoring of Magnitude of Impacts**

(modified from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

<b>Score</b>	<b>Biodiversity and ecosystem impact</b>	<b>Ecosystem Services impact</b>	<b>Economic impact (Monetary loss and response costs per year)</b>	<b>Social and human health impact, and other impacts</b>
	<i>Question 5.1-5</i>	<i>Question 5.6-8</i>	<i>Question 5.9-13</i>	<i>Question 5.14-18</i>
Minimal	Local, short-term population loss, no significant ecosystem effect	No services affected <sup>5</sup>	Up to 10,000 Euro	No social disruption. Local, mild, short-term reversible effects to individuals.
Minor	Some ecosystem impact, reversible changes, localised	Local and temporary, reversible effects to one or few services	10,000-100,000 Euro	Significant concern expressed at local level. Mild short-term reversible effects to identifiable groups, localised.
Moderate	Measureable long-term damage to populations and ecosystem, but reversible; little spread, no extinction	Measureable, temporary, local and reversible effects on one or several services	100,000-1,000,000 Euro	Temporary changes to normal activities at local level. Minor irreversible effects and/or larger numbers covered by reversible effects, localised.
Major	Long-term irreversible ecosystem change, spreading beyond local area	Local and irreversible or widespread and reversible effects on one / several services	1,000,000-10,000,000 Euro	Some permanent change of activity locally, concern expressed over wider area. Significant irreversible effects locally or reversible effects over large area.
Massive	Widespread, long-term population loss or extinction, affecting several species with serious ecosystem effects	Widespread and irreversible effects on one / several services	Above 10,000,000 Euro	Long-term social change, significant loss of employment, migration from affected area. Widespread, severe, long-term, irreversible health effects.

<sup>5</sup> Not to be confused with “no impact”.

### **ANNEX III Scoring of Confidence Levels**

(modified from Bacher et al. 2017)

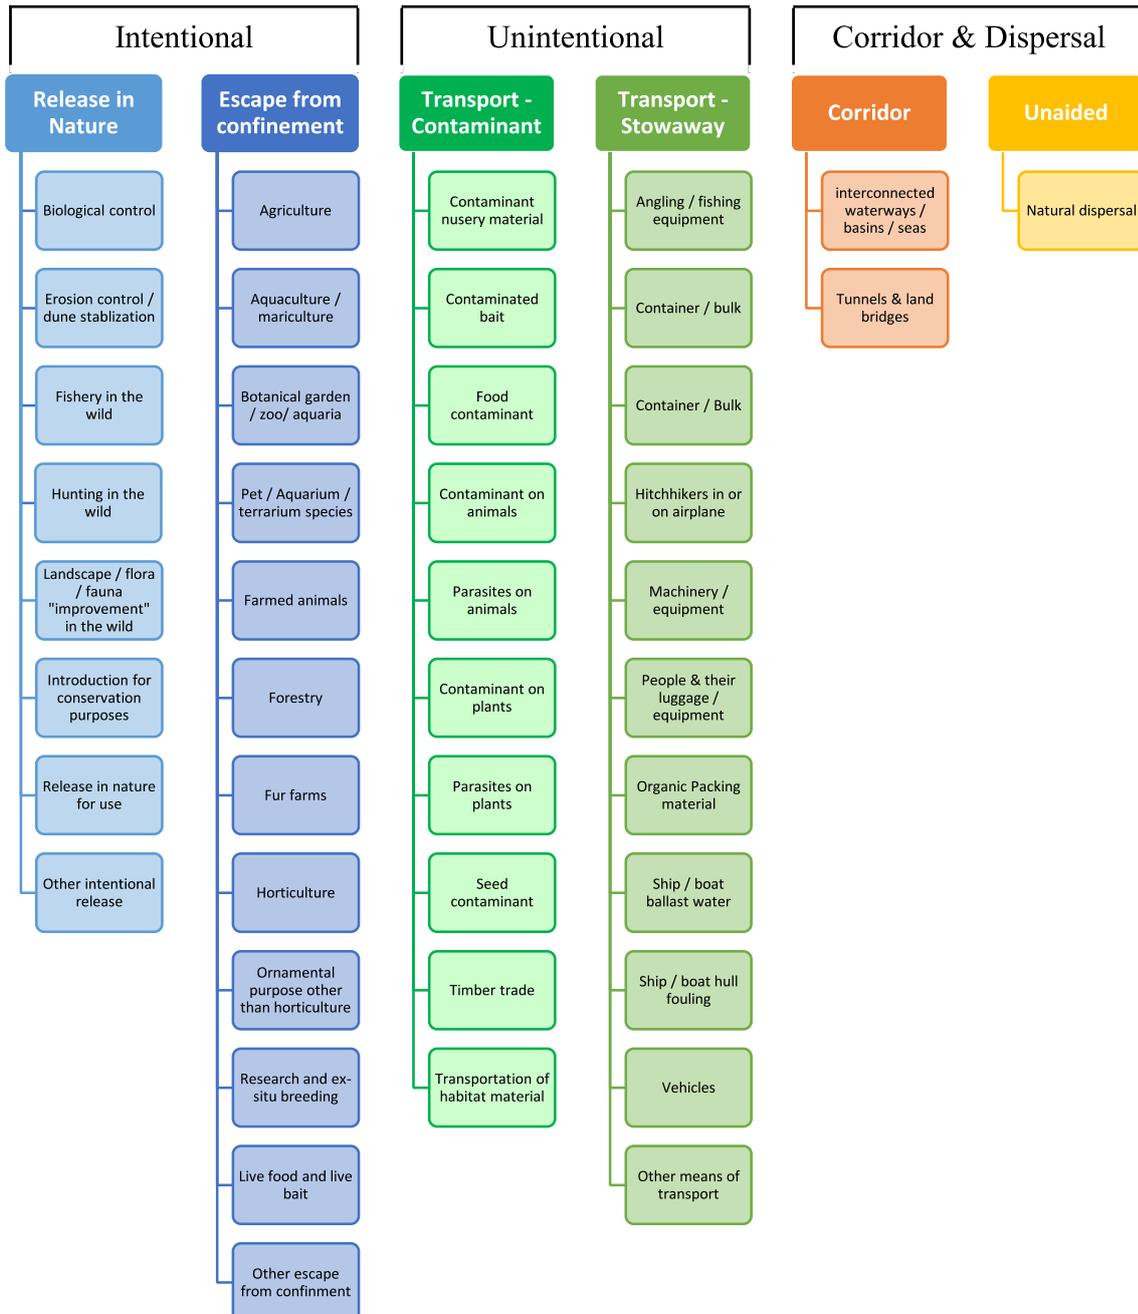

Each answer provided in the risk assessment must include an assessment of the level of confidence attached to that answer, reflecting the possibility that information needed for the answer is not available or is insufficient or available but conflicting.

The responses in the risk assessment should clearly support the choice of the confidence level.

<b>Confidence level</b>	<b>Description</b>
Low	There is no direct observational evidence to support the assessment, e.g. only inferred data have been used as supporting evidence <i>and/or</i> Impacts are recorded at a spatial scale which is unlikely to be relevant to the assessment area <i>and/or</i> Evidence is poor and difficult to interpret, e.g. because it is strongly ambiguous <i>and/or</i> The information sources are considered to be of low quality or contain information that is unreliable.
Medium	There is some direct observational evidence to support the assessment, but some information is inferred <i>and/or</i> Impacts are recorded at a small spatial scale, but rescaling of the data to relevant scales of the assessment area is considered reliable, or to embrace little uncertainty <i>and/or</i> The interpretation of the data is to some extent ambiguous or contradictory.
High	There is direct relevant observational evidence to support the assessment (including causality) <i>and</i> Impacts are recorded at a comparable scale <i>and/or</i> There are reliable/good quality data sources on impacts of the taxa <i>and</i> The interpretation of data/information is straightforward <i>and/or</i> Data/information are not controversial or contradictory.

## ANNEX IV CBD pathway categorisation scheme

Overview of CBD pathway categorisation scheme showing how the 44 pathways relate to the six main pathway categories. All of the pathways can be broadly classified into 1) those that involve intentional transport (blue), 2) those in which the taxa are unintentionally transported (green) and 3) those where taxa moved between regions without direct transportation by humans and/or via artificial corridors (orange and yellow). **Note that the pathways in the category “Escape from confinement” can be considered intentional for the introduction into the risk assessment area and unintentional for the entry into the environment.**

## ANNEX V Ecosystem services classification (CICES V5.1, simplified) and examples

For the purposes of this risk assessment, please feel free to use what seems as the most appropriate category / level / combination of impact (Section – Division – Group), reflecting information available.

Section	Division	Group	Examples (i.e. relevant CICES “classes”)
Provisioning	Biomass	<b>Cultivated <i>terrestrial</i> plants</b>	Cultivated terrestrial plants (including fungi, algae) grown for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from cultivated plants, fungi, algae and bacteria for direct use or processing (excluding genetic materials); Cultivated plants (including fungi, algae) grown as a <u>source of energy</u>  <i>Example: negative impacts of non-native organisms to crops, orchards, timber etc.</i>
		<b>Cultivated <i>aquatic</i> plants</b>	Plants cultivated by in- situ aquaculture grown for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from in-situ aquaculture for direct use or processing (excluding genetic materials); Plants cultivated by in- situ aquaculture grown as an <u>energy source</u> .  <i>Example: negative impacts of non-native organisms to aquatic plants cultivated for nutrition, gardening etc. purposes.</i>
		<b>Reared animals</b>	Animals reared for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from reared animals for direct use or processing (excluding genetic materials); Animals reared to provide <u>energy</u> (including mechanical)  <i>Example: negative impacts of non-native organisms to livestock</i>
		<b>Reared <i>aquatic</i> animals</b>	Animals reared by in-situ aquaculture for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from animals grown by in-situ aquaculture for direct use or processing (excluding genetic materials); Animals reared by in-situ aquaculture as an <u>energy source</u>  <i>Example: negative impacts of non-native organisms to fish farming</i>
		<b>Wild plants (terrestrial and aquatic)</b>	Wild plants (terrestrial and aquatic, including fungi, algae) used for <u>nutrition</u> ; <u>Fibres and other materials</u> from wild plants for direct use or processing (excluding genetic materials); Wild plants (terrestrial and aquatic, including fungi, algae) used as a <u>source of energy</u>  <i>Example: reduction in the availability of wild plants (e.g. wild berries, ornamentals) due to non-native organisms (competition, spread of disease etc.)</i>
	<b>Wild animals (terrestrial and aquatic)</b>	Wild animals (terrestrial and aquatic) used for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from wild animals for direct use or processing (excluding genetic materials); Wild animals (terrestrial and aquatic) used as a <u>source of energy</u>  <i>Example: reduction in the availability of wild animals (e.g. fish stocks, game) due to non-native organisms (competition, predations, spread of disease etc.)</i>	
	<b>Genetic material from all biota</b>	<b>Genetic material from plants, algae or fungi</b>	<u>Seeds, spores and other plant materials</u> collected for maintaining or establishing a population; Higher and lower plants (whole organisms) used to <u>breed new strains or varieties</u> ; Individual genes extracted from higher and lower plants for the

			<p><u>design and construction of new biological entities</u></p> <p><i>Example: negative impacts of non-native organisms due to interbreeding</i></p>
		<b>Genetic material from animals</b>	<p>Animal material collected for the purposes of maintaining or establishing a population; Wild animals (whole organisms) used to breed new strains or varieties; Individual genes extracted from organisms for the design and construction of new biological entities</p> <p><i>Example: negative impacts of non-native organisms due to interbreeding</i></p>
	<b>Water<sup>6</sup></b>	<b>Surface water</b> used for nutrition, materials or energy	<p>Surface water for <u>drinking</u>; Surface water used as a material (<u>non-drinking purposes</u>); Freshwater surface water, coastal and marine water used as an <u>energy source</u></p> <p><i>Example: loss of access to surface water due to spread of non-native organisms</i></p>
		<b>Ground water</b> for used for nutrition, materials or energy	<p>Ground (and subsurface) water for <u>drinking</u>; Ground water (and subsurface) used as a material (<u>non-drinking purposes</u>); Ground water (and subsurface) used as an <u>energy source</u></p> <p><i>Example: reduced availability of ground water due to spread of non-native organisms and associated increase of ground water consumption by vegetation.</i></p>
<b>Regulation &amp; Maintenance</b>	<b>Transformation</b> of biochemical or physical inputs to ecosystems	<b>Mediation of wastes or toxic substances</b> of anthropogenic origin by living processes	<p><u>Bio-remediation</u> by micro-organisms, algae, plants, and animals; <u>Filtration/sequestration/storage/accumulation</u> by micro-organisms, algae, plants, and animals</p> <p><i>Example: changes caused by non-native organisms to ecosystem functioning and ability to filtrate etc. waste or toxics</i></p>
		<b>Mediation of nuisances</b> of anthropogenic origin	<p><u>Smell reduction; noise attenuation; visual screening</u> (e.g. by means of green infrastructure)</p> <p><i>Example: changes caused by non-native organisms to ecosystem structure, leading to reduced ability to mediate nuisances.</i></p>
	<b>Regulation</b> of physical, chemical, biological conditions	<b>Baseline flows and extreme event</b> regulation	<p>Control of <u>erosion</u> rates; Buffering and attenuation of <u>mass movement</u>; <u>Hydrological cycle and water flow regulation</u> (Including flood control, and coastal protection); <u>Wind</u> protection; <u>Fire</u> protection</p> <p><i>Example: changes caused by non-native organisms to ecosystem functioning or structure leading to, for example, destabilisation of soil, increased risk or intensity of wild fires etc.</i></p>
		<b>Lifecycle maintenance, habitat and gene pool</b> protection	<p><u>Pollination</u> (or 'gamete' dispersal in a marine context); <u>Seed dispersal</u>; Maintaining <u>nursery populations and habitats</u> (Including gene pool protection)</p> <p><i>Example: changes caused by non-native organisms to the abundance and/or distribution of wild pollinators; changes to the availability / quality of nursery habitats for fisheries</i></p>
	<b>Pest and disease control</b>	<p>Pest control; Disease control</p> <p><i>Example: changes caused by non-native organisms to the</i></p>	

<sup>6</sup> Note: in the CICES classification provisioning of water is considered as an abiotic service whereas the rest of ecosystem services listed here are considered biotic.

			abundance and/or distribution of pests
		<b>Soil quality</b> regulation	<p><u>Weathering processes</u> and their effect on soil quality;  <u>Decomposition and fixing processes</u> and their effect on soil quality</p> <p><i>Example: changes caused by non-native organisms to vegetation structure and/or soil fauna leading to reduced soil quality</i></p>
		<b>Water</b> conditions	<p>Regulation of the <u>chemical condition</u> of freshwaters by living processes;  Regulation of the chemical condition of salt waters by living processes</p> <p><i>Example: changes caused by non-native organisms to buffer strips along water courses that remove nutrients in runoff and/or fish communities that regulate the resilience and resistance of water bodies to eutrophication</i></p>
		<b>Atmospheric</b> composition and conditions	<p>Regulation of <u>chemical composition</u> of atmosphere and oceans;  Regulation of <u>temperature and humidity</u>, including ventilation and transpiration</p> <p><i>Example: changes caused by non-native organisms to ecosystems' ability to sequester carbon and/or evaporative cooling (e.g. by urban trees)</i></p>
<b>Cultural</b>	<b>Direct, in-situ and outdoor interactions</b> with living systems that depend on presence in the environmental setting	<b>Physical and experiential</b> interactions with natural environment	<p>Characteristics of living systems that enable activities promoting health, recuperation or enjoyment through <u>active or immersive interactions</u>;</p> <p>Characteristics of living systems that enable activities promoting health, recuperation or enjoyment through <u>passive or observational interactions</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that make it attractive for recreation, wild life watching etc.</i></p>
		<b>Intellectual and representative</b> interactions with natural environment	<p>Characteristics of living systems that enable <u>scientific investigation</u> or the creation of traditional ecological knowledge;</p> <p>Characteristics of living systems that enable <u>education and training</u>;</p> <p>Characteristics of living systems that are resonant in terms of <u>culture or heritage</u>;</p> <p>Characteristics of living systems that enable <u>aesthetic experiences</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have cultural importance</i></p>
	<b>Indirect, remote, often indoor interactions</b> with living systems that do not require presence in the environmental setting	<b>Spiritual, symbolic</b> and other interactions with natural environment	<p>Elements of living systems that have <u>symbolic meaning</u>;</p> <p>Elements of living systems that have <u>sacred or religious meaning</u>;</p> <p>Elements of living systems used for <u>entertainment or representation</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have sacred or religious meaning</i></p>
		Other biotic characteristics that have a <b>non-use value</b>	<p>Characteristics or features of living systems that have an <u>existence value</u>;</p> <p>Characteristics or features of living systems that have an <u>option or bequest value</u></p> <p><i>Example: changes caused by non-native organisms to ecosystems designated as wilderness areas, habitats of endangered species etc.</i></p>

### References

## **Guidelines for Completing the Annex**

1 Provide a brief summary description of the most cost-effective methods drawing on the reviews in the detailed assessments

2 Provide a description of the potential method. This should be based on the available key scientific evidence which should be gathered from sources including articles and reviews in technical and scientific journals, internet searches, online databases, grey literature and relevant books and personal communications from scientists, stakeholders, conservation practitioners and governmental bodies. This information should include a full bibliographic list detailing the literature and sources considered.

3 Provide an assessment of the likely cost and effectiveness of the method. Where information is available, consider the following range of questions, accepting that not all questions will be appropriate in all circumstances.

- How effective has this approach proven to be in the past or in an analogous situation?
- How publically acceptable is the approach likely to be?
- Over what period of time would this approach need to be applied to be effective?
- What is the direct cost of implementing this approach?
- How likely are the methods used in the approach to be available?
- How likely is it that relevant licences or other approvals to undertake the approach would be difficult to obtain?
- How likely is it that health and safety issues would prevent the use of this approach?
- How significant is the environmental harm caused by this approach?
- How significant is the economic harm caused by this approach?
- How significant is the social harm caused by this approach?
- How likely is it that the approach will be criticised on welfare grounds?
- How likely is it that the approach will be acceptable to other stakeholders?

Where available, factual information on the costs of specialist equipment, or case studies of management costs from across the Union or third countries should be provided. When describing case studies, if the information is available then provide both total cost and the area over which control was undertaken so that a cost per unit area might be derived. Where such quantitative information is not available, then any qualitative information from the literature is acceptable to help guide decision making. It is accepted that in the majority of cases the information required to assess the potential total cost of management at a member state level is unlikely to be available. This would normally require information on the extent and abundance of the species which is beyond the scope of this assessment. Assessors are not expected to extrapolate the potential total costs of management at a member state level, only to report on the information provided within the literature.

4 Provide an overall assessment of the confidence that can be applied to the information provided for this method. This confidence should relate to the quality of the available information using the guidance below. It should NOT relate to the confidence in the effectiveness of the method

The confidence scores are:

- High: Information comes from published material, or current practices based on expert experience applied in one of the EU countries or third country with similar environmental, economic and social conditions.
- Medium: Information comes from published data or expert opinion, but it is not commonly applied, or it is applied in regions that may be too different from Europe (e.g. tropical regions) to guarantee that the results will be transposable.
- Low: data are not published in reliable information sources and methods are not commonly practiced or are based solely on opinion; This is for example the case of a novel situation where there is little evidence on which to base an assessment.

If there are further factors beyond these that have determined the chosen level of confidence, then provide a brief written description to support the choice of the level of confidence.

5 Measures for preventing the species being introduced intentionally or unintentionally into the territory of a Member State (cf. Articles 7(1)(a), 7(2), 13, 15), i.e. preventing a species entering by blocking its pathways, including pre-border prevention and prevention of escape or release into the environment and secondary spread whenever relevant. Measures for preventing the species reproducing while in containment should be included, if appropriate. Consider all methods that might be applied, including any that have not proven useful. Provide a description of each method in turn, using separate rows to consider each method.

6 Measures to run an effective surveillance system for achieving an early detection of a new occurrence (cf. Article 16). This section assumes that the species is not currently present in a Member State, or part of a Member State's territory.

7 Measures to achieve eradication. Preferably, but not exclusively, used at an early stage of invasion, after an early detection of a new occurrence (cf. Article 17). Consider all methods that might be applied, including any that have not proven useful. Provide a description of each method in turn, using separate rows to consider each method.

8 Measures to achieve management of the species once it has become widely spread within a Member State territory (cf. Article 19). These measures can be aimed at eradication, population control or containment of a population of the species. Consider all methods that might be applied, including any that have not proven useful. Provide a description of each method in turn, using separate rows to consider each method.

The development and completion of this template forms part of the EU project No 07.0202/2020/834529/ETU/ENV.D.2 Study on Invasive Alien Species – Development of risk assessments to tackle priority species and enhance prevention.

## **ANNEXES TO THIS FINAL REPORT**

**Risk assessment template developed under the "Study on Invasive Alien Species –  
Development of risk assessments to tackle priority species and enhance prevention"  
Contract No 07.0202/2020/834529/ETU/ENV.D.2<sup>1</sup>**

**Name of organism:** *Bipalium kewense* Moseley, 1878

**Author(s) of the assessment:**

Leigh Winsor, College of Science and Engineering, James Cook University, Townsville, QLD,  
Australia

Archie K. Murchie, Agri-Food & Biosciences Institute, Belfast, BT9 5PX

Jean-Lou Justine, ISYEB (Institut de Systématique, Évolution, Biodiversité), Muséum National  
d'Histoire Naturelle, Paris, France

Björn Beckmann, Centre for Ecology & Hydrology, Penicuik, EH26 0QB

**Risk Assessment Area:** The risk assessment area is the territory of the European Union 27 and the  
United Kingdom, excluding the EU-outermost regions.

**Peer review 1:** Dr Richard Shaw, CABI, Egham, UK

**Peer review 2:** Dr Brian Boag, James Hutton Institute, Invergowrie Dundee, UK

**Date of completion:** 15/10/2021

---

<sup>1</sup> This template is based on the Great Britain non-native species risk assessment scheme (GBNNRA). A number of amendments have been introduced to ensure compliance with Regulation (EU) 1143/2014 on IAS and relevant legislation, including the Delegated Regulation (EU) 2018/968 of 30 April 2018, supplementing Regulation (EU) No 1143/2014 of the European Parliament and of the Council with regard to risk assessments in relation to invasive alien species (see <https://eur-lex.europa.eu/legal-content/en/TXT/?uri=CELEX%3A32018R0968> ).

## SECTION A – Organism Information and Screening

### **A1. Identify the organism. Is it clearly a single taxonomic entity and can it be adequately distinguished from other entities of the same rank?**

including the following elements:

- the taxonomic family, order and class to which the species belongs;
- the scientific name and author of the species, as well as a list of the most common synonym names;
- names used in commerce (if any)
- a list of the most common subspecies, lower taxa, varieties, breeds or hybrids

As a general rule, one risk assessment should be developed for a single species. However, there may be cases where it may be justified to develop one risk assessment covering more than one species (e.g. species belonging to the same genus with comparable or identical features and impact). It shall be clearly stated if the risk assessment covers more than one species, or if it excludes or only includes certain subspecies, lower taxa, hybrids, varieties or breeds (and if so, which subspecies, lower taxa, hybrids, varieties or breeds). Any such choice must be properly justified.

Response:

*Bipalium kewense* Moseley, 1868

Phylum Platyhelminthes, Class Rhabditophora, Order Tricladida, Sub-Order Continenticola, Family Geoplanidae, Subfamily Rhynchodeminae

Synonyms: *Bipalium kewense* Moseley var *viridis* Lehnert; *Placocephalus kewensis* (Moseley, 1878), *Placocephalus isabellinus* Geba, 1909; *Bipalium costaricensis* Hyman, 1939. A comprehensive synonymy is available (Winsor, 1983).

The organism is a single taxonomic entity. There are no known valid varieties, breeds, or hybrids. COI sequences for *Bipalium kewense* suggest that it is clonal, with identical molecular records from several continents (Justine *et al.*, 2018).

Common names: Kew flatworm, Shovel-headed Garden worm; Hammerhead flatworm; Hamerhoofdlandplatworm (NL); Hammerhaidwurm (DE).

### **A2. Provide information on the existence of other species that look very similar [that may be detected in the risk assessment area, either in the environment, in confinement or associated with a pathway of introduction]**

Include both native and non-native species that could be confused with the species being assessed, including the following elements:

- other alien species with similar invasive characteristics, to be avoided as substitute species (in this case preparing a risk assessment for more than one species together may be considered);
- other alien species without similar invasive characteristics, potential substitute species;
- native species, potential misidentification and mis-targeting

Response:

*Bipalium kewense* is a long, thin flatworm, whose body shape is characterized by a typical “hammerhead” (see Figure 1, *Bipalium kewense* from Townsville, tropical north Queensland, Australia Life size). Living specimens may attain a length of up to 450 mm. The dorsal ground colour is usually a light ochre, with five black to grey-brown-coloured longitudinal stripes: a median, paired lateral, and paired marginal stripes which all begin at or near the base of the headplate where the latter joins the body at the “neck”. The headplate is usually the same colour as the body, or slightly darker, with recurved posterior margins. The median stripe is black, narrow, with sharp margins, extending caudally from below the neck over the entire body length, and is broadest over the pharyngeal area. Paired dark to pale brown-coloured lateral stripes with diffuse margins, constant over the entire body length, are separated from the median and marginal stripes by an equal width of ground colour. The paired black, fine, marginal stripes, with sharp margins, extend the entire body length. The paired lateral and marginal stripes unite just behind the neck to form an incomplete black transverse neck band, interrupted dorsally by a small median gap, and ventrally by the creeping sole. The headplate is a greyish colour with a light ochre margin. The ventral surface is a light ochre colour, with a distinct off-white creeping sole, delineated by paired, narrow, longitudinal diffuse grey-violet stripes beginning at the ventral termination of the collar, and extending the entire body length (Justine *et al.*, 2018). Variations observed in the external morphology of *B. kewense* have been described by Winsor (1983a). A specimen 450 mm long, and 7.6 mm wide weighed 1.5 g (Daly *et al.*, 1976). Juvenile specimens hatched from an egg cocoon have the same dark collar and paired dorsal medio-lateral stripes as the adults, some may exhibit a dark mid-dorsal stripe, but do not exhibit the paired marginal stripes. The headplate is lightly coloured, darker around the anterior margin; the mass of juveniles varied from 7.5 mg – 14.7 mg (Ducey *et al.*, 2006). The ground colour and darker longitudinal stripes of juveniles develop further with age.

The egg capsule or cocoon of *B. kewense* measures 5 – 6 mm diameter in two successive lays over a week (specimen from New Orleans, Louisiana, USA, Connella and Stern, 1969), and 9.5 mm diameter declining to 3 mm diameter in nine successive lays over 103 days from a single copulation, with cocoons 3 mm - 6 mm sterile (specimen from Charters Towers, Queensland, Australia, Winsor, 1984, unpubl.). The cocoon wall is stabilized by quinone tanning on exposure to air, usually within 24 hours changing in colour from lemon when freshly laid by the planarian through cherry-red, tan, dark brown then black, as has been described for species in all the subfamilies of the Geoplanidae (Winsor, 1998).

Morphologically, *B. kewense* is differentiated externally from similar striped species by the incomplete (or interrupted) black transverse band at the neck (the “collar”), the thin dorsal median longitudinal stripe that begins at or below the transverse neck band, the pattern and form of the dorsal and ventral stripes, and the relative position of body apertures. A detailed comparison with similar bipaliine taxa is provided elsewhere (Winsor 1983a; Justine *et al.*, 2018).

*Bipalium kewense* cannot be confused with any native European land flatworm species as none of the latter possess the characteristic bipaliine headplate (hammerhead). The species can be confused with *Diversibipalium multilineatum*, another five striped bipaliine species originally from Japan (Kawakatsu *et al.*, 2001), with similar characteristics, also recorded in Europe (Justine *et al.*, 2018). Corrêa (1947) considered that the juvenile *B. kewense* of Arndt (1934, Fig. 5a) collected from the Berlin Botanic Gardens to be a *Dolichoplana* (Rhynchodemini), because juvenile *B. kewense* have a headplate the same as an adult specimen and are not tapered anteriorly as in species of *Dolichoplana*. Following examination of the specimen it was later identified as *Dolichoplana feildeni* (syn *D. striata*), a non-bipaliine species alien in Europe (Winsor, 1983a).

**A3. Does a relevant earlier risk assessment exist? Give details of any previous risk assessment, including the final scores and its validity in relation to the risk assessment area.**

Response:

There are no qualitative or quantitative risk assessments available for this species.

**A4. Where is the organism native?**

including the following elements:

- an indication of the continent or part of a continent, climatic zone and habitat where the species is naturally occurring.
- if applicable, indicate whether the species could naturally spread into the risk assessment area

Response:

The natural range of *Bipalium kewense*, appears to extend from northern Vietnam south to Cambodia. There is some uncertainty in determining the likely natural range of *B. kewense*, and the co-occurrence of other Bipaliine species assists in differentiating areas of possible natural occurrences from areas where the species may have been introduced. Records of non-sexual specimens in Malaysia and Indonesia may represent southern extensions in this species natural range (Winsor, 1983a). Records from Thailand may represent the western extension of its range. All the records of *B. kewense* in Singapore appear to be from urban locations and are possibly introductions.

Based upon the occurrence of sexual and non-sexual specimens of *B. kewense* obtained from the central highlands of Vietnam at 1300 – 2000 m elevation, where they were found together with a suite

of species of Bipaliinae with similar occurrences, de Beauchamp (1939, 1961) considered that *B. kewense* originated from Vietnam. At that time, this area was relatively remote, with an average density of under 10 inhabitants per sq. km, areas of which were used for big game hunting, with a tea plantation at 1500 m, and coffee plantation at 600 m (Stuttard, 1943), and within the area of the natural occurrence of the Bipaliinae that extends throughout the Indomalayan zoogeographic realm. Non-sexual specimens have also been recorded in Ninh Binh, northern Vietnam.

The Central Highlands region in Vietnam is characterized by a Tropical Monsoon climate (“Am” in the Köppen-Geiger climate classification), and most months in the year are marked by significant rainfall, with a short dry season. The minimum temperatures range from 14.5°C (January) to 18.7°C (May), and maximum temperatures range from 23.5°C (November) to 27.1 °C (March), with precipitation ranging from 27 mm (February) to 297 mm (September), with about 2161 mm annually (data for Dalat at 1,486 m elevation from Climate-data.org 2020). Lower temperatures would be expected at the higher altitudes around 2000 m elevation. Seasonal evaporation in the highlands is dependent upon the relative humidity, cloudiness, and winds. The high plateaux of Vietnam that include the Biosphere Reserve Lang Bien, are characterized by local winds that differ in their excessive aridity from the general character of the monsoon (Stoddard, 1943).

Several forest systems are present in the area, the composition of which depends upon altitude, aspect, soil nutrients, and other factors. The vegetation of the area is characterized as lower montane forests (1000 m – 1800 m elevation) (Tran Van Do *et al.*, 2017). The plant family best represented in the upper canopy of these forests is the Fagaceae, together with the Magnoliaceae, Aceraceae, Podocarpaceae, Lauraceae, and Theaceae. The diversity of conifers is high in montane forests, with five genera present (*Podocarpus* sensu latu., *Calocedrus*, *Fokienia*, *Cephalotaxus*, and *Taxus*). Several important endemic species are present, including *Pinus dalatensis* and *P. krempfii*. Epiphytes form a notable part of the biodiversity of these montane forests. There is high diversity of the orchids in the upper canopy and ferns in the middle and lower canopy. *Pinus kesiya* extends over a broad range of montane areas of the Dalat Plateau and other uplands in southern Vietnam at elevations up to 1,800 m (World Wildlife Fund <https://www.worldwildlife.org/ecoregions/im0152>).

Unfortunately, detailed habitat data for the few records within the natural range are lacking. Of the two records from Thailand, one was from secondary rainforest, and the other unknown. The climate of both locations (Sihanoukville and Chumphon) is similar to those in Vietnam, characterized by a Tropical Monsoon climate (“Am” in the Köppen-Geiger climate classification), and most months in the year are marked by significant rainfall, with a short dry season. The sole location in Cambodia (Ream, Surat Thani) has a Tropical Savannah climate (“Aw” in the Köppen-Geiger climate classification), characterized a monthly mean temperature above 18°C in every month of the year and typically a pronounced dry season, with the driest month having precipitation less than 60mm. In essence, a tropical savanna climate tends to either see less rainfall than a tropical monsoon climate or have more pronounced dry seasons than a tropical monsoon climate. The Tropical Savannah climate are most commonly found in Africa, Asia and South America and is also prevalent in sections of Central America, northern Australia and North America, specifically in sections of Mexico and the state of Florida in the US (<https://www.weatherbase.com/weather/weather-summary.php3?s=66984&cityname=Siem+Reap,+Cambodia> ) retrieved 24 June 2021 (*B. kewense*, as an alien species, is recorded outdoors in all these countries).

*Bipalium kewense*, like all land planarians, is sensitive to moisture and atmospheric humidity. Land planarians have practically no water-saving adaptations, being dependent upon moisture in their

microhabitat, yet are sensitive to too much water and thus generally avoid wet places. Flatworms are mostly strongly seasonal in occurrence, probably reflecting attempts to maintain themselves within a constant microclimate by vertical migration through the continuum of habitat niches, between one extreme with those of the litter and soil faunas, and the other extreme with the faunas of rocks and trees (Wallwork, 1970). When the moisture conditions are optimal or too wet, and cover is present, they will occupy the cryptozoic and litter microhabitats on the soil surface and may even venture up trees. When conditions are too dry for them, they retreat into the soil. In the absence of surface cover terrestrial flatworms can live entirely in soil as permanent members of the soil fauna and can be generally regarded as facultative soil animals. Most species appear not to burrow but make use of existing pore spaces to migrate within the soil (Winsor *et al.*, 1998). Land planarians naturally disperse by creeping on the substrate surface.

Like many species of land planarians, *B. kewense* climbs trees, and given that epiphytic orchids form a notable part in the biodiversity of the montane forests within its natural range (World Wildlife Fund <https://www.worldwildlife.org/ecoregions/im0152>), this could explain the view (Bell, 1886a, 1886b) that it was introduced to Europe by the orchid trade. It could not have spread naturally into the risk assessment area.

**A5. What is the global non-native distribution of the organism outside the risk assessment area?**

Response:

*Bipalium kewense* is undoubtedly the most widespread species of land flatworm worldwide. It was first found in Hong Kong in 1856, then in Australia in 1874, before the species was formally described in 1878 from a specimen found in the hothouse, Kew Gardens, London. It is now recorded in 67 countries outside the risk assessment area. In the United States, the early records were from hothouses on the east coast, and more recent records are from outdoor urban gardens and parks in centres further inland, suggesting acclimatization (Winsor, 1983) The colonizing success of *B. kewense* can largely be attributed to its ability to reproduce asexually by fragmentation (Hyman, 1943, 1951).

When the world distribution of the species was first mapped (Graff, 1899), *B. kewense* had been recorded in eight countries or territories (other than England, Ireland, Germany, and Austria which are in the risk assessment area), namely: Australia, Brazil, Hong Kong, Madeira, New Zealand, Samoa, South Africa, and the United States of America.

With the taxonomic revision of *B. kewense*, and mapping of its distribution worldwide and in the US (Winsor, 1983a), a further 32 countries or territories were added (but excluding four countries in the risk assessment area where it had been recorded): Argentina, Azores autonomous region of Portugal, Barbados, Bermuda, Cambodia, Canada, Cape Verde Islands, Colombia, Costa Rica, El Salvador, Fiji, French Polynesia (Tahiti, Tabuai Islands), Hawaii, India, Indonesia, Israel, Jamaica, Japan, La Reunion, Madagascar, Malaysia, Mauritius, Mexico, Peru, Puerto Rico, Ryukyus Islands, Saint Helena Island, Singapore, Taiwan, Tonga, Vietnam, and Zimbabwe.

Sporadic reports of occurrence of *B. kewense* in a further 30 countries or territories outside of the risk assessment area include: Kenya, China (mainland), the Natuna Islands, Ogasawara Islands of Japan,

Sri Lanka, Thailand, and Uruguay (summarized by Ogren *et al.*, 1992), Pakistan (Justine *et al.*, 2018), Pitcairn Island (Winsor, 1992 unpubl.); Egypt (Ali, 2008); Ecuador (Wizen, 2015); Cuba (Morffe, 2016); Sao Tome (Sluys *et al.*, 2017), Caribbean French Islands (Martinique, Guadeloupe, Saint Barthelemy, Saint Martin, and Monserrat), French Guiana, Monaco, and Pakistan (Justine *et al.*, 2018). Observations and mapped locations of *B. kewense* in iNaturalist <https://www.inaturalist.org/> (individually checked and verified by Winsor in 2021 specifically in preparation for this risk assessment) in new countries outside the risk area include Chile, Galapagos Islands, Nicaragua, and Paraguay (2018); Afghanistan, Guatemala, and Philippines (2020); and Panama (2021).

**A6. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species been recorded and where is it established? The information needs be given separately for recorded (including casual or transient occurrences) and established occurrences.**

**“Established” means the process of an alien species successfully producing viable offspring with the likelihood of continued survival<sup>2</sup>.**

**A6a. Recorded: List regions**

**A6b. Established: List regions**

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

- Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea.

Comment on the sources of information on which the response is based and discuss any uncertainty in the response.

For delimitation of EU biogeographical regions please refer to <https://www.eea.europa.eu/data-and-maps/figures/biogeographical-regions-in-europe-2> (see also Annex VI).

For delimitation of EU marine regions and subregions consider the Marine Strategy Framework Directive areas; please refer to <https://www.eea.europa.eu/data-and-maps/data/msfd-regions-and-subregions/technical-document/pdf> (see also Annex VI).

Response (6a): *Bipalium kewense* is recorded from the Alpine, Atlantic, Continental, and Mediterranean biogeographic regions (see A.8 for references).

Response (6b): *Bipalium kewense* is established outdoors in the Atlantic, Continental, and Mediterranean biogeographic regions (see A.8 for references).

<sup>2</sup> Convention on Biological Diversity, Decision VI/23

**A7. In which biogeographic region(s) or marine subregion(s) in the risk assessment area could the species establish in the future under current climate and under foreseeable climate change? The information needs to be given separately for current climate and under foreseeable climate change conditions.**

**A7a. Current climate: List regions**

**A7b. Future climate: List regions**

With regard to EU biogeographic and marine (sub)regions, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

Response (7a):

Alpine, Atlantic, Black Sea, Continental, Mediterranean, Pannonian and Steppic in the risk assessment area; and in the Anatolian and Macaronesia biogeographic regions (refer to Figures 1 and 2, Annex VIII).

Response (7b):

Under Climate Change with timeframe 2070, and emission scenarios RCP 2.6 and RCP 4.5: Alpine, Atlantic, Black Sea, Continental, Mediterranean, Pannonian and Steppic in the risk assessment area; and in the Anatolian and Macaronesia biogeographic regions (Figure 1 Annex VIII). There are increases in the projected suitability for the establishment of *B. kewense* generally north and northeastwards under both RCP 2.6 and RCP 4.5 in the Atlantic, Black Sea, Continental, Pannonian and Steppic biogeographical regions in the risk assessment area, and in the Anatolian biogeographic region (Figures 3 and 4 Annex VIII). The lower to mid-levels of the Alpine region appear to become increasingly suitable for the establishment of the species under the RCP 2.6 and 4.5 scenarios. For the Mediterranean region, there is little change between the current projected suitability and those under RCP 2.6 and RCP 4.5.

In the Atlantic biogeographical region, Belgium, Denmark, Ireland, the Netherlands, and the United Kingdom contain some of the largest conglomerations of people in Europe, many of whom live near the coast ([https://www.eea.europa.eu/publications/report\\_2002\\_0524\\_154909/biogeographical-](https://www.eea.europa.eu/publications/report_2002_0524_154909/biogeographical-)

[regions-in-europe/the\\_atlantic\\_region.pdf/view](#) retrieved 25 June 2021). In the Continental region countries such as Austria, Czech Republic, Germany, Poland, and Slovakia, the urban areas are among the largest and most extensive in Europe. A large proportion of the population lives in the vicinity of forests. Some new afforestation occurs around big cities for recreational purposes ([https://www.eea.europa.eu/publications/report\\_2002\\_0524\\_154909/biogeographical-regions-in-europe/continental\\_biogeographical\\_region.pdf/view](https://www.eea.europa.eu/publications/report_2002_0524_154909/biogeographical-regions-in-europe/continental_biogeographical_region.pdf/view) retrieved 25 June 2021).

In these countries within both the Atlantic and Continental biogeographical regions, *B. kewense* is currently present largely in “protected” environments such as hothouses. Under the climate warming scenarios, there would probably no longer be the need for hothouses in these countries, and there could be a loss of containment of *B. kewense* from “protected” environments into outdoor urban gardens and parks where it could establish in the warmer conditions.

**A8. In which EU Member States has the species been recorded and in which EU Member States has it established? List them with an indication of the timeline of observations. The information needs be given separately for recorded and established occurrences.**

**A8a. Recorded: List Member States**

**A8b. Established: List Member States**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden, and the United Kingdom

The description of the invasion history of the species shall include information on countries invaded and an indication of the timeline of the first observations, establishment and spread.

Response (8a):

*Bipalium kewense* has been recorded in managed facilities (hothouses) in the following Member States:

Austria (Graff, 1893), Belgium (Woestijnje, 1907), Czech Republic (Mrazek, 1902), Denmark (Kirkegaard, 1971), Finland (Söderstrom, 1936), Germany (Graff, 1899), Ireland (Bell, 1892), Netherlands (De Waart, 2016), Poland (Paxa, 1921), Slovakia (Košel, 2002), and the United Kingdom (Moseley, 1878).

*Bipalium kewense* has been recorded in urban gardens and urban environments in the following Member States:

France, including Corsica (Justine *et al.*, 2018), Italy, including Sardinia (Gremigni, 2003), Portugal (Ogren *et al.*, 1992, Silva, 2020), Malta (T. Cassar and D. Mifsud, 2021 unpubl.), Spain (Filella-Subirà, 1983), United Kingdom Glasgow Botanic Gardens and gardens in Sussex and Liverpool (Boag *et al.*, 2010).

*Bipalium kewense* was first recorded in 1877 in the United Kingdom, in the hothouse in Kew Gardens, London (Moseley, 1878). Subsequently in 1866 in Germany, from the orchid house, Botanic Gardens, Berlin (Graff, 1899); Ireland, in the hothouse at Stafford House, Kildare, 1892 (Bell, 1892); Austria, 1893 (Graff, 1893), in a hothouse in Graz; Poland, 1898, in a hothouse, Wroclaw (Paxa, 1921); Czech Republic, 1902, in a greenhouse in Prague (Mrazek, 1902); Belgium 1907 in a hothouse (Woestinje, 1907) Netherlands 1912, in a hothouse (De Waart, 2016), Finland 1935, in a hothouse (Söderstrom, 1936), Denmark, in a hothouse (Kirkegaard, 1971), Spain 1982, in private gardens (Filella-Subirà, 1983), France 1999, in private gardens (Justine *et al.* 2018); Portugal, urban outdoors (Ogren *et al.*, 1992, Silva, 2020); Slovakia, in a hothouse (Košel, 2002), Italy 2021, urban outdoors (Bello *et al.*, 1995, Gremigni, 2003, Mori *et al.* 2021); Malta 2021, in an urban garden (T. Cassar and D. Mifsud, 2021, unpubl.).

Response (8b):

Of the foregoing countries in which *B. kewense* has been recorded, it is present in the following outdoor locations: in a private garden in Malta in 2021 (T. Cassar and D. Mifsud, 2021, unpubl.) in Portugal in private gardens in Mealharda circa 1990 and Gemunde 24 Aug 2020, (Silva, 2021, 2020), numerous outdoor occurrences in France (Justine *et al.*, 2018), in outdoor urban sites and private gardens in Italy, Mori *et al.* (2021), and outdoor locations in Spain, all from private gardens, are taken, in chronological order: Caldes d'Estrac (Barcelona) 1982, Girona (Girona) 1994, Barcelona, 1995, and Bètera (València), 1999 (Álverz-Presas *et al.* (2014).

The most comprehensive recent study of the distribution *B. kewense* is from France (Justine *et al.*, 2018). From metropolitan France, including Corsica, 36 records were obtained, with *B. kewense* established in nine administrative departments; 34 of these records were from outdoor sites, with more than half (16) from the department Pyrénées-Atlantiques. The dates of records ranged from 1999-2017, with the oldest record in the Department of Pyrénées-Atlantiques: “In France, the outdoors occurrence of *B. kewense* was reported in Orthez and Bayonne in 2005 (Vivant 2005), Urcuit in 1999, in Arthez de Béarn, Hasparren, Villefranque, Urt (all in 2014), near Jurançon (2016), Nay (2016) and Saint Jean de Luz (2016), Ustaritz (2017) and in Bayonne and Orthez again (2014). Specimens records were from Saint-Pée-sur-Nivelle (2013), Ustaritz (2014), Bassussary (2014) and Orthez (2014). All these localities are in the Department of Pyrenées-Atlantiques, plus three records from the Department of Landes, north of Pyrenées-Atlantiques, along the Atlantic coast. The remark by Vivant that the animal was collected “five times in the last 20 years”, the record from 1999, and the recent record and specimens in the same locality (Orthez) in 2014 strongly suggests that the species is now established in the open in Orthez and in several localities of the Department of Pyrenées-Atlantiques (Justine *et al.*, 2018). All these records are from gardens, and it is not known whether the species has colonized semi-natural habitats.

Additional unpublished results (2018 - 2021) confirm that the species is well established in France, mainly in the Department of the Pyrénées-Atlantiques (Justine, unpubl, records of *B. kewense* in iNaturalist [https://www.inaturalist.org/observations?place\\_id=any&subview=map&taxon\\_id=64221](https://www.inaturalist.org/observations?place_id=any&subview=map&taxon_id=64221)).

**A9. In which EU Member States could the species establish in the future under current climate and under foreseeable climate change? The information needs to be given separately for current climate and under foreseeable climate change conditions.**

**A9a. Current climate: List Member States**

**A9b. Future climate: List Member States**

With regard to EU Member States, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

Response (9a): Under present climate conditions, *B. kewense* could establish in the following European countries. Figures in brackets are the central estimate of the percentage of the country projected to be suitable in the species distribution model – please note uncertainties around these estimates (Table 3, Annex VIII): Austria (3%), Belgium (70%), Bulgaria (60%), Croatia (76%), Cyprus (100%), France (78%), central Germany (14%), Greece (92%), Hungary (43%), Italy (82%), Luxembourg (60%), Malta (not modelled but deemed suitable), Netherlands (41%), Portugal (100%), southern Romania (18%), Slovakia (2%), Slovenia (28%), Spain (89%), and the United Kingdom (but not northern Scotland) (18%) (refer also to Figures 2 and 5, Annex VIII).

*Bipalium kewense* is established outdoors in the Atlantic and Mediterranean biogeographic regions. In the Atlantic region the area most at risk is the Department of Pyrénées-Atlantiques, France. However, all current records are from gardens, and it is not known whether the species has colonised semi-natural habitats.

In order to model the establishment of *B. kewense* under current climate and under predicted climate change conditions in the 2070s under low and medium emissions scenarios (RCP2.6 and RCP4.5), climate variables based upon the biology of *B. kewense* were selected, and an ensemble model constructed (Annex VIII). The model suggested that the suitability of particular location for the establishment of *B. kewense* was most strongly determined by the minimum temperature of the coldest month in that region, followed by annual precipitation, then the presence of human-disturbed habitats, then the mean temperature of the warmest quarter, followed last by the Climatic Moisture Index for that area. The seasonality of precipitation did not impact on the suitability of an area for the establishment of *B. kewense*.

Response (9b):

Under predicted future warmer climate conditions in the 2070s, *B. kewense* could establish in the following European countries. Figures in brackets are the central estimates of the percentage of each country projected to be suitable in the species distribution model for low (RCP2.6) and medium (RCP4.5) emissions scenarios. Please note uncertainties around these estimates (Table 3, Annex VIII): Austria (30-39%), Belgium (97-98%), Bulgaria (89-94%), Croatia (95-99%), Cyprus (88-50%), Czech Republic (41-81%), southern Denmark (4-7%), France (90-92%), Germany (86-95%), Greece (95-85%), Hungary 100%), Ireland (1%), Italy 88-89%), Luxembourg (100%), Malta (not modelled, but deemed suitable), Netherlands 74-83%), western and central Poland (22-49%), Portugal (100%), Romania (59-75%), Slovakia (45-62%), Slovenia (72-82%), Spain (95-89%), southern coastal Sweden (1%), and the United Kingdom excluding Scotland (38-42%).

Refer to Figures 7(a) Annex VIII illustrating the projected suitability for *Bipalium kewense* establishment in Europe and the Mediterranean region in the 2070s under climate change scenario RCP2.6, and Figure 8(a) Annex VIII showing the projected suitability for *Bipalium kewense* establishment in Europe and the Mediterranean region in the 2070s under climate change scenario RCP4.5.

**A10. Is the organism known to be invasive (i.e. to threaten or adversely impact upon biodiversity and related ecosystem services) anywhere outside the risk assessment area?**

Response:

There is no evidence that the species is invasive (i.e. threatens or adversely impacts upon biodiversity and related ecosystem services) anywhere outside the risk assessment area. However, no studies have been conducted that would support or refute this statement. The data for this species is deficient.

*Bipalium kewense* is a minor pest in a few urban earthworm farms (vermiculture of non-native earthworm species) in New South Wales and in Queensland, Australia (Winsor, 1998) where it is readily removed by handpicking or flooding the beds.

**A11. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea,

Aegean-Levantine Sea

Response:

There is presently no evidence that the species is invasive in the risk assessment areas of the EU (i.e. threatens or adversely impacts upon biodiversity and related ecosystem services). However, no studies have been conducted that would support or refute this statement. The data for this species is deficient.

**A12. In which EU Member States has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden, and the United Kingdom

Response:

There is presently no evidence that the species is invasive in the risk assessment areas of the EU (i.e. threatens or adversely impacts upon biodiversity and related ecosystem services). However, no studies have been conducted that would support or refute this statement. The data for this species is deficient.

**A13. Describe any known socio-economic benefits of the organism.**

including the following elements:

- Description of known uses for the species, including a list and description of known uses in the risk assessment area and third countries, if relevant.
- Description of social and economic benefits deriving from those uses, including a description of the environmental, social and economic relevance of each of those uses and an indication of associated beneficiaries, quantitatively and/or qualitatively depending on what information is available.

If the information available is not sufficient to provide a description of those benefits for the entire risk assessment area, qualitative data or different case studies from across the risk assessment area or third countries shall be used, if available.

Response:

There is evidence that other species alien flatworms have been inadvertently disseminated in potted plants from infected garden centres and botanic gardens to the public or other botanic gardens. This is non-intentional transfer and if known it can adversely affect the reputation of the business or botanic garden concerned (Boag and Neilson, 2014).

*Bipalium kewense* has no known uses outside the research field. It is undoubtedly the most studied species of land planarian and acts as an experimental animal and as an example of a terrestrial flatworm, largely because of its widespread occurrence, size, and availability. There has been, and continues to be, economic benefits from funds directed to research on this organism.

*B. kewense* has been used as the subject of various anatomical and histological studies (Bergendal, 1892; Graff, 1899; Pfitzner, 1958; Hauser, 1966; Silveira, 1969, 1970, 1971, 1972, 1978; Storch and Abraham, 1972; Sun *et al.*, 1975, 1979; Storch and Welsch, 1977), behavioural studies (Lehnert, 1891; Kew, 1900; Barnwell *et al.*, 1964; Barnwell *et al.*, 1965; Barnwell, 1966; Morton and Kleinginna, 1971), biochemical studies (Campbell, 1960, 1965, 1970, 1973; Campbell and Lee, 1963; Reddy and Campbell, 1970; Tramell and Campbell, 1971; Scheid and Awapara, 1972; Phillips and Dresden, 1973; Dresden and Landsperger, 1977), biology (Lehnert, 1891; Johri, 1952; Dundee and Dundee, 1963; Froelich, 1956; Connella and Stern, 1969; Olewine, 1972; Chandler, 1974; Ducey *et al.*, 2006), genomic studies (Gastineau *et al.*, 2019), laboratory maintenance (Barnwell, 1967; Neck, 1987; Olewine and Morton, 1971), physiological studies (Daly and Matthews, 1975, 1982; Daly *et al.*, 1977), pseudoparasitism (Walton and Yokogawa, 1972; Daly *et al.*, 1976, 1977; Winsor, 1980, 1983b), regeneration (Morgan, 1900; Brøndsted, 1969), and toxicology (Arndt, 1925; Stokes *et al.*, 2014).

Understanding the processes of cell proliferation, differentiation and pattern formation in regenerative organisms can help find ways to enhance the poor regenerative abilities shown by many other animals, including humans. Studying regeneration in a relatively simple creature, like a planarian whose neoblasts act as stem cells, can hold important clues into how human cells can be coaxed to behave similarly and help humans regenerate injured or missing tissues. Some of the earliest studies on planarian regeneration used *B. kewense* as the experimental model (Morgan, 1900; Brøndsted, 1969). Progress towards understanding the mechanics of regeneration was hampered by an incomplete understanding of basic cell biology and genetics, in addition to a lack of tools for experimentation, and only recently have significant advances in molecular biology (for example Gastineau *et al.*, 2019 using *B. kewense*), genetics, and sequencing technologies reignited interest in planarians as an attractive model in which to study regeneration (Elliot and Alvarado, 2013).

The social benefits of the knowledge generated by these studies of *B. kewense* are intangible and difficult to quantify, let alone place a monetary value upon them. As such, in economic terms, these studies and their outcomes are regarded as externalities - the overall cost and benefit to society being defined as „the sum of the imputed monetary value of benefits and costs to all parties involved“ (Laffont, 2008). Research and development, and education are examples of such positive externalities (["Externalities - Definition and examples"](#). *Conceptually*. Retrieved 21 June 2021).

## SECTION B – Detailed assessment

### Important instructions:

- In the case of lack of information the assessors are requested to use a standardized answer: “No information has been found.”
- With regard to the scoring of the likelihood of events or the magnitude of impacts see Annexes I and II.
- With regard to the confidence levels, see Annex III.
- Highlight the selected response score and confidence level in **bold** but keep the other scores in normal text (so that the selected score is evident in the final document).

## 1 PROBABILITY OF INTRODUCTION AND ENTRY

### Important instructions:

- **Introduction** is the movement of the species into the risk assessment area (it may be either in captive conditions and/or in the environment, depending on the relevant pathways).
- **Entry** is the release/escape/arrival in the environment, i.e. occurrence in the wild
- Introduction and entry may coincide for species entering through pathways such as “corridor” or “unaided”, but it also may differ. If different, please consider all relevant pathways, both for the introduction into the risk assessment area and the entry in the environment.
- The classification of pathways developed by the Convention of Biological Diversity (CBD) should be used (see Annex IV). For detailed explanations of the CBD pathway classification scheme consult the IUCN/CEH guidance document<sup>3</sup> and the provided key to pathways<sup>4</sup>.
- For organisms which are already present (recorded or established) in the risk assessment area, the likelihood of introduction and entry should be scored as “very likely” by default.
- Repeated (independent) introductions and entries at separate locations in the risk assessment area should be considered here (see Qu. 1.7).

**Qu. 1.1. List relevant pathways through which the organism could be introduced into the risk assessment area and/or enter into the environment. Where possible give details about the specific origins and end points of the pathways as well as a description of any associated commodities.**

For each pathway answer questions 1.2 to 1.7 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 1.2a, 1.3a, etc. and then 1.2b, 1.3b etc. for the next pathway.

In this context a pathway is the route or mechanism of introduction and/or entry of the species.

The description of commodities with which the introduction of the species is generally associated shall include a list and description of commodities with an indication of associated risks (e.g. the

<sup>3</sup> <https://circabc.europa.eu/sd/a/738e82a8-f0a6-47c6-8f3b-aeddb535b83b/TSSR-2016-010%20CBD%20categories%20on%20pathways%20Final.pdf>

<sup>4</sup> <https://circabc.europa.eu/sd/a/0aeba7f1-c8c2-45a1-9ba3-bcb91a9f039d/TSSR-2016-010%20CBD%20pathways%20key%20full%20only.pdf>

volume of trade; the likelihood of a commodity being contaminated or acting as vector).

If there are no active pathways or potential future pathways this should be stated explicitly here, and there is no need to answer the questions 1.2-1.9.

Response:

The main driver of historic biological invasions and the passive dispersal of terrestrial flatworms was probably horticulturalists of the 19th Century using the then recently invented Wardian cases that are wooden hermetically sealed glazed cases, the forerunner of the modern terrarium, named after their inventor Dr Nathaniel Ward designed to safely transport back by sea to the hothouses and gardens of Europe rare plants (Keogh, 2020), together with soil containing cryptic exotic animal species (Winsor *et al.*, 2004, Keogh, 2020). Therefore, over 30 non-native species of land planarians, including *B. kewense*, have established in various countries outside their native range (Winsor *et al.*, 2004). In human-modified habitats, flatworms and their cocoons continue to be associated with rooted and potted plants, rhizomes, and certain types of fresh vegetable produce (Alford *et al.*, 1996). Subsequent secondary dispersal of these invasive flatworm species occurs through the exchange and purchase of plants from nurseries, botanical gardens, garden centres and gardeners (Alford *et al.*, 1996) especially infested nurseries and garden centres (Boag *et al.*, 1994; Moore *et al.*, 1998), and active inadvertent dispersal through social traditions of exchanging plants and recycling topsoil (Christensen and Mather 1998).

The pathways considered in this risk assessment for *B. kewense* are “contaminant nursery material” (unintentional), and “Botanical Garden / Zoos & Aquaria (excluding domestic aquaria)” (unintentional). These two pathways are similar and represent unintentional introduction via trade and movement of living plants.

#### Pathway name: Contaminant nursery material

**Qu. 1.2a. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

This pathway is unintentional. Trade in exotic plants is increasing and landscaping, the process of making a garden or other piece of land more attractive by altering the existing design, adding ornamental features, often requiring potted trees and shrubs, poses a particular risk. Terrestrial flatworms have been intercepted in the UK on plant material, particularly tree ferns (*Dicksonia* spp.), from Australia and New Zealand (Cannon and Baker, 2007; Matthews, 2005). Data from other EU countries on interceptions of terrestrial flatworms on imported products at ports are sparse. *Bipalium kewense* was detected in potted flowering plants (*Agapanthus*) imported from South Africa to France in August 2019 by the authorities of Paris Charles de Gaulle airport. The single specimen was barcoded for molecular confirmation of identification (Justine, 2019 unpubl.)

**Qu. 1.3a. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication.
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

With greater awareness of the problems caused by alien flatworms and more stringent EU plant health legislation under the ‘Plant Health Law’ (Regulation (EU) 2016/2031), the likelihood of entry of alien flatworms should be lessened. However, this is set against increasing international trade in plants (Migliorini *et al.*, 2015), with the value of imported plants for planting increasing by 60% over the past fifteen years (Eschen *et al.*, 2015). The key factor here is the level of importation of potted plants from affected regions. The largest risk to the risk assessment area would be from regions like China (via Hong Kong), Indonesia, Thailand, and Florida in the US, which are producers of potted plants (van Uffelen and de Groot, 2005; EPPO, 2012).

There are no data on *B. kewense* interceptions during plant trade except anecdotal records in France and U.K. only (see Q 1.2a), so an estimate of the propagule pressure is difficult. Experience with other alien flatworms would suggest that the number of individuals would be low and sporadic, with one or two individuals in a contaminated shipment.

Land planarians are hermaphrodite. *Bipalium kewense* can reproduce asexually by fragmentation. The colonizing success of *B. kewense* can largely be attributed to this asexual mode of reproduction (Hyman, 1943, 1951), in which an individual specimen can eventually give rise to a colony through reproduction by fission, as opposed to sexual reproduction that will require another sexually mature individual, and the time and energy expended in searching for this sexual partner.

In the fission process (Barnwell, 1967; Connella and Stern, 1969) one or two portions of the tail section, 1 - 4 cm long (zooids), are shed a few days after the adult fed and are able to crawl. Although fragile, there is the possibility that these zooids, especially given their small size, could pass

undetected and be transported together with potted plants. After several days or weeks, the dropped tail sections (zooids) regenerate so that they grow to become small versions of adult specimens. A regenerating *B. kewense* will not attack and eat earthworms until the head region has completely regenerated into the adult shape. However, the ability of a regenerated *B. kewense* to eat depends primarily upon a regenerated pharynx than a regenerated head (Barnwell, 1966). Adult planarians raised in laboratory terraria shed an average of one or two fragments per month (Connell and Stern, 1969). This average rate of fragment production under laboratory conditions may not be an accurate estimate of fragment production in outdoor environments. Field observations of a *B. kewense* population in Tennessee US revealed few sightings of fragments over a year, with the ratio of fragments to adult specimens was greatest during the cold months (Chandler, 1976).

The likelihood of the introduction of an egg cocoon of *B. kewense* is considered unlikely.

**Qu. 1.4a. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

Within a potted plant or enclosed in a plant’s root ball, *B. kewense* would be in a “protected” environment. The conditions necessary to keep the plant healthy, would presumably match those of the source location and therefore be amenable to *B. kewense*. Cold storage may have an impact on *B. kewense* survival as it is largely a tropical species, albeit originally from the cool central highlands in Vietnam. There are no specific data looking at this, but Barnwell (1969) noted that when the temperature dropped to -6.7°C or -9.4°C, planarians were not found in their usual places, but a few days later when conditions were warmer, they reappeared. He also stated that they could survive temperatures near -17°C, but after temperatures fell below this for several nights in 1966 in Athens, Georgia, US, no *B. kewense* were seen for over two years. The likelihood of survival of adults, egg cocoons and juveniles and fragments will vary with shipment journey time and storage conditions, which will be dependent on the plant product transported.

**Qu. 1.5a. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

	<b>likely</b> very likely		
--	------------------------------	--	--

Response:

Plant health inspection and phytosanitation are the most practical means of preventing invasion by cryptic flatworm species. Legislation in the EU now requires that plants for planting from third countries meet strict criteria. In particular, the growing media must be free from soil or subjected to suitable treatment to ensure freedom from pests (EU Commission Implementing Regulation (EU) 2019/2072). However, legislation is dependent on plant health certification by exporting producers and only a small proportion of the plant trade can be directly inspected by the importing country.

However, as of the 14<sup>th</sup> December 2019, Professional Sellers, Importers / Exporters of plants, and Online / Offline sellers of plants who may sell plants on online platforms such as eBay, Etsy, Facebook, a private website, Instagram or any other venue, will need to be able to issue plant passports in accord with the EU Plant Passport Regulation (Implementing Regulation (EU) 2017/2313), enacted to protect the environment, and trade, from plant pests and diseases (<https://www.bb-automation.com/pflanzenpass?lang=en#:~:text=The%20plant%20passport%20is%20used,producer%20to%20the%20retail%20trade> ). Inspections, if thorough, and other requirements of the EU Plant Passporting may go some way to limiting the inadvertent importation of flatworms.

Aside from plant health inspection, and the EU Plant Passport Regulation, there are no existing management practices implemented specifically against invasive flatworms. Hot water treatment has been considered for flatworm management for imported potted plants (Justine *et al.*, 2014; Murchie and Moore, 1998).

As the flatworms are sheltering within the soil or in the plant container, other pest management practices along the pathway are unlikely to affect them. For example, treatment with insecticides to control foliar pests is unlikely to penetrate the root ball or if systemic affect the flatworms as they are not feeding on the plant.

**Qu. 1.6a. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

If *B. kewense* is embedded in the growing medium or root ball, detection is difficult without destruction of the potted plant. Adult flatworms are comparatively large and distinctive, so once

uncovered would be visible easily with the naked eye. Egg capsules (cocoon) are 3-9.5 mm in diameter and would be much harder to detect and to differentiate from other detritus.

As *B. kewense* is cryptic, soil-dwelling, and nocturnal, it is most likely detected in the environment under refuges, such as plant pots or other items in close contact with the soil, when these are moved. Whilst the flatworms are likely to be noticed by gardeners in these cases, it is worthwhile bearing in mind the comments of Justine *et al.* (2018) with respect to *Bipalium* spp., *Diversibipalium* spp. in France, where the authors expressed their amazement that these highly noticeable non-native flatworms had escaped attention of scientists and officials for 20 years.

**Qu. 1.7a. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response:

Importation of potted plants into the EU occurs throughout Europe. The pathway would encompass ports to wholesale suppliers to local dissemination via garden centres, landscapers, and supermarkets. There is substantial internal trade in the EU. Increasing online trade may make dissemination points more dispersed as wholesalers may freight directly to the public.

As the flatworms would be enclosed in potted plants, opportunities for entry into the environment would also be widespread. In warm areas of Europe, ornamental plants that could house *B. kewense* may be placed directly outdoors allowing direct dissemination of the flatworm into the local environment. In northern areas of Europe such plants may be housed indoors, with less opportunity for transfer. However, during the summer months tropical plants may be housed in conservatories or glasshouses from which the flatworm could escape into the wild.

**Qu. 1.8a. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

*Bipalium kewense* has already been introduced and established in the risk assessment area through this pathway. The risk of further introductions into the EU depends on the extent of trade with regions maintaining populations of *B. kewense*, and the effectiveness of measures by the trading partners to prevent the introduction, achieve early detection, rapidly eradicate, and manage the species.

End of pathway assessment, repeat Qu. 1.3 to 1.8 as necessary using separate identifier.

**Pathway name: Botanical Garden / Zoos and Aquaria**

**Qu. 1.2b. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	Low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response:

Botanic gardens are a main pathway for the introduction / entry of *Bipalium kewense*, evidenced by the following records that include some additional records from Germany to those in earlier responses (8a and 8b): *Bipalium kewense* was first recorded in the risk assessment region in the hothouse in Kew Gardens, London, United Kingdom, 1877 (Moseley, 1878). Subsequently it was found in the orchid house, old Botanic Gardens, Berlin, Germany 1886 (Graff, 1899), and within Germany a hothouse in Frankfurt am Main, 1887, hothouses in Dresden and Leipzig in 1891, hothouse in Heidelberg, 1896, Botanic Gardens and Zoological Gardens, Hamburg, 1901 (associated with plants from Brazil), orchid house, Bellevue Palace, Berlin, 1912, palm house, Dahlem Botanic Gardens, 1923, fern house and hothouse Botanic Gardens Breslau, 1930, hothouse, Bonn, 1933, and a hothouse, Göttingen (no date) (locations summarized by Arndt, 1934) ; the hothouse at Stafford House, Kildare, Ireland, 1892 (Bell, 1892); a hothouse in Graz, Austria, 1893 (Graff, 1893); in a hothouse, Wrocław, Poland, 1898 (Paxa, 1921); a greenhouse in Prague, Czech Republic, 1902 (Mrazek, 1902); hothouse Belgium 1907 (Woestinje, 1907); hothouse in the Netherlands 1912 (De Waart, 2016), and a hothouse in Finland 1935 (Söderstrom, 1936).

Although these records are historical, there remains a high possibility that these protected locations continue to harbour populations of *B. kewense*, and may act as reservoirs of “infection”, especially if the garden sells plants to the public. For example, in Kew Gardens, *B. kewense* was found in a hothouse in 1966, and again in May 1980 by the Keeper in the tropical fern house in which the original specimen of *B. kewense* was found in 1877 (Winsor, 1983a), the implication being that the species has continued to survive in this location for 103 years (whether other people have seen specimens over the 103 years is not known; there were no museum records from this location). However, many exotic plants are transferred to hothouses, often historic in nature, and once the plants are in place they are not disturbed further. There is a possibility that Botanic Gardens will continue to be an entry point from outside the EU.

There is a single report of *B. kewense* found in the Glasgow Botanic Gardens close to but outside the hothouses (Boag et al., 2010). It was found in summer *B. kewense* outdoors in Glasgow botanic gardens but within a couple of metres of a heated greenhouse where it was established. There was no suggestion it was able to live under Scottish climatic conditions, but it did show it had the capability

to migrate when conditions were right, in other words it could have moved from one greenhouse to another when weather conditions were favourable but the general climate for the region was not (Boag 2021, unpublished).

**Qu. 1.3b. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>Low</b> medium high
-----------------	--	-------------------	------------------------------

Response:

The introduction of alien flatworms via importation of exotic plants to botanic gardens has occurred with *B. kewense* (Winsor, 1983). However, most of these introductions happened in the past when biosecurity and quarantine protocols were less stringent.

The mechanism of contamination of botanical specimen plants and propagule pressure is similar to that of nursery plants (above 1.3a). Land planarians are hermaphrodite. *Bipalium kewense* can reproduce asexually by fragmentation. The colonizing success of *B. kewense* can largely be attributed to this asexual mode of reproduction (Hyman, 1943, 1951), in which an individual specimen can eventually give rise to a colony through reproduction by fission, as opposed to sexual reproduction that will require another sexually mature individual, and the time and energy expended in searching for this sexual partner.

In the fission process (Barnwell, 1967; Connella and Stern, 1969) one or two portions of the tail section, 1 - 4 cm long, are shed a few days after the adult fed and are able to crawl. After several days or weeks, the dropped tail sections regenerate so that they grow to become small versions of adult specimens. Adult planarians raised in laboratory terraria shed an average of one or two fragments per month (Connella and Stern, 1969). This average rate of fragment production under laboratory conditions may not be an accurate estimate of fragment production in outdoor or managed environments. Field observations of a *B. kewense* population in Tennessee US revealed few sightings

of fragments over a year, with the ratio of fragments to adult specimens was greatest during the cold months (Chandler, 1976).

Botanic gardens may seek more exotic plants collected from the wild, which may increase the likelihood of contamination with flatworms compared to contamination by flatworms of locally reared plants. On the other hand, the quantities imported will be smaller and awareness of biosecurity risk and mitigation procedures are likely to be greater in botanic gardens, which justifies a reduced likelihood compared to the pathway “contaminant nursery material”. In addition, in temperate countries at least, exotic plants collected from the tropics will probably be kept in hothouses as is already the case with many locations from which *B. kewense* has been recorded. Such arrangements are likely to limit the flatworm’s entry to the human-modified environment outside the hothouse or managed facility. Estimates of the propagule pressure along this pathway are difficult to generate because of unknown variables, for example the availability of food, temperatures at which the facility is run, introduction of new plant stock, and plant hygiene practices in the facility.

**Qu. 1.4b. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

As with the nursery plant pathway (above, 1.4a), *B. kewense* is likely to survive well in transported and stored exotic plants, assuming that the conditions necessary for the plants’ survival matches that of the flatworms. Without more details of the conditions of transport of contaminated material, it is difficult to go beyond generalisations, but *B. kewense* has certainly been transported successfully around the world with plant material.

**Qu. 1.5b. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response:

The response to this question is similar to that for nursery plants (above, 1.5a). There are no management measures widely specifically implemented against *B. kewense*. One would expect that high value or rare exotic plants in transit to botanic gardens would be subject to high biosecurity assessments with intense inspection and scrutiny for pests and diseases. Biosecurity risk and

mitigation procedures are likely to be greater in botanic gardens. However, flatworms sheltering in root balls can be difficult to detect without damaging the plant, so the confidence score is low.

**Qu. 1.6b. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

*Bipalium kewense* would shelter in soil surrounding root balls and is unlikely to be detected without destructive sampling (see response above, 1.6a). For high value exotic plants, it may be possible to wash the roots and re-pot, which would expose the flatworms. However, small individuals or egg capsules may still go undetected.

As botanic gardens have dedicated botanists and gardeners and are open to the public, it could be argued that detection outside the hothouse or managed facility may be more likely as they may be trained in the recognition of pest and exotic species, than for nursery stock. However, the focus of phytosanitary and biosecurity measures, and education of staff in botanic gardens appear to be exclusively concerned with plant pests, especially microbial pathogens, insects, and invasive plant species (Hulme, 2011, Heyward with Sharrock, 2013, Wondafrash et al., 2021), rather than on non-plant pests such as alien land planarians that may be unintentionally brought into the gardens as contaminant on plants.

**Qu. 1.7b. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	Isolated <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	Low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response:

Most cities in Europe have botanic gardens and similar establishments. Typically, these would comprise both “protected” environments such as glasshouses, hothouses) and landscaped gardens.

**Qu. 1.8b. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
-----------------	---------------	-------------------	-----

	unlikely moderately likely likely <b>very likely</b>		medium <b>high</b>
--	---	--	-----------------------

Response:

There are many botanic gardens in Europe often dating from the 19<sup>th</sup> century. Most have civic, educational, conservation or academic functions. Yet, botanic gardens have been criticised as sources of invasive alien species and encouraged to adopt and implement codes of practice to prevent the spread of unwanted species (Hulme, 2011). Botanic Gardens Conservation International, the body representing some 600 institutional members in 100 countries, specifically acknowledges the threats posed by invasive alien species and the role of botanic gardens in their dissemination but also detection (Hayden, 2020). BGCI advocates careful planning, preparation and management of plant material being exchanged, together with good record keeping and robust procedures to ensure that „neither the plant itself nor any associated pests or diseases will affect the collections of the botanic garden or the wider environment“ (<https://www.bgci.org/our-work/plant-conservation/plant-health-and-biosecurity/>).

*Bipalium kewense* has certainly been introduced many times into new regions via botanic gardens, and the recent finding of *Platydemus manokwari* in a botanic garden hothouse in France (Justine *et al.*, 2018) demonstrates that this remains a viable and active pathway. As with nursery plants, the extent of the risk depends on the quantities and types of plants transported from regions with *B. kewense* to Europe by botanic gardens.

*End of pathway assessment, repeat Qu. 1.2 to 1.8 as necessary using separate identifier.*

**Qu. 1.9. Estimate the overall likelihood of introduction into the risk assessment area or entry into the environment based on all pathways and specify if different in relevant biogeographical regions in current conditions.**

Provide a thorough assessment of the risk of introduction in relevant biogeographical regions in current conditions: providing insight into the risk of introduction into the risk assessment area.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

*Bipalium kewense* has been introduced into the risk assessment area by the botanical garden and contaminated nursery material pathways in the past as evidenced by the widespread findings of this flatworm in botanical gardens and urban hothouses. The most likely pathway for introduction of *B. kewense* is with living plants, either through botanical gardens or the contaminated nursery material pathways, which appear to be still active today. Major risk factors include (a) the extent to which

botanical gardens act as reservoirs of *B. kewense*, (b) propagule pressure arising from the asexual mode of reproduction of *B. kewense* in which fragments are shed that will subsequently regenerate into mature flatworms, (c) the efficacy of phytosanitary and biosecurity measures employed by botanical gardens and nurseries to plants, (d) trade and exchange of plants between botanical gardens within and between Member States, and between Member States and other countries, and the phytosanitary and biosecurity measures taken in these countries (e) and the extent of education of botanical garden and nursery staff, and the public, about alien flatworms.

*Bipalium kewense* is established outdoors in the Atlantic and Mediterranean biogeographic regions. In the Atlantic region the area most at risk is the Department of Pyrénées-Atlantiques, France. However, all records are from gardens, and it is not known whether the species has colonised semi-natural habitats.

**Qu. 1.10. Estimate the overall likelihood of introduction into the risk assessment area or entry into the environment based on all pathways in foreseeable climate change conditions?**

Thorough assessment of the risk of introduction in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of introduction (e.g. change in trade or user preferences)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely introduction within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

*Bipalium kewense* has already been introduced to the risk assessment area through the botanical garden, and contaminated nursery material pathways. The pathways themselves (transport of exotic plants) will be little affected directly by climate change. However, as the climate warms, there are two

issues that will increase the risk of *B. kewense* establishment in the wild, and possible further introductions and entry into the wild.

The first is that the flatworm is likely to extend its range outside the risk assessment area. The current predicted areas for establishment of *B. kewense* includes substantial regions of Asia, south-eastern USA, north-western North America – Alaska, central and South America, and central east Africa (SDM Annex VIII Figure 6). With greater colonisation of these regions, the risk of inadvertent transport with ornamental or exotic plants to the risk assessment area increases. This factor will likely apply equally to the biogeographical regions suitable for establishment (e.g., mainly the Atlantic and Mediterranean regions), although as this movement is dependent on human agency, the risk will be dependent on human population density, and also the success of phytosanitary and plant passport controls. Second, as the EU climate warms, the range of garden plants likely to be grown outdoors will alter. This may include exotic plants from flatworm-infected regions and therefore increase the risk of entry of *B. kewense* into the surrounding environment. This risk will be greater in the Atlantic biogeographical region as it extends further north, and probably presents a relatively higher risk than import from external countries.

## 2 PROBABILITY OF ESTABLISHMENT

### Important instructions:

- For organisms which are already established in parts of the risk assessment area or have previously been eradicated, the likelihood of establishment should be scored as “very likely” by default.
- Discuss the risk also for those parts of the risk assessment area, where the species is not yet established.

### Qu. 2.1. How likely is it that the organism will be able to establish in the risk assessment area based on similarity of climatic and abiotic conditions in its distribution elsewhere in the world?

RESPONSE		CONFIDENCE	
	very unlikely		low
	unlikely		medium
	moderately likely		<b>high</b>
	likely		
	<b>very likely</b>		

Response:

*Bipalium kewense* is already established outdoors in the risk assessment area in the low altitude region of the Pyrénées-Atlantiques along the ocean that has an Atlantic climate, suggesting that the region is particularly suitable for land planarians (Justine *et al.*, 2018). It has also established outdoors in Malta in 2021 (T. Cassar and D. Mifsud, 2021, unpubl.) in Portugal in Mealharda and Gemunde (Silva, 2021, 2020), in Italy, especially western Italy, Mori *et al.* (2021), and outdoor locations in Spain, Caldes d’Estrac (Barcelona), Girona (Girona), Barcelona, and Bètera (València), (Álverz-Presas *et al.* (2014). Therefore, the confidence is that establishment in the risk assessment area is very likely, and confidence is high.

Countries within the natural range of *Bipalium kewense* have Köppen Climate Classification Type A Tropical climates (Tropical Rainforest, Tropical Monsoon, and Tropical Savannah climates) that do not occur in the risk assessment area, and Köppen classification Type C Temperate climates (Humid sub-tropical, and Monsoon-influenced humid subtropical climate) that are present in the risk assessment area.

The locations within the risk assessment area where *B. kewense* has established outdoors all have Köppen Climate Classification Type C climates as follows:

The low altitude region of the Pyrénées-Atlantiques in France (numerous records), the northern and eastern Italy (sparse records), and Girona, Spain have Humid sub-tropical climates characterized by the coldest month averaging above 0 °C, at least one month's average temperature above 22 °C, and at least four months averaging above 10 °C. There is no significant precipitation difference between seasons, and no dry months in the summer. This climate type extends to the UK, and the Atlantic coast of western Europe.

Most of central and western Italy (numerous records), Malta, Barcelona, and Spain have Hot summer Mediterranean climates characterized by the coldest month averaging above 0 °C, at least one month's average temperature above 22 °C, and at least four months averaging above 10 °C. There is at least three times as much precipitation in the wettest month of winter as in the driest month of summer, and driest month of summer receives less than 30 mm. This climate type extends to the Mediterranean coast of France and Greece.

Mealharda and Gemunde in Portugal, and Valencia in Spain have Cold summer Mediterranean climates characterized by the coldest month averaging above 0 °C and 1–3 months averaging above 10 °C. There is at least three times as much precipitation in the wettest month of winter as in the driest month of summer, and driest month of summer receives less than 30 mm.

Laboratory work suggests that *B. kewense* will tolerate a wide range of temperatures, with the optimum temperature for growth and reproduction being between 15.6°C and 32°C; the species will survive near freezing temperatures, but they do not regenerate or grow as rapidly at these low temperatures (Barnwell, 1967). Soil temperatures will generally be higher than air temperatures, depending upon the thermal conductivity of the substratum. In another study (Chandler, 1976) the numbers of specimens of *B. kewense* that were sighted declined when the soil temperature reached a minimum of 3.9°C (minimum air temperature in the same location was -6.6°C); sightings of *B. kewense* increased with a rise in soil temperature. “In Billère (Pyrénées-Atlantiques, France), repeated records of *B. kewense* from the same garden were obtained between September and December 2017 and January 2018, live and outdoors, even in winter; they were also found at various depths under the soil surface in January, clearly a way for the species to survive the cold season.”(Justine *et al*, 2018).

However, *B. kewense* has only been found in hothouses and not outdoors in Austria, Belgium, Czech Republic, Denmark, Finland, Germany, Netherlands, Poland, and Slovakia. Except for the Netherlands and the UK (in proximity to a hothouse), the other remaining countries all have Köppen Climate Classification Type D Continental climates, characterized by having at least one month averaging below 0 °C and at least one month averaging above 10 °C. Most of these countries have Hot summer humid continental climates, with the coldest month averaging below 0 °C, at least one month's average temperature above 22 °C, and at least four months averaging above 10 °C, with no significant precipitation difference between seasons.

As would be expected, the establishment of *B. kewense* outdoors (in countries and regions with Type C climates with the minimum temperature of the coldest month averaging above 0 °C ), and the factors limiting this, chiefly minimum temperature of the coldest month (countries with Type D climates with the minimum temperature of the coldest month averaging below 0 °C) broadly accord with the ensemble model (Annex VIII). The model suggested that the suitability of particular location for the establishment of *B. kewense* was most strongly determined by the minimum temperature of the coldest month in that region, followed by annual precipitation, (then the presence of human-disturbed habitats), then the mean temperature of the warmest quarter, followed last by the Climatic Moisture Index for that area. The seasonality of precipitation did not impact on the suitability of an area for the establishment of *B. kewense*.

(Climate data for the Köppen Climate Classifications previously discussed were derived from [https://en.wikipedia.org/wiki/K%C3%B6ppen\\_climate\\_classification](https://en.wikipedia.org/wiki/K%C3%B6ppen_climate_classification) retrieved 25 June 2021).

**Qu. 2.2. How widespread are habitats or species necessary for the survival, development and multiplication of the organism in the risk assessment area? Consider if the organism specifically requires another species to complete its life cycle.**

<b>RESPONSE</b>	very isolated isolated moderately widespread <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response:

Habitats, and prey suitable for the survival of *Bipalium kewense*, are widespread in the risk assessment area.

The habitat of the natural range of *Bipalium kewense* includes tropical montane forests and rainforests, absent in the Risk Assessment area. The preferred microhabitats of land planarians including *B. kewense* are those of the litter fauna, cryptofauna, and soil fauna (Winsor, 1998). The niches occupied by these flatworms are continuous between one extreme with those of the litter and soil faunas, and the other extreme with the faunas of rocks and trees (Wallwork, 1970). The prey of *Bipalium kewense* in its natural range is unknown. Nothing is known about the preferences of soil type by *B. kewense*, other than a requirement for a humid microhabitat.

Outside its natural range, the outdoor occurrence of *B. kewense* appears to be almost exclusively restricted to public and private gardens and parks. Unlike some other species of alien Bipaliinae, for example *Bipalium adventitium* in the USA (Ducey *et al.*, 2005), there is no evidence to date of *B. kewense* surviving, developing, and reproducing in native forests or other natural habitats in countries with Type C Temperate climates (Köppen Climate Classifications – see Qu 2.1).

In a four-year experimental study of *Bipalium kewense* it was found that of the prey proffered to the planarians, *B. kewense* very rarely predated upon slugs, but preferred live earthworms (Lehnert, 1891). This preference for earthworms by *B. kewense* has been confirmed by subsequent studies and observations (Johri, 1952; Wallen, 1954; Froehlich, 1956; Dundee and Dundee, 1963; Barnwell, 1967; Connella and Stern, 1969; Olewine, 1972; Chandler, 1974; Winsor, 1985). There are no quantitative studies on the impacts of *B. kewense* upon native or alien populations of earthworms.

Based on evidence from countries outside the natural range of *B. kewense*, and outside of the Risk Assessment area, the most common habitats of this flatworm are public and private urban parks and gardens. To these could be added private and public (communal) allotments used to grow produce for private consumption. Under the EUNIS Habitat Classification, these habitats would be classified as “Regularly or recently cultivated agricultural, horticultural and domestic habitats”, defined as “Habitats maintained solely by frequent tilling or arising from recent abandonment of previously tilled ground such as arable land and gardens. Includes tilled ground subject to inundation. Excludes lawns and sports fields (E2.6), shrub orchards (FB), tree nurseries (G5.7) and tree-crop plantations (G3.F etc.)” (European Nature Information System EUNIS <https://eunis.eea.europa.eu/habitats/352> retrieved 26 June 2021).

In these sites there are undoubtedly refuges on the soil surface for sheltering during the day and in adverse weather conditions, such as mulch, leaf litter, masonry, timber, plant pots, and especially within the soil of potted plants. In addition, there is a strong likelihood that such urban habitats will be well watered, and they are also likely to be excellent habitats for species of earthworms, thus providing prey upon which *B. kewense* feeds.

*Bipalium kewense* is already established outdoors in private urban gardens in France (Justine *et al.*, 2018), Italy (Mori *et al.*, 2021), Malta (T. Cassar and D. Mifsud, 2021 unpubl.), Portugal (Silva, 2020), Spain (Filella-Subirà, 1983; Alvarez-Presas *et al.* 2014), and United Kingdom (Boag *et al.*, 2010).

**Qu. 2.3. How likely is it that establishment will occur despite competition from existing species in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

No direct information has been found concerning competition in the establishment of *B. kewense* from existing species in any area. However, *B. kewense* is established in the risk assessment area despite potential predators so the response is very likely with high confidence. It has been postulated that invasive flatworms in Europe may be exploiting an underdeveloped predatory niche, which comes from the abundance of prey species combined with the paucity of the native flatworm fauna in Europe compared to Asia, South America, and Australasia (Boag and Yeates, 2001; Boag *et al.*, 2010).

**Qu. 2.4. How likely is it that establishment will occur despite predators, parasites or pathogens already present in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

Land planarians are apex predators in their microhabitat (Sluys, 2016). Although few of the studies on the natural enemies of flatworms specifically include *B. kewense*, the results can be reasonably extrapolated to land planarians in general because of their shared characteristics such as diet, dermal secretions, and habitat. Some species of land planarians prey on others (Boll *et al.*, 2015), including *O. nungara* (Boll and Leal-Zanchet, 2016). Amongst potential vertebrate predators, cats and amphibians find planarians distasteful, though a shrew ate a specimen of *A. triangulatus* under laboratory conditions (Cannon *et al.*, 1999) and there is anecdotal evidence that some birds in the risk assessment area may take planarians (Cannon *et al.*, 1999). The larvae and adults of staphylinid and carabid beetles have devoured *A. triangulatus* under laboratory and field conditions (Gibson *et al.*, 1997), and the larvae of the mycetophilid fly, *Planivora insignis* parasitizes some species of Tasmanian land planarians (Hickman, 1964). These largely isolated observations provide no indication of the overall impact on land planarian populations and their establishment. Gregarine parasites, common in the seminal vesicles of earthworms, are frequently found infesting the gut of flatworms (Graff, 1899), and where the planarians testes are involved, may cause sterility (Winsor *et al.*, 2004). The parasitic burden of a flatworm may be significant under conditions of physiological stress such as partial desiccation. Laboratory cultures of *B. kewense* are vulnerable to bacterial and fungal infections (Barnwell, 1969, Rodrigues, 1972). Our knowledge of pathogens and parasites of land planarians is extremely limited.

**Qu. 2.5. How likely is the organism to establish despite existing management practices in the risk assessment area? Explain if existing management practices could facilitate establishment.**

RESPONSE	CONFIDENCE
very unlikely unlikely moderately likely <b>likely</b> very likely	low <b>medium</b> high

Response:

There are no specific management practices routinely applied for *B. kewense* in the risk assessment area. Nevertheless, there are risk management practices in the applied against other pests that may have an untargeted impact on *B. kewense*. However, there is no evidence of pesticide effects on *B. kewense*, and terrestrial flatworms are difficult to target as they are normally sheltered under refuges or in the soil.

Cultivation of the soil is likely to affect *B. kewense* as they are soft-bodied organisms and susceptible to physical damage, though the species successfully reproduces by fission, and damaged specimens will readily regenerate if the conditions are conducive to this.

*Bipalium kewense* is associated with disturbed and man-modified habitats, so agricultural practices and forestry that disturb habitats and create refuges on the soil surface may benefit flatworms. These would include practices such as logging, baled silage and use of plastic membrane weed suppressants.

Prolonged, or intensive drought will dry topsoil and could destroy populations of land planarians, though in an urban environment these effects may be ameliorated by people watering their gardens. However, in the event of accompanying water restrictions the resulting reduction in moisture deficit in the soil could adversely affect planarian populations (Winsor, 2021, unpubl).

**Qu. 2.6. How likely is it that biological properties of the organism would allow it to survive eradication campaigns in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

*Bipalium kewense* is a cryptic soil dwelling species. Once established in the wild it would be difficult to eradicate from anything other than a small, localised area. Timing of any eradication campaign would be important, as flatworms are seasonal. Under adverse dry or cold weather conditions, or removal of surface litter to expose and dry the soil surface and remove surface microhabitat, land planarians, including *B. kewense*, are likely move deeper into the soil where they are still likely to find prey in the soil fauna. Egg cocoons are small (4mm – 9.5 mm diameter), black and inconspicuous, and would be readily mixed within disturbed soil, and could easily be overlooked, though sexual reproduction is rare and unlikely to occur in the risk assessment area. Hot water treatment may be used to cleanse plants of terrestrial flatworms, either by immersion (Sugiura, 2008; Murchie and Moore, 1998) or as a drench (Justine *et al.*, 2014), and these methods could be effective for *B. kewense*.

Similarly, small regenerating body fragments shed by asexual means of reproduction by adult *B. kewense* are easily overlooked and are able to hide in refugia such as tiny cracks and holes in available microhabitats such as timber and rocks. Shed fragments are vulnerable to desiccation and they cannot feed until the head and pharynx are regenerated (Barnwell, 1967).

Planarians are able to live for long periods without feeding and remain intact even after severe starvation has reduced their body size significantly (Brøndsted, 1969), though there are no experimental data for the survival and regeneration of land planarians following starvation. Depletion of potential food sources may be unsuccessful strategy in eradicating flatworms.

Cultivation of the soil is likely to affect *B. kewense* as they are soft-bodied organisms and susceptible to physical damage and dehydration. However, as the species successfully reproduces by fission, damaged specimens will readily regenerate provided the conditions are conducive for this. *Bipalium kewense* is well adapted to survive most eradication campaigns at anything other than a very small scale so the response is very likely with a medium confidence.

**Qu. 2.7. How likely are the biological characteristics of the organism to facilitate its establishment in the risk assessment area?**

including the following elements:

- a list and description of the reproduction mechanisms of the species in relation to the environmental conditions in the risk assessment area
- an indication of the propagule pressure of the species (e.g. number of gametes, seeds, eggs or propagules, number of reproductive cycles per year) of each of those reproduction mechanisms in relation to the environmental conditions in the risk assessment area.
- If relevant, comment on the likelihood of establishment based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in establishment whereas for others high propagule pressure (many thousands of individuals) may not.
- If relevant, comment on the adaptability of the organism to facilitate its establishment and if low genetic diversity in the founder population would have an influence on establishment.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

*Bipalium kewense*, in common with many species of land planarians, has biological characteristics that would facilitate its establishment in the risk assessment area. Chief of these are its modes of reproduction.

Land planarians are hermaphrodite. *Bipalium kewense* can reproduce asexually by fragmentation, a more efficient method than sexual reproduction for converting food energy to offspring, favoured in ecological circumstances over sexual reproduction when food is limiting (Calow *et al.*, 1979). The colonizing success of *B. kewense* can largely be attributed to this asexual mode of reproduction (Hyman, 1943, 1951), in which an individual specimen can give rise to a colony through reproduction by fission, as opposed to sexual reproduction that will require another sexually mature individual, and the time and energy expended in searching for this sexual partner.

In the fission process (Barnwell, 1967; Connella and Stern, 1969) one or two portions of the tail section, 1 - 4 cm long that are able to crawl, are shed a few days after the adult has fed. After several days or weeks, the dropped tail sections will regenerate so that they grow to become small versions of adult specimens. A regenerating *B. kewense* will not attack and eat earthworms until the head region has completely regenerated into the adult shape. However, the ability of a regenerated *B. kewense* to eat depends primarily upon a regenerated pharynx than a regenerated head (Barnwell, 1966). Adult planarians raised in laboratory terraria shed an average of one or two fragments per month (Connella and Stern, 1969). Field observations of a *B. kewense* population in Tennessee US revealed few sightings of fragments over a year, with the ratio of fragments to adult specimens greatest during the cold months (Chandler, 1976). Anterior fission has also been observed in damaged and diseased individuals of *B. kewense* (Ducey *et al.*, 2005).

*Bipalium kewense* also reproduces sexually, and mature specimens, indicated by the presence of a gonopore, have been found in eleven countries with tropical or subtropical climates, none of which are in the risk assessment area (Winsor, 1983a). Sexual reproduction by *B. kewense* is an uncommon or underreported event (Ducey *et al.*, 2006). Sexual maturity is seasonal. In the USA (Louisiana), adult *B. kewense* were found to be sexually mature over a five-month period from October to February, and non-sexual from March to September (Connella and Stern, 1969).

Following copulation, the fertilized eggs of the planarian are enclosed within a cocoon that is then expelled via the gonopore and attached with mucus to the substratum. The cocoon wall is stabilized by quinone tanning on exposure to air, usually within 24 hours changing in colour from lemon when freshly laid by the planarian through cherry-red, tan, dark brown then black, as has been described for species in all the subfamilies of the Geoplanidae (Winsor, 1998). The cocoon protects the developing young from desiccation.

A single specimen from New Orleans, Louisiana US (Connella and Stern 1969), laid three cocoons, 8 and 21 days apart, with one hatching after 21 days containing 3 juveniles. Another specimen from Cypress, Texas US laid a single cocoon from which emerged seven juveniles after 21 days after laying (Ducey *et al* 2006). The adult flatworm was reproducing by fission 10 days prior to, and five days following laying the cocoon. Cocoons laid by a specimen of *B. kewense* from Queensland, Australia (Charters Towers) measured 9.5 mm diameter declining to cocoons 3 mm diameter from nine successive occasions over 103 days from a single copulation, resulting in a total of six hatchlings (2 juveniles present in each of two cocoons, and one juvenile in each of two single cocoons, with one cocoon damaged); the four cocoons 3 mm - 6 mm were sterile (Winsor, 1984, unpubl.).

In Murfreesboro, Tennessee US (Type C Humid subtropical climate in the Köppen climate classification.) field observations of *B. kewense* revealed the most sightings occurred when the mean air temperature was 18.3°C, and mean soil temperature at 25 mm depth was 18.9°C. Less sightings occurred when the mean air temperature was 5°C and mean soil temperature 10.6°C, and most monthly sightings occurred when the mean air temperature was 22.8°C, and mean soil temperature 19.5°C (Chandler, 1976). Soil moisture was usually above 90% for the entire period of observations. Barnwell (1969) noted that when the temperature dropped to -6.7°C or -9.4°C, planarians were not found in their usual places, but a few days later when conditions were warmer, they reappeared. He also stated that they could survive temperatures near -17°C, but after temperatures fell below this for several nights in 1966 in Athens, Georgia, US, no *B. kewense* were seen for over two years; regions where *B. kewense* could survive outdoors would be limited by the minimum temperature of the coldest month (refer to Qu 2.1).

Like the subtropical humid climates in Tennessee and Georgia in the US, locations within the risk assessment area where *B. kewense* has established outdoors also have Köppen Climate Classification Type C climates (see details in Qu 2.1). Citizen Science observations in France report that specimens of *B. kewense* bury themselves in soil to a depth of up to 20 mm during winter (Justine, 2018, unpubl.).

*Bipalium kewense*, like all land planarians, is sensitive to moisture and atmospheric humidity. “Land planarians have practically no water-saving adaptations, being dependent upon moisture in their microhabitat, yet are sensitive to too much water and thus generally avoid wet places. Flatworms are mostly strongly seasonal in occurrence, probably reflecting attempts to maintain themselves within a constant microclimate by vertical migration through the continuum of habitat niches. When the

moisture conditions are optimal or too wet, and cover is present, they will occupy the cryptozoic and litter microhabitats on the soil surface and may even venture up trees. When conditions are too dry for them, they retreat into the soil. In the absence of surface cover terrestrial flatworms can live entirely in soil as permanent members of the soil fauna and can be generally regarded as facultative soil animals. Most species appear not to burrow but make use of existing pore spaces to migrate within the soil” (Winsor *et al.*, 1998)

The limit of desiccation without fatal effects, determined for a *Diversibipalium* sp. that can generally be applied to other land planarians, is 40%-50% of body weight (Kawaguchi, 1932). The rate of evaporation from a planarian is proportional to its surface area (Kawaguchi, 1932). *Bipalium kewense* is one of the particularly elongate species of land planarians and consequently has a relatively large surface area and is potentially more vulnerable to desiccation. This may also explain the apparent relatively low vagility of *B. kewense*, as there are costs in energy and moisture loss in moving its particularly elongate body over the substratum. This is especially evident in specimens found crawling over cement pathways in which the latter readily absorb moisture, and on asphalt pathways where the specimens may still be found at sunrise, and subsequently desiccate in the heat (Fletcher, 1887). The proportional rate of evaporation for smaller specimens is greater than for larger ones (Kawaguchi, 1932), and this would put regenerating fission propagules at risk in dry conditions. Prolonged, or intensive drought will dry topsoil and could destroy populations of land planarians, though in an urban environment these effects may be ameliorated by people watering their gardens. However, in the increasingly frequent event of accompanying water restrictions the resulting reduction in moisture deficit in the soil could adversely affect planarian populations (Winsor, 2021, unpubl). Under summer conditions in north Queensland, Australia, living specimens of *Bipalium kewense* were found coiled between an impervious plastic plant box and the hard dry soil beneath; the planarians were entirely covered with a thick coat of mucus that was more viscous than is normally encountered (Winsor, 2021, unpubl). This behaviour would protect the planarian from desiccation, but for what duration is unknown.

Low propagule pressure through asexual reproduction could result in the establishment of the species if climatic conditions were favourable. The rarity of sexual reproduction in the species, and the relatively low fecundity of this means of reproduction, suggests that propagules generated through sexual reproduction are insignificant compared to those produced by asexual reproduction. It is not known whether low genetic diversity in the founder population would have an influence on establishment of the species. However, genetic analyses suggests that many introduced populations are clonal.

**Qu. 2.8. If the organism does not establish, then how likely is it that casual populations will continue to occur?**

Consider, for example, a species which cannot reproduce in the risk assessment area, because of unsuitable climatic conditions or host plants, but is present because of recurring introduction, entry and release events. This may also apply for long-living organisms.

<b>RESPONSE</b>	N/A very unlikely	<b>CONFIDENCE</b>	low medium
-----------------	----------------------	-------------------	---------------

	unlikely moderately likely likely very likely		high
--	--	--	------

Response:

Even if specimens of *B. kewense* do not establish in an area, there is a possibility that they could be re-introduced via potted plants.

*Bipalium kewense* is already established outdoors in some countries within the risk assessment area. However, continuing trade in plants from regions in which the species is established will continue to pose a risk of introduction to uninfected areas. If such an introduction is to a “protected environment” (e.g. a hothouse) in an uninfected region, a flatworm population will probably survive and likely establish within these limited confines. In the wild, if conditions are not suitable for establishment, then it is unlikely that a transient population would survive. It would either establish or die-off.

*Bipalium kewense* is one of the particularly elongate species of land planarians and consequently has a relatively large surface area and is potentially more vulnerable to desiccation. This may also explain the apparent relatively low vagility of *B. kewense*, as there are costs in energy and moisture loss in moving its particularly elongate body over the substratum. The rate of evaporation for smaller specimens is greater than for larger ones (Kawaguchi, 1932), and this would put regenerating fission propagules at risk in dry conditions. Under summer conditions in north Queensland, Australia, living specimens of *Bipalium kewense* were found coiled between an impervious plastic plant box and the hard dry soil beneath; the planarians were entirely covered with a thick coat of mucus that was more viscous than is normally encountered (Winsor, 2021, unpubl). This behaviour would protect the planarian from desiccation, but for what duration is unknown. Prolonged, or intensive drought will dry topsoil and could destroy populations of land planarians, though in an urban environment these effects may be ameliorated by people watering their gardens. However, in the event of accompanying water restrictions the resulting reduction in moisture deficit in the soil could adversely affect planarian populations (Winsor, 2021, unpubl.). When drought conditions ease, re-introduction of *B. kewense* could occur if people re-establish their gardens using contaminated nursery material.

**Qu. 2.9. Estimate the overall likelihood of establishment in the risk assessment area under current climatic conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under current climatic conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in current conditions: providing insight in the risk of establishment in (new areas in) the risk assessment area.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

*Bipalium kewense* is a predominantly a tropical and subtropical species, and at present it is established in urban gardens outdoors in the risk assessment area. Therefore the score is very likely with high confidence.

In the Atlantic biogeographical region, *B. kewense* is established outdoors in France in the department Pyrénées-Atlantiques, the climate of which appears particularly conducive to flatworms, and food and habitat are readily available in the urban gardens that thrive in this climate (Justine *et al.* 2018). In the United Kingdom, *B. kewense* has been recorded from “protected” environments (e.g. hothouses), just outside hothouses of the Glasgow Botanic Gardens, and urban gardens in Liverpool and Sussex (Boag *et al.*, 2010). Australian and New Zealand land planarians have been recorded outdoors from the warmer regions in the U.K. such as the Isles of Scilly or Cornwall, Continental (Jones, 2005), but to date not *B. kewense*.

In the Mediterranean biogeographic region, the species is established in Italy (Mori *et al.* 2021), Malta (T. Cassar and D. Mifsud, 2021 unpubl.), Portugal (Silva, 2020), and Spain (Filella-Subirà, 1983; Alvarez-Presas *et al.* 2014). In urban gardens the availability of food (earthworms) is unlikely to be a limiting factor. If the urban habitat is conducive to land planarians, the species could establish in Cyprus, Greece and Turkey. For example the Australian flatworm *Caenoplana bicolor* is established in western Crete, in the urban environment of Vryses square with Plane trees and the Vryisianos stream (Vardinoyannis and Alexandrakis, 2019). This type of habitat would probably also suit *B. kewense*.

In the Continental biogeographical region, *B. kewense* has only been recorded in “protected” environments (e.g. hothouses) in Austria, Belgium, Czech Republic, Denmark, Finland, Germany, Netherlands, Poland, Slovakia, and the United Kingdom. The main factor constraining the establishment of *B. kewense* outdoors in this biogeographic region is chiefly the minimum temperature of the coldest month (See Qu 2.1).

**Qu. 2.10. Estimate the overall likelihood of establishment in the risk assessment area under foreseeable climate change conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under foreseeable climate change conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of establishment (e.g. increase in average winter temperature, increase in drought periods)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely establishment within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided.

However, if new, original models are executed for this risk assessment, the following RCP pathways

shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

With warmer temperatures and increased rainfall, climate change is highly likely to make biogeographical regions more amenable for the expanded establishment of *B. kewense* so the score remains very likely with high confidence.

Under Climate Change with timeframe 2070, and emission scenarios RCP 2.6 and RCP 4.5: Alpine, Atlantic, Black Sea, Continental, Mediterranean, Pannonian and Steppic in the risk assessment area; and in the Anatolian and Macaronesia biogeographic regions (Refer to Figure 1 Annex VIII). There are increases in the projected suitability for the establishment of *B. kewense* generally north and northeastwards under both RCP 2.6 and RCP 4.5 in the Atlantic, Black Sea, Continental, Pannonian and Steppic biogeographical regions in the risk assessment area, and in the Anatolian biogeographic region (Refer to Figures 3 and 4 Annex VIII). The lower to mid-levels of the Alpine region appear to become increasing suitable for the establishment of the species under the RCP 2.6 and 4.5 scenarios. For the Mediterranean region, there is little change between the current projected suitability and those under RCP 2.6 and RCP 4.5. However, in the Macaronesia region, the projected suitability for the establishment of *B. kewense* is the same for current and RCP 2.6 scenarios, but a decline in suitability under the RCP 4.5 scenario as region will exceed the mean temperature of the warmest quarter.

### 3 PROBABILITY OF SPREAD

**Important instructions:**

- Spread is defined as the expansion of the geographical distribution of an alien species within the risk assessment area.
- Repeated releases at separate locations do not represent continuous spread and should be considered in the probability of introduction and entry section (Qu. 1.7).

**Qu. 3.1. How important is the expected spread of this organism within the risk assessment area by natural means? (List and comment on each of the mechanisms for natural spread.)**

including the following elements:

- a list and description of the natural spread mechanisms of the species in relation to the environmental conditions in the risk assessment area.
- an indication of the rate of spread discussed in relation to the species biology and the environmental conditions in the risk assessment area.

The description of spread patterns here refers to the CBD pathway category “Unaided (Natural Spread)”. It should include elements of the species life history and behavioural traits able to explain its ability to spread, including: reproduction or growth strategy, dispersal capacity, longevity, dietary requirements, environmental and climatic requirements, specialist or generalist characteristics.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response:

Terrestrial flatworms move by creeping on the soil surface. In general, human-aided dispersal is long distance with natural dispersal local. Flatworms will gradually move out from the initial foci to colonise favourable surrounding areas. *Bipalium kewense* appears to have low vagility (Winsor, 2021 unpubl.). Natural spread within the risk assessment area will be dependent on climatic conditions. It may be that *B. kewense* is restricted to particular microhabitats and is unable to move naturally between these.

The life stages of *B. kewense* (mainly fission, with adult and regenerating propagules, and very rarely egg capsule and resulting juveniles) are all soil-litter bound and there is no specific dispersal phase. Some species of terrestrial flatworms can survive long periods of submersion in water, and it is possible that they can be dispersed by rafting on various objects such as logs in floodwater, or by sea, although this has not been confirmed by direct observation in the field. The occurrence of *B. kewense* on the second terrace of the Guadeloupe River in the Guadeloupe River State Park, Kendall County Texas US, was attributed to flood-borne specimens from an upstream urban area (Neck, 1987). There

is no evidence to support dispersal of *B. kewense* by birds or other animals, though other flatworm species have been reported on pet and livestock fur (Moore et al., 1998).

*Bipalium kewense* feeds exclusively upon earthworms and there is no evidence of dispersal to follow prey populations; rather, the flatworms will move locally to hunt individuals.

**Qu. 3.2a. List and describe relevant pathways of spread other than "unaided". For each pathway answer questions 3.3 to 3.9 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 3.3a, 3.4a, etc. and then 3.3b, 3.4b etc. for the next pathway.**

including the following elements:

- a list and description of pathways of spread with an indication of their importance and associated risks (e.g. the likelihood of spread in the risk assessment area, based on these pathways; likelihood of survival, or reproduction, or increase during transport and storage; ability and likelihood of transfer from the pathway to a suitable habitat or host) in relation to the environmental conditions in the risk assessment area.
- an indication of the rate of spread for each pathway discussed in relation to the species biology and the environmental conditions in the risk assessment area.
- All relevant pathways of spread (except “Unaided (Natural Spread)”, which is assessed in Qu. 3.1) should be considered. The classification of pathways developed by the Convention of Biological Diversity shall be used (see Annex IV).

Response:

Invasive alien terrestrial flatworms are cryptic soil-dwelling organisms that are mostly spread through human activities. As with ‘introduction into the risk assessment area’, the most likely pathway for spread of *B. kewense* within the risk assessment area, at least initially, involves potted plants.

*Bipalium kewense* was described from a specimen found in a hothouse at Kew Gardens, and subsequently in gardens with direct relations with Kew, but around this period the species was also found in hothouses that had no connection with Kew; the consensus of opinion at that time was that both Kew and other hothouses had been stocked from an unidentified common source, and all were agreed that it had come to them in connection with orchids from Burma (Bell, 1886a, 1886b) during the Victorian craze for orchids that lasted up to the first World War (Hansen 2001). There is no evidence that this pathway “Botanical Garden / zoo /aquaria” remains active for *B. kewense* and will not be discussed further (See also Q 1.2b). There is a report (Boag *et al.*, 2010), of a specimen of *B. kewense* found in the Glasgow Botanic Gardens, close to but outside the glasshouses. It is not known whether the specimen escaped from the glasshouses, or came to that spot via some other pathway such as contaminate nursery material (unintentional), or transportation of habitat material (unintentional).

Potted plants can be bought by the public and disseminated from garden centres, nurseries, DIY stores and supermarkets and these have all been classed under the ‘Contaminant nursery material’ pathway (unintentional). The second pathway considered is ‘Transportation of habitat material’ (unintentional). This refers to the movement of soil and compost, which may contain *B. kewense*. A third pathway is ‘Machinery/equipment’. There is some overlap with the movement of soil, as flatworms may be carried in soil adhering to machinery or equipment. A fourth pathway is Contaminant on plants

(except parasites, species transported by host/vector” in which there is personal transfer of potentially contaminant plants between gardeners .

For another flatworm species (*Arthurdendyus triangulatus*) a range of miscellaneous pathways for spread have been documented, including being caught on pet and livestock fur, stuck to plastic silage bale wrapping and broadcast with farmyard manure (Boag and Yeates, 2001; Moore *et al.*, 1998; Boag *et al.*, 1999). However there is no evidence of these pathways being active for *B. kewense*.

For all pathways, contamination with *B. kewense* is likely to be sporadic and random. The potential propagule pressure along these pathways is likely to be individually low; however, a single adult flatworm reproducing asexually could eventually give rise to a population under suitable conditions. Given the rarity and climatic constraints on sexual reproduction in *B. kewense*, the potential for this to happen from a single fertilized egg capsule is extremely low in the risk assessment area.

Pathway name: **Contaminant nursery material**

**Qu. 3.3a. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response:

There is evidence that other alien flatworms have been unintentionally disseminated in potted plants from infected garden centres to the public ( key reference Alford *et al.*, 1996). There is no direct evidence of *B. kewense* being disseminated in this way within the risk assessment area, or outside it; it is assumed that like other alien flatworms for which there is evidence, this is pathway also applies to *B. kewense*.

**Qu. 3.4a. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication.
- if appropriate, indicate the rate of spread along this pathway.
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response:

Unintentional transport of *B. kewense* via contaminant nursery material is considered the most likely means for spread of *B. kewense*. Usually, such spread is anecdotal and undocumented. However, Fletcher (1887) gives the historic example of specimens of *B. kewense* found in Hyde Park, Sydney, that had evidently strayed from the enclosure around Captain Cook's statue, which had been stocked with plants from the Botanic Gardens nursery.

Low propagule pressure through asexual reproduction (refer to Qu 2.7) could still result in the establishment of the species if climatic conditions were favourable. Similarly the species may be re-introduced via the same pathway following eradication (refer to Qu 2.6).

There are no data or estimates on the number or volume of specimens passing along this pathway in the course of a year, but the trade pathway is large with more than 22 billion euros of plant and flowers produced in the EU in 2019. ([https://ec.europa.eu/info/sites/default/files/food-farming-fisheries/plants\\_and\\_plant\\_products/documents/flowers-ornamental-plants-statistics\\_en.pdf](https://ec.europa.eu/info/sites/default/files/food-farming-fisheries/plants_and_plant_products/documents/flowers-ornamental-plants-statistics_en.pdf)).

*Bipalium kewense* is one of the particularly elongate species of land planarians and consequently has a relatively large surface area and is potentially more vulnerable to desiccation than for example the smaller alien species *Obama nungara*. This may explain the apparent relatively low vagility of *B. kewense*, as there are costs in energy and moisture loss in moving its particularly elongate body over the substratum. This is especially evident in specimens found crawling over cement pathways in which the latter readily absorb moisture, and on asphalt pathways where the specimens may still be found at sunrise, and subsequently desiccate in the heat (Fletcher, 1887).

Generally, *B. kewense* is only found in the open at night when the humidity is relatively high, and on wet overcast days, possibly seeking earthworm prey that is also often in the open under these conditions. The distance the flatworm travels appears to be only within a few metres from its normal place of refuge but may vary depending upon the availability of prey and alternative refugia (Winsor, 2021, unpubl.).

**Qu. 3.5a. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

	very likely		
--	-------------	--	--

Response:

If *B. kewense* is transferred with potted plants containing soil, then providing these plants are not exposed to temperature extremes, and sufficient moisture is retained, it is likely that flatworms will survive. Reproduction by fragmentation may be possible in transit and during storage in the garden centres or nurseries depending upon the availability of earthworms, as asexual reproduction generally follows feeding on prey.

**Qu. 3.6a. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

National phytosanitary measures within Member States may be implemented at nurseries / garden centers to control flatworms, if a consignment is suspected to be contaminated, but are rarely executed in practice. In such a case, use of hot-water treatment shows promise for flatworm management (Murchie and Moore, 1998; Sugiura, 2008a; Justine *et al.*, 2014). However, we know of no instances where any routine management is practiced against invasive flatworms.

**Qu. 3.7a. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

*Bipalium kewense* is a cryptic, nocturnal soil and litter-dwelling species. It can shelter within plant pots, root balls and within plant material making it difficult to detect unless the plants are uprooted and checked by experts, and the growing medium and root balls examined directly. *Bipalium kewense* has already spread along this pathway, and has been largely undetected, as documented in France (Justine *et al.*, 2018). It is very likely that its spread would be undetected and confidence is high.

**Qu. 3.8a. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

If local conditions are favourable, it is highly probably that *B. kewense* would transfer from plant root balls or plant pots) to an urban garden or other site where there was earthworm prey. This is essentially direct transfer to an urban environment.

**Qu. 3.9a. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly <b>slowly</b> moderately rapidly very rapidly	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response:

If *B. kewense* established itself in garden centres or nurseries in the risk assessment area, then there is great capacity for secondary spread through this means, especially in countries with temperate climates (Type C climates with the minimum temperature of the coldest month averaging above 0 °C. see Qu 2.1) where the species is presently established outdoors in urban gardens.

However, *B. kewense* will have limited distribution within the risk assessment area in countries with the minimum temperature of the coldest month averaging below 0 °C (Type D climates – see Qu 2.1 ) where the species is only found in “protected facilities” (e.g. hothouses).

The extent of spread is difficult to predict as although most garden centres will operate locally, some may trade on the internet, whilst customers may purchase plants on holiday or travelling. Such spread is therefore likely to be mostly localised but with some random long-distance transfers.

As transfer of plants is human-mediated and likely to be via cars and vans, environmental conditions are unlikely to have an impact on this means of transfer *per se*. *Bipalium kewense* has already established in suitable climates within the risk assessment area. However, spread has not been

particularly fast compared to species such as *Obama nungara*. Justine *et al.* (2018) admitted surprise that *B. kewense* has probably been undetected in some regions of France for over 20 years, which also suggests that spread had not been extensive or rapid.

There is no quantitative data available that would facilitate estimates for the potential rate of spread for *B. kewense* or other flatworm species.

*End of pathway assessment, repeat Qu. 3.3 to 3.9. as necessary using separate identifier.*

**Pathway name: Transportation of habitat material**

**Qu. 3.3b. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	Low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response:

Terrestrial flatworms may be spread with contaminated soil or material left on the soil surface beneath which they have sheltered. Such transport is unintentional.

**Qu. 3.4b. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication.
- if appropriate, indicate the rate of spread along this pathway.
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	Low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

Movement of topsoil, mulch, and compost have spread terrestrial flatworms, such as *A. triangulatus* (Justine *et al.*, 2014; Cannon *et al.*, 1999; Christensen and Mather, 1998; Moore *et al.*, 1998). Given that *B. kewense* shelters under soil refuges in the same way as *A. triangulatus*, it is reasonable to assume that this flatworm species could be spread in a similar manner. As with potted plants, much will depend on the ability of *B. kewense* to survive outdoors within the risk assessment area. Such

spread is largely random and unpredictable. There are no specific data for *B. kewense*. The volume of topsoil and compost movement is such that the starter populations will be larger than with individual potted plants making the chance of successful establishment higher.

**Qu. 3.5b. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>Low</b> medium high
-----------------	--	-------------------	------------------------------

Response:

Soil, mulch, and compost can provide microhabitats that retain moisture and buffer temperature fluctuations. Depending on the environmental conditions, *B. kewense* would likely survive transport and storage in soil especially if the volume is large. Large fragile elongate specimens may get damaged in the process of loading and unloading, possibly resulting in additional propagules via reproductive fragmentation.

**Qu. 3.6b. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	Low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

Management practices vary depending on the substrate moved. There are currently no management practices that would prevent transport of *B. kewense* if carried in large quantities of soil, mulch, or compost. Subsequent cultivation of the soil would be detrimental to *B. kewense* as the flatworm could be physically damaged (bearing in mind comments about regeneration of fragments).

**Qu. 3.7b. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely	<b>CONFIDENCE</b>	Low medium <b>high</b>
-----------------	--	-------------------	------------------------------

	<b>very likely</b>		
--	--------------------	--	--

Response:

Detecting *B. kewense*, a cryptic and a brown-ochre coloured flatworm, in large quantities of soil, mulch, or compost would be exceedingly difficult. Most often terrestrial flatworms are found in the location afterwards, and retrospective association made with a recent delivery of materials.

**Qu. 3.8b. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	Low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

Topsoil, mulch, or compost used in garden and landscaping would directly transfer *B. kewense* into a suitable habitat assuming that the minimum temperature of the coldest month in the area averaged above 0 °C.

**Qu. 3.9b. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	Low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response:

As with movements of ornamental and garden plants, most topsoil, mulch, and compost will be used in the local vicinity. It is difficult to quantify the potential for spread *B. kewense* as there is a deficiency of relevant data. As with potted plants, much will depend on the ability of the flatworm and any fragments resulting from asexual reproduction of *B. kewense*, to survive outdoors provided that the minimum temperature of the coldest month in the area averaged above 0 °C.

If the topsoil, mulch, and compost are heaped and the flatworm can burrow into and below the mass, then it is expected that specimens would survive in this “semi-protected” environment. However if the topsoil, mulch, or compost is spread, then there is a high likelihood that the flatworms would desiccate.

*End of pathway assessment, repeat Qu. 3.3 to 3.9. as necessary using separate identifier.*

**Pathway name: Machinery/equipment (transport stowaway)**

**Qu. 3.3c. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	Low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response:

Transfer along this pathway is unintentional. Terrestrial flatworms can be carried in soil remnants left on machinery or equipment. In addition, flatworms are covered in mucus and may adhere directly to machinery and equipment, and in particular wooden and plastic pallets that have remained in-situ for some period of time.

**Qu. 3.4c. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication.
- if appropriate, indicate the rate of spread along this pathway.
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>Low</b> <b>medium</b> high
-----------------	--	-------------------	-------------------------------------

Response:

There are no records of *B. kewense* being transported inadvertently in soil on boots or machinery. However, it is possible that flatworms will stick directly to soil-working machinery or equipment, especially wooden and plastic pallets in contact with the soil, and particularly if it is left to stand in one place for a prolonged period prior to relocation and thus allowing flatworms time to settle underneath. This is random and sporadic spread. There are no data available to estimate the propagule pressure. The rate of spread along this pathway will be determined by the movement of machines or equipment including pallets. As these are likely to horticultural or agricultural, most movement will be local. The likelihood of transport in this manner and the confidence level is dependent on distance. The longer the distance travelled the less likely flatworms will survive as they will be subject to mechanical damage and desiccation (please see below, Qu 3.5c).

**Qu. 3.5c. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response:

Adult *B. kewense* are unlikely to survive well when transported stuck to machinery or equipment, including wooden and plastic pallets. They will be prone to desiccation, exposed to temperature extremes and physical damage. Flatworms are only likely to survive short-range transport along this pathway. Egg cocoons may be more resilient than adults and being smaller and immobile, may be carried embedded within small quantities of soil stuck to machinery, but there is no evidence of this occurring for *B. kewense*.

**Qu. 3.6c. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response:

Sometimes agricultural equipment and machinery may be power washed and / or sprayed with disinfectant between sites for biosecurity purposes. The effects of disinfectants on *B. kewense* are not

known but the power washing process may dislodge them. Working machinery is likely to be detrimental to *B. kewense* survival as moving parts will increase the risk of physical damage but bearing in mind the ability of this flatworm to regrow from fragments.

**Qu. 3.7c. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response:

Other terrestrial flatworm species have been seen in transit on equipment or machinery, but this is mostly happenstance. In Scotland and Northern Ireland, *A. triangulatus* has been seen on hay and silage bales and the equipment used to move these (Boag *et al.*, 1999; Moore *et al.*, 1998). There is no evidence of spread of *Bipalium kewense* via this, or the food contaminant pathways.

**Qu. 3.8c. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response:

Soil-working machinery or equipment could transfer *B. kewense* directly to a new soil habitat. However, terrestrial flatworms are susceptible to physical damage, especially elongate specimens such as *B. kewense*, and may not survive intensive cultivation practices. Furthermore, the absence of refuges and greater movement of air (and hence lower relative humidity) that occur near the centre of fields, may explain why terrestrial flatworms have difficulty in becoming established in arable land, yet can readily be found in nurseries, gardens centres and urban gardens (Yeates *et al.*, 1998). Movement of more static equipment, especially wooden and plastic pallets resting on the soil surface, to garden and semi-natural sites poses the greatest risk for this pathway.

**Qu. 3.9c. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly <b>slowly</b> moderately rapidly very rapidly	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response:

Agricultural and horticultural machinery and equipment are predominantly used locally, although sometimes they can be moved long distances between sites. There are no quantitative data on the rate of spread of *B. kewense* or other terrestrial flatworms along this pathway. As with the other pathways above, it is likely to be random and sporadic.

*End of pathway assessment, repeat Qu. 3.3 to 3.9. as necessary using separate identifier.*

Pathway name: “**Contaminant on plants (except parasites, species transported by host/vector)**”  
Unintentional.

**Qu. 3.3d. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response:

The pathway “Contaminant on plants” concerns the unintentional transfer of potentially contaminated plants between gardeners. There is a single report of this type of occurrence in London, Ontario, Canada (Judd, 1957), where a resident obtained two plants of *Amaryllis* that had been potted and kept in a greenhouse for the previous six months; on receipt the plants were placed in a sink and thoroughly watered with liquid fertilizer; a few minutes later a specimen of *B. kewense* emerged from one of the pots.

**Qu. 3.4d. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or

frequency of passage through pathway), including the likelihood of reinvasion after eradication.

- if appropriate, indicate the rate of spread along this pathway.
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response:

There are no data or estimates on the number or volume of specimens passing along this pathway in the course of a year. Exchange of plants and seeds (plant swapping) is a widespread social practice amongst gardeners.

Low propagule pressure through asexual reproduction of *B. kewense* (refer to Qu 2.7) could still result in the establishment of the species if conditions were favourable in the area to which the contaminated potted plant was taken (refer to Qu 2.1).

Similarly the species may be re-introduced via the same pathway following eradication (refer to Qu 2.6).

**Qu. 3.5d. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

If *B. kewense* is transferred with potted plants containing soil, then providing these plants are not exposed to temperature extremes, and sufficient moisture is retained, it is likely that flatworms will survive. Reproduction by fragmentation may be possible in transit and during storage in the garden centres or nurseries depending upon the availability of earthworms, as asexual reproduction generally follows feeding on prey.

**Qu. 3.6d. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response:

National phytosanitary measures within Member States may be implemented at nurseries / garden centers to control flatworms but such measures are highly unlikely to be implemented by private individuals socially exchanging plants.

**Qu. 3.7d. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

*Bipalium kewense* is a cryptic, nocturnal soil and litter-dwelling species. It can shelter within plant pots, root balls and within plant material making it difficult to detect unless the plants are uprooted and checked by experts, and the growing medium and root balls examined directly. The state of knowledge by the average home gardener about alien flatworms throughout the risk assessment area is not known, but from the lack of public awareness of terrestrial flatworms in France (Justine *et al.*, 2018) it is probably poor, possibly because the planarians are generally cryptic and concealed. However, many urban gardeners have joined the citizen science network organized in France for collecting information about land planarians (Justine *et al.*, 2018), and as a result the awareness of the public about land planarians has improved. *Bipalium kewense* has already spread along this pathway in Canada (Judd, 1957), but is not documented in the risk assessment area.

**Qu. 3.8d. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely unlikely	<b>CONFIDENCE</b>	low medium
-----------------	---------------------------	-------------------	---------------

	moderately likely likely very likely		<b>high</b>
--	--	--	-------------

Response:

If climatic conditions are favourable ( see Qu 2.1), it is highly probable that *B. kewense* would transfer from plant pots arising from a social plant exchange to an urban garden where there was earthworm prey. Also the plants may well be planted out into the garden after being transported in pots.

**Qu. 3.9d. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly <b>slowly</b> moderately rapidly very rapidly	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response:

If *B. kewense* established itself in urban gardens in the risk assessment area, then there is great capacity for spread through this pathway, especially in countries with temperate climates (Type C climates with the minimum temperature of the coldest month averaging above 0 °C. see Qu 2.1) where the species is presently established outdoors in urban gardens.

However, *B. kewense* will have limited potential for spread via social plant exchanges within the risk assessment area in countries with the minimum temperature of the coldest month averaging below 0 °C (Type D climates – see Qu 2.1 ) where the species has only been found in “protected facilities” (e.g. hothouses).

The extent of spread is difficult to predict as social plant exchanges are likely to be local, such as within families and social networks. Such spread is therefore likely to be mostly localised but with some random long-distance transfers.

As transfer of plants is human-mediated and likely to be via cars and vans, environmental conditions are unlikely to have an impact on this means of transfer *per se*. *Bipalium kewense* has already established in suitable climates within the risk assessment area. Justine *et al.* (2018) admitted surprise that *B. kewense* has probably been undetected in some regions of France for over 20 years, which also suggests that spread had not been extensive or rapid.

There is no quantitative data available that would facilitate estimates for the potential rate of spread for *B. kewense* or other flatworm species via this pathway.

*End of pathway assessment, repeat Qu. 3.3 to 3.9. as necessary using separate identifier.*

**Qu. 3.10. Within the risk assessment area, how difficult would it be to contain the organism in relation to these pathways of spread?**

<b>RESPONSE</b>	very easy easy with some difficulty difficult <b>very difficult</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response:

*Bipalium kewense* is a cryptic soil-dwelling flatworm that is already present in the risk assessment area. It can be spread by potted plants, soil, and agricultural/horticultural equipment. The potential individual pathways within this context are numerous and exceedingly difficult to manage. Other than direct and potentially destructive inspection, *B. kewense* would be difficult to detect and there are no universal control measures that could be applied to bulk quantities of either plants, soil, mulch, or compost.

**Qu. 3.11. Estimate the overall potential rate of spread in relevant biogeographical regions under current conditions for this organism in the risk assessment area (indicate any key issues and provide quantitative data where possible).**

Thorough assessment of the risk of spread in relevant biogeographical regions in current conditions, providing insight in the risk of spread into (new areas in) the risk assessment area.

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response:

*Bipalium kewense* is a predominantly a tropical and subtropical species, and at present it is established in urban gardens outdoors in the risk assessment area.

Wherever it is established *B. kewense* will most likely continue to be spread via various pathways given that the species has been in the risk assessment area mainly within “protected” environments such as hothouses since the late 19<sup>th</sup> Century, and outdoors in more recent times. Potted plants kept in the same locality would be the initial reservoir for spread within the risk assessment area; spread via contaminant nursery material, and contaminant on plants via the horticultural trade or between amateur gardeners would be difficult to detect and manage.

Local spread would possibly occur via the machinery / equipment pathway through transport of soil or equipment and materials in contact with the soil surface. Given the right conditions, *B. kewense* might also gradually colonise surrounding areas through natural dispersal.

In the Atlantic biogeographical region, *B. kewense* is established outdoors in France in the department Pyrénées-Atlantiques, the climate of which appears particularly conducive to flatworms, and food and habitat are readily available in the urban gardens that thrive in this climate (Justine *et al.* 2018). In the U.K., *B. kewense* has only been recorded from “protected” environments (e.g. hothouses). Australian and New Zealand land planarians have been recorded outdoors from the warmer regions in the U.K. such as the Isles of Scilly or Cornwall, Continental (Jones, 2005), but to date not *B. kewense*.

In the Mediterranean biogeographic region, the species is established in Italy (Mori *et al.* 2021), Malta (T. Cassar and D. Mifsud, 2021 unpubl.), Portugal (Silva, 2020), and Spain (Filella-Subirà, 1983; Alvarez-Presas *et al.* 2014). In urban gardens the availability of food (earthworms) is unlikely to be a limiting factor. If the urban habitat is conducive to land planarians, the species could establish in Cyprus, Greece and Turkey. For example the Australian flatworm *Caenoplana bicolor* is established in western Crete, in the urban environment of Vryses square with Plane trees and the Vrysianos stream (Vardinoyannis and Alexandrakis, 2019). This type of habitat would probably also suit *B. kewense*.

In the Continental biogeographical region, *B. kewense* has only been recorded in “protected” environments (e.g. hothouses) in Austria, Belgium, Czech Republic, Denmark, Finland, Germany, Netherlands, Poland, Slovakia, and the United Kingdom. The main factor constraining the establishment of *B. kewense* outdoors in this biogeographic region is chiefly the minimum temperature of the coldest month (See Qu 2.1).

The rate of spread of *B. kewense* in the biogeographical regions in the risk assessment area under current conditions can be crudely estimated as follows: based upon literature records, the first occurrence of *Bipalium kewense* in countries and territories in the risk assessment area (RAA) can be divided into two distinct periods between 1877-1971 and 1982-2021.

The first period concerns the occurrence of the species in managed facilities such as hothouses largely in the Alpine, Atlantic, and Continental biogeographic regions, from 1877 – 1912, with a rate of spread of one country every 4.4 years, slowing between 1913 and 2002 with an overall rate (1877 – 2002) of one country every 11.4 years. These reports concern land planarians such as *B. kewense*, *Dolichoplana striata*, and some South American species brought to Europe from overseas via Wardian Cases largely during the period of Empires. The three later hothouse records in 1935, 1971 and 2002 may have been as a result of distribution from existing sources within the risk assessment area.

The second period concerns the occurrence of the species outdoors in urban situations largely in the southern Atlantic and Mediterranean biogeographic regions from 1982 - 2002, with a rate of one country every 4 years, starting to slow between 2002 – 2021 with only a single report, and an overall rate (1982-2021) of one country every 6.5 years. These reports possibly concern “new arrivals” via the plant trade rather than redistribution from managed facilities and may have been spread together with other alien land planarians such as recently reported outdoor occurrences of species of *Caenoplana*, *Bipalium*, *Diversibipalium* and *Obama* that have not generally been recorded in managed facilities.

Both periods are characterised by a rapid series of species occurrence reports, followed by a slowing of reports trending towards a plateauing of occurrences. Given these approximately parallel trends,

under current conditions, it is expected that the rate of spread (taken as the rate of publication of occurrences in new countries within the risk assessment area) should slow. However, the rate of spread within countries where *B. kewense* is present outdoors could increase. A more accurate study might be based on identified museum specimens, and / or dated photographs confirmed as of *B. kewense*, as in GBIF and iNaturalist. Also, new reports in all countries should be considered.

An additional indicator for the rate of spread of *B. kewense* that could be used to predict possible areas of likely establishment and measure spread rate is new urban developments within the Atlantic and Mediterranean biogeographic regions. In Australia, through enquiries to State museums and posts on iNaturalist Australia and Questagame, the interstate spread of a suite of native and alien land planarians via contaminant nursery material (unintentional) and transportation of habitat material (unintentional) is being casually monitored and suggests that the spread of the flatworms has some relationship to new housing developments in outer suburbs where owners plant gardens and landscape their properties (Winsor, 2021 unpubl.).

**Qu. 3.12. Estimate the overall potential rate of spread in relevant biogeographical regions in foreseeable climate change conditions (provide quantitative data where possible).**

Thorough assessment of the risk of spread in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk, specifically if rates of spread are likely slowed down or accelerated.

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response:

*Bipalium kewense* is mostly found in tropical and subtropical regions, albeit at altitude within these areas (Justine *et al.*, 2014). The optimum temperature for rearing *B. kewense* is between 15.6°C and 32°C and the flatworm is dependent on high humidity and soil moisture (Barnwell, 1968, as see Qu 2.7). Increased temperature and rainfall brought upon climate change could increase the rate of natural spread of *B. kewense*. For the human-dependent pathways, it is more difficult to suggest an effect of climate change. Changes in consumer preference for ornamental plants and the possibility of growing more exotic species may lead to greater south-to-north European plant trade, which would facilitate spread of *B. kewense*. The Atlantic biogeographical region would be most affected by this scenario as it extends further north.

## 4 MAGNITUDE OF IMPACT

Important instructions:

- Questions 4.1-4.5 relate to biodiversity and ecosystem impacts, 4.6-4.8 to impacts on ecosystem services, 4.9-4.13 to economic impact, 4.14-4.15 to social and human health impact, and 4.16-4.18 to other impacts. These impacts can be interlinked, for example, a disease may cause impacts on biodiversity and/or ecosystem functioning that leads to impacts on ecosystem services and finally economic impacts. In such cases the assessor should try to note the different impacts where most appropriate, cross-referencing between questions when needed.
- Each set of questions starts with the impact elsewhere in the world, then considers impacts in the risk assessment area (=EU excluding outermost regions) separating known impacts to date (i.e. past and current impacts) from potential future impacts (including foreseeable climate change).
- Only negative impacts are considered in this section (socio-economic benefits are considered in Qu. A.7)
- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”.

### Biodiversity and ecosystem impacts

**Qu. 4.1. How important is the impact of the organism on biodiversity at all levels of organisation caused by the organism in its non-native range excluding the risk assessment area?**

including the following elements:

- Biodiversity means the variability among living organisms from all sources, including terrestrial, marine and other aquatic ecosystems and the ecological complexes of which they are part; this includes diversity within species, between species and of ecosystems.
- impacted chemical, physical or structural characteristics and functioning of ecosystems

RESPONSE		CONFIDENCE	
	minimal		low
	<b>minor</b>		<b>medium</b>
	moderate		high
	major		
	massive		

Response:

No specific information has been found on this issue. Full evaluation of the impacts of *B. kewense* is hampered by the absence of ecological studies.

The prey of *Bipalium kewense* in its natural range is unknown.

However, in a four-year experimental study of two species of land planarians *Rhynchodemus sylvaticus*, a molluscivorous species, and *Bipalium kewense* (Lehnert, 1891), it was found that of the prey proffered to the planarians, *B. kewense* very rarely predated upon slugs, but preferred live

earthworms. This prey preference, confirmed by subsequent studies and observations (Johri, 1952; Wallen, 1954, Froehlich, 1956, Dundee and Dundee, 1963; Barnwell, 1967; Connella and Stern, 1969; Olewine, 1972; Chandler, 1974, Winsor, 1985), is reinforced to the extent that the collagenase present in this species is most active against earthworm (invertebrate-type) collagen (Dresden and Landsperger, 1977).

There are no quantitative studies on the impacts of *B. kewense* upon native or alien populations of earthworms.

*Bipalium kewense* is practicably solely a predator of earthworms, yet in New South Wales and Queensland, Australia it is regarded as an occasional minor pest in some urban domestic and commercial vermiculture farms that cultivate alien species of earthworms, where it is readily controlled by hand picking following water-flooding the beds (Winsor, 1998). Distribution data worldwide suggests that *B. kewense* is largely restricted to urban gardens, parks, and human-modified habitats. In Australia, the common earthworms in south-eastern urban gardens are mostly introductions from Europe with the Grey worm, *Aporrectodea caliginosa*, an alien species of earthworm originally from and common in the UK, to be most common species in urban habitats and orchards, with native species rarer in disturbed habitats (Baker *et al.*, 1997); consequently, these introduced earthworms that predominate in urban habitats (public and private gardens and parks) are the most likely prey for *B. kewense* in south-eastern Australia.

In one study under laboratory conditions (Connella and Stern, 1969), *B. kewense* was fed the native North American earthworm species *Diplocardia singularis* raised specifically for that purpose.

Therefore despite *B. kewense* being recorded in many countries around the world, only isolated accounts of predation of “earthworms”, largely under experimental conditions, have been reported (Lehnert, 1891, Johri, 1952, Dundee and Dundee, 1963, Connella and Stern, 1969, Olewine, 1972; Chandler, 1974, Winsor *et al.*, 2004, Ducey *et al.*, 2006).

Data on predatory behaviour and reproduction are available for two invasive bipaliines in North America *Bipalium adventitium* (key recent reference Ducey *et al.*, 2005), and *Bipalium* sp. cf *vagum* (Ducey *et al.*, 2007), though unlike *B. kewense* both these species are relatively small (5-10 cm long, and 3.5 cm long respectively), and propagate principally by sexual rather than asexual reproduction. Given the different principal reproductive strategies, and relative fecundity, the ecological impacts of *B. adventitium* may not necessarily extrapolate to become those of *B. kewense*.

Whilst these studies confirm that *B. kewense* feeds upon earthworms, the actual impact of the planarian on earthworm populations and possibly flow-on effects on biodiversity are unknown.

**Qu. 4.2. How important is the current known impact of the organism on biodiversity at all levels of organisation (e.g. decline in native species, changes in native species communities, hybridisation) in the risk assessment area (include any past impact in your response)?**

Discuss impacts that are currently occurring or are likely occurring or have occurred in the past in the risk assessment area. Where there is no direct evidence of impact in the risk assessment area (for example no studies have been conducted), evidence from outside of the risk assessment area can be used to infer impacts within the risk assessment area.

<b>RESPONSE</b>	minimal <b>minor</b>	<b>CONFIDENCE</b>	low <b>medium</b>
-----------------	-------------------------	-------------------	----------------------

	moderate major massive		high
--	------------------------------	--	------

Response:

No information has been found on this issue. *Bipalium kewense* does not appear to be established outside urban and agricultural land, or in wild habitats in the risk assessment area.

However, following treatment of pasture land via contaminated “transportation of habitat material”, the species *Bipalium kewense* established in grassland in the warmer far north of the North Island of New Zealand. European earthworms have been deliberately introduced into pasture in New Zealand to increase their yields and *B. kewense* might have a negative impact if they were to significantly reduce the numbers of the European earthworms (Boag 2021, unpublished).

No studies have been conducted on the ecological impact of the *B. kewense* on earthworm populations, nor on species preyed upon by the flatworm, either within the risk assessment area, or in other countries outside the risk assessment area where the species is established. Whilst not conclusive, the lack of studies on these topics suggest that concerns have not been raised nor obvious impacts reported.

**Qu. 4.3. How important is the potential future impact of the organism on biodiversity at all levels of organisation likely to be in the risk assessment area?**

See comment above. The potential future impact shall be assessed only for the risk assessment area.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response:

Unlike *Arthurdendyus triangulatus*, *Bipalium kewense* does not appear to have invaded large areas of agricultural land and there are no records from pasture in the Risk Assessment Area; *Bipalium kewense* established in grassland in the warmer far north of New Zealand; whether there is any impact on earthworm populations in this area is unknown. At the present time, *B. kewense* is mostly regarded as a species of urban habitats in Europe. Data from the species distribution models (Appendix VIII) suggest that *B. kewense* will spread under climate change scenarios and will likely invade natural habitats. However, the impact of *B. kewense* on earthworms seems to be less than other invasive alien flatworms (e.g. *A. triangulatus*) and it does not appear to achieve the high population densities seen with *O. nungara*.

**Qu. 4.4. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism currently in the risk assessment area?**

including the following elements:

- native species impacted, including red list species, endemic species and species listed in the Birds and Habitats directives
- protected sites impacted, in particular Natura 2000
- habitats impacted, in particular habitats listed in the Habitats Directive, or red list habitats
- the ecological status of water bodies according to the Water Framework Directive and environmental status of the marine environment according to the Marine Strategy Framework Directive

<b>RESPONSE</b>	<b>minimal</b> minor moderate major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response:

No specific information has been found on the issue. However, there is no evidence that *Bipalium kewense* is established in natural habitats in the risk assessment areas.

**Qu. 4.5. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.4.

<b>RESPONSE</b>	<b>minimal</b> minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response:

No information has been found on the issue. The impact on habitats and sites is difficult to determine at this stage, as the earthworm species preyed upon by *B. kewense* in outdoor locations, currently all urban, have not been identified.

## Ecosystem Services impacts

**Qu. 4.6. How important is the impact of the organism on provisioning, regulating, and cultural**

**services in its non-native range excluding the risk assessment area?**

- For a list of services use the CICES classification V5.1 provided in Annex V.
- Impacts on ecosystem services build on the observed impacts on biodiversity (habitat, species, genetic, functional) but focus exclusively on reflecting these changes in relation to their links with socio-economic well-being.
- Quantitative data should be provided whenever available and references duly reported.

<b>RESPONSE</b>	<b>N/A</b>	<b>CONFIDENCE</b>	low medium high
	minimal minor moderate major massive		

Response:

No information has been found on the issue. The impact on habitats and sites is difficult to determine at this stage, as the earthworm species preyed upon by *B. kewense* in outdoor locations, currently all urban, have not been identified.

**Qu. 4.7. How important is the impact of the organism on provisioning, regulating, and cultural services currently in the different biogeographic regions or marine sub-regions where the species has established in the risk assessment area (include any past impact in your response)?**

- See guidance to Qu. 4.6.

<b>RESPONSE</b>	<b>N/A</b>	<b>CONFIDENCE</b>	low medium high
	minimal minor moderate major massive		

Response:

No information has been found on the issue. The impact on habitats and sites is difficult to determine at this stage, as the earthworm species preyed upon by *B. kewense* in outdoor locations, currently all urban, have not been identified.

**Qu. 4.8. How important is the impact of the organism on provisioning, regulating, and cultural services likely to be in the different biogeographic regions or marine sub-regions where the**

**species can establish in the risk assessment area in the future?**

- See guidance to Qu. 4.6.

<b>RESPONSE</b>	N/A minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response:

No information has been found on this issue that specifically relates to *Bipalium kewense*. Although *Bipalium kewense* is an earthworm predator it does not seem to occur in the high population densities seen in other invasive earthworm predators, *A. triangulatus* and *O. nungara*. It has not been recorded from fields and agricultural land, nor natural habitats in the Risk Assessment Area, and has only been recorded in urban habitats such as gardens and parks.

### Economic impacts

**Qu. 4.9. How great is the overall economic cost caused by the organism within its current area of distribution (excluding the risk assessment area), including both costs of / loss due to damage and the cost of current management.**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the world these should be reported here. The assessment of the potential costs of / loss due to damage shall describe those costs quantitatively and/or qualitatively depending on what information is available. Cost of / loss due to damage within different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage. As far as possible, it would be useful to separate costs of / loss due to the organism from costs of current management.

<b>RESPONSE</b>	N/A minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response:

No information has been found on this issue that specifically relates to *Bipalium kewense* in the Risk Assessment Area.

*Bipalium kewense* has been recorded as a minimal pest of urban earthworm farming cultivating alien earthworms species in Australia and is readily controlled by occasional hand picking from water-flooded beds as required. (The native Australian flatworm species, *Dolichoplana* sp., was more damaging for commercial earthworm farmers (Winsor, 1998) as the earthworm stock provided to these franchisee farmers was found to be already contaminated by the flatworm, and as a consequence at least one grower lost his business (Winsor, 2021 unpubl.)).

*Bipalium kewense* is established in grassland in the warmer far north of the North Island of New Zealand. New Zealand depends upon agricultural exports, mainly from sheep and cattle, for their livelihood. European earthworms have been deliberately introduced into pasture in New Zealand to increase their yields and *B. kewense* might have a negative impact if they were to significantly reduce the numbers of the European earthworms (Boag 2021, unpublished).

In the absence of data on this question from the RAA, the question is regarded as inapplicable to the species.

**Qu. 4.10. How great is the economic cost of / loss due to damage (excluding costs of management) of the organism currently in the risk assessment area (include any past costs in your response)?**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the EU these should be reported here. Assessment of the potential costs of damage on human health, safety, and the economy, including the cost of non-action. A full economic assessment at EU scale might not be possible, but qualitative data or different case studies from across the EU (or third countries if relevant) may provide useful information to inform decision making. In absence of specific studies or other direct evidence this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. Cost of / loss due to damage within different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

RESPONSE	N/A	CONFIDENCE	low
	minimal		medium
	minor		high
	moderate		
	major		
	massive		

Response:

No information has been found on the issue specifically relating to *Bipalium kewense*, and the question considered Not Applicable to the species.

There is evidence that other species alien flatworms have been inadvertently disseminated in potted plants from infected garden centres and botanic gardens to the public or other botanic gardens. This is non-intentional transfer and if known it can adversely affect the reputation of the business or botanic garden concerned (Boag and Neilson, 2014).

**Qu. 4.11. How great is the economic cost of / loss due to damage (excluding costs of management) of the organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.10.

<b>RESPONSE</b>	N/A minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response:

No information has been found on the issue.

There is no evidence of *B. kewense* causing economic losses in any of the countries that it has become established. Following treatment of pasture land via contaminated “transportation of habitat material”, the species *Bipalium kewense* established in grassland in the warmer far north of the North Island of New Zealand. European earthworms have been deliberately introduced into pasture in New Zealand to increase their yields and *B. kewense* might have a negative impact if they were to significantly reduce the numbers of the European earthworms (Boag 2021, unpublished).

In addition, unlike *A. triangulatus*, and apart from the single example in New Zealand (above) it has not established widely in agricultural pasture, where predation on earthworms causes economic losses to grass production (Murchie, 2018). There is potential that *B. kewense* could migrate from garden locations to surrounding habitats but so far it does not appear to have done so, despite being established outdoors in France for c. 30 years.

**Qu. 4.12. How great are the economic costs / losses associated with managing this organism currently in the risk assessment area (include any past costs in your response)?**

- In absence of specific studies or other direct evidence this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”.

<b>RESPONSE</b>	N/A minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response:

No information has been found on the issue, hence rated as Not Applicable

*Bipalium kewense* has not established in natural or agricultural habitats in the risk assessment area but rather in “protected” sites such as hothouses, and in urban gardens. Management practices are therefore limited to these locations and are not thought to be costly. Management of the flatworm in private urban gardens would presumably be up to landowners to implement, if indeed they were concerned. Management practices for other invasive alien flatworms in Europe, e.g. *A. triangulatus* are mainly physical control measure applied by horticultural producers, garden centres and nurseries (EPPO, 2001b; MAFF, 1996). The extent of implementation of these and the associated costs are unknown.

**Qu. 4.13. How great are the economic costs / losses associated with managing this organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.12.

<b>RESPONSE</b>	N/A minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response:

No information has been found on the issue, hence rated as Not Applicable

At the present time, there are no published economic costs associated with managing this flatworm.

In the future management options applied to other more damaging flatworm species, would equally affect *B. kewense* but would not necessarily be justified for this species alone unless problems become more apparent than have been currently observed.

## Social and Human health impacts

**Qu. 4.14. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism for the risk assessment area and for third countries, if relevant (e.g. with similar eco-climatic conditions).**

The description of the known impact and the assessment of potential future impact on human health, safety and the economy, shall, if relevant, include information on

- illnesses, allergies or other affections to humans that may derive directly or indirectly from a species;
- damages provoked directly or indirectly by a species with consequences for the safety of people, property or infrastructure;

- direct or indirect disruption of, or other consequences for, an economic or social activity due to the presence of a species.

Social and human health impacts can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>	minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

*Bipalium kewense* is not known to have any important social or human health impacts.

However, there is evidence that other species alien flatworms have been inadvertently disseminated in potted plants from infected garden centres and botanic gardens to the public or other botanic gardens. This non-intentional transfer if known, can adversely affect the reputation of the business or botanic garden concerned (Boag and Neilson, 2014).

The presence of invasive alien flatworms can be distressing to some gardeners as they regard these species to be ‘slimy’ and harmful.

*Bipalium kewense* has been implicated in cases of gastrointestinal pseudoparasitism (where there is no harm to humans, native or domestic animals), based upon circumstantial evidence, of humans (Walton and Yokogawa, 1972; Daly *et al.*, 1977).

Three toxins have been reported from *B. kewense*: a cardiotoxin, related in its effects but not necessarily in its chemistry, to cardiac glucosides, that is localized in dermal mucus, and a haemolytic toxin distributed throughout the planarian body (Arndt, 1925). More recently tetrodotoxin (TTX) was detected in *B. kewense*, largely concentrated in the head region, used to subdue large earthworm prey by reducing it to a partial paralytic state to facilitate feeding (Stokes *et al.*, 2014). The presence of TTX may also serve for defence by *B. kewense* against predators, and the species may accumulate TTX in the egg cocoon as does *Bipalium adventitium* (Stokes *et al.*, 2014). There is no evidence that these toxins result in any injury to humans through normal handling.

On the basis of this evidence, the impacts are considered minimal (only relating to possible loss of reputation of nurseries selling contaminated stock) with high confidence.

**Qu. 4.15. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism in the future for the risk assessment area.**

- In absence of specific studies or other direct evidence this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”.

<b>RESPONSE</b>	<b>N/A</b> minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	--	-------------------	-----------------------

Response:

No information has been found on this issue, hence rated as Not Applicable.

It is expected that the importance of social, health or other impacts caused by the organism (as in Qu 4.14) would change little in the future.

### Other impacts

**Qu. 4.16. How important is the organism in facilitating other damaging organisms (e.g. diseases) as food source, a host, a symbiont or a vector etc.?**

<b>RESPONSE</b>	<b>N/A</b> minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response:

Unlike species of the Rhynchodemid planarians, species of the Bipaliinae that includes *Bipalium kewense* have not yet been implicated as paratenic or carrier hosts of the Rat Lung worm, the nematode *Angiostrongylus cantonensis* that is responsible for eosinophilic meningitis, especially in the Pacific Region, and other species of *Angiostrongylus*. *Bipalium kewense* predate solely upon earthworms and does not predate upon land molluscs.

On the basis of the biological characteristics of *B. kewense*, this question is Not Applicable to the species.

**Qu. 4.17. How important might other impacts not already covered by previous questions be resulting from introduction of the organism?**

<b>RESPONSE</b>	<b>N/A</b>	<b>CONFIDENCE</b>	low
-----------------	------------	-------------------	-----

	minimal minor moderate major massive		medium high
--	--	--	----------------

Response:

No information has been found on the issue, hence rated as Not Applicable.

*Bipalium kewense* has been present in the risk assessment area in “protected” environment sites, such as hothouses etc., for some 144 years, and possibly in outdoor locations for at least 30 years.

The absence of ecological studies on this species hampers an informed assessment of possible impacts. However, there are no reports of *B. kewense* impacting on specific members of the soil fauna, such as earthworm species identified in studies within the risk assessment area (Rutgers et al., 2016).

Boag *et al.* (2010) argue that there is a readily available niche for land planarians from the southern hemisphere to exploit in Europe and North America, and this seems to be supported by recent accounts of alien land planarians in France (Justine *et al.*, 2018) and in Italy (Mori *et al.*, 2021), and the spread of Hammerhead flatworms in North America, perhaps facilitated by *Lumbricus terrestris*, itself a problematic alien species in North America (Murchie and Gordon, 2013).

*Bipalium kewense* has been implicated in cases of gastrointestinal pseudoparasitism, based upon circumstantial evidence, of humans (Walton and Yokogawa, 1972; Daly *et al.*, 1977), a dog and a cat (Daly *et al.*, 1976). On the basis of experimental physiological studies of *B. kewense* (Daly *et al.* 1977) demonstrated the failure to establish even short-term passage of the flatworm in the digestive tract of dogs, lethality of 37°C body temperature, and sensitivity to faeces makes gastrointestinal pseudoparasitism unlikely in these organisms. A more reasonable explanation for the phenomenon is the accidental attachment, in an outdoor environment, of highly sticky specimens of *B. kewense* to dogs, cats and humans. This phenomenon has observed in interactions between other species of land planarians and native and domestic animals (Winsor, 1980).

The presence of toxins in *B. kewense*, together with repugnatorial dermal secretions, may explain the three reports of vomiting of specimens of *B. kewense* by cats (Winsor, 1983b). These toxins are significant only in the flatworm’s natural environment in obtaining prey, and in defense against potential predators.

In the absence of information on additional potential impacts resulting from the introduction of *B. kewense*, the response is that the question is not applicable to this species.

**Qu. 4.18. How important are the expected impacts of the organism despite any natural control by other organisms, such as predators, parasites or pathogens that may already be present in the risk assessment area?**

<b>RESPONSE</b>	<b>N/A</b> minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	--	-------------------	-----------------------

Response:

No information has been found on the issue, and the question regarded as Not Applicable to the species.

The impact on *B. kewense* by predators, parasites (nematodes) and pathogens is expected to be low (Winsor 2021, unpublished), and the importance of the expected impacts of *B. kewense*, essentially be unchanged.

**Qu. 4.19. Estimate the overall impact in the risk assessment area under current climate conditions. In addition, details of overall impact in relevant biogeographical regions should be provided.**

Thorough assessment of the overall impact on biodiversity and ecosystem services, with impacts on economy as well as social and human health as aggravating factors, in current conditions.

<b>RESPONSE</b>	<b>minimal</b> minor moderate major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response:

*Bipalium kewense* is exclusively a predator of earthworms. It has been present in the risk assessment area for some 144 years, initially in botanic garden and urban hothouses, and in outdoor urban environments for at least 30 years in south-eastern France. Despite numerous studies in which *B. kewense* was used as a representative of a free-living triclad flatworm, there is a deficiency of ecological studies for this species. There are no quantitative studies on the impacts of populations of *B. kewense* upon earthworms.

However, world-wide, *B. kewense* has not been implicated in the observable decline of earthworm populations, nor implicated in concerns about the demise of earthworms causing changes to pastureland in the risk assessment area (U.K.) as is the situation for the New Zealand flatworm *A. triangulatus*. Nor has it exhibited invasiveness of outdoor natural habitats as has *B. adventitium* in the US. *Bipalium kewense* has had no discernable impacts on ecological services, the economy, or adversely impacted aspects of social and human health. There is presently no evidence to suggest that it will cease being benign.

The response to this question is that the impacts are considered minimal (relating to possible loss of reputation of nurseries selling contaminated stock, and despite the deficiency of ecological studies and absence of quantitative studies on the impacts of the species earthworm populations) with medium confidence based on comparison with other alien terrestrial flatworms and ratings elsewhere in this section.

**Qu. 4.20. Estimate the overall impact in the risk assessment area in foreseeable climate change conditions. In addition, details of overall impact in relevant biogeographical regions should be provided.**

Thorough assessment of the overall impact on biodiversity and ecosystem services, with impacts on economy as well as social and human health as aggravating factors, under future conditions.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response:

Under Climate Change with timeframe 2070, and emission scenarios RCP 2.6 and RCP 4.5 there are increases in the projected suitability for the establishment of *B. kewense* generally north and northeastwards under both RCP 2.6 and RCP 4.5 in the Atlantic, Black Sea, Continental, Pannonian and Steppic biogeographical regions in the risk assessment area, and in the Anatolian biogeographic region (refer to Figures 3 and 4 Annex VIII). The lower to mid-levels of the Alpine region appear to become increasing suitable for the establishment of the species under the RCP 2.6 and 4.5 scenarios.

For the Mediterranean region, there is little change between the current projected suitability and those under RCP 2.6 and RCP 4.5. Arid and desert conditions are increasing, and water will become more and more scarce ( [https://www.eea.europa.eu/publications/report\\_2002\\_0524\\_154909/biogeographical-regions-in-europe/mediterranean\\_biogeographical\\_region.pdf/view](https://www.eea.europa.eu/publications/report_2002_0524_154909/biogeographical-regions-in-europe/mediterranean_biogeographical_region.pdf/view) retrieved 25 June 2021), making this region inimical for the establishment of *B. kewense*.

These predicted changes to the climate in the risk assessment area could result in the establishment and spread of *B. kewense* as the Continental, Alpine and Boreal biogeographical regions warm and become more temperate.

In the Atlantic biogeographical region Belgium, Denmark, Ireland, the Netherlands, and the United Kingdom contain some of the largest conglomeration of people in Europe, any of whom live near the coast ([https://www.eea.europa.eu/publications/report\\_2002\\_0524\\_154909/biogeographical-regions-in-europe/the\\_atlantic\\_region.pdf/view](https://www.eea.europa.eu/publications/report_2002_0524_154909/biogeographical-regions-in-europe/the_atlantic_region.pdf/view) retrieved 25 June 2021). In the Continental region countries such as Austria, Czech Republic, Germany, Poland, and Slovakia, the urban areas are among the largest and most extensive in Europe. A large proportion of the population lives in the vicinity of

forests. Some new afforestation occurs around big cities for recreational purposes ([https://www.eea.europa.eu/publications/report\\_2002\\_0524\\_154909/biogeographical-regions-in-europe/continental\\_biogeografical\\_region.pdf/view](https://www.eea.europa.eu/publications/report_2002_0524_154909/biogeographical-regions-in-europe/continental_biogeografical_region.pdf/view) retrieved 25 June 2021).

In these countries within both the Atlantic and Continental biogeographical regions, *B. kewense* is currently present only in “protected” environments such as hothouses. Under the climate warming scenarios, there would probably no longer be the need for hothouses in these countries, and there could be a loss of containment of *B. kewense* from “protected” environments into outdoor urban gardens and parks where it could establish in the warmer conditions. This would bring *B. kewense* into contact with a broader range of potential prey species, but the impact would likely remain localised and reversible. ‘Low’ confidence reflects a lack of current information on the ecological impact of *B. kewense* under current conditions but especially given potential additional prey species.

Any impacts on biodiversity, ecosystem services and human health are likely to increase under climate change and mostly occur in the same biogeographic regions.

## RISK SUMMARIES

	RESPONSE	CONFIDENCE	COMMENT
<b>Summarise Introduction and Entry*</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	low medium <b>high</b>	<i>Bipalium kewense</i> has already been unintentionally introduced via the live plant trade, especially potted plants for gardens and via the botanical garden pathway. The species has been present in “protected” environments (e.g. hothouses) in Europe for 144 years, and in urban outdoor habitats for possibly 30+ years. Climate change will probably see the movement of the flatworm from the “protected” facilities into outdoor urban gardens and parks.
<b>Summarise Establishment*</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	low medium <b>high</b>	The species is already established outdoors in urban gardens in several Member States: France, Italy, Portugal, Spain, and Malta. It is expected that the outdoor occurrence of <i>B. kewense</i> will follow the increasing urbanization in the risk assessment area. Climate change will enable the increased spread northwards from the present biographical regions where <i>B. kewense</i> occurs.
<b>Summarise Spread*</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>low</b> medium high	<i>Bipalium kewense</i> was originally spread by human-assisted transport over long distances followed subsequently by slow and local natural dispersal within urban habitats. Flatworms can be readily spread via ‘Contaminant nursery material’ pathway that includes potted plants and plants for planting; the ‘Transportation of habitat material’ (unintentional) pathway movement of soil and compost, which may contain <i>B. kewense</i> . The ‘Machinery / equipment’ pathway with which there is some overlap with the movement of soil, as flatworms may be carried in soil adhering to machinery or equipment. The “Contaminant on plants” pathway concerns the personal exchange of potentially contaminant plants between gardeners. This will probably lead to moderately rapid spread but confidence in this score is low because of lack of monitoring data.

<b>Summarise Impact*</b>	minimal <b>minor</b> moderate major massive	<b>low</b> medium high	There is lack of information on the ecological, economic, and social impact of <i>B. kewense</i> , despite the flatworm having colonized urban habitats in many regions worldwide and having been the subject of numerous scientific studies. It is likely that there would only be local impacts on ecosystems and only localised control costs and public concern. If future data becomes available revealing biodiversity impacts the PRA would need to be revised.
<b>Conclusion of the risk assessment (overall risk)</b>	low <b>moderate</b> high	<b>low</b> medium high	<i>Bipalium kewense</i> is the most widely dispersed flatworm species in the world. It is established in many EU Member States and it is likely that it will continue to spread, at least in urban situations. While the risk assessment area has been colonized by many other species of terrestrial flatworms that have had clear deleterious consequences, no information to this effect was found for <i>B. kewense</i> . However, deleterious impacts on soil invertebrates are not as readily observed as above-ground impacts and it remains feasible that <i>B. kewense</i> predation could have unforeseen effects on soil fauna. The overall assessment is therefore ‘moderate’ based on expert opinion regarding the ability of the flatworm to establish and spread, and that it predated upon earthworms; in the absence of detailed studies on the impact of <i>B. kewense</i> , the confidence however is low.

\*in current climate conditions and in foreseeable future climate conditions

## Distribution Summary

Please answer as follows:

- Yes if recorded, established or invasive
- if not recorded, established or invasive
- ? Unknown; data deficient

The columns refer to the answers to Questions A5 to A12 under Section A.

For data on marine species at the Member State level, delete Member States that have no marine borders. In all other cases, provide answers for all columns.

Member States, and the United Kingdom

	Recorded	Established (currently)	Possible establishment (under current climate)	Possible establishment (under foreseeable climate)	Invasive (currently)
Austria	Yes	-	Yes	Yes

## ANNEX I Scoring of Likelihoods of Events

(taken from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

<b>Score</b>	<b>Description</b>	<b>Frequency</b>
Very unlikely	This sort of event is theoretically possible, but is never known to have occurred and is not expected to occur	1 in 10,000 years
Unlikely	This sort of event has occurred somewhere at least once in the last millennium	1 in 1,000 years
Moderately likely	This sort of event has occurred somewhere at least once in the last century	1 in 100 years
Likely	This sort of event has happened on several occasions elsewhere, or on at least once in the last decade	1 in 10 years
Very likely	This sort of event happens continually and would be expected to occur	Once a year

## ANNEX II Scoring of Magnitude of Impacts

(modified from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

Score	Biodiversity and ecosystem impact	Ecosystem Services impact	Economic impact (Monetary loss and response costs per year)	Social and human health impact, and other impacts
	<i>Question 5.1-5</i>	<i>Question 5.6-8</i>	<i>Question 5.9-13</i>	<i>Question 5.14-18</i>
Minimal	Local, short-term population loss, no significant ecosystem effect	No services affected <sup>5</sup>	Up to 10,000 Euro	No social disruption. Local, mild, short-term reversible effects to individuals.
Minor	Some ecosystem impact, reversible changes, localised	Local and temporary, reversible effects to one or few services	10,000-100,000 Euro	Significant concern expressed at local level. Mild short-term reversible effects to identifiable groups, localised.
Moderate	Measureable long-term damage to populations and ecosystem, but reversible; little spread, no extinction	Measureable, temporary, local and reversible effects on one or several services	100,000-1,000,000 Euro	Temporary changes to normal activities at local level. Minor irreversible effects and/or larger numbers covered by reversible effects, localised.
Major	Long-term irreversible ecosystem change, spreading beyond local area	Local and irreversible or widespread and reversible effects on one / several services	1,000,000-10,000,000 Euro	Some permanent change of activity locally, concern expressed over wider area. Significant irreversible effects locally or reversible effects over large area.
Massive	Widespread, long-term population loss or extinction, affecting several species with serious ecosystem effects	Widespread and irreversible effects on one / several services	Above 10,000,000 Euro	Long-term social change, significant loss of employment, migration from affected area. Widespread, severe, long-term, irreversible health effects.

<sup>5</sup> Not to be confused with “no impact”.

## ANNEX III Scoring of Confidence Levels

(modified from Bacher *et al.* 2017)

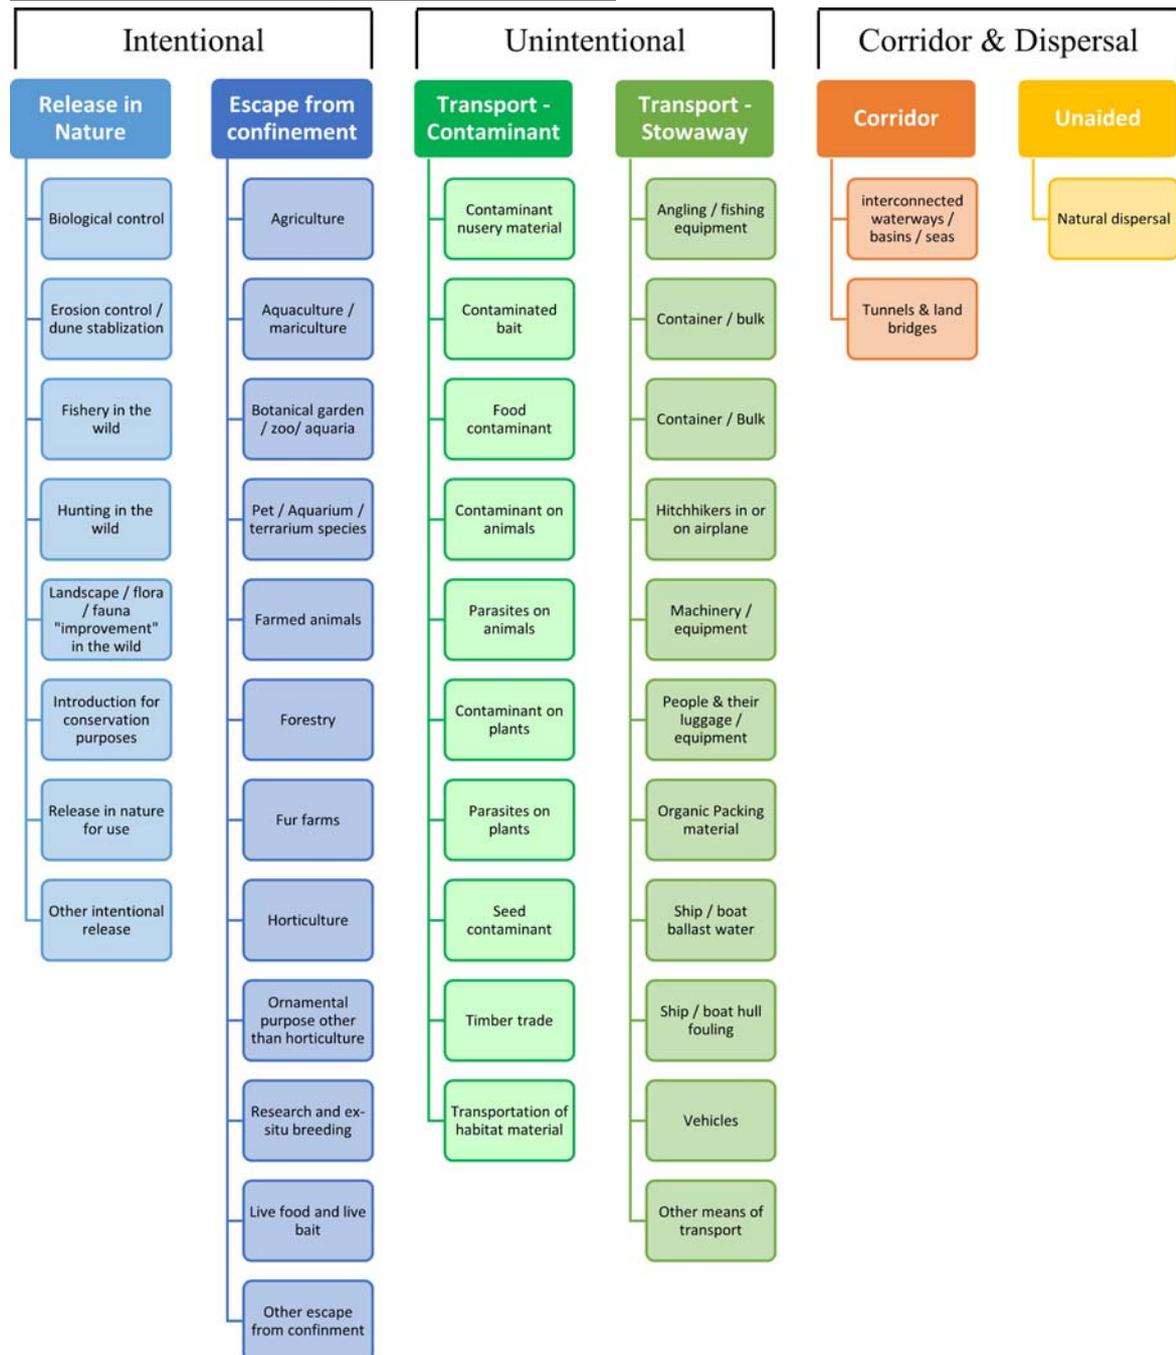

Each answer provided in the risk assessment must include an assessment of the level of confidence attached to that answer, reflecting the possibility that information needed for the answer is not available or is insufficient or available but conflicting.

The responses in the risk assessment should clearly support the choice of the confidence level.

Confidence level	Description
Low	There is no direct observational evidence to support the assessment, e.g. only inferred data have been used as supporting evidence <i>and/or</i> Impacts are recorded at a spatial scale which is unlikely to be relevant to the assessment area <i>and/or</i> Evidence is poor and difficult to interpret, e.g. because it is strongly ambiguous <i>and/or</i> The information sources are considered to be of low quality or contain information that is unreliable.
Medium	There is some direct observational evidence to support the assessment, but some information is inferred <i>and/or</i> Impacts are recorded at a small spatial scale, but rescaling of the data to relevant scales of the assessment area is considered reliable, or to embrace little uncertainty <i>and/or</i> The interpretation of the data is to some extent ambiguous or contradictory.
High	There is direct relevant observational evidence to support the assessment (including causality) <i>and</i> Impacts are recorded at a comparable scale <i>and/or</i> There are reliable/good quality data sources on impacts of the taxa <i>and</i> The interpretation of data/information is straightforward <i>and/or</i> Data/information are not controversial or contradictory.

## ANNEX IV CBD pathway categorisation scheme

Overview of CBD pathway categorisation scheme showing how the 44 pathways relate to the six main pathway categories. All of the pathways can be broadly classified into 1) those that involve intentional transport (blue), 2) those in which the taxa are unintentionally transported (green) and 3) those where taxa moved between regions without direct transportation by humans and/or via artificial corridors (orange and yellow). **Note that the pathways in the category “Escape from confinement” can be considered intentional for the introduction into the risk assessment area and unintentional for the entry into the environment.**

## ANNEX V Ecosystem services classification (CICES V5.1, simplified) and examples

For the purposes of this risk assessment, please feel free to use what seems as the most appropriate category / level / combination of impact (Section – Division – Group), reflecting information available.

Section	Division	Group	Examples (i.e. relevant CICES “classes”)
Provisioning	Biomass	<b>Cultivated <i>terrestrial</i> plants</b>	Cultivated terrestrial plants (including fungi, algae) grown for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from cultivated plants, fungi, algae and bacteria for direct use or processing (excluding genetic materials); Cultivated plants (including fungi, algae) grown as a <u>source of energy</u>  <i>Example: negative impacts of non-native organisms to crops, orchards, timber etc.</i>
		<b>Cultivated <i>aquatic</i> plants</b>	Plants cultivated by in- situ aquaculture grown for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from in-situ aquaculture for direct use or processing (excluding genetic materials); Plants cultivated by in- situ aquaculture grown as an <u>energy source</u> .  <i>Example: negative impacts of non-native organisms to aquatic plants cultivated for nutrition, gardening etc. purposes.</i>
		<b>Reared animals</b>	Animals reared for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from reared animals for direct use or processing (excluding genetic materials); Animals reared to provide <u>energy</u> (including mechanical)  <i>Example: negative impacts of non-native organisms to livestock</i>
		<b>Reared <i>aquatic</i> animals</b>	Animals reared by in-situ aquaculture for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from animals grown by in-situ aquaculture for direct use or processing (excluding genetic materials); Animals reared by in-situ aquaculture as an <u>energy source</u>  <i>Example: negative impacts of non-native organisms to fish farming</i>
		<b>Wild plants (terrestrial and aquatic)</b>	Wild plants (terrestrial and aquatic, including fungi, algae) used for <u>nutrition</u> ; <u>Fibres and other materials</u> from wild plants for direct use or processing (excluding genetic materials); Wild plants (terrestrial and aquatic, including fungi, algae) used as a <u>source of energy</u> <i>Example: reduction in the availability of wild plants (e.g. wild berries, ornamentals) due to non-native organisms (competition, spread of disease etc.)</i>
		<b>Wild animals (terrestrial and aquatic)</b>	Wild animals (terrestrial and aquatic) used for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from wild animals for direct use or processing (excluding genetic materials); Wild animals (terrestrial and aquatic) used as a <u>source of energy</u>  <i>Example: reduction in the availability of wild animals (e.g. fish</i>

			stocks, game) due to non-native organisms (competition, predations, spread of disease etc.)
	<b>Genetic material</b> from all biota	<b>Genetic material</b> from plants, algae or fungi	<u>Seeds, spores and other plant materials</u> collected for maintaining or establishing a population; Higher and lower plants (whole organisms) used to <u>breed new strains or varieties</u> ; Individual genes extracted from higher and lower plants for the <u>design and construction of new biological entities</u>  <i>Example: negative impacts of non-native organisms due to interbreeding</i>
		<b>Genetic material</b> from animals	Animal material collected for the purposes of maintaining or establishing a population; Wild animals (whole organisms) used to breed new strains or varieties; Individual genes extracted from organisms for the design and construction of new biological entities  <i>Example: negative impacts of non-native organisms due to interbreeding</i>
	<b>Water</b> <sup>6</sup>	<b>Surface water</b> used for nutrition, materials or energy	Surface water for <u>drinking</u> ; Surface water used as a material ( <u>non-drinking purposes</u> ); Freshwater surface water, coastal and marine water used as an <u>energy source</u>  <i>Example: loss of access to surface water due to spread of non-native organisms</i>
		<b>Ground water</b> for used for nutrition, materials or energy	Ground (and subsurface) water for <u>drinking</u> ; Ground water (and subsurface) used as a material ( <u>non-drinking purposes</u> ); Ground water (and subsurface) used as an <u>energy source</u>  <i>Example: reduced availability of ground water due to spread of non-native organisms and associated increase of ground water consumption by vegetation.</i>
<b>Regulation &amp; Maintenance</b>	<b>Transformation</b> of biochemical or physical inputs to ecosystems	<b>Mediation of wastes or toxic substances</b> of anthropogenic origin by living processes	<u>Bio-remediation</u> by micro-organisms, algae, plants, and animals; <u>Filtration/sequestration/storage/accumulation</u> by micro-organisms, algae, plants, and animals  <i>Example: changes caused by non-native organisms to ecosystem functioning and ability to filtrate etc. waste or toxics</i>
		<b>Mediation of nuisances</b> of anthropogenic origin	<u>Smell reduction</u> ; <u>noise attenuation</u> ; <u>visual screening</u> (e.g. by means of green infrastructure)  <i>Example: changes caused by non-native organisms to ecosystem structure, leading to reduced ability to mediate nuisances.</i>
	<b>Regulation</b> of physical, chemical, biological conditions	<b>Baseline flows and extreme event</b> regulation	Control of <u>erosion</u> rates; Buffering and attenuation of <u>mass movement</u> ; <u>Hydrological cycle and water flow regulation</u> (Including flood control, and coastal protection); <u>Wind</u> protection; <u>Fire</u> protection  <i>Example: changes caused by non-native organisms to ecosystem functioning or structure leading to, for example, destabilisation of soil, increased risk or intensity of wild fires etc.</i>

<sup>6</sup> Note: in the CICES classification provisioning of water is considered as an abiotic service whereas the rest of ecosystem services listed here are considered biotic.

		<p><b>Lifecycle maintenance</b>, habitat and gene pool protection</p>	<p><u>Pollination</u> (or 'gamete' dispersal in a marine context); <u>Seed dispersal</u>; Maintaining <u>nursery populations and habitats</u> (Including gene pool protection)</p> <p><i>Example: changes caused by non-native organisms to the abundance and/or distribution of wild pollinators; changes to the availability / quality of nursery habitats for fisheries</i></p>
		<p><b>Pest and disease control</b></p>	<p>Pest control; Disease control</p> <p><i>Example: changes caused by non-native organisms to the abundance and/or distribution of pests</i></p>
		<p><b>Soil quality</b> regulation</p>	<p><u>Weathering processes</u> and their effect on soil quality; <u>Decomposition and fixing processes</u> and their effect on soil quality</p> <p><i>Example: changes caused by non-native organisms to vegetation structure and/or soil fauna leading to reduced soil quality</i></p>
		<p><b>Water</b> conditions</p>	<p>Regulation of the <u>chemical condition</u> of freshwaters by living processes; Regulation of the chemical condition of salt waters by living processes</p> <p><i>Example: changes caused by non-native organisms to buffer strips along water courses that remove nutrients in runoff and/or fish communities that regulate the resilience and resistance of water bodies to eutrophication</i></p>
		<p><b>Atmospheric</b> composition and conditions</p>	<p>Regulation of <u>chemical composition</u> of atmosphere and oceans; Regulation of <u>temperature and humidity</u>, including ventilation and transpiration</p> <p><i>Example: changes caused by non-native organisms to ecosystems' ability to sequester carbon and/or evaporative cooling (e.g. by urban trees)</i></p>
Cultural	Direct, in-situ and outdoor interactions with living systems that depend on presence in the environmental setting	<p><b>Physical and experiential</b> interactions with natural environment</p>	<p>Characteristics of living systems that that enable activities promoting health, recuperation or enjoyment through <u>active or immersive interactions</u>;</p> <p>Characteristics of living systems that enable activities promoting health, recuperation or enjoyment through <u>passive or observational interactions</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that make it attractive for recreation, wild life watching etc.</i></p>
		<p><b>Intellectual and representative</b> interactions with natural environment</p>	<p>Characteristics of living systems that enable <u>scientific investigation</u> or the creation of traditional ecological knowledge;</p> <p>Characteristics of living systems that enable <u>education and training</u>;</p> <p>Characteristics of living systems that are resonant in terms of <u>culture or heritage</u>;</p> <p>Characteristics of living systems that enable <u>aesthetic experiences</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have cultural importance</i></p>

	<b>Indirect, remote, often indoor interactions</b> with living systems that do not require presence in the environmental setting	<b>Spiritual, symbolic</b> and other interactions with natural environment	Elements of living systems that have <u>symbolic meaning</u> ; Elements of living systems that have <u>sacred or religious meaning</u> ; Elements of living systems used for <u>entertainment or representation</u>  <i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have sacred or religious meaning</i>
		Other biotic characteristics that have a <b>non-use value</b>	Characteristics or features of living systems that have an <u>existence value</u> ; Characteristics or features of living systems that have an <u>option or bequest value</u>  <i>Example: changes caused by non-native organisms to ecosystems designated as wilderness areas, habitats of endangered species etc.</i>

## ANNEX VIII Species Distribution Model

### Projection of environmental suitability for *Bipalium kewense* establishment in Europe

Björn Beckmann, Leigh Winsor, Jean-Lou Justine, Archie Murchie and Dan Chapman

19 June 2021

#### *Aim*

To project the suitability for potential establishment of *Bipalium kewense* in Europe, under current and predicted future climatic conditions.

#### *Data for modelling*

Species occurrence data were obtained from iNaturalist (1776 records), the Global Biodiversity Information Facility (GBIF) (1001 records), the Biodiversity Information Serving Our Nation database (BISON) (145 records), the Atlas of Living Australia (9 records), and additional records from the risk assessment team. We scrutinised occurrence records from regions where the species is not known to be established and removed any dubious records or where the georeferencing was too imprecise (e.g. records referenced to a country or island centroid) or outside of the coverage of the predictor layers (e.g. small island or coastal occurrences). The remaining records were gridded at a 0.25 x 0.25 degree resolution for modelling, yielding 688 grid cells with occurrences (Figure 1a). As a proxy for recording effort, the density of Platyhelminthes records held by GBIF was also compiled on the same grid (Figure 1b).

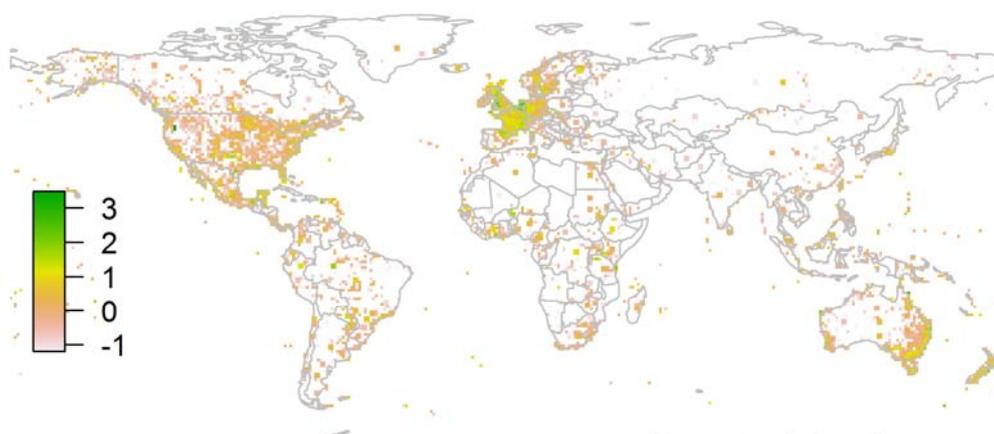

[Page Break](#)

**Figure 1.** (a) Occurrence records obtained for *Bipalium kewense* and used in the modelling, showing native and invaded distributions. (b) The recording density of Platyhelminthes on GBIF, which was used as a proxy for recording effort.

(a) Species distribution used in modelling

(b) Estimated recording effort (log<sub>10</sub>-scaled)

Climate data were selected from the 'Bioclim' variables contained within the WorldClim database (Hijmans et al., 2005), originally at 5 arcminute resolution (0.083 x 0.083 degrees of longitude/latitude) and aggregated to a 0.25 x 0.25 degree grid for use in the model.

Based on the biology of *Bipalium kewense*, the following climate variables were used in the modelling:

- Minimum temperature of the coldest month (Bio6)
- Mean temperature of the warmest quarter (Bio10)
- Annual precipitation (Bio12)
- Precipitation seasonality (Bio15)
- Climatic moisture index (CMI): ratio of mean annual precipitation to potential evapotranspiration, log+1 transformed. For its calculation, monthly potential evapotranspirations were estimated from the WorldClim monthly temperature data and solar radiation using the simple method of Zomer et al. (2008) which is based on the Hargreaves evapotranspiration equation (Hargreaves, 1994).

To estimate the effect of climate change on the potential distribution, equivalent modelled future climate conditions for the 2070s under the Representative Concentration Pathways (RCP) 2.6 and

4.5 were also obtained. These represent low and medium emissions scenarios, respectively. The above variables were obtained as averages of outputs of eight Global Climate Models (BCC-CSM1-1, CCSM4, GISS-E2-R, HadGEM2-AO, IPSL-CM5A-LR, MIROC-ESM, MRI-CGCM3, NorESM1-M), downscaled and calibrated against the WorldClim baseline (see [http://www.worldclim.org/cmip5\\_5m](http://www.worldclim.org/cmip5_5m) ).

The following habitat layers were also used:

- Human influence index (HII): As many non-native invasive species associate with anthropogenically disturbed habitats. We used the Global Human Influence Index Dataset of the Last of the Wild Project (Wildlife Conservation Society - WCS & Center for International Earth Science Information Network - CIESIN - Columbia University, 2005), which is developed from nine global data layers covering human population pressure (population density), human land use and infrastructure (built-up areas, nighttime lights, land use/land cover) and human access (coastlines, roads, railroads, navigable rivers). The index ranges between 0 and 1 and was  $\ln+1$  transformed for the modelling to improve normality.

### *Species distribution model*

A presence-background (presence-only) ensemble modelling strategy was employed using the BIOMOD2 R package version 3.4.6 (Thuiller et al., 2020, Thuiller et al., 2009). These models contrast the environment at the species' occurrence locations against a random sample of the global background environmental conditions (often termed 'pseudo-absences') in order to characterise and project suitability for occurrence. This approach has been developed for distributions that are in equilibrium with the environment. Because invasive species' distributions are not at equilibrium and subject to dispersal constraints at a global scale, we took care to minimise the inclusion of locations suitable for the species but where it has not been able to disperse to (Chapman et al. 2019). Therefore the background sampling region included:

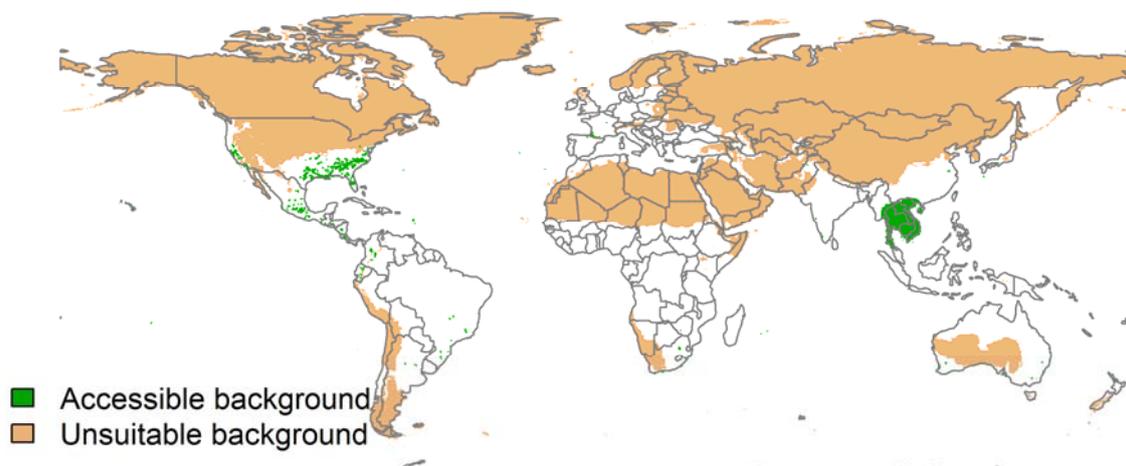

- The area accessible by native *Bipalium kewense* populations, in which the species is likely to have had sufficient time to disperse to all locations. Based on presumed maximum dispersal distances, the accessible region was defined as a 300km buffer around the native range occurrences; AND
- A 30km buffer around the non-native occurrences, encompassing regions likely to have had high propagule pressure for introduction by humans and/or dispersal of the species; AND
- Regions where we have an *a priori* expectation of high unsuitability for the species so that absence is assumed irrespective of dispersal constraints (see Figure 2). The following rules were applied to define a region expected to be highly unsuitable for *Bipalium kewense* at the spatial scale of the model:
  - Minimum temperature of the coldest month (Bio6) < -7°C
  - Mean temperature of the warmest quarter (Bio10) < 13°C
  - Annual precipitation (Bio12) < 270mm

Altogether, 1.2% of occurrence grid cells were located in the unsuitable background region.

Within the unsuitable background region, 10 samples of 5000 randomly sampled grid cells were obtained. In the accessible background (comprising the accessible areas around native

and non-native occurrences as detailed above), the same number of pseudo-absence samples were drawn as there were presence records (688), weighting the sampling by a proxy for recording effort (Figure 2).

**Figure 2.** The background from which pseudo-absence samples were taken in the modelling of *Bipalium kewense*. Samples were taken from a 300km buffer around the native range and a 30km buffer around non-native occurrences (together forming the accessible background), and from areas expected to be highly unsuitable for the species (the unsuitable background region). Samples from the accessible background were weighted by a proxy for recording effort (Figure 1(b)).

Each dataset (i.e. combination of the presences and the individual background samples) was randomly split into 80% for model training and 20% for model evaluation. With each training dataset, seven statistical algorithms were fitted with the default BIOMOD2 settings and rescaled using logistic regression, except where specified below:

- Generalised linear model (GLM)
- Generalised boosting model (GBM)
- Generalised additive model (GAM) with a maximum of four degrees of freedom per smoothing spline
- Artificial neural network (ANN)
- Multivariate adaptive regression splines (MARS)
- Random forest (RF)
- Maxent

Since the total background sample was larger than the number of occurrences, prevalence fitting weights were applied to give equal overall importance to the occurrences and the background. Normalised variable importance was assessed and variable response functions were produced using BIOMOD2's default procedure.

Model predictive performance was assessed by the following three measures:

- AUC, the area under the receiver operating characteristic curve (Fielding & Bell 1997). Predictions of presence-absence models can be compared with a subset of records set aside for model evaluation (here 20%) by constructing a confusion matrix with the number of true positive, false positive, false negative and true negative cases. For models generating non-dichotomous scores (as here) a threshold can be applied to transform the scores into a dichotomous set of presence-absence predictions. Two measures that can be derived from the confusion matrix are sensitivity (the proportion of observed presences that are predicted as such, quantifying omission errors), and specificity (the proportion of observed absences that are predicted as such, quantifying commission errors). A receiver operating characteristic (ROC) curve can be constructed by using all possible thresholds to classify the scores into confusion matrices, obtaining sensitivity and specificity for each matrix, and plotting sensitivity against the corresponding proportion of false positives (equal to  $1 - \text{specificity}$ ). The use of all possible thresholds avoids the need for a selection of a single threshold, which is often arbitrary, and allows appreciation of the trade-off between sensitivity and specificity. The area under the ROC curve (AUC) is often used as a single threshold-independent measure for model performance (Manel, Williams & Ormerod 2001). AUC is the probability that a randomly selected presence has a higher model-predicted suitability than a randomly selected absence (Allouche et al. 2006).
- Cohen's Kappa (Cohen 1960). This measure corrects the overall accuracy of model predictions (ratio of the sum of true presences plus true absences to the total number of records) by the accuracy expected to occur by chance. The kappa statistic ranges from -1 to +1, where +1 indicates perfect agreement and values of zero or less indicate a performance no better than random. Advantages of kappa are its simplicity, the fact that both commission and omission errors are accounted for in one parameter, and its relative tolerance to zero values in the confusion matrix (Manel, Williams & Ormerod 2001). However, Kappa has been criticised for being sensitive to prevalence (the proportion of sites in which the species was recorded as present) and may therefore be inappropriate for comparisons of model accuracy between species or regions (McPherson, Jetz & Rogers 2004, Allouche et al. 2006).
- TSS, the true skill statistic (Allouche et al. 2006). TSS is defined as sensitivity + specificity - 1, and corrects for Kappa's dependency on prevalence. TSS compares the number of correct forecasts, minus those attributable to random guessing, to that of a hypothetical set of perfect forecasts. Like kappa, TSS takes into account both omission and commission errors, and success as a result of random guessing, and ranges from -1 to +1, where +1 indicates perfect agreement and values of zero or less indicate a performance no better than random (Allouche et al. 2006).

An ensemble model was created by first rejecting poorly performing algorithms with relatively extreme low AUC values and then averaging the predictions of the remaining algorithms, weighted by their AUC. To identify poorly performing algorithms, AUC values were converted into modified z-scores based on their difference to the median and the median absolute deviation across all algorithms (Iglewicz & Hoaglin 1993). Algorithms with  $z < -2$  were rejected. In this way, ensemble projections were made for each dataset and then averaged to give an overall suitability, as well as its standard deviation.

Projections were classified into suitable and unsuitable regions using a "lowest presence threshold" (Pearson et al. 2007), setting the cut-off as the lowest value at which 98% of all presence records are classified correctly under the current climate (here 0.59). In order to express the sensitivity of classifications to the choice of this threshold, thresholds at which 95% and 99% of records are classified correctly (here 0.71 and 0.45 respectively) were used in the calculation of error bars in Figs. 9 and 10 below in addition to taking account of uncertainty in the projections themselves.

We also produced a limiting factor map for Europe following Elith et al. (2010). For this, projections were made separately with each individual variable fixed at a near-optimal value. These were chosen as the median values at the occurrence grid cells. Then, the most strongly limiting factors were identified as the ones resulting in the highest increase in suitability in each grid cell.

Page Break

## Results

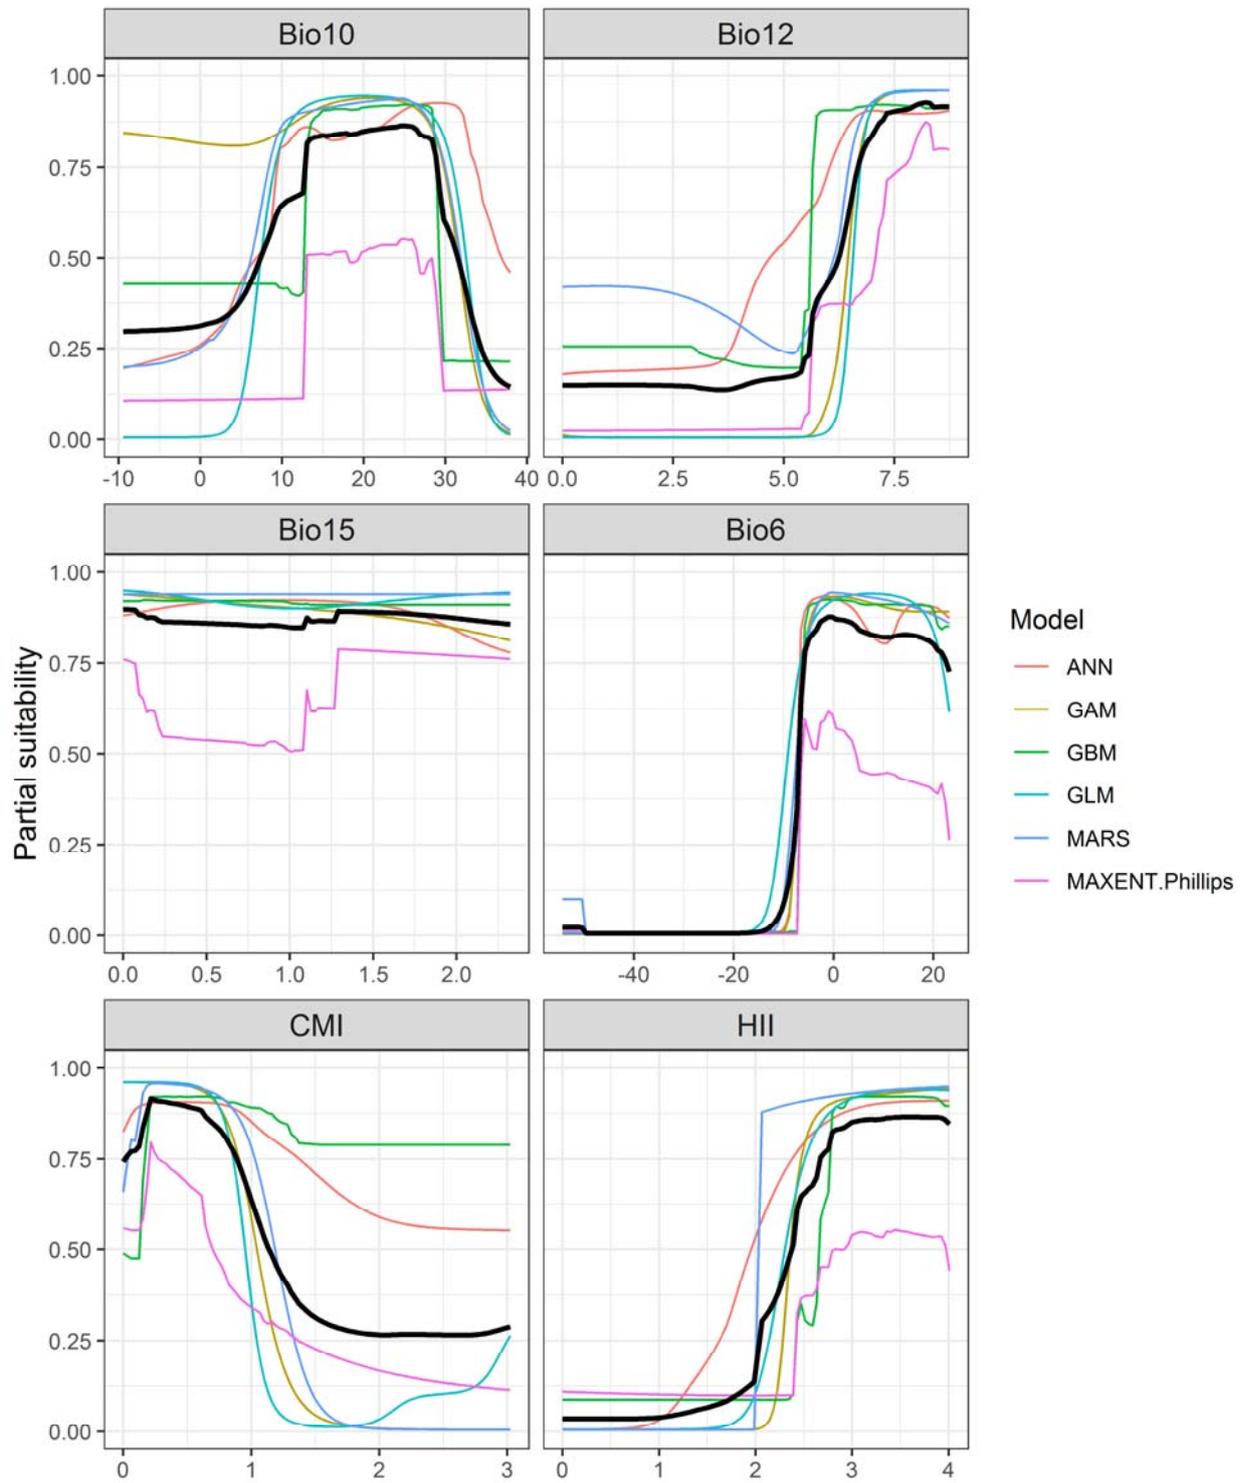

The ensemble model suggested that suitability for *Bipalium kewense* was most strongly determined by Minimum temperature of the coldest month (Bio6), accounting for 37.5% of variation explained, followed by Annual precipitation (Bio12) (23.5%), Human influence index (HII) (22.5%), Mean temperature of the warmest quarter (Bio10) (9.7%), Climatic moisture index (CMI) (6.4%) and Precipitation seasonality (Bio15) (0.4%) (Table 1, Figure 3).

**Table 1.** Summary of the cross-validation predictive performance (AUC, Kappa, TSS) and variable importance of the fitted model algorithms and the ensemble (AUC-weighted average of the best performing algorithms). Results are the average from models fitted to 10 different background samples of the data.

Algorithm	AUC	Kappa	TSS	Used in the ensemble	Variable importance (%)					
					Minimum temperature of the coldest month (Bio6)	Annual precipitation (Bio12)	Human influence index (HII)	Mean temperature of the warmest quarter (Bio10)	Climatic moisture index (CMI)	Precipitation seasonality (Bio15)
GLM	0.944	0.623	0.873	yes	24	37	21	8	10	0
GAM	0.951	0.621	0.875	yes	30	34	25	3	7	0
GBM	0.944	0.618	0.875	yes	47	10	28	12	3	0
ANN	0.953	0.627	0.871	yes	48	15	19	14	4	0
MARS	0.949	0.619	0.876	yes	37	22	25	8	8	0
RF	0.920	0.595	0.865	no	45	21	13	11	5	5
Maxent	0.945	0.617	0.872	yes	40	22	17	13	7	1

**Figure 3.** Partial response plots from the fitted models. Thin coloured lines show responses from the algorithms in the ensemble, while the thick black line is their ensemble. In each plot, other model variables are held at their median value in the training data. Some of the divergence among algorithms is because of their different treatment of interactions among variables.

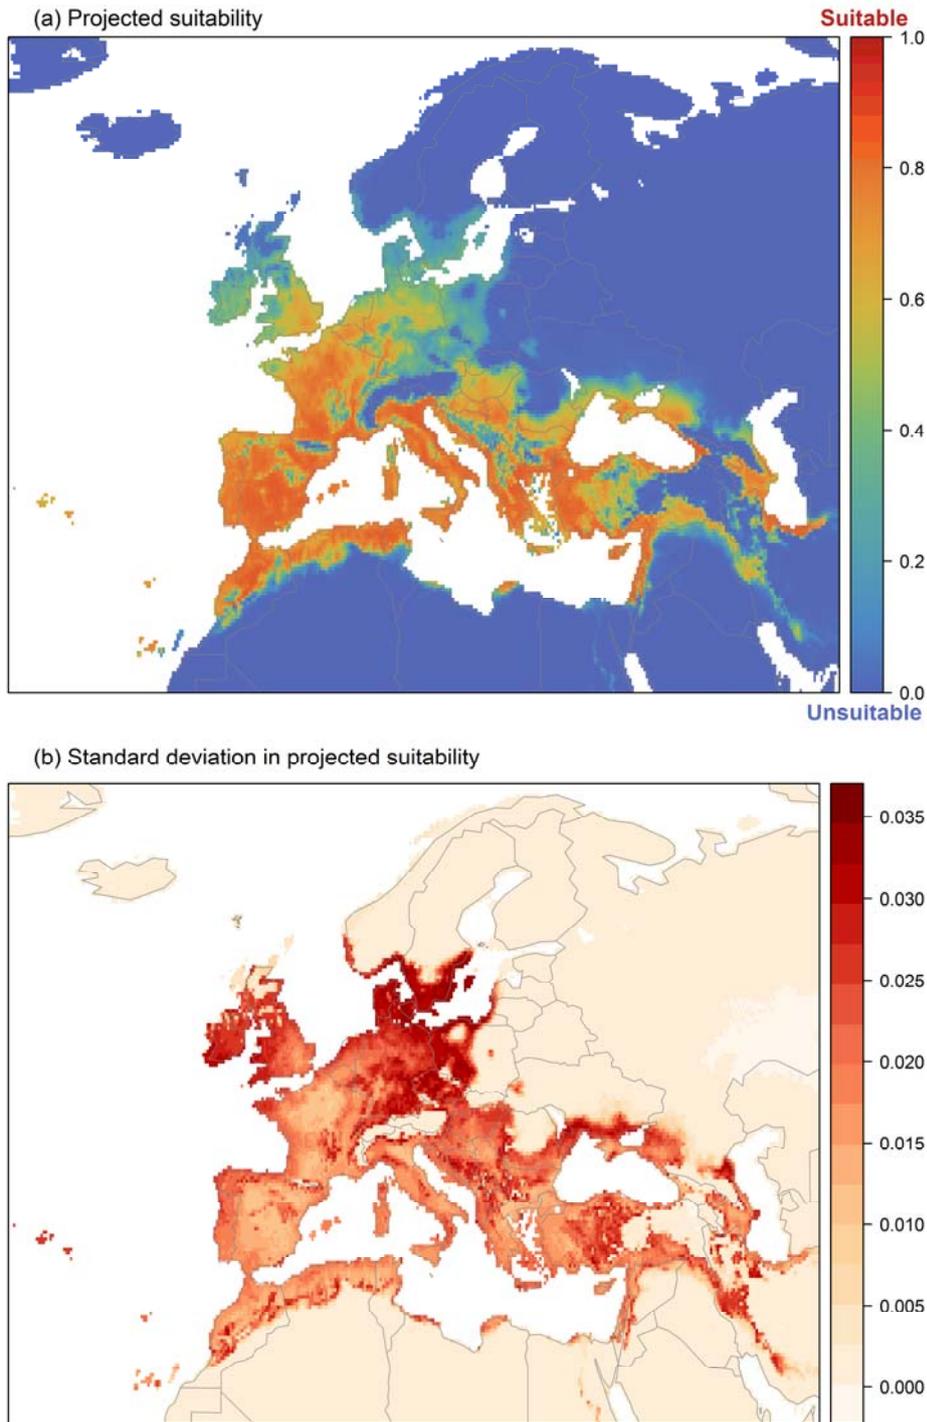

Page Break

**Figure 4.** (a) Projected global suitability for *Bivalium kewense* establishment in the current climate. For visualisation, the projection has been aggregated to a 0.5 x 0.5 degree resolution, by taking the maximum suitability of constituent higher resolution grid cells. Values > 0.59 are suitable for the species, with 98% of global presence records above this threshold. Values below 0.59 indicate lower relative suitability. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

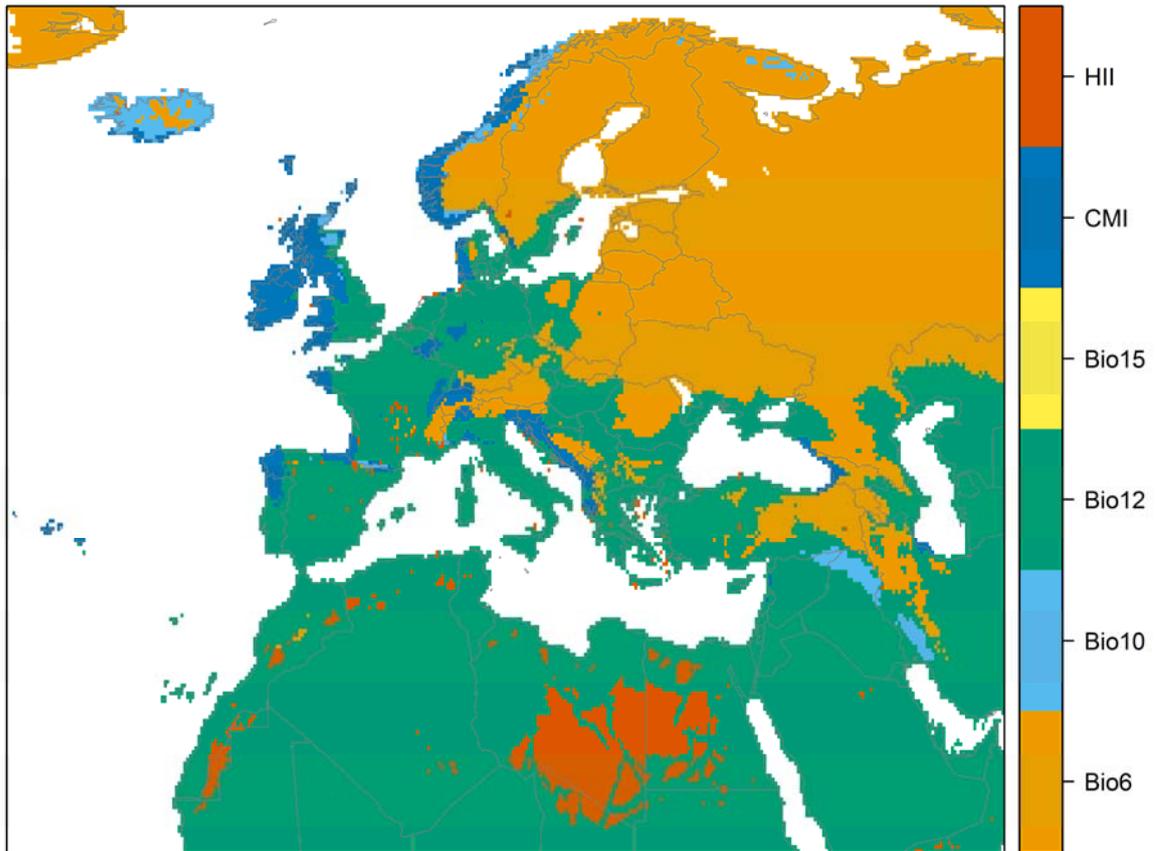

Page Break

**Figure 5.** (a) Projected current suitability for *Bipalium kewense* establishment in Europe and the Mediterranean region. Values > 0.59 are suitable for the species, with 98% of global presence records above this threshold. Values below 0.59 indicate lower relative suitability. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

## *Caveats to the modelling*

To remove spatial recording biases, the selection of the background sample from the accessible background was weighted by the density of Platyhelminthes records on the Global Biodiversity Information Facility (GBIF). While this is preferable to not accounting for recording bias at all, it may not provide the perfect measure of recording bias.

There was substantial variation among modelling algorithms in the partial response plots (Figure 3). In part this will reflect their different treatment of interactions among variables. Since partial plots are made with other variables held at their median, there may be values of a particular variable at which this does not provide a realistic combination of variables to predict from.

Other variables potentially affecting the distribution of the species, such as types of land cover were not included in the model.

<b>Date completed</b>	<b>15/10/2021</b>

### Summary<sup>1</sup>

Highlight of measures that provide the most cost-effective options to prevent the introduction, achieve early detection, rapidly eradicate and manage the species, including significant gaps in information or knowledge to identify cost-effective measures.

*Bipalium kewense* is an alien terrestrial flatworm, originally from South East Asia. It is the most widespread species of terrestrial flatworm worldwide. In the risk assessment area, it has been recorded from many European countries, albeit mainly in hothouses (the species name relates to Royal Botanic Gardens, Kew, London, UK). Nevertheless, *B. kewense* has established outdoors in France, Italy, Malta, Portugal and Spain. *Bipalium kewense* is a potentially problematic species because it is a predator of earthworms. If established in a region, eradication and management options are very limited. Prevention of introduction, prevention of establishment and prevention of spread are by far the best options.

Unintentional introduction: Legislative control and phytosanitary practices at exporting plant producers would be the first step to prevent introduction of *B. kewense*. If *B. kewense* is found, detention notices should be enforced to prevent further stock movement. Plants from the same consignment should be traced and thoroughly examined for flatworms.

Detection: An education and awareness programme should be implemented to raise the profile of *B. kewense* and the potential risk it poses to the environment within the industry. Importing nurseries, botanic gardens or garden centres should inspect their stock regularly for non-indigenous flatworms.

Eradication: Eradication is only likely to be feasible in very small, controlled areas before the species has entered the wild. If on concrete, biocides could be used, but on a soil-base, removal and scorching would be necessary. The flatworm can reproduce by fragmentation, so may regenerate if physically damaged. If *B. kewense* spreads to the agricultural land and the wild, eradication will be virtually impossible.

Long-term management: Management options are limited. There are no chemical or classical biological control methods currently available for invasive alien flatworms. Spread may be limited by good biosecurity measures, cleaning machinery and equipment before moving between sites. Soil, compost and rooted plants should not be moved from infested gardens or other sites.

Detailed assessment			
	Description of measures <sup>2</sup>	Assessment of implementation cost and cost-effectiveness (per measure) <sup>3</sup>	Level of confidence <sup>4</sup>
<p><b>Methods to achieve prevention of intentional and unintentional introduction<sup>5</sup></b></p>	<p><b>Plant health inspection</b>  Terrestrial flatworms are mostly introduced via inadvertent transport by the plant trade, particularly nursery and potted plants. Regular plant health inspections and surveillance are necessary to prevent establishment. Current EU Commission Implementing Regulation (EU) 2019/2072 stipulates the special requirements for growing medium attached to plants to sustain them and this largely prohibits soil but includes plants imported bare root or maintained on an artificial media. If implemented correctly, this should reduce the likelihood of <i>B. kewense</i> being carried in plant containers. Legislation to guarantee that exported plants are free from infestation by invasive flatworms would be helpful.</p> <p>EPPO (2001) guidelines for another alien flatworm <i>Arthurdendyus triangulatus</i> specify that:  1) Plants are grown on slatted benches</p>	<p><b>Plant health inspection</b>  Plant health inspections and surveillance are important universal controls for crop pests and pathogens, as well as preventing incursion of invasive species. They are widely accepted and expected across the horticulture sector. It is likely that surveillance for <i>B. kewense</i> would be incorporated into routine surveillance. However, examination for soil-borne or cryptic pests such as <i>B. kewense</i> is likely to be very time-consuming and expensive. Plant inspections at source would be more effective than portal inspections. Environmental DNA technologies could aid in detection but have not been tested as yet. There would be an incremental cost from increasing the level of plant health inspection at ports of entry as well as the cost of training inspectors in new monitoring and control measures, which could be passed on to the industry.</p>	<p><b>Medium</b></p> <p>(Some information from published sources on terrestrial flatworms but not applied to <i>B. kewense</i>)</p>

	<p>2) The consignment must come from a place of production found free from flatworms</p> <p>3) The consignment must have been subjected to a disinfestation treatment to eliminate flatworms.</p>		
	<p><b>Hot-water treatment</b>  Hot water treatment may be used to cleanse plants of terrestrial flatworms, either by immersion (Sugiura, 2008; Murchie and Moore, 1998) or as a drench (Justine <i>et al.</i>, 2014). The temperature will depend on the flatworm species. For <i>A. triangulatus</i>, immersion in water at 34°C, resulted in death after 5 minutes (Murchie and Moore, 1998). No data are available for <i>B. kewense</i>. Treatment at source would be preferable, as this would meet the requirement that the consignment has been subject to disinfestation treatment (as above). The guidelines above can be stipulated by importers and National Plant Protection Organisations.</p>	<p><b>Hot-water treatment</b>  Hot water treatment is used for nematode control and could be effective for <i>B. kewense</i>. The method is likely to be acceptable to the public for <i>B. kewense</i> management as these measures have been agreed for other invasive flatworms and hot water is the recommended method of euthanising them when found in domestic settings. However, on a commercial scale it requires specialist equipment and risks damaging the plants. There may be some health and safety implications of hot water treatment such as scalding but these are likely to be routine. Justine <i>et al.</i> (2014) considered that drenching may be more practical in a commercial setting. There is little information on whether hot-water treatment has been used for flatworm control at any nurseries or producers. Placing compost in glasshouses to raise the temperature has been occasionally used against <i>A. triangulatus</i> but its effectiveness against <i>B. kewense</i>, a sub-tropical species, would be reduced. There are no environmental implications for heat-treatment control as measures will take place in a managed</p>	<p><b>Medium</b>  (Some information from published sources on terrestrial flatworms but not applied to <i>B. kewense</i>)</p>

		environment at a local scale. Eradication at site would need to be implemented as rapidly as possible.	
<b>Methods to achieve early detection<sup>6</sup></b>	<p><b>Awareness and education (detection by industry and public)</b></p> <p>UK and Irish guidelines (MAFF, 1996; Kelly, 2012) for nurseries and garden centres suggest the following methods to detect terrestrial flatworms:</p> <ol style="list-style-type: none"> <li>1) Check regularly under matting or pots standing directly on the ground for flatworms or their egg cocoons.</li> <li>2) Lift plants from their pots frequently to check for the presence of flatworms or their egg cocoons. Standing potted plants in water overnight has been practised by some gardeners as a means of detecting <i>A. triangulatus</i> (B. Boag 2005, pers. comm.).</li> <li>3) Set traps (e.g. gravel or sand filled polythene bags) along the edges of the holding especially where it adjoins private gardens. Regularly check these for the presence of flatworms or their egg cocoons.</li> <li>4) Inspect all outgoing consignments of plants carefully whether for export or not.</li> </ol> <p>For <i>A. triangulatus</i>, pictorial identification guides have been produced and it is</p>	<p><b>Awareness and education (detection by industry and public)</b></p> <p>As <i>B. kewense</i> is likely to be spread from nurseries, garden centres and botanic gardens, detection at these sites would be most cost-effective. Raising awareness of invasive flatworms and their potential impact to industry and consumers, would be one of the most effective ways to detect this species. The methods proposed are low-cost and easily implemented as part of normal nursery practice. Awareness and vigilance are key. If a nursery or garden centre were found to disseminate <i>B. kewense</i> in their plants, this would cause significant reputational damage with consequent loss in consumer confidence. There is therefore a clear commercial incentive for producers to be involved.</p> <p>Citizen science approaches have been used to map the spread of invasive flatworms, including <i>B. kewense</i> (Moore <i>et al.</i>, 1998; Justine <i>et al.</i>, 2020; Justine <i>et al.</i>, 2015; Justine <i>et al.</i>, 2018). This is a valuable approach that has become increasingly effective with the development of mobile phone cameras and online recording applications.</p> <p>Large adult flatworms are distinctive from other soil organisms such as earthworms and insect larvae. However, for species identification</p>	<p><b>High</b></p> <p>(Professionally produced guidelines for invasive flatworm detection published and available on several websites)</p>

	<p>recommended that similar be done for <i>B. kewense</i>.</p> <p>Environmental DNA (eDNA) technologies could be used for detection by, for example, analysing water samples passed through growing media held in plant pots.</p>	<p>specialist training would be required. A citizen science approach would cost tens of thousands of euros, but this would comprise many hours of individual unpaid activity, rather than direct costs to government or industry. There are environmental benefits of engaging the public in this process, as it aids in the overall awareness of invasive species and other issues. The health and safety and welfare issues are minimal.</p> <p>Detection is likely if industry and the public can be proactively engaged. As <i>B. kewense</i> has not established in all its potential European range, ongoing vigilance is required, and refresher messages should be disseminated to promote continued engagement.</p>	
<p><b>Methods to achieve eradication<sup>7</sup></b></p>	<p>Eradication has only been attempted in infested earthworm farms Australia where <i>B. kewense</i> can be a minor pest, by simple hand picking or by water-flooding the beds (Winsor, 1998). Eradication is likely only to be possible if detected very early (within weeks) in a small, controlled area, following intensive treatments, such as physical removal, soil removal, soil scorching, soil flooding and treatments with biocides. Fumigation may be a possibility for eradicating <i>B. kewense</i> in hothouses, providing phytotoxic effects were kept to a minimum; however, this has not been assessed.</p>	<p><b>Hand picking and water flooding</b></p> <p>This technique has been successful in removing <i>B. kewense</i> from earthworm beds in Australia. There are no environmental or ethical constraints to this method. However, this is a labour-intensive approach and limited to an enclosed area.</p> <p><b>Scorching / soil removal</b></p> <p>Murchie (2017) considered that soil removal and scorching could eradicate invasive flatworms from a small area. However, such techniques have not been tested against flatworms and may not be effective if flatworms hide deep in the soil. Furthermore, any removed soil would also have to</p>	<p><b>Low</b></p> <p>Hand-picking and water-flooding have been successful in earthworm beds but only in a small area. Flatworms may re-invade over time.</p>

	<p>Once established in the wider environment, eradication of <i>B. kewense</i> is unlikely. Removal trapping was attempted for <i>A. triangulatus</i> as a means of eradication/management but was not successful, as shelter traps did not capture a sufficiently high proportion of the population and also it was very labour intensive (Cannon <i>et al.</i>, 1999; Blackshaw <i>et al.</i>, 1996).</p>	<p>be treated to eliminate flatworms therein, most likely with a form of heat treatment or freezing. Scorching and / or soil removal is only effective for very small areas (10s of m<sup>2</sup>) and at the very early stages of detection. Even so, the likely costs for small-scale eradication at a suspected nursery / garden site would be in the tens of thousands of euros if soil needed to be removed and monitoring implemented. Scorching and soil removal would have health and safety implications and need to be carried out by professional operators. The environmental impact would be highly localised. Stakeholders are generally likely to be supportive but may call for financial support to fund the eradication process or seek compensation for damaged produce and / or facilities. Eradication will be rapid if techniques are successful, but these are untested.</p> <p><b>Fumigation</b></p> <p>Fumigation is carried out in commercial glasshouses to eliminate outbreaks of phytophagous pests. There is therefore potential that this method could be used for eradication of <i>B. kewense</i> in hothouses. However, this has not been tested and it is questionable whether the fumigant used would be effective against terrestrial flatworms and whether it would penetrate the soil to target flatworms therein. Use</p>	
--	---	---	--

		of fumigants is subject to strict procedures and must be carried out by licensed personnel.	
<b>Methods to achieve management<sup>8</sup></b>	<p><b>Management options</b></p> <p>In general, prevention of spread through the measures detailed in the ‘prevention of introduction’ section (above) would be valuable for management, particularly education and awareness, coupled with good biosecurity/phytosanitary measures and limitations on the movement of infested soil or plants.</p> <p>Techniques developed for eradication could be extended where appropriate to a control/management scenario. For example, water-flooding and hand picking of <i>B. kewense</i> as used in earthworm beds (Winsor, 1998), may be classed more as management than eradication if it has to be continually applied to prevent re-infestation.</p> <p>If native species are threatened by the presence of flatworms, species conservation measures may be required. For earthworms, this may entail methods to enhance their populations such as minimum-till cultivation and application of farmyard manure.</p> <p>Chemical control has not been used against terrestrial flatworms. No pesticides are approved for control and it is difficult</p>	<p><b>Management options</b></p> <p>Management options for <i>B. kewense</i> are extremely limited and only hand removal has been used in the field (as described under the eradication section) (Winsor, 1998). Hand collection of flatworms may be possible within a limited area (e.g. earthworm beds, small gardens) but is very labour-intensive and therefore costly. As an indicator, a retired gardener collected and removed <i>A. triangulatus</i> from shelter traps on a weekly basis, taking c. 45 minutes each time (A.K. Murchie 2021, unpubl.). If this was extrapolated to a larger area, the costs in terms of person-hours would be substantial.</p> <p>Chemical control will depend on identifying a suitable active ingredient and applying it in a way that minimises any effects on earthworms and other soil fauna. Even if this could be done, widespread use of pesticides in natural environments is likely to be met with public scrutiny and could have other environmental consequences (e.g. non-target impacts, water pollution, etc.).</p> <p>It is probable that native predatory beetles and some birds will feed upon <i>B. kewense</i> in Europe and their activity should be encouraged through land management practices and judicious use of pesticides. However, terrestrial flatworms are</p>	<p><b>Medium</b></p> <p>(Little evidence of successful management techniques described in the literature)</p>

	<p>to target flatworms in the soil, whilst avoiding impacts on non-target organisms. B. Boag quoted in Murchie (2017) reported that slug pellets (metaldehyde) had an impact on <i>A. triangulatus</i> sheltering under refuges on the soil surface. Veterinary anti-helminthics could potentially target invasive alien flatworms but this has not been tested and there would be significant regulatory hurdles to widespread environmental use.</p> <p>No specific predators, parasitoids or pathogens have been documented as potential biocontrol agents for <i>B. kewense</i>.</p>	<p>generally distasteful and native predation would be insufficient to limit populations. Protection and enhancement of earthworms through conservation measures may mitigate some flatworm damage. This could be a long-term and costly commitment, although it would be a beneficial approach despite the flatworm threat. The large-scale management of such a cryptic and inaccessible species is impractical and unproven and would probably be limited to preventing further local spread. Unfortunately, there are no examples of terrestrial flatworm management programmes on which to base cost estimates for the management of <i>B. kewense</i>.</p>

## Guidelines for Completing the Annex

1 Provide a brief summary description of the most cost-effective methods drawing on the reviews in the detailed assessments

2 Provide a description of the potential method. This should be based on the available key scientific evidence which should be gathered from sources including articles and reviews in technical and scientific journals, internet searches, online databases, grey literature and relevant books and personal communications from scientists, stakeholders, conservation practitioners and governmental bodies. This information should include a full bibliographic list detailing the literature and sources considered.

3 Provide an assessment of the likely cost and effectiveness of the method. Where information is available, consider the following range of questions, accepting that not all questions will be appropriate in all circumstances.

- How effective has this approach proven to be in the past or in an analogous situation?
- How publically acceptable is the approach likely to be?
- Over what period of time would this approach need to be applied to be effective?
- What is the direct cost of implementing this approach?
- How likely are the methods used in the approach to be available?
- How likely is it that relevant licences or other approvals to undertake the approach would be difficult to obtain?
- How likely is it that health and safety issues would prevent the use of this approach?
- How significant is the environmental harm caused by this approach?
- How significant is the economic harm caused by this approach?
- How significant is the social harm caused by this approach?
- How likely is it that the approach will be criticised on welfare grounds?
- How likely is it that the approach will be acceptable to other stakeholders?

Where available, factual information on the costs of specialist equipment, or case studies of management costs from across the Union or third countries should be provided. When describing case studies, if the information is available then provide both total cost and the area over which control was undertaken so that a cost per unit area might be derived. Where such quantitative information is not available, then any qualitative information from the literature is acceptable to help guide decision making. It is accepted that in the majority of cases the information required to assess the potential total cost of management at a member state level is unlikely to be available. This would normally require information on the extent and abundance of the species which is beyond the scope of this assessment. Assessors are not expected to extrapolate the potential total costs of management at a member state level, only to report on the information provided within the literature.

4 Provide an overall assessment of the confidence that can be applied to the information provided for this method. This confidence should relate to the quality of the available information using the guidance below. It should NOT relate to the confidence in the effectiveness of the method

The confidence scores are:

- **High:** Information comes from published material, or current practices based on expert experience applied in one of the EU countries or third country with similar environmental, economic and social conditions.
- **Medium:** Information comes from published data or expert opinion, but it is not commonly applied, or it is applied in regions that may be too different from Europe (e.g. tropical regions) to guarantee that the results will be transposable.
- **Low:** data are not published in reliable information sources and methods are not commonly practiced or are based solely on opinion; This is for example the case of a novel situation where there is little evidence on which to base an assessment.

If there are further factors beyond these that have determined the chosen level of confidence, then provide a brief written description to support the choice of the level of confidence.

5 Measures for preventing the species being introduced intentionally or unintentionally into the territory of a Member State (cf. Articles 7(1)(a), 7(2), 13, 15), i.e. preventing a species entering by blocking its pathways, including pre-border prevention and prevention of escape or release into the environment and secondary spread whenever relevant. Measures for preventing the species reproducing while in containment should be included, if appropriate. Consider all methods that might be applied, including any that have not proven useful. Provide a description of each method in turn, using separate rows to consider each method.

6 Measures to run an effective surveillance system for achieving an early detection of a new occurrence (cf. Article 16). This section assumes that the species is not currently present in a Member State, or part of a Member State's territory.

7 Measures to achieve eradication. Preferably, but not exclusively, used at an early stage of invasion, after an early detection of a new occurrence (cf. Article 17). Consider all methods that might be applied, including any that have not proven useful. Provide a description of each method in turn, using separate rows to consider each method.

8 Measures to achieve management of the species once it has become widely spread within a Member State territory (cf. Article 19). These measures can be aimed at eradication, population control or containment of a population of the species. Consider all methods that might be applied, including any that have not proven useful. Provide a description of each method in turn, using separate rows to consider each method.

The development and completion of this template forms part of the EU project **No 07.0202/2020/834529/ETU/ENV.D.2** Study on Invasive Alien Species – Development of risk assessments to tackle priority species and enhance prevention.

**Risk assessment template developed under the "Study on Invasive Alien Species – Development of risk assessments to tackle priority species and enhance prevention"  
Contract No 07.0202/2020/834529/ETU/ENV.D.2<sup>1</sup>**

**Name of organism:** Sika deer (*Cervus nippon*)

**Author(s) of the assessment:**

*Riccardo Scalera, IUCN SSC Invasive Species Specialist Group, Rome, Italy*

*Tim Adriaens, Research Institute for Nature and Forest (INBO), Brussels, Belgium*

*Bram D'hondt, Institute for Nature and Forest Research (INBO), Brussels, Belgium*

*Peter Robertson, Newcastle University, United Kingdom*

*Björn Beckmann, Centre for Ecology and Hydrology (CEH), Wallingford, United Kingdom*

**Risk Assessment Area:** The risk assessment area is the territory of the European Union 27 and the United Kingdom, excluding the EU-outermost regions

**Peer review 1:** Wojciech Solarz, Institute of Nature Conservation, Polish Academy of Sciences, Kraków, Poland

**Peer review 2:** Alastair I. Ward, University of Hull, Hull, United Kingdom

**Date of completion:** 15/10/2021

ANNEX VIII Projection of environmental suitability for sika deer *Cervus nippon* establishment in Europe ..... 81

## SECTION A – Organism Information and Screening

### A1. Identify the organism. Is it clearly a single taxonomic entity and can it be adequately distinguished from other entities of the same rank?

including the following elements:

- the taxonomic family, order and class to which the species belongs;
- the scientific name and author of the species, as well as a list of the most common synonym names;
- names used in commerce (if any)
- a list of the most common subspecies, lower taxa, varieties, breeds or hybrids

As a general rule, one risk assessment should be developed for a single species. However, there may be cases where it may be justified to develop one risk assessment covering more than one species (e.g. species belonging to the same genus with comparable or identical features and impact). It shall be clearly stated if the risk assessment covers more than one species, or if it excludes or only includes certain subspecies, lower taxa, hybrids, varieties or breeds (and if so, which subspecies, lower taxa, hybrids, varieties or breeds). Any such choice must be properly justified.

This risk assessment covers one species, the sika deer *Cervus nippon* Temminck, 1838, also known as Japanese Sika (deer) (Class: Mammalia, Order: Artiodactyla, Family: Cervidae, Subfamily: Cervinae, Genus: *Cervus*).

Synonym(s): Main synonyms are *Cervus sika* and *Cervus japonicus* (for additional information see Feldhamer 1980).

Sika are native to Japan, Taiwan and Eastern Asia (namely China, Korea, Russia, Vietnam) and two main lineages are recognised, a northern and a southern one, with several subspecies, ranging from 10 to 16 (see, for example, Wilson and Reeder 2005, Wilson and Mittermeier 2011) whose validity is questionable. The study of the species taxonomy is also affected by the fact that many source populations have uncertain or mixed origin due to several introductions and translocations that occurred in the past (Feldhamer 1980, Wilson and Reeder 2005, Wilson and Mittermeier 2011, Harris 2015, CABI 2021). Some subspecies are possibly extinct in the wild (Wilson and Mittermeier 2011).

For the purpose of the present risk assessment, it is important to point out that sika deer represent a monophyletic lineage that is endemic to Asia and has speciated long ago away from *C. elaphus* (Cook et al. 1999). It is also of interest to remark that introduced populations are mostly from animals originating from Japan, but also from other parts of Asia (as in the case of the Czech Republic, Linnell and Zachos 2011). However, the exact geographical origin of sika deer introduced in Europe cannot be clearly ascertained due to the lack of documented evidences, and the fact that different subspecies had been mixed and intercrossed (Bartoš 2009). In particular, animals introduced in Europe are deemed to originate mainly from captive Asian populations, which were probably subject to human manipulation through farming, artificial selection and translocations (Baiwy et al. 2013).

Sika may hybridise and produce fertile offspring with the only congeneric species in the risk assessment area, the native red deer *Cervus elaphus* (Wilson and Reeder 2005). Introgression may also occur, as the fertile hybrids usually backcross with either parent species, and this leads to increased phenotypic similarity between the two species, which makes further hybridization more likely (Zachos and Hartl 2011). Hybrids occur when sika are introduced outside their natural range, however, sika and red deer also hybridize naturally where they overlap in Far East Russia (Bartoš 2009). Since sika and sika-red deer hybrids are present in Europe both in

captivity and in the wild, and since many free ranging populations of sika include to some extent sika-hybrids (Baiwy et al. 2013), the present risk assessment applies both to pure sika deer and its hybrids.

**A2. Provide information on the existence of other species that look very similar [that may be detected in the risk assessment area, either in the environment, in confinement or associated with a pathway of introduction]**

Include both native and non-native species that could be confused with the species being assessed, including the following elements:

- other alien species with similar invasive characteristics, to be avoided as substitute species (in this case preparing a risk assessment for more than one species together may be considered);
- other alien species without similar invasive characteristics, potential substitute species;
- native species, potential misidentification and mis-targeting

Sika are small to medium-sized deer, and are extremely variable in size and body weight both between and within subspecies. Females are about 60-95 cm at shoulder height, and males 65-115 cm. Their weight ranges from 20-90 kg in females and 30-140 kg in males (Wilson and Mittermeier 2011). Sexual dimorphism is very pronounced, as body measurements of adult males averaged 8.7% more than those of females (Feldhamer 1980), while males are 40-70% heavier than females (Wilson and Mittermeier 2011). The species shows extensive variation in size and colours within and between populations (Baiwy et al. 2013). Pelage can vary from chestnut to yellow in summer, and grey to almost black in winter, depending on the subspecies. Similarly, the distinct white spots can be present throughout the year, or only in summer, depending on the subspecies. The rump (caudal) patch, which is the most characteristic feature, is white with a black outline on top, and is crossed by the tail, which is white with a median black stripe of variable thickness. Also the head has some distinctive features, with dark lines above the eyes and a short stubby muzzle which give sika deer a typical “frowning” expression (Booy et al. 2015). The pale U-shaped band between the eyes is also distinctive. A good distinguishing character is the prominent white scent gland often visible on the lower hind legs. Stags have relatively simple antlers, but can grow up to 98 cm long. At maturity, they usually develop up to four points on each side (CABI 2021, Feldhamer 1980, Wilson and Mittermeier 2011).

Sika can be easily mistaken for red deer and fallow deer (*Dama dama*). In general, adult sika are similar in size to adult fallow deer but smaller than red deer (CABI 2021). Adult sika can be confused with adult fallow deer for the spotted coat and the tail that look very similar. The rump can help distinguish the three species, as most fallow deer have a peculiar dark border, which is absent in the red deer, and which is only partially developed in the sika. The antlers may look similar to those of the red deer, but in sika, the brow tines of the antlers are always at an acute angle to the main beam of the antler while in red deer, they present an obtuse angle (CABI 2021). Moreover, the antlers of the sika are not palmate as in the fallow deer. While adult red deer and sika are usually easier to distinguish because of the lack of the spotted coat and of dark stripes in tail and rump patch, calves can be similar.

Hybrids can be difficult to distinguish from red deer or pure sika (CABI 2021). First generation (F1) hybrids show traits of both species, and introgressed hybrids are difficult to identify in the field (MacDevitt et al. 2009, Lammertsma et al. 2012). Not surprisingly, the presence of sika

hybrids may go undetected for a long time, and may be disbelieved even by hunters until demonstrated by DNA analysis (Lammertsma et al. 2012). Some authors stressed that species determination of shot specimen is difficult even for experienced gamekeepers and zoologists (Macháček et al. 2014).

**A3. Does a relevant earlier risk assessment exist? Give details of any previous risk assessment, including the final scores and its validity in relation to the risk assessment area.**

Sika deer was assessed at the EU level in 2014, following a workshop (Roy et al. 2015) aimed at assessing and integrating the information from a previous risk assessment made at the GB level which resulted in a “high” risk with “low” uncertainty (GB Non-Native Species Secretariat 2011). The participants to the workshop confirmed the compliance of the GB risk assessment with the EU Regulation No 1143/2014 and therefore its conclusions were upscaled at the EU level. However, the species was not retained for being listed among those of Union concern at that time.

A risk assessment for the sika deer exists for Poland (Solarz et al. 2018). The species is considered very invasive based on its impact on the environment, and the resulting statement in relation to the risk for the country is that the sika is a “*High risk species, occurring in the wild, with isolated populations (black list)*” (Solarz et al. 2018). It is one of the top six priority species for management actions and, possibly, eradication according to the level of spread, impacts and manageability. In relation to the risk assessment area, this result may be considered valid particularly for the Continental biogeographic region.

A risk analysis of the sika deer was carried out in Belgium (Baiwy et al. 2013), and as reported in the summary of impact “*It is very likely that the establishment of sika deer in Belgium will result in an increase of the biomass and density of deer per hectare and will produce strong negative impacts on native vegetation through overgrazing, especially on acidic soils. It could also cause the local decline of native deer species, favour disease transmission to native ungulates and induce extensive hybridization with the red deer. During irruptive events, a degradation of the conservation status of ecosystems is also expected to occur locally (alteration of vegetation, inhibition of tree regeneration, soil trampling, etc.)*.” Also in this case, in relation to the risk assessment area, such conclusions may be considered valid for the Continental biogeographic region.

In the Netherlands, the risk assessment of the sika deer (Lammertsma et al. 2012) resulted the species being classified as a category A “black list species” and since the sika is not yet naturalized in the country, is also classified as an “Alert list species” (according to the ISEIA score Branquart et al. 2007). Otherwise, the threat category in the Dutch risk assessment using Bomford (2003) is “extreme”. The main concerns in the country are damage to forestry (silviculture, timber production) and agriculture, Natura 2000 areas, competition with native ungulates and hybridization and introgression with native red deer.

In Ireland, the sika was considered among the 15 high risk impact terrestrial vertebrates (O’Flynn et al. 2014).

In Italy, the sika deer is the second one in the ranked lists of priority species for management actions and, possibly, eradication according to the predicted likelihood of spread, potential impacts on biodiversity and well-being and manageability (Bertolino et al. 2020).

In Germany, sika deer has been assessed with the GABLIS-protocol (Rabitsch & Nehring 2015). The result of the assessment was “potentially invasive – Watch List”, based on the – at this time – still rare hybridization with red deer.

A global assessment was also carried out to rank alien ungulates based on their risks of causing environmental impacts using the EICAT classification: the highest impact score reached by the sika is "Major" (Volery et al. 2021, IUCN 2020a, 2020b). The species was previously assessed also by Nentwig et al. (2018) according to whom out of 486 alien species established in Europe from a wide range of taxonomic groups, the sika deer ranked 31, among those with the highest environmental and socioeconomic impact (following the generic impact scoring system GISS, as calculated by Nentwig et al. 2010).

**A4. Where is the organism native?**

including the following elements:

- an indication of the continent or part of a continent, climatic zone and habitat where the species is naturally occurring
- if applicable, indicate whether the species could naturally spread into the risk assessment area

The sika is native to Japan, Taiwan and east Asia, from eastern Russia to China (where it is now rare and localized). In Taiwan it was reintroduced; it occurred also in North and South Korea, and Vietnam, where it is now probably extinct (see Wilson and Reader 2005, Harris 2015, CABI 2021).

In its native range the sika deer inhabits a wide range of habitats in low-elevation plains and surrounding hills, and a wide range of forest types, from the tropical jungles of Vietnam to broad-leaved deciduous forests of Far East Russia and northern Japan, with a preference for early succession stages over mature woodlands (Baiwy et al. 2013). Low temperatures in winter and the depth of snow cover are the main limiting factors. In a study carried out in Japan, Kaji et al. (2004) suggest that there is strong density dependence in population and the availability of food is a limiting factor in concordance with climatic factors such as variation in snow depth and/or duration of deep snow (see also Kaji et al. 2009, Takatsuki 1992). In particular, more than 40 cm of snow is considered limiting by Wilson and Mittermeier (2011) while according to Genovesi and Putman (2009) sika deer is favored by warm climates (12° to 46° N) and selects areas where snowfall does not exceed 10-20 cm and where snow-free sites are available. In Japan, sika deer are mostly concentrated in areas with snow depths less than 50 cm, with some populations living in the 'habitable area' of 50-100 cm of snow, but they rarely live in the 'inhabitable area' with snow depths higher than 100 cm (Takatsuki 1992).

The species appears highly adaptable and is found on a wide range of forest habitats with dense undergrowth and adjacent open grounds, from the sea level up to 3000 meters a.s.l. according to Wilson and Mittermeier (2011) (but only up to 1800 meters according to Feldhamer 1980). In Europe, managed and natural forests such as coniferous or mixed forests (on acidic soils with dense undergrowth), are the preferred habitats, but since sika are an opportunistic species and forage in open, grassy areas, they are also found in open mid-forest spaces, heathlands, meadows near the forest border, plantations and orchards, grasslands (grazing systems), freshwater marshes and riverbanks, moorlands and estuarine reed beds, saltmarshes provided some woodland cover is available (Lammertsma et al. 2012, Baiwy et al. 2013, Harris 2015, Solarz et al. 2018, CABI 2021). Overall, sika deer has a very broad ecological amplitude. Its

distribution and habitat selection are also affected by landscape configuration and human disturbance (Uzal et al. 2013).

With respect to feeding ecology, sika may act both as a browser and a grazer, and feed on a wide variety of plant species (Harris 2015, Takatsuki 2009b). Food composition is highly variable and depends on genetic groups, resource availability, vegetation type and climatic conditions (Baiwy et al. 2013, Takatsuki 2009b). Like other ungulates sika deer feed on a variety of grasses, herbs, young shoots of trees and shrubs, and even fruit (Solarz et al. 2018). Their diet is most often constituted of graminoids, forbs, shrubs, twigs, tree foliage, fruits, fungi and agricultural crops, but also pine needles, bark, gorse, with no significant reliance on any particular food sources (CABI 2021, Baiwy et al. 2013, Harris 2015). In fact, also plants that are usually considered unpalatable to deer are eaten (Feldhamer 1980). In total, more than a hundred species of plant are known to be part of the sika deer diet. Feldhamer and Demarais (2008) reported details on plant species found in the diet of sika in the US.

Both habitat and diet requirements are described and discussed extensively in the monograph by McCullough et al. (2009).

**A5. What is the global non-native distribution of the organism outside the risk assessment area?**

Outside the risk assessment area, the sika deer was successfully introduced in the following countries: Armenia, Azerbaijan, New Zealand, Philippines (Solo Island), United States, and also small islands off Japan (Kerama Islands, Ryukyu Islands). For details, see Long (2003), Lever (1985), Wilson and Reader (2005), Harris et al. (2015), CABI (2021).

The species is also present in Europe outside the risk assessment area, e.g. in Switzerland, Ukraine, western Russia (including in the Kaliningrad District of Russian Federation), and possibly Moldova (Bartoš 2009, Biedrzycka et al. 2012, CABI 2021).

Historic introductions of sika deer occurred also in Australia, South Africa, and possibly Morocco and Madagascar, but no established populations are confirmed (Long 2003, Lever 1985). Nevertheless, in Australia, the species is still being kept in captivity, for example in deer farms in Victoria (Forsyth et al. 2015).

**A6. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species been recorded and where is it established? The information needs be given separately for recorded (including casual or transient occurrences) and established occurrences. “Established” means the process of an alien species successfully producing viable offspring with the likelihood of continued survival<sup>2</sup>.**

**A6a. Recorded: List regions**

**A6b. Established: List regions**

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

<sup>2</sup> Convention on Biological Diversity, Decision VI/23

Marine subregions:

- Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea.

Comment on the sources of information on which the response is based and discuss any uncertainty in the response.

For delimitation of EU biogeographical regions please refer to <https://www.eea.europa.eu/data-and-maps/figures/biogeographical-regions-in-europe-2> (see also Annex VI).

For delimitation of EU marine regions and subregions consider the Marine Strategy Framework Directive areas; please refer to <https://www.eea.europa.eu/data-and-maps/data/msfd-regions-and-subregions/technical-document/pdf> (see also Annex VI).

Response (6a): Alpine, Atlantic, Boreal, Continental, Mediterranean, Pannonian.

Response (6b): Alpine, Atlantic, Boreal, Continental, Mediterranean, Pannonian.

The source of information on which the response is based can be found in Qu. A8.

**A7. In which biogeographic region(s) or marine subregion(s) in the risk assessment area could the species establish in the future under current climate and under foreseeable climate change? The information needs be given separately for current climate and under foreseeable climate change conditions.**

**A7a. Current climate: List regions**

**A7b. Future climate: List regions**

With regard to EU biogeographic and marine (sub)regions, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

Response (7a):

Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic (see details in Annex VIII).

Response (7b):

Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic (see details in Annex VIII).

Note: establishment and invasiveness in Boreal and Alpine biogeographic regions is uncertain because of species sensitivity to deep snow cover as described above (Kaji et al. 2004). Moreover, it is uncertain how sika will respond to the gradual desertification of the Mediterranean region (Alastair I Ward, pers. comm. 2021).

**A8. In which EU Member States has the species been recorded and in which EU Member States has it established? List them with an indication of the timeline of observations. The information needs be given separately for recorded and established occurrences.**

**A8a. Recorded: List Member States**

**A8b. Established: List Member States**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden

The description of the invasion history of the species shall include information on countries invaded and an indication of the timeline of the first observations, establishment and spread.

Response (8a): Austria, Belgium, Czech Republic, Denmark, Estonia, Finland, France, Germany, Hungary, Ireland, Italy, Lithuania, Luxembourg, Netherlands, Poland; and the United Kingdom.

Response (8b): Austria, Czech Republic, Denmark, France, Germany, Hungary, Ireland, Lithuania, Poland; and the United Kingdom.

The first introductions of sika deer in the risk assessment area date back to 1860 in Ireland (McDevitt et al. 2009). In the same year the first introductions were carried out also in the UK (GB Non-Native Species Secretariat 2011).

In France, sika were successively introduced at least since 1966 (Pascal et al. 2006, Bartoš 2009, Lever 1985). In the Czech Republic sika were introduced in 1891 (Bartoš 2009, Lever 1985), in Germany in 1893 (Bartoš 2009) with the first releases into the wild in 1930 (Niethammer 1963). In Denmark, the first introductions of sika deer occurred in 1900 (Asferg and Madsen 2007) while in Austria the species was first introduced in 1907 (Bartoš 2009). In Hungary the sika was introduced in 1910 (Bartoš 2009), while in Poland the species was introduced in 1985 with first releases into the wild in 1910 (Bartoš 2009).

In Lithuania the sika deer was released into the wild in 1954 (Pūraitė and Paulauskas 2016, Baleišis et al. 1987), where there is documented evidence of hybridization with red deer where both species are known to occur (Biedrzycka et al. 2012). A study by Pūraitė and Paulauskas (2016) suggests hybridization of the two species in the wild, as there were wild living specimens, which are attributed to red deer according to their phenotype, but are closer to sika deer according to their genotype.

There are records of the species also in Estonia where sika deer were introduced in 1956, but the population is probably extinct at present, although single immigrants from neighboring areas may occur (Bartoš 2009).

Also in Luxembourg the species was first reported in 2012-2013, when some hunted animals were identified as sika. The presence of the species in the area was explained with the escape of sika deer from an enclosure in Gemünd, Germany, near the Luxembourg border, between 2011 and 2012 (Cellina and Schley 2014). It is not clear whether the species is currently established in Luxembourg.

In Belgium casual observations of sika deer were reported from different localities during recent years (Baiwy et al. 2013). In particular, two individuals were seen in Les Marionville (Saint-Ghislain) in November 2011 (Lammertsma et al. 2012) and a single male was shot in 2011 in the Famenne, near Houyet (Cellina and Schley 2014). In Flanders, sika deer have been present in Limburg province (Zonhoven) since 2012 and reproduce since at least 2018 (e.g. <https://waarnemingen.be/observation/160293818/>).

In the Netherlands sika deer were reported near 's-Graveland since 2005 on several occasions, but also here no established population is considered present (Lammertsma et al. 2012).

The species and its hybrids were recently reported also for Italy (Raganella Pelliccioni et al. 2013) in the Modena and Bolzano provinces, where animals have apparently been present since the early 2000s (Ferri et al. 2014, Ferri et al. 2016).

According to Bartoš (2009) there are internet advertisements for hunting sika deer in countries such as Finland, Bulgaria, and Slovenia, suggesting the existence of the species there as well, but it was not possible to confirm the status of the species. The only additional information retrieved for Finland is that sika deer is listed in Section 5 of the Hunting Act among the 34 mammal game species (see <https://mmm.fi/en/wildlife-and-game/hunting-and-game-management/finnish-game-resources>). An advertisement for hunting sika deer was also found for Slovakia (i.e. <http://www.shootingenterprise.com/japanese-sika-deer-hunting-and-stalking>). However, Moravčíková et al. (2017) did not confirm the species occurrence in the country. Moreover, no sign of hybridisation of red deer was found in Slovakia based on genetic studies (Moravčíková et al. 2017).

**A9. In which EU Member States could the species establish in the future under current climate and under foreseeable climate change? The information needs be given separately for current climate and under foreseeable climate change conditions.**

**A9a. Current climate: List Member States**

**A9b. Future climate: List Member States**

With regard to EU Member States, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global

warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

Response (9a):

Austria, Belgium, Bulgaria, Croatia, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden; and the United Kingdom (see Annex VIII for details).

The result also shows that the high level of uncertainty in the case of Cyprus does not allow to assess the actual suitability of the country for the species, while no data is available for Malta.

Response (9b):

Austria, Belgium, Bulgaria, Croatia, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden; and the United Kingdom (see Annex VIII for details).

The result also shows that the high level of uncertainty in the case of Cyprus does not allow to assess the actual suitability of the country for the species, while no data is available for Malta.

**A10. Is the organism known to be invasive (i.e. to threaten or adversely impact upon biodiversity and related ecosystem services) anywhere outside the risk assessment area?**

The species is considered invasive in many countries outside its native range, for example in the US (Feldhamer and Demarais 2008) and New Zealand (Davidson 1973).

As detailed in the section below, sika is known to pose a threat to native species through competition with other deer species and through hybridisation with native red deer. They can also have an impact on vegetation and habitats, which in turn can affect ecosystem services, as well as human health, crops and the economy. The effects of sika deer on vegetation in its native range Japan was reviewed by Takatsuki (2009a). In Japan, roadkills and rail accidents are also reported (Kaji et al. 2010).

Further details and refs. see answer to Qu 4.1 below.

**A11. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea

Response:

Alpine, Atlantic, Boreal, Continental, Mediterranean, Pannonian.

**A12. In which EU Member States has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden

Response: Czech Republic, Denmark, France, Ireland, Poland; and the United Kingdom. The list of Member States could be extended to other countries where the presence of hybrids has been recorded (although the establishment of the species is not confirmed yet, e.g. Italy and Lithuania) because if sika hybrids are within a population of red deer, then hybrids must be established and therefore sika are invading and invasive even if pure sika (if any of those exist anywhere) are not present (Alastair I Ward, pers. comm. 2021).

**A13. Describe any known socio-economic benefits of the organism.**

including the following elements:

- Description of known uses for the species, including a list and description of known uses in the risk assessment area and third countries, if relevant.
- Description of social and economic benefits deriving from those uses, including a description of the environmental, social and economic relevance of each of those uses and an indication of associated beneficiaries, quantitatively and/or qualitatively depending on what information is available.

If the information available is not sufficient to provide a description of those benefits for the entire risk assessment area, qualitative data or different case studies from across the risk assessment area or third countries shall be used, if available.

As summarised by Roy et al. (2014) and CABI (2021) the sika deer is a game species frequently introduced outside Asia as an additional asset for hunting, although there is little or no quantitative information available on the economic value of this.

As noted by the GB Non-Native Species Secretariat (2011) for UK, sika stags have increasingly become a valuable sporting asset (Pérez-Espona et al. 2009), and the species seems still in high demand for hunting purposes.

In Germany the International Sika Deer Society forced policy to step back from eradication attempts in NRW (<http://sikawild.org/ausrottung>). The number of animals culled per year is low in most European countries (a few hundred individuals) with an associated hunting value of several hundred to more than 2000 euro per individual (e.g. [12](http://www.globus-</a></p></div><div data-bbox=)

[jagdreisen.de/de/jagdlaender/europa/schottland/jagd-auf-sikahirsche/](http://www.premium-jagdreisen.de/de/jagdlaender/europa/schottland/jagd-auf-sikahirsche/) , [http://www.premium-jagdreisen.de/product\\_info.php?products\\_id=29](http://www.premium-jagdreisen.de/product_info.php?products_id=29) (Solarz & Okarma, 2014).

Sika are also widely kept on farms for production of venison and, at least within their native range, antler velvet – in China, Japan and Russia. Economic values vary with demand, and although sika are farmed for meat in numbers significantly lower than other cervids, may be an important constituent of local economies. For example, in Poland, the commercial value of farmed sika deer was roughly estimated at 215,000 to 251,000 € (Solarz & Okarma, 2014).

In the US, the primary goal of deer farms is the production of brood stock, venison, and by-products such as antler velvet and hides, but some enterprises also offer opportunities for visitor viewing and photography (Feldhamer and Demarais 2008).

The species is kept in zoological gardens and for ornamental purposes by private owners. The ISIS database roughly estimates that 885 individuals are kept across 48 European institutions (ISIS, 2014). Sika deer are also perceived as a local attraction for nature lovers and the general public (Solarz & Okarma, 2014).

## SECTION B – Detailed assessment

### Important instructions:

- In the case of lack of information the assessors are requested to use a standardized answer: “No information has been found.” In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable).
- With regard to the scoring of the likelihood of events or the magnitude of impacts see Annexes I and II.
- With regard to the confidence levels, see Annex III.
- Highlight the selected response score and confidence level in **bold** but keep the other scores in normal text (so that the selected score is evident in the final document).

## 1 PROBABILITY OF INTRODUCTION AND ENTRY

### Important instructions:

- **Introduction** is the movement of the species into the risk assessment area (it may be either in captive conditions and/or in the environment, depending on the relevant pathways).
- **Entry** is the release/escape/arrival in the environment, i.e. occurrence in the wild
- Introduction and entry may coincide for species entering through pathways such as “corridor” or “unaided”, but it also may differ. If different, please consider all relevant pathways, both for the introduction into the risk assessment area and the entry in the environment.
- The classification of pathways developed by the Convention of Biological Diversity (CBD) should be used (see Annex IV). For detailed explanations of the CBD pathway classification scheme consult the IUCN/CEH guidance document<sup>3</sup> and the provided key to pathways<sup>4</sup>.
- For organisms which are already present (recorded or established) in the risk assessment area, the likelihood of introduction and entry should be scored as “very likely” by default.
- Repeated (independent) introductions and entries at separate locations in the risk assessment area should be considered here (see Qu. 1.7).

**Qu. 1.1. List relevant pathways through which the organism could be introduced into the risk assessment area and/or enter into the environment. Where possible give details about the specific origins and end points of the pathways as well as a description of any associated commodities.**

For each pathway answer questions 1.2 to 1.8 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you

<sup>3</sup> <https://circabc.europa.eu/sd/a/7e5f0bd4-34e8-4719-a2f7-c0cd7ec6a86e/2020-CBD-pathways-interpretation.pdf>

<sup>4</sup> <https://circabc.europa.eu/sd/a/0aeba7f1-c8c2-45a1-9ba3-bcb91a9f039d/TSSR-2016-010%20CBD%20pathways%20key%20full%20only.pdf>

consider more than one pathway, e.g. 1.2a, 1.3a, etc. and then 1.2b, 1.3b etc. for the next pathway.

In this context a pathway is the route or mechanism of introduction and/or entry of the species.

The description of commodities with which the introduction of the species is generally associated shall include a list and description of commodities with an indication of associated risks (e.g. the volume of trade; the likelihood of a commodity being contaminated or acting as vector).

If there are no active pathways or potential future pathways this should be stated explicitly here, and there is no need to answer the questions 1.2-1.9.

The following active pathways of introduction have been identified in the risk assessment area:

- a) Hunting (Release in nature)
- b) Farmed animals (including animals left under limited control) (Escape from confinement)
- c) Botanical garden/zoo/aquaria (excluding domestic aquaria) (Escape from confinement)
- d) Natural dispersal across borders of invasive alien species that have been introduced through pathways 1 to 5.

For some of the introductions carried out in Europe the ultimate purpose of the releases is not explicitly reported, therefore it is not possible to establish with certainty which is the relevant pathway. For example, in Lithuania fenced sika deer herds are numerous and possibly formed hybrids with red deer after escape (Baleišis et al. 1987, Andersone-Lilley et al. 2010), but details on the purpose of the enclosures, e.g. whether for hunting, farming or ornamental purposes are not provided. The same applies in the case of Austria where sika escaped from the enclosures when they fell into disrepair or were destroyed at the end of World War II (Bartoš 2009). However, the three pathways a), b), and c) above are considered active in the EU and as such are described in detail in the next questions below. Here follows a short summary of the main evidence regarding the relevant introductions in the EU (with examples also from other countries, if appropriate).

- a) There is documented evidence that the species was introduced into the EU through for **hunting purposes**, and it is possible to expect further introductions of this species through the same pathway, although data on relevant frequency and volumes of animals are not available. In France, for example, deliberate introductions into the wild of sika as a game species were carried out during the twentieth century (Pascal et al. 2006). Also in Denmark the species was introduced as a game species for hunting purposes (Asferg and Madsen 2007). The species was bred for game and used for sport hunting also in the European part of the former USSR (Bartoš 2009), as well as in other countries outside Europe, e.g. in the US (Feldhamer and Demarais 2008). For some of the introductions carried out in Europe the ultimate purpose of the releases is not explicitly reported, therefore it is not possible to establish with certainty whether there was any link with the hunting sector. For example, in Poland no information about cases of intentional introduction of species for hunting purposes was retrieved for at least several decades, if not for a century (Wojciech Solarz, pers. comm. 2021), however according to Solarz et al. (2018) there is some risk of introducing this species in new areas because

some hunters are interested in introducing sika deer in locations not suitable for the red deer (although so far no relocations from the two existing Polish populations took place). Moreover, in Europe, as reported by Bartoš (2009), various breeders intentionally crossed red and sika deer for trophy improvement, although this was rarely documented, which led to the risk of deer translocations being carried out with animals of unknown status. In his review Bartoš (2009) pointed out how “European hunters’ interests may be the main factor leading to ignoring the threat of sika deer presence”.

- b) **Deer farming** for sika has been growing consistently in Europe (with the notable exception of Denmark where there are some legal restrictions) and escapes from farms are reported in the risk assessment area (Bartoš 2009). For example, in Poland the species is kept in deer farms and agrotourism farms (the number of farm deer may exceed 1,000 individuals) where cases of escapes are known (Solarz et al. 2018). In Lithuania, about 1,000 sika deer are farmed in the Kaunas and Klaipeda districts (Bartoš 2009). Also in the Netherlands a possible pathway is escape or deliberate release from deer farms, which according to Lammertsma et al. (2012) was the origin of all of the present European populations. In Italy, deer farming is also present, and the escape of 3-4 sika deer from a farm was reported in Emilia Romagna in 1999 (Ferri et al. 2014). According to Bartoš (2009) there is an unknown number of farms keeping sika deer in continental Europe, however numbers and locations continually change over time, and only fragmentary information is available, hence it is difficult to get any reliable data and/or trend estimates. In Germany, according to Bartoš (2009), frequent escapes of sika deer from an enclosure near Neuhaus, Möhnesee, occurred. Conversely, in Belgium, deer farming is not considered as a major pathway for introduction in the country (Baiwy et al. 2013). In Denmark the species was frequently kept in deer farms (Asferg and Madsen 2007). In the UK, escape of sika as well as of sika-red hybrids from deer farms is considered a main pathway (GB Non-Native Species Secretariat 2011). In fact, escape from farms is a well-known risk also in regions other than the EU, e.g. in the US (Feldhamer and Demarais 2008) and in Asia, particularly in China, where sika are widely kept in captivity for farming of venison or antler velvet (Harris 2015, CABI 2021). Also, the translocation of sika from the Russian far east to Ukraine and other areas of the former Soviet Union, e.g. around 1933, was aimed at meeting the increasing demand for medical products from antlers (Bartoš 2009).
- c) Escapes of sika deer from **deer parks** are well documented in the risk assessment area (Bartoš 2009). For example, in France, an increasing number of small free-living sika deer populations have been reported during the last decades, mostly as a result of escapes from deer parks (Baiwy et al. 2013). In this country the reported origin of the sika deer in the Forêt de la Harth, is the Mulhouse Zoo and the Huttenheim enclosure near Strasbourg (Bartoš 2009). In Poland the species is kept in zoological gardens, as well as minizoo where cases of escapes are known (Solarz et al. 2018). According to Bartoš (2009), in Czech Republic, sika deer were frequently imported in the late nineteenth and early twentieth century for deer parks, from where they escaped (see also Dvořák and Palyzová 2016). Also, in Denmark, sika were introduced in deer parks and zoos from where they managed to escape and disperse over long distances, but their numbers have declined since the 1970s (Asferg and Madsen 2007, Bartoš 2009). In Germany, the largest sika population (in Möhnesee) apparently originated from Hagenbeck and from the Hellabrun Zoo (Munich), while the second largest population located at Hochrhein originated from Basel Zoo (Switzerland), along with St. Peter Game Park in Freiburg, and Hagenbeck (Hamburg) (Bartoš 2009). The most probable pathway of sika deer entry in Belgium, where observations of isolated specimens escaped from captivity have been reported in recent years, is the accidental/deliberated

releases of individuals from deer parks (Baiwy et al. 2013). Sika deer destined to hobby parks as ornamental species have been imported to Belgium several times from Ireland and Germany (Baiwy et al. 2013). Similarly, a possible pathway in the Netherlands is escape or deliberate release from enclosed parks, which was the origin of all of the present European populations (Lammertsma et al. 2012). In this country, sika are kept in several parks, and the few observed sika deer reported in the wild near ‘s Graveland are deemed likely to originate from captivity (Lammertsma et al. 2012). In Ireland, sika were introduced in deer parks, some of which are not enclosed (Carden et al. 2011). Also, in the UK, escape of sika as well as of sika-red hybrids from enclosed parks is considered a main pathway from the late 19th century onwards (GB Non-Native Species Secretariat 2011).

- d) The “Natural dispersal across borders of invasive alien species that have been introduced through pathways 1 to 5” is the fourth pathway still active in the EU, see details below.

Another pathway known for the sika is “Landscape / flora / fauna “improvement” in the wild (release in nature)”. This pathway is only known in regions other than Europe, for example in New Zealand, e.g. in relation to introductions carried out by acclimatisation societies which were active in the 19<sup>th</sup> century (Nugent and Speedy 2021, Banwell, 2009). Sika deer were also translocated from the Russian far east to Ukraine and other areas of the former Soviet Union to supplement sika deer populations that had declined during the second half of the nineteenth century (Bartoš 2009). Such translocations can be assigned to the pathway “Introduction for conservation purposes or wildlife management”. However, as no escapes are reported in Europe from the two pathways above, they are not considered active in the risk assessment area, and not considered further in this risk assessment.

**a) Pathway name: Hunting (release in nature)**

**Qu. 1.2a. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	<b>intentional</b> unintentional	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

This pathway refers to animals introduced into the risk assessment area to be hunted for venison and/or to provide recreational hunting opportunities (including collection of hunting trophies).

Sika were widely introduced to many countries to hunting parks from which they have subsequently escaped or have been released. Only fragmentary information is available on numbers and locations where sika were introduced for hunting, hence it is difficult to get any reliable data and/or trend estimates (Bartoš 2009).

Both the introduction and the entry in the risk assessment area through this pathway is intentional (except in the case of misidentification, in which case the entry (and possibly the introduction as well) would be unintentional. See further details below.

**Qu. 1.3a. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

As discussed under Qu. 1.1, there is documented evidence that the species was introduced into the EU through for hunting purposes, although it is unlikely that large numbers of animals (e.g. hundreds) are introduced for hunting within the course of one year. Depending on the objectives of the release, it would be expected, however, to be a number large enough to establish viable wild populations, considering that a very small number of hinds and a few stags are deemed sufficient to found a new population. In New Zealand, for example, it is documented that a herd descended from only 4-5 deer, of which one male only (Nugent and Speedy 2021). Also in Japan, a population introduced in a small island descended from one male and two females only (Kaji et al. 2009). Also in the EU, there is evidence of populations founded by few individuals, i.e. in Poland, where one of the two populations went through narrow bottlenecks down to 5 individuals, from which it recovered successively (Solarz 2011, and <https://www.iop.krakow.pl/gatunkiobce/default4e83.html?nazwa=opis&id=108&je=pl> ).

The capacity to hybridise with red deer and produce offspring with intermediate morphological features carries the inherent risk of introducing sika hybrids mislabelled as red deer, as postulated for Italy (Ferri et al. 2014, Ferri et al. 2016).

**Qu. 1.4a. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

The species is able to survive during passage along the pathway, as demonstrated by the fact that it has been successfully introduced in several countries in the EU and that secondary translocations occurred too. Hence, it is very likely that the animals survive during transport and storage along this pathway, which has an interest in ensuring animal welfare standards,

although overall sika appear more prone to and suffer higher levels of mortality as result of stress from handling and transport than red and fallow deer (GB Non-Native Species Secretariat 2011). The species is unlikely to reproduce or increase during transport, but this might happen during extended periods of storage.

**Qu. 1.5a. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

The likelihood of the sika deer to survive existing management practices in a released area will vary depending on the type of hunting regime applied to ungulate in general and the extent of disturbance in the area (e.g. agricultural practices). In principle it might be high, provided that the species requirements are duly considered and ensured. According to the GB Non-Native Species Secretariat (2011), sika “is very adaptable and has established and persisted under current agricultural and forestry practices and commercial exploitation by shooting”.

**Qu. 1.6a. How likely is the organism to be introduced into the risk assessment area or enter into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

In principle, the intentional introduction for hunting purposes cannot go undetected (but see below about the risk of misidentification and/or mislabelling, particularly of hybrids).

This is a medium sized deer which may be easily detected by hunters (as well as naturalists, and farmers, provided that access in hunting estates is allowed) but only in areas where there are no other similar deer species or hybrids (e.g. sika are mistaken by some for fallow or red deer, see section A.2). In fact, as pointed out by the GB Non-Native Species Secretariat (2011), the co-occurrence of other deer species would allow the presence and spread of sika and sika hybrids to go undetected for a long time not only by landowners and the general public (which may not be fully familiar with deer species) but even by hunters, until demonstrated by DNA analysis (Bartoš 2009, Biedrzycka et al. 2012, Lammertsma et al. 2012).

The preliminary results of the surveys carried out in Italy show that the species is present in the country and was likely imported as a generic “deer” (hence was likely considered to be red deer *C. elaphus*) or simply the documentation of the animals imported for deer farming were not

checked. This led to the hypothesis that such deer could originate from animals introduced from Scotland (where hybrids are known to occur) which have escaped in the area where sika and their hybrids were now detected (Ferri et al. 2014, Ferri et al. 2016). It required a large awareness campaign among hunters to start detecting more sika individuals in the wild, and there is concern that the species may be more widespread than is currently known (Ferri et al. 2014, Ferri et al. 2016).

As a result, sika deer is moderately likely to be introduced in the risk assessment area undetected (although this is valid for authorised releases only, as any illegal introduction would very likely go undetected).

**Qu. 1.7a. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Possible points of introduction and subsequent entry are widespread. This is supported by the fact that the sika deer has already escaped (or been deliberately released) several times from various locations in the risk assessment area.

**Qu. 1.8a. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

The species was already introduced to the risk assessment area in the past along this pathway, although this was explicitly documented in only a limited number of occasions.

**b) Pathway name: Farmed animals (including animals left under limited control)  
(Escape from confinement)**

**Qu. 1.2b. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	<b>intentional</b> unintentional	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

This pathway refers to animals that have been introduced for farming into deer farms, where they were kept with the primary purpose to provide food (it does not include animals held in zoos, deer parks and the likes, which are treated below in chapters 1.2c to 1.7c).

Sika were widely introduced to many countries to deer farms from which they have subsequently escaped or have been released. However, the number of sika deer farms present in the EU is unknown, and no information is available about the numbers of sika deer kept in such facilities.

The introduction in the risk assessment area through this pathway is intentional. However, the entry into the environment is either intentional or unintentional, depending on whether it is the result of deliberate releases or accidental escapes.

**Qu. 1.3b. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**  
including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

As discussed under Qu. 1.1, there is documented evidence that the species was introduced in the EU through this pathway, and it is possible to expect further introductions of sika deer motivated by farming purposes, although quantitative data are lacking.

It is not very likely that large numbers of animals are introduced for farming within one year. Introduction is not expected to take place with large quantities (e.g. hundreds) of animals at one time. It would be expected, however, to be a number large enough to establish viable wild populations, considering that a very small number of hinds and a few stags are deemed sufficient to found a new population. This also leads to the conclusions that in the event of an escape or a deliberate release, a few individuals may fund a new population. In New Zealand, for example, it is documented that a herd descended from only 4-5 deer, of which one male only (Nugent and Speedy 2021). Also in Japan, a population introduced in a small island descended from

**Qu. 1.4b. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

The species is able to survive during passage along the pathway, as demonstrated by the fact that it has been frequently kept in captive facilities and from there successfully introduced in the past in several countries in the EU. Hence, it is very likely that the animals survive during transport and storage along the pathway, provided appropriate animal welfare standards are ensured (as reported by the GB Non-Native Species Secretariat (2011) overall sika appear more prone to and suffer higher levels of mortality as result of stress from handling and transport than is the case for red and fallow deer). Also, the likelihood of the sika deer to survive, reproduce, or increase in a fenced area is high, provided that the species requirements are duly considered and ensured. The species is unlikely to reproduce or increase during such transport.

**Qu. 1.5b. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

The likelihood of the sika deer to survive existing management practices in a fenced area will vary depending on the type of deer management and extent of disturbance in the area. In principle it might be very likely, provided that the species requirements are duly considered and ensured. According to GB Non-Native Species Secretariat (2011), sika “is very adaptable and has established and persisted under current agri-forestry practices and commercial exploitation by shooting”.

See answer to Qu. 1.5a.

**Qu. 1.6b. How likely is the organism to be introduced into the risk assessment area or enter into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

In principle, the intentional introduction for farming purposes cannot go undetected (but see below about the risk of misidentification and/or mislabelling, particularly of hybrids). However, things may be different for escaped animals.

See answer to Qu. 1.6a.

**Qu. 1.7b. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Possible points of introduction and subsequent entry are widespread. This is supported by the fact that the sika deer has already escaped (or been deliberately released) several times from various locations as documented in the risk assessment area (see also Qu 1.3b).

**Qu. 1.8b. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

The species has already entered the wild through this pathway (as escapee from a deer farm), and the risk for such events to happen again is very high as long as animals are kept in such facilities. Despite the lack of precise information about the distribution of deer farms in Europe, the quality of the deer farm facilities, the numbers of animals they hold and their security appliances and contingency plans (if available), sika deer are deemed to be abundant in deer farms and hence likelihood of further introductions or transport of animals between existing facilities (from outside the EU into the risk assessment area) and/or entry into the environment is very likely.

**c) Pathway name: Botanical garden/zoo/aquaria (excluding domestic aquaria)  
(Escape from confinement)**

**Qu. 1.2c. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	<b>intentional</b> unintentional	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Sika deer are known to be kept in deer parks, zoological gardens, minizoo's, hobby zoo's, wildlife parks and similar captive facilities for ornamental reasons.

The introduction in the risk assessment area through this pathway is intentional. However, the entry into the environment is either intentional or unintentional, depending on whether it is the result of deliberate releases or accidental escapes.

**Qu. 1.3c. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**  
including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

According to Bartoš (2009) there is an unknown number of deer parks and zoological gardens containing sika deer in continental Europe. Numbers and locations continually change over time, and only fragmentary information is available, hence it is difficult to get any reliable data and/or trend estimates.

As discussed under Qu. 1.1, there is documented evidence that sika deer was introduced into the EU for deer farming, and it is possible to expect further introductions of this species for the purposes of keeping animals in deer parks and zoological facilities. It is considered unlikely that large numbers of animals escape from zoos or deer parks within the same year yet few founders are needed to establish new populations in the environment. It would be expected, however, to be a number large enough to establish viable wild populations, considering that a very small number of hinds and a few stags are deemed sufficient to found a new population (see also Qu. 1.3b).

**Qu. 1.4c. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely	<b>CONFIDENCE</b>	Low medium
-----------------	---------------------------	-------------------	---------------

	moderately likely likely <b>very likely</b>		<b>high</b>
--	---	--	-------------

The species is able to survive during passage along the pathway, as demonstrated by the fact that it has been frequently kept in captive facilities and from there successfully introduced in the past in several countries in the EU. Hence, it is very likely that the animals survive during transport and storage along the pathway, provided appropriate animal welfare standards are ensured (as reported by the GB Non-Native Species Secretariat (2011) overall sika appear more prone to and suffer higher levels of mortality as result of stress from man-handling and transport than is the case for red and fallow deer). Also, the likelihood of the sika deer to survive, reproduce, or increase in a fenced area is high, provided that the species requirements are duly considered and ensured. The species is unlikely to reproduce or increase during such transport, but this can definitely happen once released in the wild.

See Qu 1.4b.

**Qu. 1.5c. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

The likelihood of the sika deer to survive existing management practices in a fenced area will vary depending on the type of deer management and extent of disturbance in the area. In principle it might be high, provided that the species requirements are duly considered and ensured. According to GB Non-Native Species Secretariat (2011), sika “is very adaptable and has established and persisted under current agri-forestry practices and commercial exploitation by shooting”.

See Qu 1.5b.

**Qu. 1.6c. How likely is the organism to be introduced into the risk assessment area or enter into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

In principle, the intentional introduction in deer parks, zoological gardens, and similar captive facilities cannot go undetected (but see below about the risk of misidentification and/or mislabelling, particularly of hybrids). However, things may be different for escaped animals.

See Qu. 1.6a.

**Qu. 1.7c. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Possible points of introduction and subsequent entry are widespread. This is supported by the fact that the sika deer has already escaped (or been deliberately released) several times from various locations as documented in the risk assessment area.

**Qu. 1.8c. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

The species has already entered the wild through this pathway (as escapee from a zoo or deer park), and the risk for such events to happen again is high as long as animals are kept in such facilities. Despite the lack of precise information about the distribution of zoos and deer parks in Europe where the species is held and their biosecurity, sika deer are known to be abundant in zoos and deer parks and hence likelihood of further introductions or transport of animals between existing facilities (from outside the EU into the risk assessment area) is likely.

**d) Pathway name: Natural dispersal across borders of invasive alien species that have been introduced through pathways 1 to 5.**

**Qu. 1.2d. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

This pathway refers to animals that spread to new regions by natural dispersal, without action or assistance by humans, from regions in which they are alien and were introduced by one of the other introduction pathways.

This pathway is unintentional, as it depends on the dispersal capacities of the species. It is facilitated by the habitat conditions present in the area (including, for instance, the forest management regime and the recreational hunting practices, the extent of suitable ecological corridors etc.).

**Qu. 1.3d. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**  
including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

According to Solarz et al (2018) the dispersal capacity of the species would allow the immigration of individuals from outside the risk assessment area, e.g. from Kaliningrad Oblast (Russia), to Poland. The same authors report that records from northern Poland suggest that there could have been immigration in the past, when single individuals could have dispersed from the Kaliningrad Oblast to the area of the Kadyń population. Also the occurrence of the species in Estonia may be due to animals dispersing from Russia, for example there is evidence of single individuals dispersed to Alutaguse from the population in neighboring areas of Russia (Bartoš 2009).

Further introductions of this species due to natural dispersal from areas outside the risk assessment area, particularly from Russia, are likely to occur. It is considered possible that large numbers of animals can disperse naturally across countries within one year.

**Qu. 1.4d. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely	<b>CONFIDENCE</b>	low medium
-----------------	---------------------------	-------------------	---------------

	<b>moderately likely</b> likely very likely		<b>high</b>
--	---	--	-------------

The likelihood of the animals to survive, reproduce, or increase during natural dispersal will vary on the extent of deer management and disturbance in the area (for examples in relation to land use practices, hunting, and other pressures). According to GB Non-Native Species Secretariat (2011), sika “is very adaptable and has established and persisted under current agri-forestry practices and commercial exploitation by shooting”.

**Qu. 1.5d. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

See Qu. 1.4d.

**Qu. 1.6d. How likely is the organism to be introduced into the risk assessment area or enter into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

The unintentional introduction due to natural dispersal may go undetected, at least in early stage of colonisation, until it gets the attention of hunters, naturalists, and farmers (but also in this case only in areas where there are no other similar deer species or hybrids, because sika can be mistaken for fallow or red deer, see section A.2). In fact, as pointed out by the GB Non-Native Species Secretariat (2011), the co-occurrence of other deer species would allow the presence and spread of sika and sika hybrids to go undetected for a long time not only by landowners and the general public not fully familiar with deer species, but even by hunters until demonstrated by DNA analysis (Bartoš 2009, Biedrzycka et al. 2012, Lammertsma et al. 2012).

See answer to Qu. 1.6a.

**Qu. 1.7d. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	<b>isolated</b> widespread ubiquitous	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Possible points of entry are possibly isolated, i.e. mostly localised in the European Russia, i.e. in the Kaliningrad District of Russian Federation (Biedrzycka et al. 2012), Switzerland, Ukraine, and possibly Moldova (Bartoš 2009, CABI 2021).

**Qu. 1.8d. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

The species was already introduced into the risk assessment area in the past along this pathway (see Qu. 1.3d and the case of single individuals deemed to immigrate into the Polish population from Russia), and the risk for such events to happen again is high as long as animals are present in the wild in EU neighbouring countries. Hence likelihood of natural spread of animals from outside the EU into the risk assessment area is likely.

**Qu. 1.9. Estimate the overall likelihood of introduction into the risk assessment area or entry into the environment based on all pathways and specify if different in relevant biogeographical regions in current conditions.**  
Provide a thorough assessment of the risk of introduction in relevant biogeographical regions in current conditions: providing insight in to the risk of introduction into the risk assessment area.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

The most likely pathway of sika deer entry into the wild within the EU, as documented in the risk assessment area already, is the escape of individuals from deer parks and deer farms and, less likely, the deliberate release for hunting. Natural dispersal across EU-borders is another important pathway.

This seems to contradict CABI (2021), according to which further introductions seem unlikely because most countries/states now do not allow deliberate introductions or releases of exotic ungulates. CABI (2021) also argued that there is now a greater awareness of risks associated with such introductions through damage to agriculture and forestry, competition with native wildlife species and the risk of hybridization with red deer. However, as documented above, as long as sika populations exist in the wild in neighbouring regions, along with deer parks and deer farms within EU Member States and neighboring countries, the risk of further escapes/releases or dispersal cannot be ruled out. Therefore the overall risk is deemed very likely.

**Qu. 1.10. Estimate the overall likelihood of introduction into the risk assessment area or entry into the environment based on all pathways in foreseeable climate change conditions?**

Thorough assessment of the risk of introduction in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of introduction (e.g. change in trade or user preferences)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely introduction within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

There is no evidence that climate change will have any effect on the likelihood of introduction or entry into the environment via hunting, farming or keeping animals in zoological facilities. The degree to which natural dispersal from regions outside the risk assessment area could be affected by climate change, is unknown.

## 2 PROBABILITY OF ESTABLISHMENT

**Important instructions:**

- For organisms which are already established in parts of the risk assessment area or have previously been eradicated, the likelihood of establishment should be scored as “very likely” by default.
- Discuss the risk also for those parts of the risk assessment area, where the species is not yet established.

**Qu. 2.1. How likely is it that the organism will be able to establish in the risk assessment area based on similarity of climatic and abiotic conditions in its distribution elsewhere in the world?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

The species is already established in the risk assessment area, where the environmental conditions are in general similar to those of the native and alien range of the species. Sika are well adapted across a wide range of regions characterized by a diversity of climatic and abiotic conditions (see descriptions in A.4) which are likely to favour the establishment of the species in the risk assessment area.

For example, according to GB Non-Native Species Secretariat (2011), sika have adapted well to the mild climatic conditions of southern Britain and the more extreme and cooler conditions in northern Scotland. Such considerations apply to many other European countries as well.

In Belgium, according to Baiwy et al. (2013) the sika deer is likely to establish in most parts of the country on the basis of climatic conditions.

**Qu. 2.2. How widespread are habitats or species necessary for the survival, development and multiplication of the organism in the risk assessment area? Consider if the organism specifically requires another species to complete its life cycle.**

<b>RESPONSE</b>	very isolated isolated moderately widespread <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Sika deer seem characterised by a high degree of flexibility and are well adapted to a wide variety of natural and semi-natural habitats and food, according to availability (see descriptions in A.4). Habitats and food necessary for its survival, development and reproduction are widespread throughout the risk assessment area, as demonstrated by the successful establishment of the species in several locations in the risk assessment area.

As noted by Lammertsma et al. (2012) for the Netherlands, it is plausible that sika and sika-hybrids can occupy the same habitats as red deer, which is a widespread species in the risk assessment area.

No other organism is required for sika deer to complete its life cycle.

**Qu. 2.3. How likely is it that establishment will occur despite competition from existing species in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

There is potential for competition with the native red deer and roe deer (*Capreolus capreolus*), as well as other ungulates in the risk assessment area, but as noted for other introduced deer species such competition is unlikely to prevent establishment (sika may in fact outcompete native ungulates). See Qu. 4.2 for details.

As pointed out by Baiwy et al. (2013) invasion histories of sika deer in habitats already occupied by other ungulate species in the UK, Germany and North America show that competition is unlikely to prevent its establishment or even slow down population expansion. Similarly, Lammertsma et al. (2012) noted that sika deer are sympatric with other deer species in Europe, but competition with these species did not prevent establishment in Germany and the Czech Republic, as well as the UK (GB Non-Native Species Secretariat 2011).

**Qu. 2.4. How likely is it that establishment will occur despite predators, parasites or pathogens already present in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

The risk assessment area is certainly characterised by the presence of potential predators, parasites or pathogens of sika deer - the same that would be considered for other ungulates, like the wolf (*Canis lupus*), which is a main predator (Wilson and Mittermeier 2011), but also lynx (*Lynx lynx*), red fox (*Vulpes vulpes*) and raptors. However, there are several species of native and alien deer already occurring in the risk assessment area, and predators do not seem to represent a limiting factor for their populations (Feldhamer 1980). In any case, such predators are not widespread in large parts of Europe. For Belgium, the only predator mentioned in the national risk assessment for sika (Baiwy et al. 2013) is the red fox, which may play a role in limiting population growth rate through predation on fawns. This risk assessment however predated the arrival and establishment of the wolf in Belgium. Similarly, as noted by the GB Non-Native Species Secretariat (2011) the only abundant natural enemy in the UK is the red fox,

which may predate on neonates, and potentially some raptors (e.g. the golden eagle *Aquila chrysaetos*) which could also take sika fawns, but have been rarely reported to do so.

In Europe, sika deer can be infected by numerous endemic wildlife diseases and parasites (see Baiwy et al. 2013, Böhm et al. 2007) but they do not seem to suffer very much from them and usually show a high resistance to infection (although several of those diseases often represent lethal infections among farmed deer).

**Qu. 2.5. How likely is the organism to establish despite existing management practices in the risk assessment area? Explain if existing management practices could facilitate establishment.**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Deer in Europe are usually subject to hunting and culling, which are regulated by law (see Bartoš 2009, Apollonio et al. 2010). However, the management of the sika or its commercial exploitation by shooting did not seem to prevent its establishment (which in any case would not be the goal of this kind of management at all).

On the other hand, the species persisted under current agricultural and forestry practices, e.g. in the UK, where the GB Non-Native Species Secretariat (2011) also noted that “Continued increases in afforestation in general would produce further suitable habitat, aiding the spread and establishment of sika, whereas current policies to establish fewer conifer thickets (one of their preferred habitats) in preference for more deciduous planting may possibly negate this to some extent”.

Poaching and overhunting are also factors which may lead to the extinction of introduced populations, but this did not seem to represent a limiting factor for their populations in the risk assessment area. It can be expected that many populations introduced for hunting are subject to sustainable harvesting as for red deer.

**Qu. 2.6. How likely is it that biological properties of the organism would allow it to survive eradication campaigns in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Sika deer are medium sized animals and there are effective eradication methods available. However, one particular concern associated with the effective eradication of sika deer is hybridisation with native red deer. The presence of hybrids complicates the practicalities of eradication programmes, as it would require the selective culling of animals with hybrid characteristics which are not always easily identifiable in the field. As pointed out by the GB Non-Native Species Secretariat (2011) regarding the situation in the UK. However, it should

be noted that several sika populations are likely to be represented by sika-hybrid, which would entail the need to remove also those red deer population showing a certain level of introgression, which may be considered unlikely given the many caveats and constraints of a similar operation.

**Qu. 2.7. How likely are the biological characteristics of the organism to facilitate its establishment in the risk assessment area?**

including the following elements:

- a list and description of the reproduction mechanisms of the species in relation to the environmental conditions in the risk assessment area
- an indication of the propagule pressure of the species (e.g. number of gametes, seeds, eggs or propagules, number of reproductive cycles per year) of each of those reproduction mechanisms in relation to the environmental conditions in the risk assessment area.
- If relevant, comment on the likelihood of establishment based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in establishment whereas for others high propagule pressure (many thousands of individuals) may not.
- If relevant, comment on the adaptability of the organism to facilitate its establishment and if low genetic diversity in the founder population would have an influence on establishment.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

The sika deer presents a suite of life-history traits typical of successful invasive deer species such as a large native range with high local abundance, a gregarious behaviour, a wide habitat and diet breadth, a long life span, an early sexual maturity (Baiwy et al. 2013). Moreover sika may be able to overcome severe environmental conditions sometimes better than the local species (Bartoš 2009). The resilience of sika towards changes in its environment is also considered greater than for red deer (Ferretti and Lovari 2014). The diverse dietary requirements and the ecological flexibility which characterise the sika deer, along with the species’ adaptability may facilitate the establishment of the species. Low numbers of founding individuals were not associated with a significant reduction in genetic diversity (founder effect) as shown in a study in Germany and Austria (Pitra and Lutz 2005). Another trait that is deemed to be correlated with greater establishment success is the interspecific variation in adult body size (overall or within sex): according to González-Suárez et al (2015) sika deer was predicted to establish a population in about 88% of introductions of 10 individuals (observed success was 82%, nine out of 11 attempts, with a median of seven released individuals)

According to Harris (2015) the species is crepuscular (i.e. active primarily during the twilight period), but sometimes active by day and night, and forages solitarily or in small herds, with dominant males with harems during the period of rut. Potentially sika reach reproductive maturity at one year and can live up to 15-16 years, and may reach 25 years in captivity (Wilson and Mittermeier 2011). However, the mean life span reported in a study in Japan is 2.1–3.1 years for males and 3.6–3.9 years for females (Kaji et al. 2010). In Europe, sika deer breed in September-November (exceptionally until mid-February), hence the rutting season may overlap

with that of red deer, with which they hybridise (Bartoš 2009, Baiwy et al. 2013, Biedrzycka et al. 2012, Harris 2015, CABI 2021). Sika are polygamous and the breeding group of a successful territorial male may number as many as 12 females (Feldhamer 1980). Mating strategy within sika may be much more flexible (Endo 2009), with stags adopting a number of different strategies depending on circumstance, and hinds reaching puberty at 16-18 months, and thereafter breeding each year (Wilson and Mittermeier 2011, CABI 2021). Sika usually give birth between April and June to a single fawn, occasionally twins, after a 30 weeks gestation period (Feldhamer 1980). The reproductive rate is high, with a conception rate of 80-90% and an adult pregnancy rate of 85-100% (hence higher than for red deer). No signs of density-dependent reduction in fecundity among sika were reported, not even at population densities up to 35 animals per km<sup>2</sup>, but juvenile mortality can be high, with about 50% of fawns surviving their first winter in Ireland and Japan (Feldhamer 1980, CABI 2021). Apparently, as discussed in the sections above (see for example point 1.3a), it seems that a very small number of hinds and a few stags are sufficient to establish a new population. In New Zealand it is documented that a herd descended from only 4-5 deer, with one male only (Nugent and Speedy 2021). Also, in Japan, a population introduced to a small island descended from one male and two females only (Kaji et al. 2009). Increase in population size can be very high following introduction or colonization of new areas and density can exceed 50-100 individuals per km<sup>2</sup>. An irruptive population in Japan increased from 54 animals in 1986 to 592 animals in 1998, then after a decline to 177 animals in 1999, it reached a second peak of 626 animals in 2003, decreased to 341 deer in 2004, and eventually reached a third peak of 603 in 2005 (Kaji et al. 2004, Kaji et al. 2009). As summarized by CABI (2021) sika are less social than other deer species, living in small groups or solitarily (sexes are strongly segregated) with group size depending on the type of habitat (Wilson and Mittermeier 2011).

**Qu. 2.8. If the organism does not establish, then how likely is it that casual populations will continue to occur?**

Consider, for example, a species which cannot reproduce in the risk assessment area, because of unsuitable climatic conditions or host plants, but is present because of recurring introduction, entry and release events. This may also apply for long-living organisms.

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

It is likely that high numbers of individuals are still kept and bred in captivity in the risk assessment area, which leads to a constant risk of some being intentionally released or accidentally escaping in the wild, building up casual occurrences.

The risk that casual population will occur seems likely, but no sufficient data are available to support any statement on this regard.

**Qu. 2.9. Estimate the overall likelihood of establishment in the risk assessment area under current climatic conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under current climatic conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in current conditions: providing insight in the risk of establishment in (new areas in) the risk assessment area.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

The species is already established in the risk assessment area and it is very likely that this will continue in current climatic conditions.

**Qu. 2.10. Estimate the overall likelihood of establishment in the risk assessment area under foreseeable climate change conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under foreseeable climate change conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of establishment (e.g. increase in average winter temperature, increase in drought periods)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely establishment within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Under foreseeable climate change conditions, the projected suitability for sika establishment is relatively stable in both the Atlantic and Continental biogeographic regions, while it is deemed to increase in the Alpine and Boreal biogeographic regions. Conversely, in the Mediterranean biogeographic region the suitability is expected to decrease in future climate change (see Annex VIII for details).

In contrast to the results of the SDM in Annex VIII, Polaina et al. (2021) predict suitability only in Western Europe (Ireland, UK, France, Belgium, Netherlands, Germany, Denmark), and a decline (contraction to the north-west) with climate change. While the modelling approach of the study in general seems valid, it may suffer from three flaws for this species: 1) The model uses 18 predictors, which is a large number, especially given the low number of presence points used (368). 2) The predictors are the same as for all the other species studied (mammals, birds, a reptile and an amphibian), suggesting little species-specific selection of predictors. The two most important predictors in the model (temperature seasonality and precipitation seasonality) would not a priori be considered particularly important for the species, while others that should be considered important, such as snow cover, are missing. 3) While the definition of the area for drawing pseudo-absences is based on a global climate model for the species, the projection of suitability is based on presences only in some European countries, and excludes presences in Ukraine and Russia as well as occurrences in the native range and North America. Taken together, these three issues seem to result in far too specific a fit of the model to the Western European presence points of the species, and poor ability to extrapolate to other areas and climates. In a large meta-analysis of invasive alien species distribution models, Liu et al. (2020) make exactly these points – models are most likely to have poor transferability between regions and climates if they are based on few presence points, many predictors, and little species-specific expert input.

As described by Ward (2005), sika have expanded their range in the UK at an annual rate of 5.3% in recent years and are predicted to be capable of spreading throughout the majority of Great Britain (Acevedo et al. 2010). Each of the few significant population declines throughout the 100-year history of the species presence in Poland was contributed by severe winter conditions, particularly by the deep snow cover (Solarz & Okarma 2014). The species favours warm climates, naturally ranging throughout the subtropics of Japan and China. Warmer, wetter conditions and milder winters in the risk assessment area, as predicted by climate change models, are therefore likely to favour the establishment of sika in Europe.

### 3 PROBABILITY OF SPREAD

**Important instructions:**

- Spread is defined as the expansion of the geographical distribution of an alien species within the risk assessment area.
- Repeated releases at separate locations do not represent continuous spread and should be considered in the probability of introduction and entry section (Qu. 1.7).

**Qu. 3.1. How important is the expected spread of this organism within the risk assessment area by natural means? (List and comment on each of the mechanisms for natural spread.)**

including the following elements:

- a list and description of the natural spread mechanisms of the species in relation to the environmental conditions in the risk assessment area.
- an indication of the rate of spread discussed in relation to the species biology and the environmental conditions in the risk assessment area.

The description of spread patterns here refers to the CBD pathway category “Unaided (Natural Spread)”. It should include elements of the species life history and behavioural traits able to explain its ability to spread, including: reproduction or growth strategy, dispersal capacity, longevity, dietary requirements, environmental and climatic requirements, specialist or generalist characteristics.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

The potential of sika deer to spread within the risk assessment area by natural means is likely to be major. Sika have the capacity to migrate long distances, especially in mountainous areas, although characterized as sedentary (Bartoš 2009, Wilson and Mittermeier 2011). Overall, patterns of dispersal and range expansion seem to be depending on local population densities, sex and age of animals (young males are likely to disperse longer distances), presence of barriers such as railways and canals, types of habitats and water availability, presence of woodland corridors, extent of deer management and disturbance (Ward 2005, GB Non-Native Species Secretariat 2011, CABI 2021, Harris 2015). Although the information on dispersal patterns is often anecdotal, showing the need to fill in a number of gaps in knowledge through dedicated research (CABI 2021), there are several data which may help understand the spread potentialities of the species, as described below.

In New Zealand sika deer dispersed rapidly at a speed reaching 1.6 km per year (Davidson 1973, Nugent et al. 2001), while in the UK the range expansion was estimated at 3-5 km per year (Ward 2005). In Poland for some reason, both populations have been remaining virtually within the same small areas since their introduction in 1910 (Wojciech Solarz, pers. comm. 2021) However, travel distances up to 80-160 km/year are also reported, e.g. in Poland (Bartoš, 2009), although this is an estimate of possible migration of single individuals that appeared in areas where there were no sika, and whose appearance could as well be a result of an escape from some local farm (Wojciech Solarz, pers. comm. 2021). This is in line with data of seasonal (altitudinal) migration distances reported in Japan, where sika are known to cover mean distances of 35 km between winter and summer ranges (Wilson and Mittermeier 2011). Also,

a study on female sika deer in their native range in Japan, showed that the distance of their seasonal movements ranged between 7.2 and 101.7 km (Igota et al. 2004). Sika deer are excellent swimmers and can travel 12 km by swimming in the sea (Feldhamer 1980).

In Ireland, between 1978-2008 the range increased by 353%, with an annual rate of 5%, while range expansion in the UK varied from 5.3% to 7.3% yearly, depending on the studies, mostly as a consequence of both slow natural expansion and accidental escapes from parks and farms (Ward 2005, Pérez-Espona et al. 2009; Carden et al. 2011). Also in the Czech Republic, in the period 2003 – 2010, sika population occupied on average 55 thousand ha of new territories every year (Dvořák and Palyzová 2016).

It is worth to consider that in the UK, where natural spread is considered a main pathway, the establishment of new populations may be supported not only by the recruitment of further animals through the concurrent releases from enclosures, but also by the possibility of dispersing animals hybridising with red deer, if failing to encounter members of their own species (GB Non-Native Species Secretariat 2011). This may increase the risk of the animals to pass unnoticed, and the population of sika-hybrids to further spread. However, there are populations in the UK which showed a very slow expansion of their range, probably because of the presence of barriers, such as roads, railways and urban settlements (GB Non-Native Species Secretariat 2011, Carden et al. 2011). In Poland, although sika deer have been established for over 100 years, there was no significant expansion of their range, maybe due to limiting factors such as low temperatures in winter and the depth of snow cover (Solarz et al. 2018, Kopij 2017). No natural spread was reported in Austria and Denmark either (Baiwy et al. 2013, Asferg and Madsen 2007).

**Qu. 3.2a. List and describe relevant pathways of spread other than "unaided". For each pathway answer questions 3.3 to 3.9 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 3.3a, 3.4a, etc. and then 3.3b, 3.4b etc. for the next pathway.**

including the following elements:

- a list and description of pathways of spread with an indication of their importance and associated risks (e.g. the likelihood of spread in the risk assessment area, based on these pathways; likelihood of survival, or reproduction, or increase during transport and storage; ability and likelihood of transfer from the pathway to a suitable habitat or host) in relation to the environmental conditions in the risk assessment area.
- an indication of the rate of spread for each pathway discussed in relation to the species biology and the environmental conditions in the risk assessment area.
- All relevant pathways of spread (except "Unaided (Natural Spread)", which is assessed in Qu. 3.1) should be considered. The classification of pathways developed by the Convention of Biological Diversity shall be used (see Annex IV).

No specific pathways other than the natural spread was identified, other than those already discussed under Qu. 1.1.

**Qu. 3.3a. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional unintentional	<b>CONFIDENCE</b>	low medium high
-----------------	------------------------------	-------------------	-----------------------

Response: N/A

**Qu. 3.4a. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low medium high

Response: N/A

**Qu. 3.9a. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly slowly moderately rapidly very rapidly	<b>CONFIDENCE</b>	low medium high
-----------------	--	-------------------	-----------------------

Response: N/A

**Qu. 3.10. Within the risk assessment area, how difficult would it be to contain the organism in relation to these pathways of spread?**

<b>RESPONSE</b>	very easy easy with some difficulty difficult <b>very difficult</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Effective containment measures to prevent the spread of sika deer through the pathway above are the same as those to control/eradicate the species (see for example discussion on **Qu. 2.6.**), hence their applicability is context dependent, and depends on the size of the population and the invasion stage.

Like for many other invasive alien species of vertebrates, eradication is likely achievable only in parts of the risk assessment area where recent introductions have occurred or sub-populations remain quite localized, and in any case nationwide containment is likely to be prohibitively costly, as pointed out by the GB Non-Native Species Secretariat (2011) regarding the situation in the UK. However, it should be noted that several sika populations are likely to be represented by sika-hybrid, which would entail the need to remove also those red deer population showing a certain level of introgression, which may be considered unlikely given the many caveats and constraints of a similar operation.

In the UK according to the GB Non-Native Species Secretariat (2011) *“the past level of culling has mostly failed to prevent range expansion in many areas, in large part likely due to lack of coordination of culling across sub-population ranges, with some landowners carrying out little or no control of numbers. However, in some areas such as the New Forest, where Sika have been established for many years, regular culling has succeeded in containing numbers, with limited range expansion observed over the past 30 years”*.

In Ireland there were several outlying records which may be a result of illegal translocations (Carden et al. 2011, Murphy et al. 2013), but the purpose of such introductions is not reported. It is not always easy to deal with illegal movement of species, as it requires the enforcement of a sound legislation and the implementation of effective communication campaigns.

**Qu. 3.11. Estimate the overall potential rate of spread in relevant biogeographical regions under current conditions for this organism in the risk assessment area (indicate any key issues and provide quantitative data where possible).**

Thorough assessment of the risk of spread in relevant biogeographical regions in current conditions, providing insight in the risk of spread into (new areas in) the risk assessment area.

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

There is documented evidence that the species spread in some EU countries by natural means, and it is possible to expect this to happen also in the future. For example, a possible pathway in the Netherlands is dispersal from seven established populations in Germany, especially from the Möhnesee area, which lies approximately 80 km from the Dutch border although this is considered not likely to occur given the current hunting management of the species in Germany (Lammertsma et al. 2012). On the other hand, sika were recorded to migrate 80-160 km in Poland (although there is no certainty, as discussed in Qu. 3.1), and were often seen roaming together with red deer (Bartoš 2009). Also in Luxembourg the presence of the species in the area was explained with the escape of sika deer from an enclosure in Gemünd, Germany, near the Luxembourg border (Cellina and Schley 2014). Similarly, a possible pathway of sika deer entry in Belgium is the natural spread of individuals from neighboring countries (Baiwy et al.

2013). It is worth to point out that also the sika population in Switzerland originated from animals dispersed from the population in Germany (Bartoš 2009).

Therefore, in the light of the evidence of the species spread by natural means within the EU, and the data discussed in Qu. 3.1, the rate of spread is considered moderate, as the species may suddenly appear in any Member State with sika populations (or their hybrids) already occurring in neighbouring countries.

**Qu. 3.12. Estimate the overall potential rate of spread in relevant biogeographical regions in foreseeable climate change conditions (provide quantitative data where possible).**

Thorough assessment of the risk of spread in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk, specifically if rates of spread are likely slowed down or accelerated.

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

The rate of spread is expected to be the same whether in current conditions or future climate change conditions, because there are no specific elements of the species biology (i.e. in relation to dispersal patterns) which seem affected by the climate, except for the area which may be suitable, which may increase as shown in Annex VIII (i.e. in Northern Europe, in relation to a potential decrease of snow cover).

## 4 MAGNITUDE OF IMPACT

Important instructions:

- Questions 4.1-4.5 relate to biodiversity and ecosystem impacts, 4.6-4.8 to impacts on ecosystem services, 4.9-4.13 to economic impact, 4.14-4.15 to social and human health impact, and 4.16-4.18 to other impacts. These impacts can be interlinked, for example, a disease may cause impacts on biodiversity and/or ecosystem functioning that leads to impacts on ecosystem services and finally economic impacts. In such cases the assessor should try to note the different impacts where most appropriate, cross-referencing between questions when needed.
- Each set of questions starts with the impact elsewhere in the world, then considers impacts in the risk assessment area (=EU excluding outermost regions) separating known impacts to date (i.e. past and current impacts) from potential future impacts (including foreseeable climate change).
- Only negative impacts are considered in this section (socio-economic benefits are considered in Qu. A.7)
- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable).

### Biodiversity and ecosystem impacts

**Qu. 4.1. How important is the impact of the organism on biodiversity at all levels of organisation caused by the organism in its non-native range excluding the risk assessment area?**

including the following elements:

- Biodiversity means the variability among living organisms from all sources, including terrestrial, marine and other aquatic ecosystems and the ecological complexes of which they are part; this includes diversity within species, between species and of ecosystems
- impacted chemical, physical or structural characteristics and functioning of ecosystems

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Sika is known to pose a threat to native species through competition with other deer species and through hybridisation with native red deer. They can also have an impact on vegetation and habitats, which in turn can affect ecosystem services, as well as on health, crops and the economy.

According to Bartoš (2009) sika appear to be successful competitors with local deer species due to anatomical and behavioral features. This is particularly the case with the red deer, e.g. in Russia and New Zealand, or white-tailed deer (*Odocoileus virginianus*) in North America (Feldhamer and Demarais 2008, CABI 2021, Lever 1994).

In New Zealand, competition between sika deer and red deer is reported. In areas where the vegetation had been heavily browsed by red deer, sika replaced them demonstrating greater adaptability and further degrading the plant communities (Lever 1994). In the United States, sika are displacing white-tailed deer because of their wider range of diet (Feldhamer and Demarais 2008, Lever 1994). In this country, the occurrence of parasites in sika is also reported, although no specific information on transmission is provided (Mason 1994). However, this shows the potential for the spread of pathogens to native wildlife.

There are studies carried out in the species native range, which are reported here to provide examples on additional possible impact of the species in its introduced range. In Japan, particularly in places where sika population density is high, the species demonstrates strong negative effects on vegetation in both agricultural and forested habitats, including on overall regeneration in many natural forests and conifer plantation (Takatsuki 2009a, Takatsuki and Ito 2009, Akashi et al. 2011). Deer grazing and browsing may cause significant changes in vegetation structure and species composition as well as significant soil erosion and changes in water flow (Diaz et al. 2005, Takatsuki 2009a, Lammertsma et al. 2012) which overall are deemed to exceed the impacts of comparable deer species (Baiwy et al. 2013). A recent study on dung beetles (Scarabaeinae) carried out in Japan, showed a larval resource shift from carnivore feces to deer feces associated with an increase in deer density (despite a number of caveats), which may affect ecosystem functions such as soil nutrient cycling and seed dispersal (Yama et al. 2019). By modifying the composition and physical structure of habitats deer may exert cascading effects on other animals (Reimoser and Putman 2011). For example, in a site in Japan, it was demonstrated that foraging opportunities and population densities of raccoon dogs (*Nyctereutes procyonoides*) and Japanese badgers (*Meles anakuma*) increased in response to the increased abundance of earthworms and insects caused by the habitat modification of high deer density (Seki and Koganezawa 2013, Seki et al. 2014). Other indirect effects of sika deer, although not well studied, seem to be the reduction of understory bamboo cover, which in turn improved the survival of tree seedlings and caused the decline of wood mice *Apodemus* spp. (Takatsuki 2009a). In Japan, high population densities of sika led to irreversible changes on the vegetation, with some plants locally decreasing to near extinction (Kaji et al. 2009, Baiwy et al. 2013). For example, a study carried out in a subalpine area at Mt. Kita showed that the impact of sika deer was more severe in the *Betula* forests than in grasslands, where more plant species are available for browsing. Specifically, browsing on less frequently occurring plants (including red listed species) led to deterioration of the vegetation, the disappearance of common species and consequently the homogenization of vegetation (Nagaite 2012).

**Qu. 4.2. How important is the current known impact of the organism on biodiversity at all levels of organisation (e.g. decline in native species, changes in native species communities, hybridisation) in the risk assessment area (include any past impact in your response)?**  
 Discuss impacts that are currently occurring or are likely occurring or have occurred in the past in the risk assessment area. Where there is no direct evidence of impact in the risk assessment area (for example no studies have been conducted), evidence from outside of the risk assessment area can be used to infer impacts within the risk assessment area.

<b>RESPONSE</b>	minimal	<b>CONFIDENCE</b>	low
-----------------	---------	-------------------	-----

	minor moderate <b>major</b> massive		medium <b>high</b>
--	--	--	-----------------------

### Competition with native ungulates

Sika deer competes with native ungulate species like roe deer, red deer, and wild boar, for both food and space (but also through mate competition with red deer), apparently reducing the fitness of other species (for example by outcompeting roe deer or disturbing red deer rutting) because of their ecological flexibility, as well as their anatomical and behavioural features (Bartoš 2009, Lammertsma et al. 2012, Macháček et al. 2014). However, there are very few definitive studies of the effects of sika on other deer species (Ferretti and Lovari 2014).

As reported by Solarz et al. (2018) sika deer have a strong effect on herbaceous vegetation, thus limiting the feeding base of European bison (*Bison bonasus*), although the lack of dedicated research makes it difficult to clearly state to what extent the food niche of these two species would overlap.

In general, outcomes of competition dynamics between sika and other ungulates cannot be predicted and differs between areas (Bartoš 2009). The lack of evidence in the scientific literature does not allow to demonstrate unequivocally the effect of competition between sika and other deer, also because most deer populations are under a management regime (CABI 2021, Ferretti and Lovari 2014, Solarz et al. 2018). Anecdotal observations, correlative studies and spatial segregation suggest that native deer species as well as other introduced ungulates (e.g. fallow deer) may decline in areas invaded by sika deer due to competition (Baiwy et al. 2013). On the other hand, there are studies which lead to the conclusion that sika are weak competitors and are not expected to displace native species (e.g. Acevedo et al. 2010 for the UK), but recognize that additional risks may occur, such as spread of diseases and genetic introgression). Overall, direct competition for resources between red deer and sika is not well documented in UK (GB Non-Native Species Secretariat 2011), despite the documented overlap of diet (Ferretti and Lovari 2014). Similarly, some overlap of habitat use was noted between roe deer and sika, but this did not seem to have any direct competitive effects in terms of population dynamics (Ferretti and Lovari 2014).

### Hybridisation with red deer

A peculiar type of interspecific interaction is mate competition of sika deer with red deer. In particular, red deer stags (especially young) may be attacked by sika males, which are extremely aggressive in the rutting season and may mate with red deer hinds, with the inherent risk of hybridization and introgression between the two species (Zachos and Hartl 2011, Baiwy et al. 2013, Pérez-Espona et al. 2009). Because red deer harems are dispersed over large areas, even a low number of successful sika stags may trigger the hybridization process by simultaneously siring multiple hybrids (Zachos and Hartl 2011). The impact of hybridisation between sika and red deer is one of the greatest threats associated to the spread of this invasive alien species (see Linnell and Zachos 2011, Zachos and Hartl 2011, Bartoš 2009).

So far, hybridization between the two species has been documented in Ireland, Germany, Czech Republic, Lithuania, Austria and the United Kingdom (Pérez-Espona et al. 2009, Ferretti and Lovari 2014, Linnell and Zachos 2011, Bartoš 2009) as well as France (Pascal et al. 2006), Italy (Ferri et al. 2014, Ferri et al. 2016), Poland, Kaliningrad District (Russia), and Lithuania (Biedrzycka et al. 2012). It is likely that this list is not exhaustive, as shown by the unexpectedly

documented cases in countries where the species was not even known to occur, like in Italy (Ferri et al. 2014, Ferri et al. 2016). Some authors have also noted the development of a "hybrid swarm", e.g. in Poland (Biedrzycka et al. 2012), in the UK (Scotland, Senn and Pemberton 2009), although evidence is not always straightforward, e.g. see the case in Ireland (MacDevitt et al. 2009).

According to Bartoš (2009) in many areas where sika coexist with red deer, it is still believed by many hunters that no interbreeding has occurred, despite evidence to the contrary, including modern genetic techniques. Disregard of hybridization has resulted in introgression of sika and red deer genes in many areas (Bartoš 2009). Interbreeding of sika with red deer seems to be a rare event in general (Pérez-Espona et al. 2009) and there are sites where no hybrids are reported, however, the presence of isolated sika males in areas (harems) with red deer hinds may increase the likelihood of cross breeding (Pérez-Espona et al. 2009, Bartoš 2009). Overall, the impact may be locally significant, for example the level of introgression found in a study carried out in 5 regions in Poland, the Kaliningrad District (Russia), and Lithuania, is 15.5% in all regions studied (Biedrzycka et al. 2012), but reached up to 47% in some extremely strongly hybridised populations, i.e. in Ireland (Smith et al. 2014). Ireland is also known to have reported the first hybrids between sika deer and red deer in Europe (Powerscourt 1884), although red deer populations are alien too in this country (Smith et al. 2014).

As pointed out by Linnell and Zachos (2011) hybridisation in the wild between sika and red deer is not as common as previously feared but it nonetheless does occur, at least locally, in frequencies high enough to threaten the genetic integrity of red deer populations. For example, Goodman et al (1999) demonstrated how hybridisation is generally rarer than expected across Scotland (UK), but is quite pronounced at some locations. Future range shifts of both species may create new conditions of sympatry, which may increase the opportunities for further hybridization (Zachos and Hartl 2011).

### **Impact on vegetation and ecosystems**

In Europe, sika deer can reach higher local densities than red deer and can induce strong vegetation damage due to overgrazing, as shown in a long term study in Ireland (Perrin et al. 2006, 2011). The impact seems especially evident on acidic soils (Baiwy et al. 2013), and may favour the spread of alien plants (Ferretti and Lovari 2014).

In the UK, sika have caused detrimental impacts on the biodiversity of ground vegetation in semi-natural heathland and wetland areas when present at high density (GB Non-Native Species Secretariat 2011). Severe and permanent changes in the structure and composition of vegetation in forests, heaths and wetlands are reported. In particular, the ecological impacts of sika deer on saltmarshes in the UK are described in detail (Diaz et al. 2005, Hannaford et al. 2006). Here, excessive browsing caused local decrease in number of several plant species, such as spartina (*Spartina anglica*) in saltmarshes. However, the studies also highlight that depending on the intensity of grazing, the effect of sika may be beneficial in terms of conservation management.

In forest habitats in Ireland sika deer suppressed the natural regeneration of most tree species (but canopy condition was another factor affecting regeneration), with the exception of the few plants not eaten, such as European beech *Fagus sylvatica* (Perrin et al. 2006, 2011).

The sika deer has a great potential for negative impacts on ecosystems (Ferretti and Lovari 2014). As noted by Baiwy et al. (2013) during irruptive events, a degradation of the conservation status of ecosystems is also expected to occur locally (alteration of vegetation, inhibition of tree regeneration, soil trampling, etc.).

No specific impacts on ecosystems is documented in France (Pascal et al. 2006).

By modifying the structure of forest ecosystems and the natural dynamics of vegetation through excessive browsing and trampling, sika may also cause soil erosion with cascading effects and this may also affect forest animal species, particularly soil invertebrates, birds nesting on the ground and in shrubs, small rodents and their predators (Reimoser and Putman 2011, Diaz et al. 2005, Baiwy et al. 2013, Solarz et al. 2018).

In conclusion, as pointed out by Lammertsma et al. (2012), effects of sika will depend on factors like population dynamics and density, habitat use, diet, available vegetation, interactions with other ungulates and site management.

**Qu. 4.3. How important is the potential future impact of the organism on biodiversity at all levels of organisation likely to be in the risk assessment area?**

See comment above. The potential future impact shall be assessed only for the risk assessment area. A potential increase in the distribution range due to climate change does not *per se* justify a higher impact score.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

In the event of substantial spread and increase in numbers of sika deer to new parts of the risk assessment area, the impact may be expected to increase in scale. The risk of introgression with native red deer populations is irreversible. Because there is evidence that this has already occurred and is still occurring, the confidence is high.

**Qu. 4.4. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism currently in the risk assessment area?**

including the following elements:

- native species impacted, including red list species, endemic species and species listed in the Birds and Habitats directives
- protected sites impacted, in particular Natura 2000
- habitats impacted, in particular habitats listed in the Habitats Directive, or red list habitats
- the ecological status of water bodies according to the Water Framework Directive and environmental status of the marine environment according to the Marine Strategy Framework Directive

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

The sika deer represents a potential threat for a series of species and habitats protected by the Birds and Habitats directives, as well as a number of IUCN red-listed species in the risk assessment area. According to the IUCN Red list, because of the risk of hybridisation sika deer represent a main threat for the red deer, although the species is considered of Low concern at the global level (Lovari et al. 2018). The level of threat however may increase should the sika be further introduced and spread, and may be locally relevant in case of distinct isolated populations of red deer, such as the one in the Mesola wood (Po Delta Park, Italy). As mentioned above, the sika may also represent a threat to other ungulates, including *Cervus elaphus corsicanus*, whose populations in Corsica (France) and Sardinia (Italy) are protected by the Habitats directive (although their occurrence in the Tyrrhenian islands is due to ancient introductions). In Poland it is expected that, as a result of competition with native ungulates, the further spread of sika deer could cause decreases in the population size of native species, including those of special concern like the European bison *B. bonasus* (Solarz et al. 2018). While it cannot be excluded that interspecific interactions with sika deer may lead to the local decline of native deer species, they seem unlikely to cause large-scale species displacement (Baiwy et al. 2013).

Sika impact woodland habitats and saltmarshes by browsing on plants and trampling ground flora (Diaz et al. 2005, Hannaford et al. 2006, Perrin et al. 2006, 2011). In Ireland, the potential negative impact on woodland habitats protected under the European Union’s Habitats Directive is stressed by Carden et al. (2011). Besides the fact that several plants may be susceptible to sika deer impact, it is necessary to consider the cascading effects that sika deer populations may exert on other animals through the modification of vegetation structure and composition (Baiwy et al. 2013).

**Qu. 4.5. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.3. and 4.4.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

In the event of substantial spread and increase in numbers of sika deer to new parts of the risk assessment area, the impact may be expected to increase accordingly. While there is no documented evidence of the species being able to cause the extinction of native species, the long-term irreversible risk of introgression on the European populations of red deer may be relevant.

**Ecosystem Services impacts**

**Qu. 4.6. How important is the impact of the organism on provisioning, regulating, and cultural services in its non-native range excluding the risk assessment area?**

- For a list of services use the CICES classification V5.1 provided in Annex V.

- Impacts on ecosystem services build on the observed impacts on biodiversity (habitat, species, genetic, functional) but focus exclusively on reflecting these changes in relation to their links with socio-economic well-being.
- Quantitative data should be provided whenever available and references duly reported.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Sika deer is known to affect several ecosystem services, not only through the impacts on biodiversity (through competition on other ungulates, hybridisation with red deer, and damages to vegetation and ecosystems), but also due to the impacts documented on agricultural crops through browsing and bark stripping.

The erosion caused by the trampling behaviour associated with the death of trees caused by the habit to wipe their antlers on the barks, may result in destabilisation of stream banks, changes in stream flow and increased erosion. In New Zealand soil erosion was accelerated by sika through thinning of understory caused by excessive trampling (Lever 1994).

The potential effect on the nitrogen cycle has been suggested as documented for ungulates in general (Hobbs 1996, Solarz 2018). The role of sika deer in the transmission of diseases is a possible threat to both wildlife and livestock, and to humans (Solarz et al. 2018). On the basis of the impacts described above, the following list of potential impacts on ecosystem services was compiled:

#### Provisioning (Biomass)

- Cultivated terrestrial plants
- Reared animals
- Wild plants (terrestrial and aquatic)
- Wild animals (terrestrial and aquatic)
- Genetic material from animals

#### Regulation & Maintenance (Regulation of physical, chemical, biological conditions)

- Regulation of baseline flows and extreme event
- Lifecycle maintenance, habitat and gene pool protection
- Pest and disease control
- Regulation of soil quality

#### Cultural (Direct, in-situ and outdoor interactions with living systems that depend on presence in the environmental setting)

- Physical and experiential interactions with natural environment
- Intellectual and representative interactions with natural environment

**Qu. 4.7. How important is the impact of the organism on provisioning, regulating, and cultural services currently in the different biogeographic regions or marine sub-regions where the species has established in the risk assessment area (include any past impact in your response)?**

- See guidance to Qu. 4.6.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

The impacts on ecosystem services for the risk assessment area are the same as described in Qu. 4.6.

Specific references for the risk assessment area, are the following. Damages through fraying and bark stripping are reported in Ireland (Lever 1994). In the UK, intensive trampling was documented to trigger soil erosion processes on heaths and saltmarshes (Diaz et al. 2005).

Despite the lack of quantitative data, some impacts (particularly on provisioning services) is well documented in the risk assessment area, hence the medium confidence score.

**Qu. 4.8. How important is the impact of the organism on provisioning, regulating, and cultural services likely to be in the different biogeographic regions or marine sub-regions where the species can establish in the risk assessment area in the future?**

- See guidance to Qu. 4.6.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

In the event of substantial spread and increase in numbers of sika deer to new parts of the risk assessment area, the impact may be expected to increase accordingly. There is no evidence, however, that the level of impact will increase in the future. The level of confidence is medium because despite the lack of quantitative data, some impacts (particularly on provisioning services) are well documented in the risk assessment area.

## **Economic impacts**

**Qu. 4.9. How great is the overall economic cost caused by the organism within its current area of distribution (excluding the risk assessment area), including both costs of / loss due to damage and the cost of current management.**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the world these should be reported here. The assessment of the potential costs of / loss due to damage shall describe those costs quantitatively and/or qualitatively depending on what information is available. Cost of / loss due to damage within different

economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage. As far as possible, it would be useful to separate costs of / loss due to the organism from costs of current management.

<b>RESPONSE</b>	minimal minor moderate major <b>massive</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

According to Harris (2015) in its native range in Japan, the sika deer is considered an agricultural and forest-plantation pest (see also Kaji et al. 2010).

On the island of Hokkaido, damage to forestry and agriculture increased to nearly 2 billion Japanese yen (JPY) (corresponding to 18 million USD) by 1990 and to over 5 billion JPY (corresponding to 45 million USD) by 1996 (Kaji 1999, Kaji et al. 2010). Damage to crops in Japan were significant in 2010 and were estimated at around 4.1 million USD, and the damage caused was demonstrated in 36.1% of 341 farms (Tsukada et al. 2013). In a dairy farm in central Japan, sika deer consumed an estimated 20% of the total herbage production with an economic loss estimated to exceed USD 0.13 million per year (Tsukada 2013). The level of herbage damage caused by sika deer, however, was different among different meadows (Tsukada et al. 2013). According to Kawata (2011) cost of agricultural/forestry damage caused by sika deer in Hokkaido, Japan, are slightly different, as they equal 0.35, 2.1 and 24 million USD, in 1970, 1980, and 1990 respectively; the damage reached its peak in 1996 with a cost of 60 million USD, and eventually the total cost of damage stabilized at around 36 million USD after 2000.

**Qu. 4.10. How great is the economic cost of / loss due to damage (excluding costs of management) of the organism currently in the risk assessment area (include any past costs in your response)?**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the EU these should be reported here. Assessment of the potential costs of damage on human health, safety, and the economy, including the cost of non-action. A full economic assessment at EU scale might not be possible, but qualitative data or different case studies from across the EU (or third countries if relevant) may provide useful information to inform decision making. In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable). Cost of / loss due to damage within different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Commercial forest plantations are used by sika deer for both food and cover and may suffer extensive damage due to bark stripping, browsing and antler abrasions (Murphy et al. 2013). In Ireland, where deer are generally perceived as a problem for the damage they cause to woodland, the types of impacts and damage in plantation forests and crops were reviewed by Murphy et al. (2013). The same authors also stressed that calculating the potential economic cost of damage is difficult since relatively few studies have been carried out in the country, and national baseline quantitative data are lacking. However, in Ireland, the potential loss of income caused by sika deer was estimated at approximately €1,200 per ha (Murphy et al. 2013).

In the UK, extensive damage by sika is reported to commercial forestry, especially at high density in Scotland, both through browsing of young trees and shoots, as well as bark-stripping, bole scoring and fraying (Gill et al. 2000, see also GB Non-Native Species Secretariat 2011). Damage to forestry is also considered significant in a number of countries to which sika have been introduced, once populations reach sufficient density (CABI 2021). In particular, damage levels to regenerating woodland are considered broadly tolerable if densities do not exceed 4 deer per 100 ha (Reimoser and Putman 2011). However, this threshold refers primarily to impacts of red and sika deer in commercial forests in Scotland, hence any generalisation would be too speculative in the absence of a detailed characterisation of other (potentially) affected plantations. Also Gill et al. (2000) in their review on the economic implications of deer damage in Scotland pointed out that no estimates are available specifically for sika deer, although it is likely that in certain habitat types the damage inflicted by this species is higher than that by the native red and roe deer.

On the other hand, agricultural crop damage has not been reported as of widespread economic significance in the UK. Economic losses to agriculture have not been studied in detail specifically for sika, but even at high density tend to be of mostly localised importance without causing a significant economic problem on a regional or a national scale (GB Non-Native Species Secretariat 2011, Putman et al. 2011, Pérez-Espona et al. 2009). In England, the economic losses to agriculture attributable to sika may be about £100,000, which is about 2% of the costs due to all deer species (Wilson 2003).

Similar conclusions arise from experience with sika in other European countries, where damage to arable and horticultural crops currently appears to be of minor significance (Pérez-Espona et al. 2009). These populations, however, are controlled at low densities by hunting. If sika deer were not controlled, it is likely that significant damage would occur to agricultural crops (Lammertsma et al. 2012). On the other hand, as pointed out by Solarz et al. (2018) there are no published studies on the effect of the species on the condition or yield of crops by changing the properties of the agroecosystem, including the circulation of nutrients, hydrology, physical properties, and trophic networks.

As reported by the GB Non-Native Species Secretariat (2011) for UK, it is important to note that much of the potential habitat available for the sika in the risk assessment area already has one or more other ungulates present (and often under management), hence economic impacts may not necessarily be additive or increase, unless the overall numbers of deer increase. Also, as noted for the UK, the presence of sika hybrids may compromise the genetic integrity of native red deer stocks, potentially reducing their trophy value, hence leading into net changes to income (e.g. through stalking and trophy shooting) and other associated economic losses which are however difficult to predict (GB Non-Native Species Secretariat 2011).

**Qu. 4.11. How great is the economic cost of / loss due to damage (excluding costs of management) of the organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.10.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Overabundant deer are known to inflict major economic losses in forestry and, although to a lesser extent (hence with a reduced level of impact), can also cause damages in agriculture, and transportation and contribute to the transmission of several animal and human diseases. In the event of substantial spread and increase in numbers of sika deer to new parts of the risk assessment area, the impact (which in fact is calculated in euro/ha) may be expected to increase accordingly.

**Qu. 4.12. How great are the economic costs / losses associated with managing this organism currently in the risk assessment area (include any past costs in your response)?**

- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable).

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Economic costs associated with managing the sika deer in the risk assessment area would depend on the objective and the status of the species.

In Ireland, a study carried out on a sample site demonstrated that the cost and maintenance of fencing reduced returns by €1,971.59 per ha, which was higher than the loss of €459.83 per ha were no fencing was used (Murphy et al. 2013). The losses without fencing were approximately one quarter of the overall costs of erecting and maintaining fencing, but the authors recognize that the cost benefit of fencing may differ in different types of plantations. In any case, it is worth mentioning that fencing may also have side effects, since the complete exclusion of grazing animals may be beneficial in terms of natural regeneration for certain species of woodlands, as shown on a long term study in Ireland, but may be undesirable if the management objectives are to achieve high levels of ground flora diversity (Perrin et al. 2006, 2011) and allowing for native deer species migrations.

In general, as noted by the GB Non-Native Species Secretariat (2011) for UK, within forest plantations greater effort tends to be required per sika culled as compared to red deer.

**Qu. 4.13. How great are the economic costs / losses associated with managing this organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.12.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

In the event of substantial spread and increase in numbers of sika deer to new parts of the risk assessment area, the costs may be expected to increase accordingly. If the species spreads and is to be managed, some costs are bound to be incurred, even if there is no information on what these costs currently are. The spread of sika may cause extensive indirect costs for the reduction of damages to ecosystems or crops, or for roadside protections, due to the need for high net fences or culling by professional hunters and government agencies (GB Non-Native Species Secretariat 2011, Baiwy et al. 2013). However, it is not possible to estimate the exact monetary value, as it depends on deer management systems and policies involved, which vary considerably across the different countries of Europe depending on species present, legislation, cultural tradition and the status of deer as *res nullius* or *res communis*.

In the UK, according to a review on the economic implications of deer damage in Scotland (Gill et al. 2000) culling appears to be a far more cost effective option than fencing (which could cost in the region 10-30% of yield for Sitka spruce) in view of the fact that much of the cost of deer control can be offset against revenue from venison.

## Social and human health impacts

**Qu. 4.14. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism for the risk assessment area and for third countries, if relevant (e.g. with similar eco-climatic conditions).**

The description of the known impact and the assessment of potential future impact on human health, safety and the economy, shall, if relevant, include information on

- illnesses, allergies or other affections to humans that may derive directly or indirectly from a species;
- damages provoked directly or indirectly by a species with consequences for the safety of people, property or infrastructure;
- direct or indirect disruption of, or other consequences for, an economic or social activity due to the presence of a species.

Social and human health impacts can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Overall, as pointed out for alien mammals in general (Capizzi et al. 2018), sika deer can act as vectors of both alien and native pathogens, and as host of either native or alien parasites (which in turn can be acting as vectors of either native or alien pathogens). In this way sika deer may either introduce new pathogens, alter the epidemiology of local pathogens, become reservoir hosts, and increase disease risk for humans, along with other species (e.g. by introducing changes in the vector-host-parasite relationship).

A short review of disease and parasites found in sika deer in both its native and alien range, is found in Feldhamer (1980). Feldhamer and Demarais (2008) reported those disease and parasites found in sika in the US. Current and possible future infections of sika deer which may have an impact on livestock and/or human health in the UK are reviewed by Böhm et al. (2007). In Japan, there is direct evidence for zoonotic transmission of hepatitis E virus from sika deer to human beings (Tei et al. 2003) although prevalence in sika deer was found to be lower than the in two other possible reservoirs, pigs and wild boar (Matsuura et al. 2007).

In addition to carrying diseases that can infect humans, sika deer may cause road and rail collisions. In Denmark, a total of 33,605 collision sites between medium-sized and large wildlife and vehicles were recorded from 2003 to 2012, of which 141 sika (Elmeros et al. 2014). Deer/vehicle collisions with sika were estimated at 350-600 per year by Langbein (2007), contributing to about 1% of all deer/vehicle collisions in England and Scotland (Langbein 2007, 2011). Sika do not appear any more prone to involvement in such collisions than other deer species. In Japan, on Hokkaido, the number deer-vehicle traffic accidents increased from 293 in 1993 to 1,474 in 2007, successively 1,628 accidents were reported in 2008 and 1,838 in 2009 (Kawata 2011). In the same region, deer-train collisions involving sika deer were also reported: on a 330 km railway section there were 696 accidents between 1987 and 1995 (Onoyama et al. 1998).

As pointed out by Solarz at al. (2018) there is no available information suggesting that the species has biological, physical and/or chemical properties that are harmful to people, although it cannot be ruled out that because of sika deer size, there may be cases of kicking or injuring with antlers in specific circumstances, i.e. when in contact with humans.

**Qu. 4.15. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism in the future for the risk assessment area.**

- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable).

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

In the event of substantial spread and increase in numbers of sika deer to new parts of the risk assessment area, the impact may be expected to increase accordingly.

For example, it was pointed out In the UK, by the GB Non-Native Species Secretariat (2011), in the event of substantial spread and increase in numbers of sika to new parts of the risk assessment area, increased social harm through deer/vehicle collisions may be expected.

**Other impacts**

**Qu. 4.16. How important is the organism in facilitating other damaging organisms (e.g. diseases) as food source, a host, a symbiont or a vector etc.?**

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

The sika deer, as other ungulates, can be a carrier of a number of diseases and parasites that may be harmful to native species. Deer, in general, may transmit infectious diseases directly to other species of deer (as well as to livestock, and to humans), especially if their density is high (Côté et al. 2004). The risk of disease transmission is not limited to the animals in the wild, since sika deer kept in captivity may be acting as a source of infection as well. As Feldhamer and Demarais (2008) noted, disease transmission may occur between captive deer and livestock, and between captive deer and free-ranging wildlife populations adjacent to the fences.

Bovine tuberculosis and avian tuberculosis have been found in sika deer - both in free-living populations and in captivity - which can be infecting both animals, as well as humans (Solarz et al. 2018). In particular, Bovine tuberculosis has been recorded in sika deer in Ireland, the UK (GB Non-Native Species Secretariat 2011, Delahay et al. 2002), and New Zealand (Nugent et al. 2001). In the UK and Ireland sika are not the principal wildlife reservoir for Bovine tuberculosis but have a potential role in perpetuating the disease (Ward and Smith 2012). In the UK, like all other established deer species are carriers of ticks *Ixodes ricinus* which are a vector for Lyme disease (GB Non-Native Species Secretariat 2011).

In Eastern and Central Europe, sika are deemed to play an important role in the epidemiology of the highly pathogenic *Ashworthius sidemi* (Vadlejch et al. 2017, Solarz et al. 2018). In the previous century this non-specific blood-sucking gastrointestinal nematode of Asiatic origin was introduced with sika into Europe, e.g. Slovakia, Czech Republic and France as well as Ukraine (Demiaszkiewicz 2014, Demiaszkiewicz et al. 2013, Ferté et al. 2000, Kotrla and Kotrly 1973) and since then it spread in Poland too (Vadlejch et al. 2017). *Ashworthius sidemi* is known to infect European bison, roe deer, red deer, fallow deer, elk (*Alces alces*) as well as domestic sheep (*Ovis aries*) and cattle (*Bos taurus*) (see Vadlejch et al. 2017, Hoberg 2010, Baiwy et al. 2013, Demiaszkiewicz et al. 2013). This is creating greatest concern particularly for the conservation of European bison, for which diseases are considered a main threat (Plumb et al. 2020). Although there has been no case of death caused by this nematode, it may reduce the condition of bison and lead to death, especially of young animals, according to Solarz et al. (2018).

In Ireland a study on the prevalence and distribution in free-ranging deer, of a number of existing and emerging pathogens - namely bovine viral diarrhoea virus (BVDV), bovine herpesvirus-1 (BoHV-1), Schmallenberg virus (SBV) and bluetongue virus (BTV) - indicates that sika do not represent a risk for the transmission of these viruses to cattle and sheep although they can be infected (Graham et al. 2017). An example is relative to the chronic wasting disease which keeps emerging in Norway and is known to be transmissible to sika, so this species could exacerbate an epidemic (Osterholm et al. 2019).

In conclusion, it is evident that a lot of European diseases and parasites of ungulates may infect sika deer and could potentially be amplified by it (reservoir function) and spillback to native deer. Some of them like bovine tuberculosis and sarcoptic mange may even be at threat for wildlife populations. However, few information is available in the scientific literature about the potential role of sika in this as compared to other deer species, but it has clearly the capacity to increase native disease persistence and prevalence due to the formation of overabundant populations (Baiwy et al. 2013).

**Qu. 4.17. How important might other impacts not already covered by previous questions be resulting from introduction of the organism?**

<b>RESPONSE</b>	N/A minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

No information has been found.

**Qu. 4.18. How important are the expected impacts of the organism despite any natural control by other organisms, such as predators, parasites or pathogens that may already be present in the risk assessment area?**

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

As described in Qu.2.4 the risk assessment area is certainly characterised by the presence of potential predators, parasites or pathogens of sika deer. However, there are several species of native and alien deer already occurring, and this does not seem to represent a limiting factor for the relevant populations. In fact, the role of predators in controlling ungulate populations remains uncertain as pointed out by Côté et al. (2004), and is considered not effective, at least in some ecosystems.

**Qu. 4.19. Estimate the overall impact in the risk assessment area under current climate conditions. In addition, details of overall impact in relevant biogeographical regions should be provided.**

Thorough assessment of the overall impact on biodiversity and ecosystem services, with impacts on economy as well as social and human health as aggravating factors, in current conditions.

<b>RESPONSE</b>	minimal minor	<b>CONFIDENCE</b>	low medium
-----------------	------------------	-------------------	---------------

	moderate <b>major</b> massive		<b>high</b>
--	-------------------------------------	--	-------------

The species is known to exert a multifaceted impact on both biodiversity and ecosystem services, by feeding on native vegetation and contributing to the loss of habitat structure and function (hence indirectly affecting other species, including birds, reptiles, invertebrates, etc.). Hybridisation with red deer and competition with other ungulates is documented. The species is known to contribute to the spread of diseases and pathogens affecting wild animals, livestock and humans. It can also damage crops and compete with livestock. Moreover, it can be a threat for human health in relation to possible deer/vehicle collisions. It is worth pointing it out that the species does not even have to establish to generate problems. Even single escapees may be dangerous, particularly with regard to hybridisation and parasite transmission.

The overall impact is deemed similar in all biogeographical regions where the species is known to occur.

**Qu. 4.20. Estimate the overall impact in the risk assessment area in foreseeable climate change conditions. In addition, details of overall impact in relevant biogeographical regions should be provided.**

Thorough assessment of the overall impact on biodiversity and ecosystem services, with impacts on economy as well as social and human health as aggravating factors, under future conditions.

- See also guidance to Qu. 4.3.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

In foreseeable climate change conditions, the area suitable for the species in the risk assessment area may increase in the Alpine and Boreal biogeographic regions (see Annex VIII), hence the impact may be expected to increase accordingly. In case of a future expansion of the species range, other habitats and native species may be affected.

<b>RISK SUMMARIES</b>			
	<b>RESPONSE</b>	<b>CONFIDENCE</b>	<b>COMMENT</b>
<b>Summarise Introduction and Entry*</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	low medium <b>high</b>	Sika have been widely introduced to numerous countries in the risk assessment area (in the wild and in confinements). Further introductions for hunting, farming or exhibitions are very likely. Releases or escapes from captive facilities have been documented in the past in the risk assessment area and are very likely to take place again.
<b>Summarise Establishment*</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	low medium <b>high</b>	The species is already established in several EU Member States and in neighbouring countries such as the UK. The species life-history, available habitat conditions and management practices in the EU offer the potential to support self-sustaining populations of sika deer also in other countries and biogeographical regions.
<b>Summarise Spread*</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	low medium <b>high</b>	Natural spread into new parts of the risk assessment area has occurred already and is likely to occur also in the future. Occasional releases from parks and farms may aid dispersing individuals to establish new populations.
<b>Summarise Impact*</b>	minimal minor moderate <b>major</b> massive	low medium <b>high</b>	The species is known to exert a multifaceted impact on both biodiversity and ecosystem services, by feeding on native vegetation and contributing to the loss of habitat structure and function (hence indirectly affecting other species, including birds, reptiles, invertebrates, etc.). Competition with other ungulates is documented, and hybridisation with native red deer <i>Cervus elaphus</i> is representing a major threat due

			to genetic introgression. The species is known to contribute to the spread of diseases and pathogens affecting wildlife, livestock and humans. This could have an impact on native species, for example the European bison ( <i>Bison bonasus</i> ) as a consequence of the spread of the pathogenic nematode <i>Ashworthius sidemi</i> . Sika can also damage forest (commercial) plantations and crops and can be a threat in relation to possible road and rail collisions.
<b>Conclusion of the risk assessment (overall risk)</b>	low moderate <b>high</b>	low medium <b>high</b>	The sika deer represents a high risk in the risk assessment area, given the ability to establish in the wild, the potential for spread, and the documented impact in most MS where established populations occur and other parts of the introduced range.

\*in current climate conditions and in foreseeable future climate conditions

## Distribution Summary

Please answer as follows:

- Yes if recorded, established or invasive
- if not recorded, established or invasive
- ? Unknown; data deficient

The columns refer to the answers to Questions A5 to A12 under Section A.

For data on marine species at the Member State level, delete Member States that have no marine borders. In all other cases, provide answers for all columns.

### Member States and the United Kingdom

	Recorded	Established (currently)	Possible establishment (under current climate)	Possible establishment (under foreseeable climate)	Invasive (currently)
Austria	Yes	Yes	Yes	Yes	
Belgium	Yes		Yes	Yes	
Bulgaria			Yes	Yes	
Croatia			Yes	Yes

## ANNEX I Scoring of Likelihoods of Events

(taken from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

<b>Score</b>	<b>Description</b>	<b>Frequency</b>
Very unlikely	This sort of event is theoretically possible, but is never known to have occurred and is not expected to occur	1 in 10,000 years
Unlikely	This sort of event has occurred somewhere at least once in the last millenium	1 in 1,000 years
Moderately likely	This sort of event has occurred somewhere at least once in the last century	1 in 100 years
Likely	This sort of event has happened on several occasions elsewhere, or on at least once in the last decade	1 in 10 years
Very likely	This sort of event happens continually and would be expected to occur	Once a year

## ANNEX II Scoring of Magnitude of Impacts

(modified from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

Score	Biodiversity and ecosystem impact	Ecosystem Services impact	Economic impact (Monetary loss and response costs per year)	Social and human health impact, and other impacts
	<i>Question 5.1-5</i>	<i>Question 5.6-8</i>	<i>Question 5.9-13</i>	<i>Question 5.14-18</i>
Minimal	Local, short-term population loss, no significant ecosystem effect	No services affected <sup>5</sup>	Up to 10,000 Euro	No social disruption. Local, mild, short-term reversible effects to individuals.
Minor	Some ecosystem impact, reversible changes, localised	Local and temporary, reversible effects to one or few services	10,000-100,000 Euro	Significant concern expressed at local level. Mild short-term reversible effects to identifiable groups, localised.
Moderate	Measureable long-term damage to populations and ecosystem, but reversible; little spread, no extinction	Measureable, temporary, local and reversible effects on one or several services	100,000-1,000,000 Euro	Temporary changes to normal activities at local level. Minor irreversible effects and/or larger numbers covered by reversible effects, localised.
Major	Long-term irreversible ecosystem change, spreading beyond local area	Local and irreversible or widespread and reversible effects on one / several services	1,000,000-10,000,000 Euro	Some permanent change of activity locally, concern expressed over wider area. Significant irreversible effects locally or reversible effects over large area.
Massive	Widespread, long-term population loss or extinction, affecting several species with serious ecosystem effects	Widespread and irreversible effects on one / several services	Above 10,000,000 Euro	Long-term social change, significant loss of employment, migration from affected area. Widespread, severe, long-term, irreversible health effects.

<sup>5</sup> Not to be confused with “no impact”.

## ANNEX III Scoring of Confidence Levels

(modified from Bacher et al. 2017)

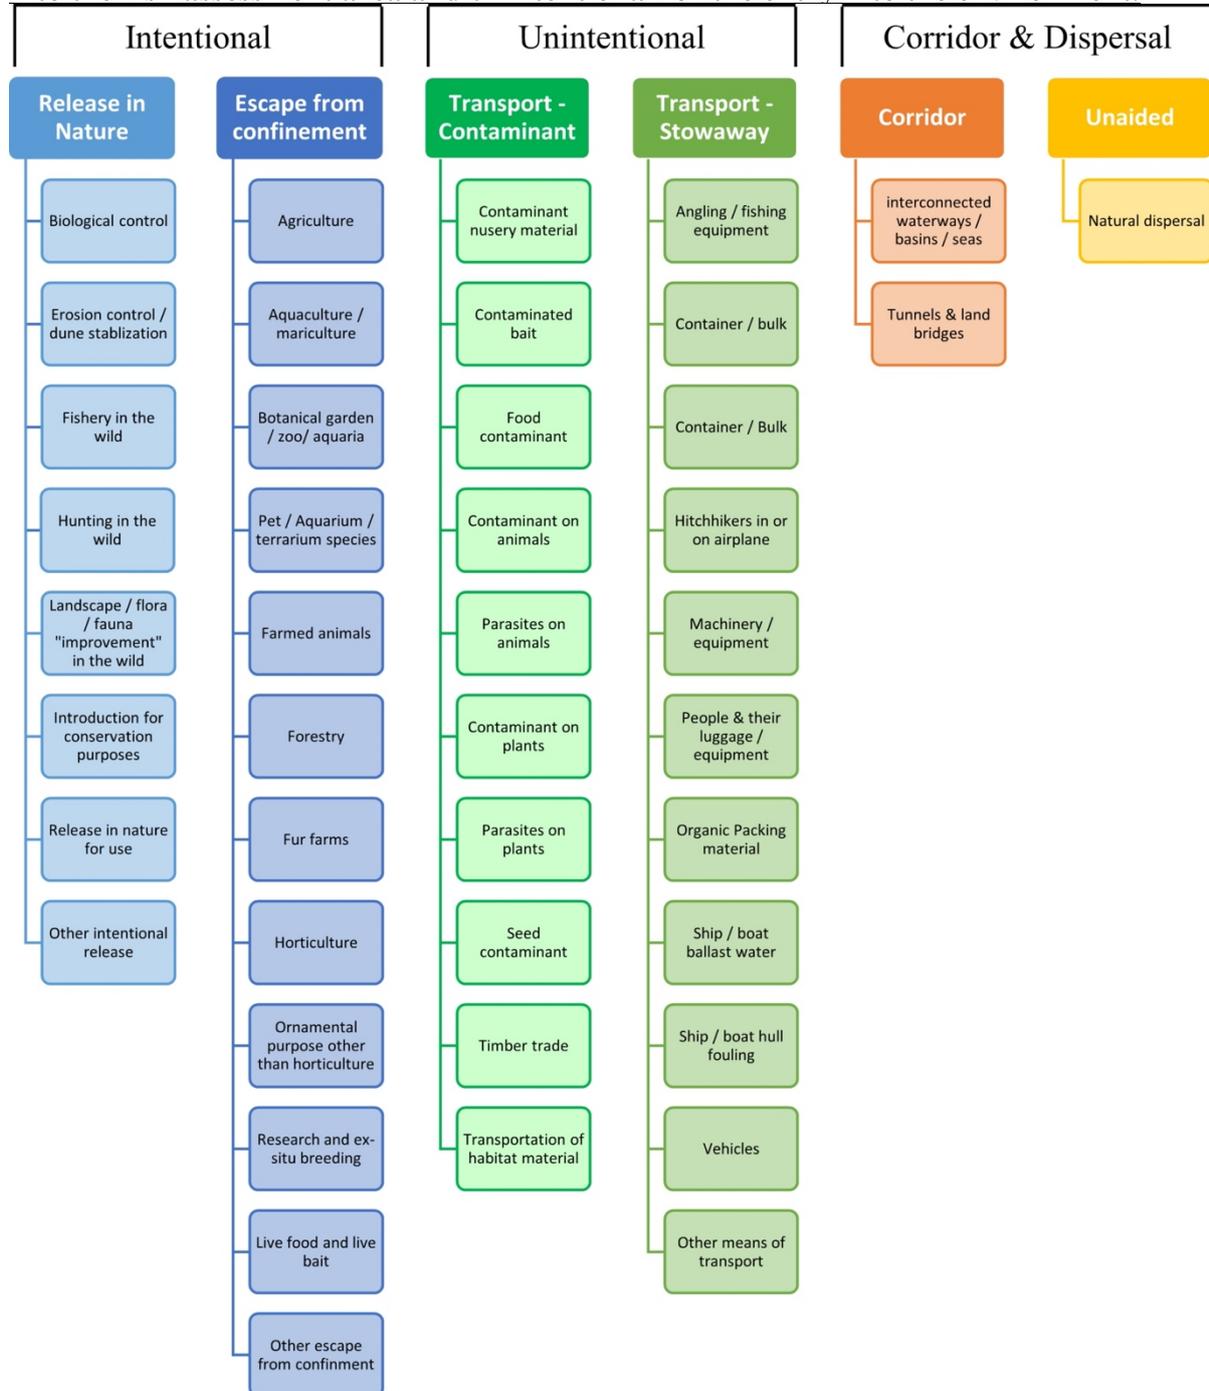

Each answer provided in the risk assessment must include an assessment of the level of confidence attached to that answer, reflecting the possibility that information needed for the answer is not available or is insufficient or available but conflicting.

The responses in the risk assessment should clearly support the choice of the confidence level.

<b>Confidence level</b>	<b>Description</b>
Low	There is no direct observational evidence to support the assessment, e.g. only inferred data have been used as supporting evidence <i>and/or</i> Impacts are recorded at a spatial scale which is unlikely to be relevant to the assessment area <i>and/or</i> Evidence is poor and difficult to interpret, e.g. because it is strongly ambiguous <i>and/or</i> The information sources are considered to be of low quality or contain information that is unreliable.
Medium	There is some direct observational evidence to support the assessment, but some information is inferred <i>and/or</i> Impacts are recorded at a small spatial scale, but rescaling of the data to relevant scales of the assessment area is considered reliable, or to embrace little uncertainty <i>and/or</i> The interpretation of the data is to some extent ambiguous or contradictory.
High	There is direct relevant observational evidence to support the assessment (including causality) <i>and</i> Impacts are recorded at a comparable scale <i>and/or</i> There are reliable/good quality data sources on impacts of the taxa <i>and</i> The interpretation of data/information is straightforward <i>and/or</i> Data/information are not controversial or contradictory.

## ANNEX IV CBD pathway categorisation scheme

Overview of CBD pathway categorisation scheme showing how the 44 pathways relate to the six main pathway categories. All of the pathways can be broadly classified into 1) those that involve intentional transport (blue), 2) those in which the taxa are unintentionally transported (green) and 3) those where taxa moved between regions without direct transportation by humans and/or via artificial corridors (orange and yellow). **Note that the pathways in the category “Escape from confinement” can be considered intentional for the introduction into the risk assessment area and unintentional for the entry into the environment.**

## ANNEX V Ecosystem services classification (CICES V5.1, simplified) and examples

For the purposes of this risk assessment, please feel free to use what seems as the most appropriate category / level / combination of impact (Section – Division – Group), reflecting information available.

Section	Division	Group	Examples (i.e. relevant CICES “classes”)
Provisioning	Biomass	<b>Cultivated <i>terrestrial</i> plants</b>	Cultivated terrestrial plants (including fungi, algae) grown for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from cultivated plants, fungi, algae and bacteria for direct use or processing (excluding genetic materials); Cultivated plants (including fungi, algae) grown as a <u>source of energy</u>  <i>Example: negative impacts of non-native organisms to crops, orchards, timber etc.</i>
		<b>Cultivated <i>aquatic</i> plants</b>	Plants cultivated by in- situ aquaculture grown for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from in-situ aquaculture for direct use or processing (excluding genetic materials); Plants cultivated by in- situ aquaculture grown as an <u>energy source</u> .  <i>Example: negative impacts of non-native organisms to aquatic plants cultivated for nutrition, gardening etc. purposes.</i>
		<b>Reared animals</b>	Animals reared for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from reared animals for direct use or processing (excluding genetic materials); Animals reared to provide <u>energy</u> (including mechanical)  <i>Example: negative impacts of non-native organisms to livestock</i>
		<b>Reared <i>aquatic</i> animals</b>	Animals reared by in-situ aquaculture for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from animals grown by in-situ aquaculture for direct use or processing (excluding genetic materials); Animals reared by in-situ aquaculture as an <u>energy source</u>  <i>Example: negative impacts of non-native organisms to fish farming</i>
		<b>Wild plants (terrestrial and aquatic)</b>	Wild plants (terrestrial and aquatic, including fungi, algae) used for <u>nutrition</u> ; <u>Fibres and other materials</u> from wild plants for direct use or processing (excluding genetic materials); Wild plants (terrestrial and aquatic, including fungi, algae) used as a <u>source of energy</u>  <i>Example: reduction in the availability of wild plants (e.g. wild berries, ornamentals) due to non-native organisms (competition, spread of disease etc.)</i>
		<b>Wild animals (terrestrial and aquatic)</b>	Wild animals (terrestrial and aquatic) used for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from wild animals for direct use or processing (excluding genetic materials); Wild animals (terrestrial and aquatic) used as a <u>source of energy</u>  <i>Example: reduction in the availability of wild animals (e.g. fish stocks, game) due to non-native organisms (competition, predations, spread of disease etc.)</i>

	<b>Genetic material</b> from all biota	<b>Genetic material</b> from plants, algae or fungi	<p><u>Seeds, spores and other plant materials</u> collected for maintaining or establishing a population; Higher and lower plants (whole organisms) used to <u>breed new strains or varieties</u>; Individual genes extracted from higher and lower plants for the <u>design and construction of new biological entities</u></p> <p><i>Example: negative impacts of non-native organisms due to interbreeding</i></p>
		<b>Genetic material</b> from animals	<p>Animal material collected for the purposes of maintaining or establishing a population; Wild animals (whole organisms) used to breed new strains or varieties; Individual genes extracted from organisms for the design and construction of new biological entities</p> <p><i>Example: negative impacts of non-native organisms due to interbreeding</i></p>
	<b>Water</b> <sup>6</sup>	<b>Surface water</b> used for nutrition, materials or energy	<p>Surface water for <u>drinking</u>; Surface water used as a material (<u>non-drinking purposes</u>); Freshwater surface water, coastal and marine water used as an <u>energy source</u></p> <p><i>Example: loss of access to surface water due to spread of non-native organisms</i></p>
		<b>Ground water</b> for used for nutrition, materials or energy	<p>Ground (and subsurface) water for <u>drinking</u>; Ground water (and subsurface) used as a material (<u>non-drinking purposes</u>); Ground water (and subsurface) used as an <u>energy source</u></p> <p><i>Example: reduced availability of ground water due to spread of non-native organisms and associated increase of ground water consumption by vegetation.</i></p>
<b>Regulation &amp; Maintenance</b>	<b>Transformation</b> of biochemical or physical inputs to ecosystems	<b>Mediation of wastes or toxic substances</b> of anthropogenic origin by living processes	<p><u>Bio-remediation</u> by micro-organisms, algae, plants, and animals; <u>Filtration/sequestration/storage/accumulation</u> by micro-organisms, algae, plants, and animals</p> <p><i>Example: changes caused by non-native organisms to ecosystem functioning and ability to filtrate etc. waste or toxics</i></p>
		<b>Mediation of nuisances</b> of anthropogenic origin	<p><u>Smell reduction; noise attenuation; visual screening</u> (e.g. by means of green infrastructure)</p> <p><i>Example: changes caused by non-native organisms to ecosystem structure, leading to reduced ability to mediate nuisances.</i></p>
	<b>Regulation</b> of physical, chemical, biological conditions	<b>Baseline flows and extreme event</b> regulation	<p>Control of <u>erosion</u> rates; Buffering and attenuation of <u>mass movement</u>; <u>Hydrological cycle and water flow regulation</u> (Including flood control, and coastal protection); <u>Wind</u> protection; <u>Fire</u> protection</p> <p><i>Example: changes caused by non-native organisms to ecosystem functioning or structure leading to, for example, destabilisation of soil, increased risk or intensity of wild fires etc.</i></p>
<b>Lifecycle maintenance</b> , habitat and gene pool protection		<p><u>Pollination</u> (or 'gamete' dispersal in a marine context); <u>Seed dispersal</u>; Maintaining <u>nursery populations and habitats</u> (Including gene pool protection)</p>	

<sup>6</sup> Note: in the CICES classification provisioning of water is considered as an abiotic service whereas the rest of ecosystem services listed here are considered biotic.

			<p><i>Example: changes caused by non-native organisms to the abundance and/or distribution of wild pollinators; changes to the availability / quality of nursery habitats for fisheries</i></p>
		<b>Pest and disease control</b>	<p>Pest control; Disease control</p> <p><i>Example: changes caused by non-native organisms to the abundance and/or distribution of pests</i></p>
		<b>Soil quality regulation</b>	<p><u>Weathering processes</u> and their effect on soil quality; <u>Decomposition and fixing processes</u> and their effect on soil quality</p> <p><i>Example: changes caused by non-native organisms to vegetation structure and/or soil fauna leading to reduced soil quality</i></p>
		<b>Water conditions</b>	<p>Regulation of the <u>chemical condition</u> of freshwaters by living processes; Regulation of the chemical condition of salt waters by living processes</p> <p><i>Example: changes caused by non-native organisms to buffer strips along water courses that remove nutrients in runoff and/or fish communities that regulate the resilience and resistance of water bodies to eutrophication</i></p>
		<b>Atmospheric composition and conditions</b>	<p>Regulation of <u>chemical composition</u> of atmosphere and oceans; Regulation of <u>temperature and humidity</u>, including ventilation and transpiration</p> <p><i>Example: changes caused by non-native organisms to ecosystems' ability to sequester carbon and/or evaporative cooling (e.g. by urban trees)</i></p>
<b>Cultural</b>	<b>Direct, in-situ and outdoor interactions</b> with living systems that depend on presence in the environmental setting	<b>Physical and experiential</b> interactions with natural environment	<p>Characteristics of living systems that that enable activities promoting health, recuperation or enjoyment through <u>active or immersive interactions</u>;</p> <p>Characteristics of living systems that enable activities promoting health, recuperation or enjoyment through <u>passive or observational interactions</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that make it attractive for recreation, wild life watching etc.</i></p>
		<b>Intellectual and representative</b> interactions with natural environment	<p>Characteristics of living systems that enable <u>scientific investigation</u> or the creation of traditional ecological knowledge;</p> <p>Characteristics of living systems that enable <u>education and training</u>;</p> <p>Characteristics of living systems that are resonant in terms of <u>culture or heritage</u>;</p> <p>Characteristics of living systems that enable <u>aesthetic experiences</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have cultural importance</i></p>
	<b>Indirect, remote, often indoor interactions</b> with living systems that do not require presence in the environmental setting	<b>Spiritual, symbolic</b> and other interactions with natural environment	<p>Elements of living systems that have <u>symbolic meaning</u>;</p> <p>Elements of living systems that have <u>sacred or religious meaning</u>;</p> <p>Elements of living systems used for <u>entertainment or representation</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have sacred or religious meaning</i></p>
		Other biotic characteristics that have a <b>non-use value</b>	<p>Characteristics or features of living systems that have an <u>existence value</u>;</p>

			<p>Characteristics or features of living systems that have an <u>option or bequest value</u></p> <p><i>Example: changes caused by non-native organisms to ecosystems designated as wilderness areas, habitats of endangered species etc.</i></p>

## **ANNEX VIII Projection of environmental suitability for sika deer *Cervus nippon* establishment in Europe**

Björn Beckmann, Riccardo Scalera, Tim Adriaens, Wolfgang Rabitsch and Dan Chapman

31 May 2021

### ***Aim***

To project the suitability for potential establishment of *Cervus nippon* in Europe, under current and predicted future climatic conditions.

### ***Data for modelling***

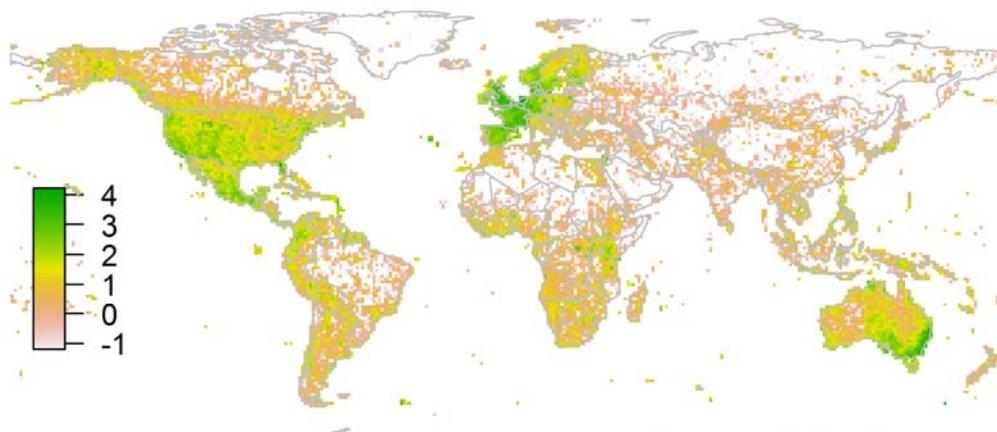

Species occurrence data were obtained from the Global Biodiversity Information Facility (GBIF) (5114 records), iNaturalist (793 records), the Biodiversity Information Serving Our Nation database (BISON) (31 records), the Atlas of Living Australia (14 records), and additional records from the risk assessment team. We scrutinised occurrence records from regions where the species is not known to be established and removed any dubious records or where the georeferencing was too imprecise (e.g. records referenced to a country or island centroid) or outside of the coverage of the predictor layers (e.g. small island or coastal occurrences). We removed records dated pre-1950, as these might refer to populations no longer in existence. The remaining records were gridded at a 0.25 x 0.25 degree resolution for modelling, yielding 550 grid cells with occurrences (Figure 1a). As a proxy for recording effort, the density of Mammalia records held by GBIF was also compiled on the same grid (Figure 1b).

**Figure 1.** (a) Occurrence records obtained for *Cervus nippon* and used in the modelling, showing native and invaded distributions. (b) The recording density of Mammalia on GBIF, which was used as a proxy for recording effort.

(a) Species distribution used in modelling

(b) Estimated recording effort (log10-scaled)

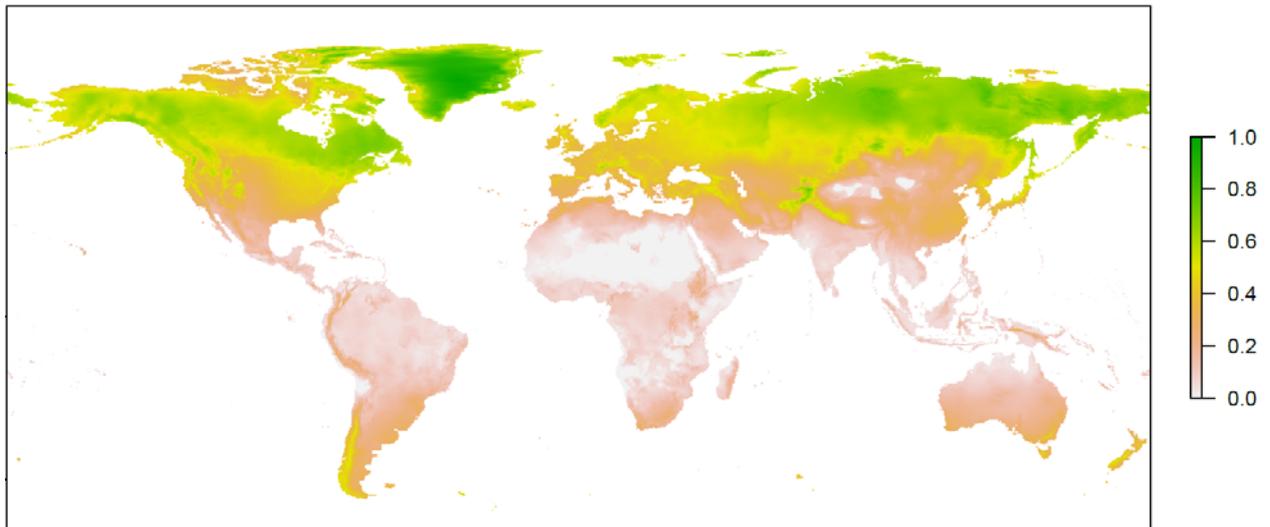

Climate data were selected from the 'Bioclim' variables contained within the WorldClim database (Hijmans et al., 2005), originally at 5 arcminute resolution (0.083 x 0.083 degrees of longitude/latitude) and aggregated to a 0.25 x 0.25 degree grid for use in the model.

Based on the biology of *Cervus nippon*, the following climate variables were used in the modelling:

- Minimum temperature of the coldest month (Bio6)
- Mean temperature of the warmest quarter (Bio10)
- Annual precipitation (Bio12)
- As a proxy for potential depth and duration of snow cover (Snow), the inverse of the mean temperature of the coldest quarter (Bio11) was multiplied with mean precipitation of the coldest quarter (Bio19), to produce a number that is greatest in areas where winters are both cold and have high precipitation. The numbers were scaled to values between 0 and 1 (Fig. 2).

**Figure 2.** Proxy for potential snow cover (Snow): the inverse of the mean temperature of the coldest quarter (Bio11) was multiplied with mean precipitation of the coldest quarter (Bio19), to produce a number that is greatest in areas where winters are both cold and have high precipitation. The numbers were scaled to values between 0 and 1.

To estimate the effect of climate change on the potential distribution, equivalent modelled future climate conditions for the 2070s under the Representative Concentration Pathways (RCP) 2.6 and 4.5 were also obtained. These represent low and medium emissions scenarios, respectively. The above variables were obtained as averages of outputs of eight Global Climate Models (BCC-CSM1-1, CCSM4, GISS-E2-R, HadGEM2-AO, IPSL-CM5A-LR, MIROC-ESM, MRI-CGCM3, NorESM1-M), downscaled and calibrated against the WorldClim baseline (see [http://www.worldclim.org/cmip5\\_5m](http://www.worldclim.org/cmip5_5m)).

The following habitat layers were also used:

- Tree cover (Tree): This was estimated from the MODerate-resolution Imaging Spectroradiometer (MODIS) satellite continuous tree cover raster product, produced by the Global Land Cover Facility (<http://glcf.umd.edu/data/vcf/>). The raw product contains the percentage cover by trees in each 0.002083 x 0.002083 degree grid cell. We aggregated this to the mean cover in our 0.25 x 0.25 degree grid cells.

### *Species distribution model*

A presence-background (presence-only) ensemble modelling strategy was employed using the BIOMOD2 R package version 3.4.6 (Thuiller et al., 2020, Thuiller et al., 2009). These models contrast the environment at the species' occurrence locations against a random sample of the global background environmental conditions (often termed 'pseudo-absences') in order to characterise and project suitability for occurrence. This approach has been developed for distributions that are in equilibrium with the environment. Because invasive species' distributions are not at equilibrium and subject to dispersal constraints at a global scale, we took care to minimise the inclusion of locations suitable for the species but where it has not been able to disperse to (Chapman et al. 2019). Therefore the background sampling region included:

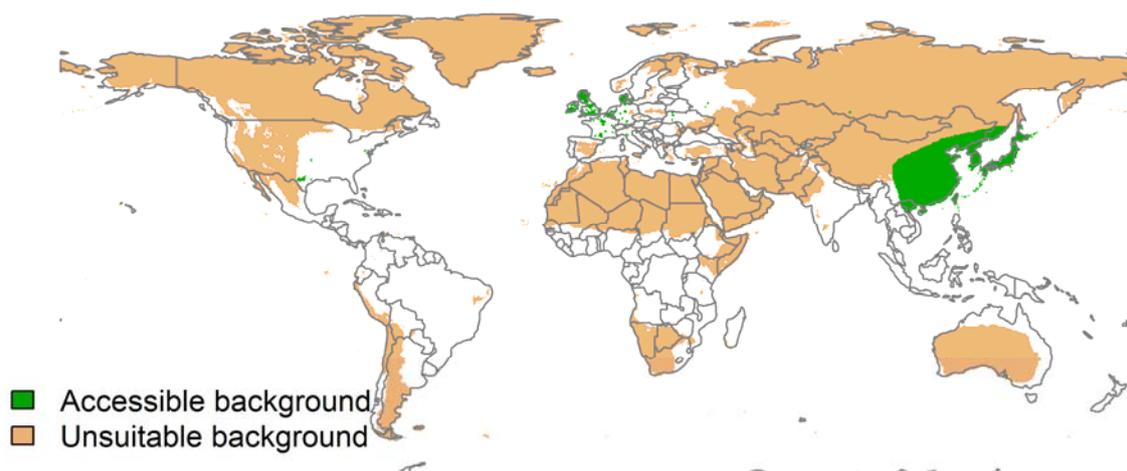

- The area accessible by native *Cervus nippon* populations, in which the species is likely to have had sufficient time to disperse to all locations. Based on presumed maximum dispersal distances, the accessible region was defined as a 300km buffer around the native range occurrences; AND

- A 30km buffer around the non-native occurrences, encompassing regions likely to have had high propagule pressure for introduction by humans and/or dispersal of the species; AND
- Regions where we have an *a priori* expectation of high unsuitability for the species so that absence is assumed irrespective of dispersal constraints (see Figure 2). The following rules were applied to define a region expected to be highly unsuitable for *Cervus nippon* at the spatial scale of the model:
  - Minimum temperature of the coldest month (Bio6) < -18°C
  - Mean temperature of the warmest quarter (Bio10) < 9°C
  - Annual precipitation (Bio12) < 545mm
  - Proxy for potential snow cover (Snow) > 0.6

Altogether, only 1.1% of occurrence grid cells were located in the unsuitable background region.

Within the unsuitable background region, 10 samples of 5000 randomly sampled grid cells were obtained. In the accessible background (comprising the accessible areas around native and non-native occurrences as detailed above), the same number of pseudo-absence samples were drawn as there were presence records (550), weighting the sampling by a proxy for recording effort (Figure 2).

**Figure 2.** The background from which pseudo-absence samples were taken in the modelling of *Cervus nippon*. Samples were taken from a 300km buffer around the native range and a 30km buffer around non-native occurrences (together forming the accessible background), and from areas expected to be highly unsuitable for the species (the unsuitable background region). Samples from the accessible background were weighted by a proxy for recording effort (Figure 1(b)).

Each dataset (i.e. combination of the presences and the individual background samples) was randomly split into 80% for model training and 20% for model evaluation. With each training dataset, seven statistical algorithms were fitted with the default BIOMOD2 settings and rescaled using logistic regression, except where specified below:

- Generalised linear model (GLM)

- Generalised boosting model (GBM)
- Generalised additive model (GAM) with a maximum of four degrees of freedom per smoothing spline
- Artificial neural network (ANN)
- Multivariate adaptive regression splines (MARS)
- Random forest (RF)
- Maxent

Since the total background sample was larger than the number of occurrences, prevalence fitting weights were applied to give equal overall importance to the occurrences and the background. Normalised variable importance was assessed and variable response functions were produced using BIOMOD2's default procedure.

Model predictive performance was assessed by the following three measures:

- AUC, the area under the receiver operating characteristic curve (Fielding & Bell 1997). Predictions of presence-absence models can be compared with a subset of records set aside for model evaluation (here 20%) by constructing a confusion matrix with the number of true positive, false positive, false negative and true negative cases. For models generating non-dichotomous scores (as here) a threshold can be applied to transform the scores into a dichotomous set of presence-absence predictions. Two measures that can be derived from the confusion matrix are sensitivity (the proportion of observed presences that are predicted as such, quantifying omission errors), and specificity (the proportion of observed absences that are predicted as such, quantifying commission errors). A receiver operating characteristic (ROC) curve can be constructed by using all possible thresholds to classify the scores into confusion matrices, obtaining sensitivity and specificity for each matrix, and plotting sensitivity against the corresponding proportion of false positives (equal to  $1 - \text{specificity}$ ). The use of all possible thresholds avoids the need for a selection of a single threshold, which is often arbitrary, and allows appreciation of the trade-off between sensitivity and specificity. The area under the ROC curve (AUC) is often used as a single threshold-independent measure for model performance (Manel, Williams & Ormerod 2001). AUC is the probability that a randomly selected presence has a higher model-predicted suitability than a randomly selected absence (Allouche et al. 2006).
- Cohen's Kappa (Cohen 1960). This measure corrects the overall accuracy of model predictions (ratio of the sum of true presences plus true absences to the total number of records) by the accuracy expected to occur by chance. The kappa statistic ranges from -1 to +1, where +1 indicates perfect agreement and values of zero or less indicate a performance no better than random. Advantages of kappa are its simplicity, the fact that both commission and omission errors are accounted for in one parameter, and its relative tolerance to zero values in the confusion matrix (Manel, Williams & Ormerod 2001). However, Kappa has been criticised for being sensitive to prevalence (the proportion of sites in which the species was recorded as present) and may therefore be inappropriate for comparisons of model accuracy between species or regions (McPherson, Jetz & Rogers 2004, Allouche et al. 2006).
- TSS, the true skill statistic (Allouche et al. 2006). TSS is defined as sensitivity + specificity - 1, and corrects for Kappa's dependency on prevalence. TSS compares the

number of correct forecasts, minus those attributable to random guessing, to that of a hypothetical set of perfect forecasts. Like kappa, TSS takes into account both omission and commission errors, and success as a result of random guessing, and ranges from -1 to +1, where +1 indicates perfect agreement and values of zero or less indicate a performance no better than random (Allouche et al. 2006).

An ensemble model was created by first rejecting poorly performing algorithms with relatively extreme low AUC values and then averaging the predictions of the remaining algorithms, weighted by their AUC. To identify poorly performing algorithms, AUC values were converted into modified z-scores based on their difference to the median and the median absolute deviation across all algorithms (Iglewicz & Hoaglin 1993). Algorithms with  $z < -2$  were rejected. In this way, ensemble projections were made for each dataset and then averaged to give an overall suitability, as well as its standard deviation.

Projections were classified into suitable and unsuitable regions using a “lowest presence threshold” (Pearson et al. 2007), setting the cut-off as the lowest value at which 98% of all presence records are classified correctly under the current climate (here 0.64). In order to express the sensitivity of classifications to the choice of this threshold, thresholds at which 95% and 99% of records are classified correctly (here 0.73 and 0.49 respectively) were used in the calculation of error bars in Figs. 9 and 10 below in addition to taking account of uncertainty in the projections themselves.

We also produced a limiting factor map for Europe following Elith et al. (2010). For this, projections were made separately with each individual variable fixed at a near-optimal value. These were chosen as the median values at the occurrence grid cells. Then, the most strongly limiting factors were identified as the ones resulting in the highest increase in suitability in each grid cell.

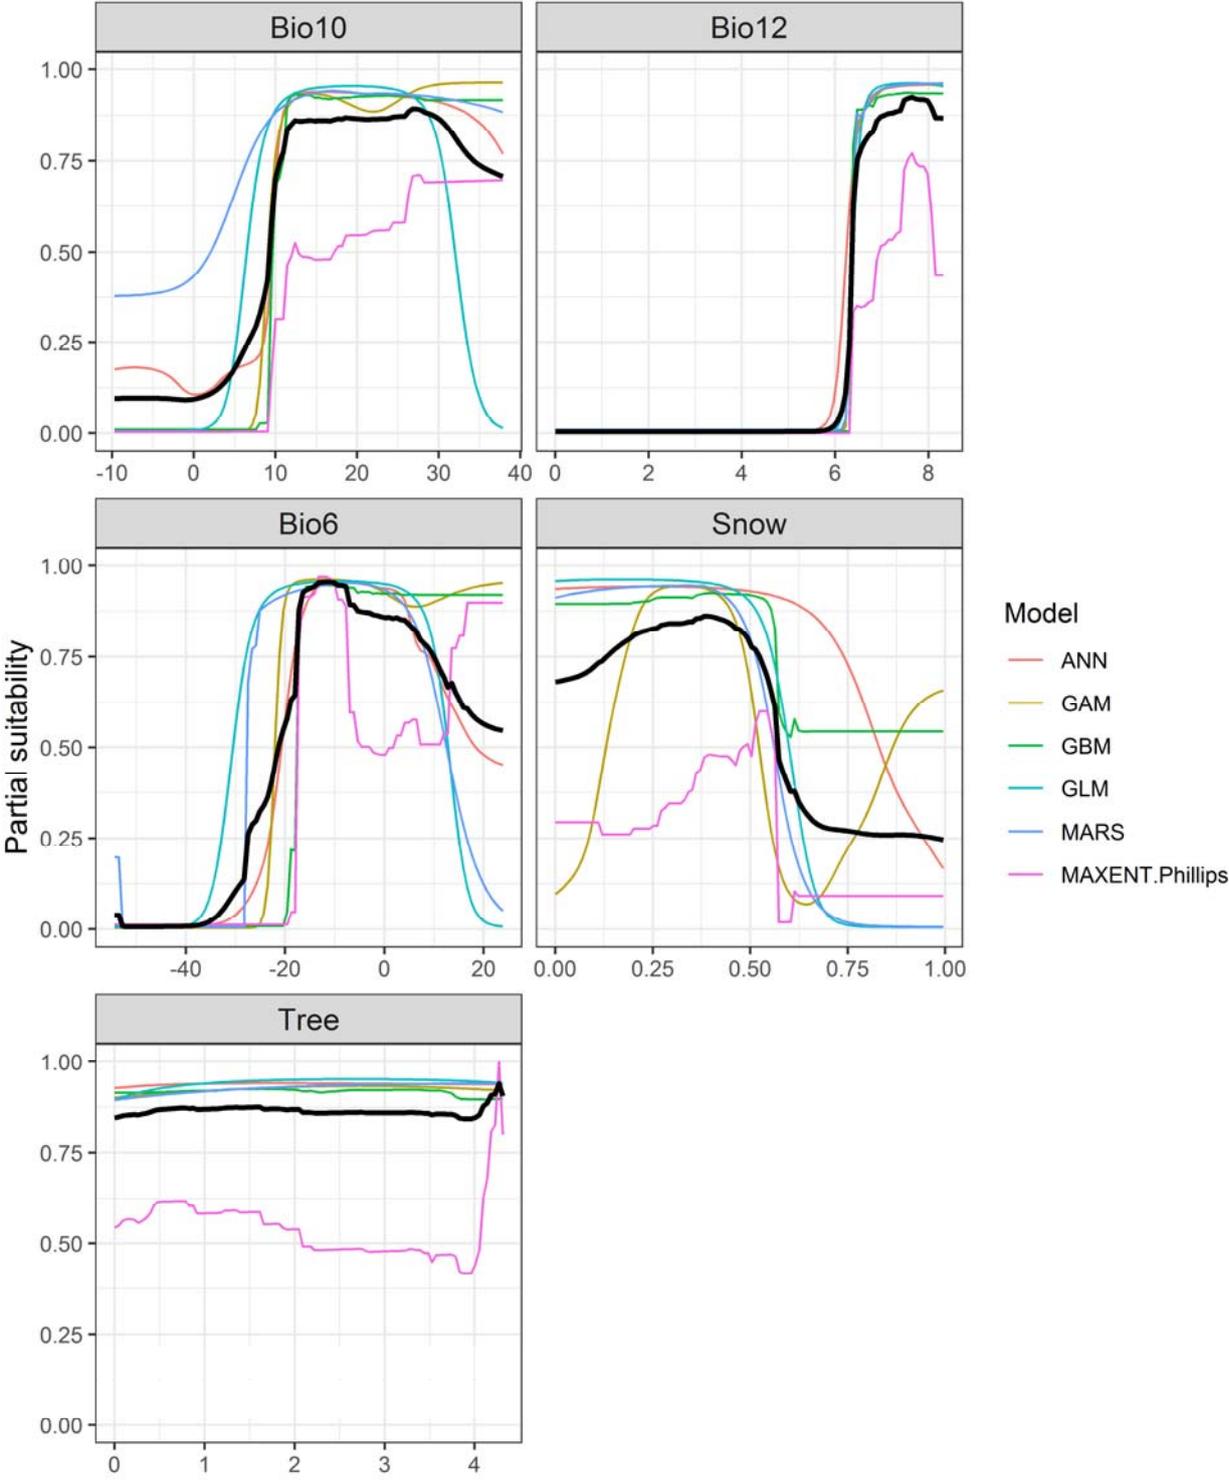

## Results

The ensemble model suggested that suitability for *Cervus nippon* was most strongly determined by Annual precipitation (Bio12), accounting for 53.8% of variation explained, followed by Minimum temperature of the coldest month (Bio6) (21.3%), Proxy for potential snow cover (Snow) (12.3%), Mean temperature of the warmest quarter (Bio10) (11.4%) and Global tree cover (Tree) (1.2%) (Table 1, Figure 3).

**Table 1.** Summary of the cross-validation predictive performance (AUC, Kappa, TSS) and variable importance of the fitted model algorithms and the ensemble (AUC-weighted average of the best performing algorithms). Results are the average from models fitted to 10 different background samples of the data.

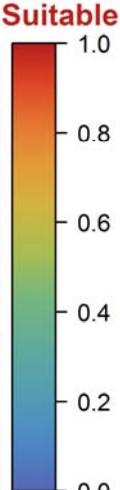

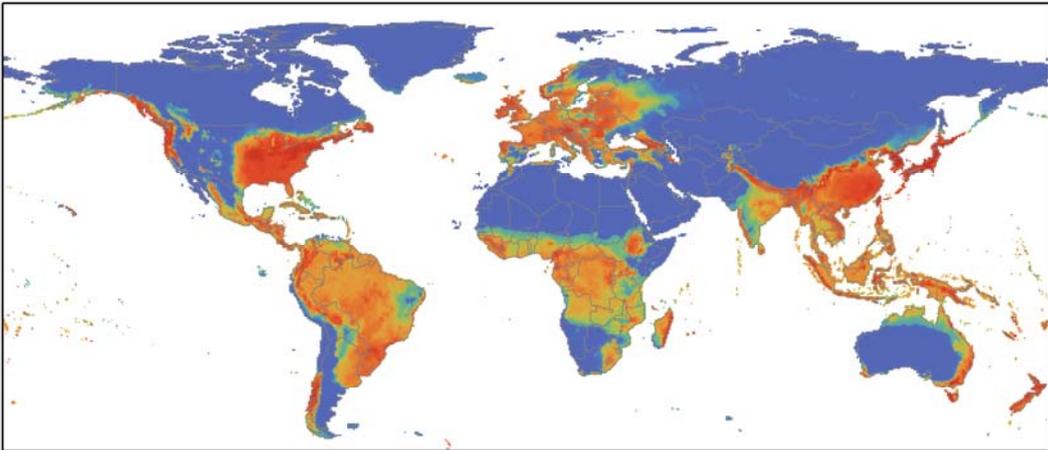

Algorithm	AUC	Kappa	TSS	Used in the ensemble	Variable importance (%)				
					Annual precipitation (Bio12)	Minimum temperature of the coldest month (Bio6)	Proxy for potential snow cover (Snow)	Mean temperature of the warmest quarter (Bio10)	Global tree cover (Tree)
GLM	0.958	0.611	0.887	yes	56	15	15	12	1
GAM	0.961	0.618	0.890	yes	50	19	18	12	0
GBM	0.957	0.611	0.887	yes	58	25	3	13	0
ANN	0.960	0.608	0.882	yes	50	26	8	13	2
MARS	0.954	0.600	0.883	yes	60	19	17	4	0
RF	0.941	0.592	0.883	no	59	19	7	10	5
Maxent	0.955	0.611	0.881	yes	48	23	13	13	3
<b>Ensemble</b>	<b>0.961</b>	<b>0.615</b>	<b>0.890</b>		<b>54</b>	<b>21</b>	<b>12</b>	<b>11</b>	<b>1</b>

**Figure 3.** Partial response plots from the fitted models. Thin coloured lines show responses from the algorithms in the ensemble, while the thick black line is their ensemble. In each plot, other model variables are held at their median value in the training data. Some of the divergence among algorithms is because of their different treatment of interactions among variables.

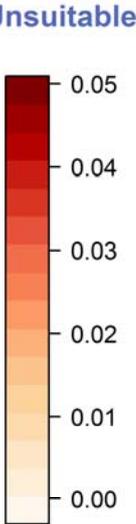

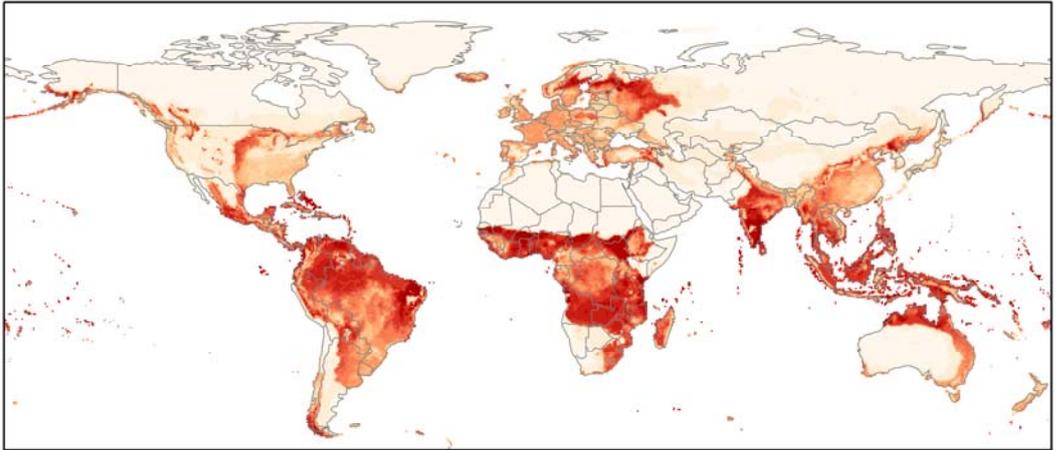

**Figure 4.** (a) Projected global suitability for *Cervus nippon* establishment in the current climate. For visualisation, the projection has been aggregated to a 0.5 x 0.5 degree resolution, by taking the maximum suitability of constituent higher resolution grid cells. Values > 0.64 are suitable for the species, with 98% of global presence records above this threshold. Values below 0.64 indicate lower relative suitability. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

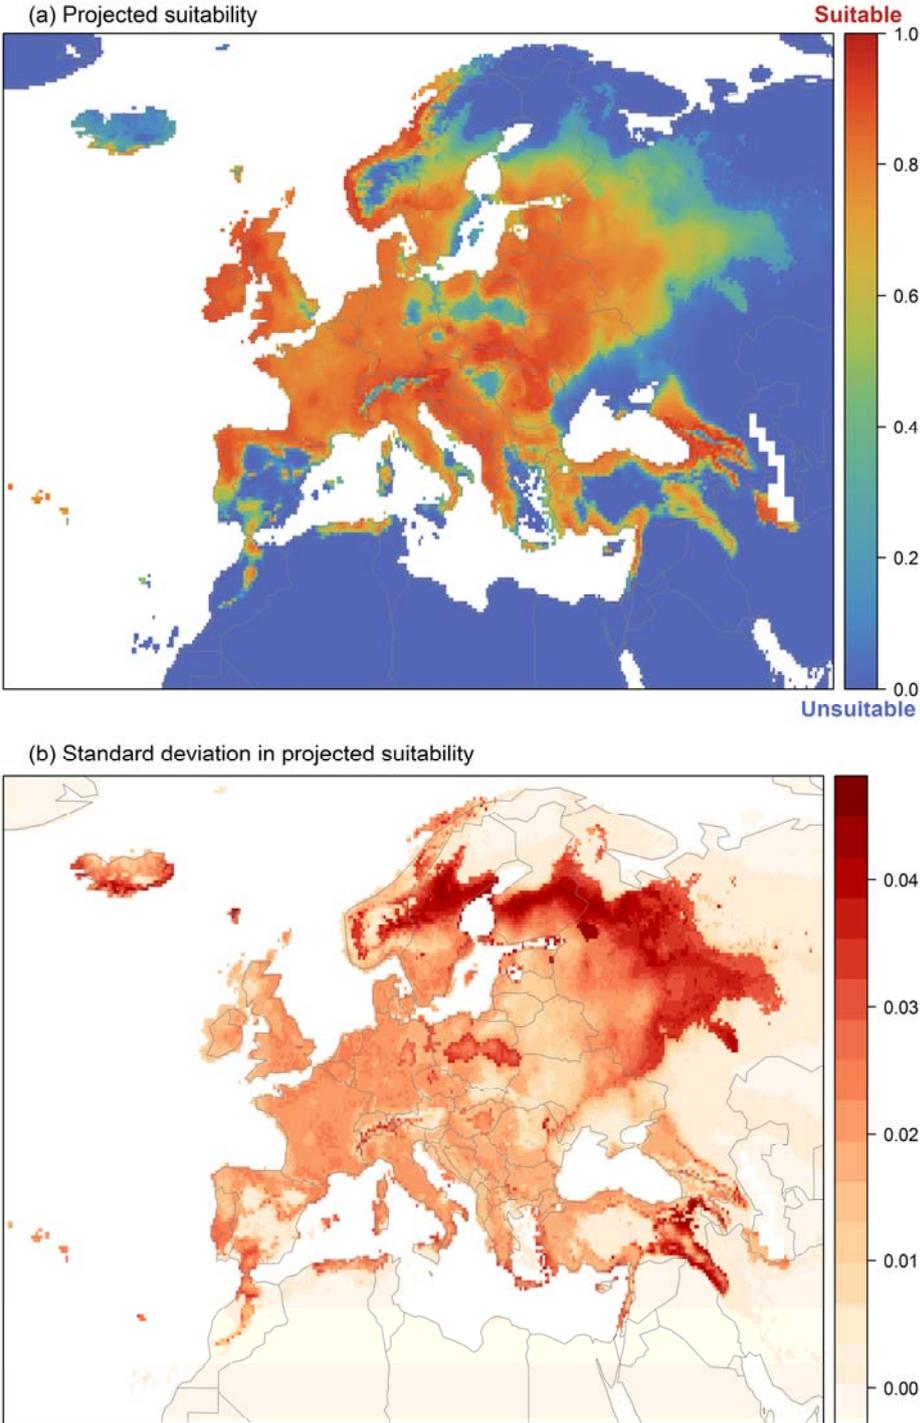

(a) Projected suitability

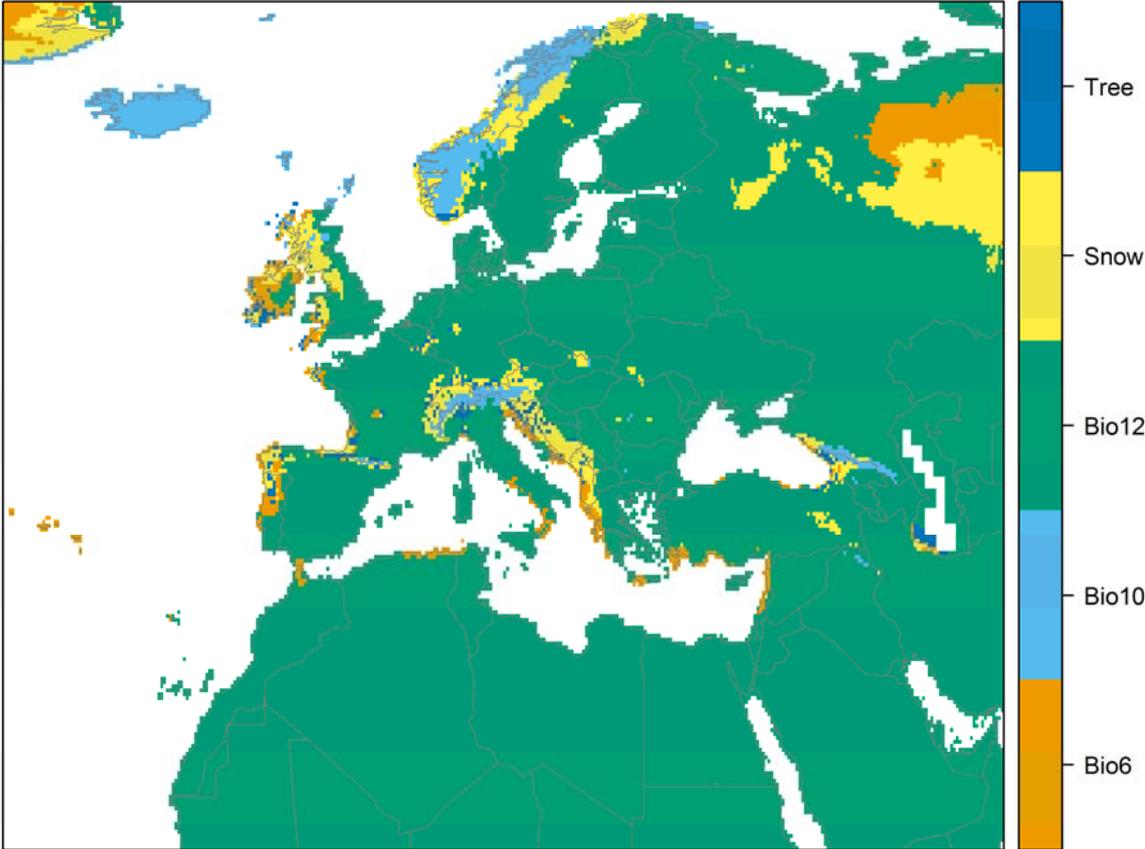

(b) Standard deviation in projected suitability

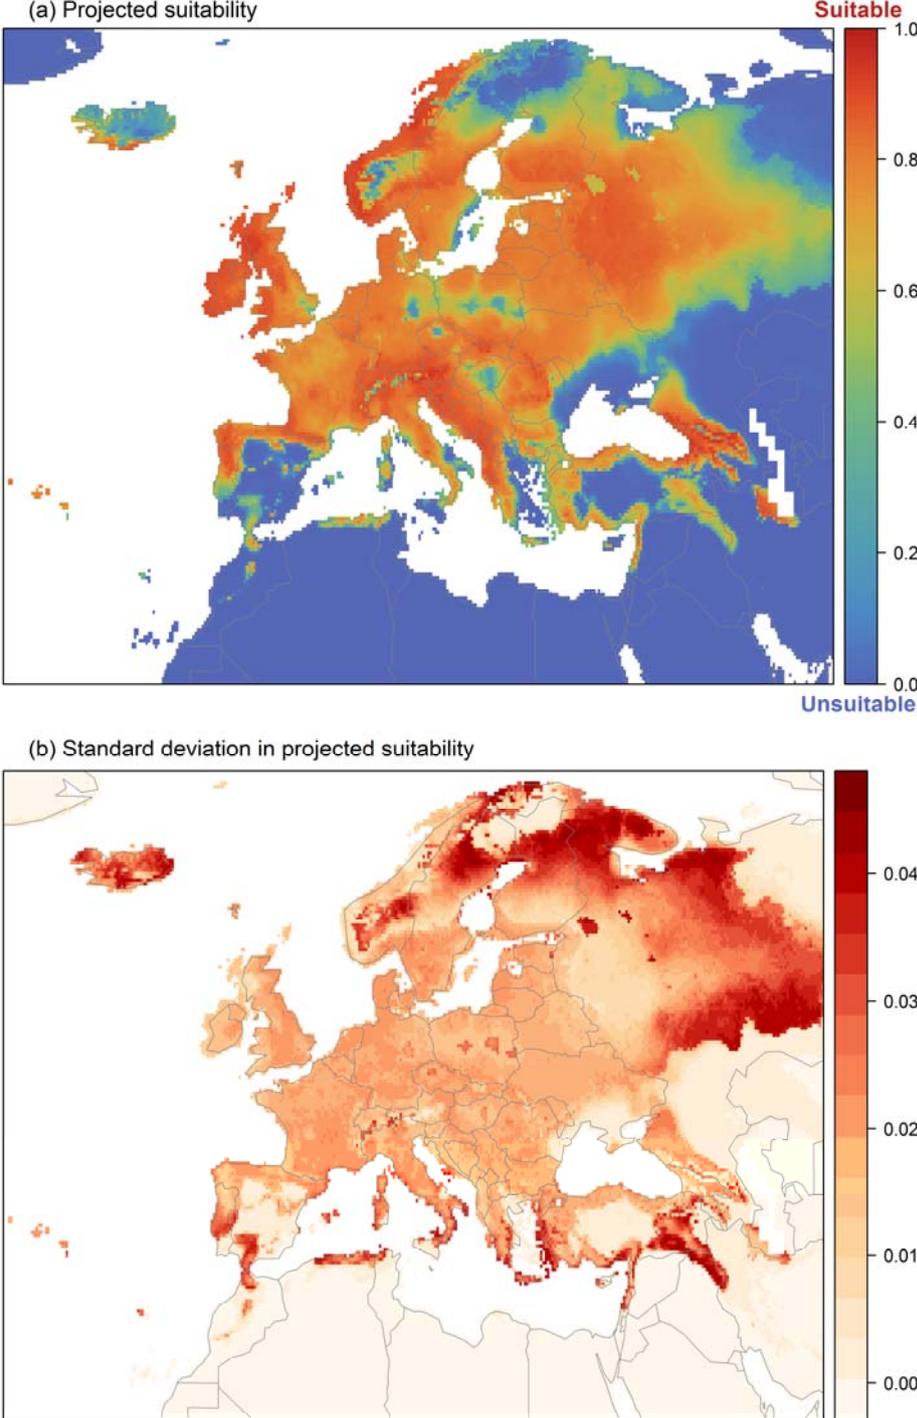

**Figure 5.** (a) Projected current suitability for *Cervus nippon* establishment in Europe and the Mediterranean region. Values > 0.64 are suitable for the species, with 98% of global presence records above this threshold. Values below 0.64 indicate lower relative suitability. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

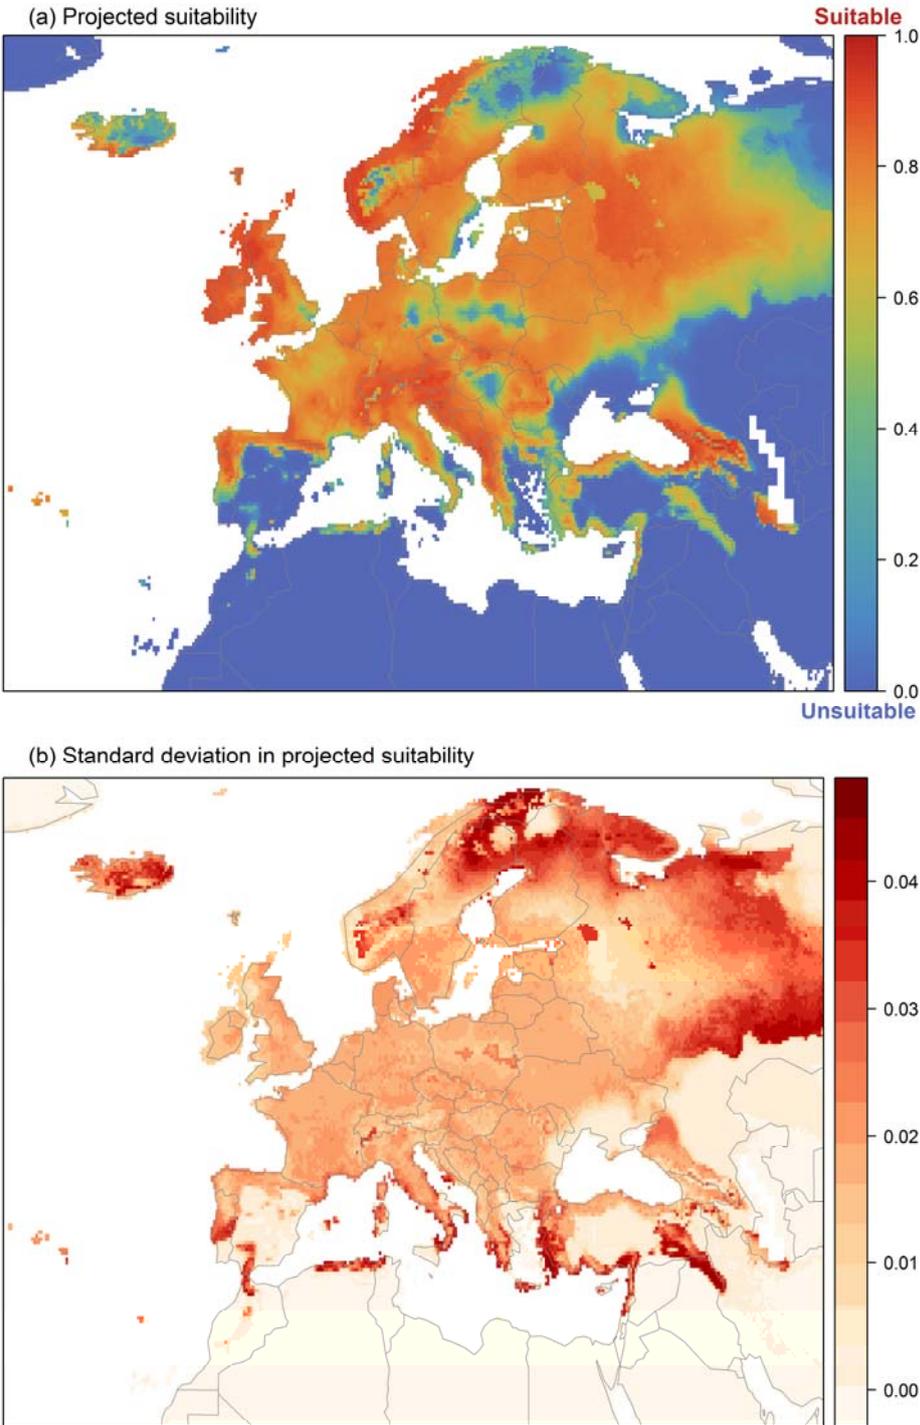

**Figure 6.** The most strongly limiting factors for *Cervus nippon* establishment estimated by the model in Europe and the Mediterranean region in current climatic conditions.

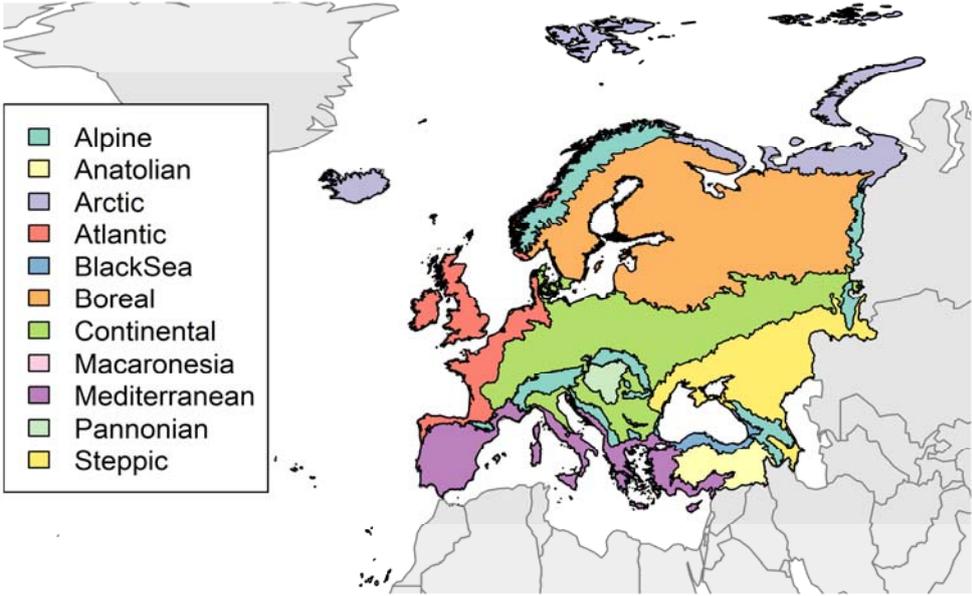

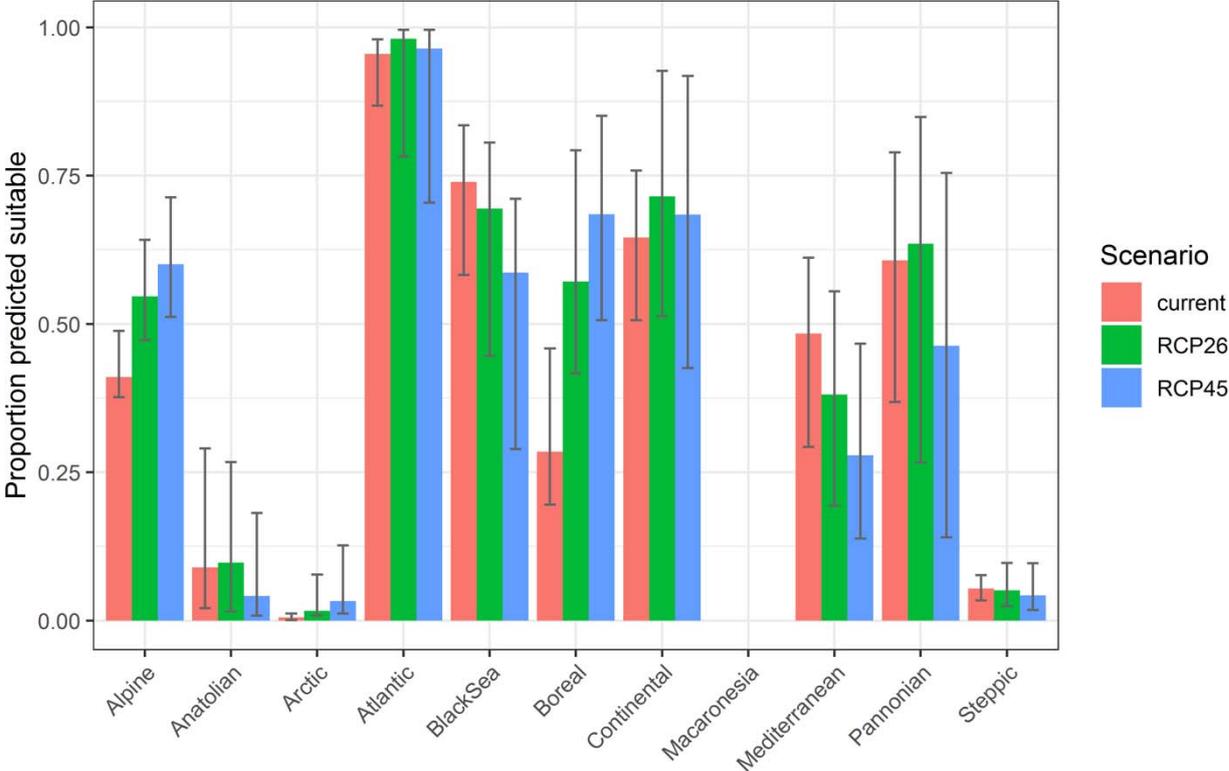

**Figure 7.** (a) Projected suitability for *Cervus nippon* establishment in Europe and the Mediterranean region in the 2070s under climate change scenario RCP2.6. Values > 0.64 are suitable for the species, with 98% of global presence records above this threshold under current climate. Values below 0.64 indicate lower relative suitability. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

**Figure 8.** (a) Projected suitability for *Cervus nippon* establishment in Europe and the Mediterranean region in the 2070s under climate change scenario RCP4.5. Values > 0.64 are suitable for the species, with 98% of global presence records above this threshold under current climate. Values below 0.64 indicate lower relative suitability. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

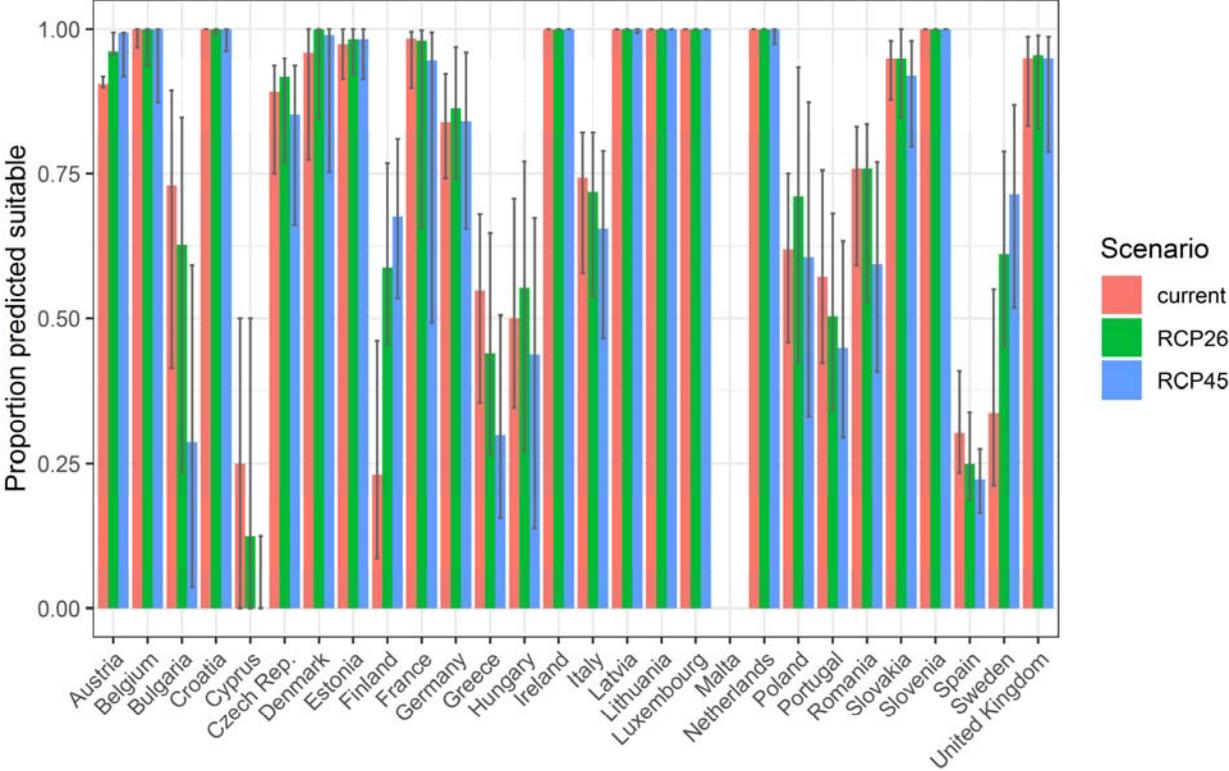

**Figure 9.** Variation in projected suitability for *Cervus nippon* establishment among Biogeographical Regions of Europe (<https://www.eea.europa.eu/data-and-maps/data/biogeographical-regions-europe-3>). The bar plots show the proportion of grid cells in each region classified as suitable (with values > 0.64) in the current climate and projected climate for the 2070s under two RCP emissions scenarios. Error bars indicate uncertainty due to both the choice of classification threshold (cf. p.6) and uncertainty in the projections themselves (cf. part (b) of Figs. 5,7,8). The location of each region is also shown. The Arctic and Macaronesian regions are not part of the study area, but are included for completeness.

### *Caveats to the modelling*

To remove spatial recording biases, the selection of the background sample from the accessible background was weighted by the density of Mammalia records on the Global Biodiversity Information Facility (GBIF). While this is preferable to not accounting for recording bias at all, it may not provide the perfect measure of recording bias.

There was substantial variation among modelling algorithms in the partial response plots (Figure 3). In part this will reflect their different treatment of interactions among variables. Since partial plots are made with other variables held at their median, there may be values of a particular variable at which this does not provide a realistic combination of variables to predict from.

Other variables potentially affecting the distribution of the species, such as types of land cover other than trees were not included in the model.

## Annex with evidence on measures and their implementation cost and cost-effectiveness

<b>Species (scientific name)</b>	<b><i>Cervus nippon</i></b>
<b>Species (common name)</b>	<b>Sika Deer</b>
<b>Author(s)</b>	<b>Peter Robertson</b>
<b>Reviewer</b>	<b>Alastair Ward, Wojciech Solarz</b>
<b>Date Completed</b>	<b>15/10/2021</b>

### Summary<sup>1</sup>

Highlight of measures that provide the most cost-effective options to prevent the introduction, achieve early detection, rapidly eradicate and manage the species, including significant gaps in information or knowledge to identify cost-effective measures.

Sika deer have been widely introduced globally through escapes from ornamental collections, deer farms and releases to supplement hunting. The adoption and enforcement of appropriate legislation and codes of best practice to reduce the risks posed by these pathways should reduce the probability of further introductions in Europe. This can be assisted by raising public awareness of the impacts of non-native deer and invasive alien species in general. The effective reporting of new incursions, with records obtained from citizen science initiatives and through existing hunting networks, will reduce the costs of rapid response to new incursions. However, Sika deer are now present in many different European countries including Austria, Belgium, Denmark, Estonia, Finland, France, Germany, Ireland, Latvia, Lithuania, Netherlands, Norway, Poland, Russia, Romania, Sweden, Switzerland, and the United Kingdom. The further spread of these widely established species within Europe probably poses a greater threat than further introductions from elsewhere.

Shooting with a rifle is the most widely used and cost-effective method used to control deer, including Sika. There is little specific evidence available on the eradication of Sika deer, although there are current plans for its eradication from a forested region in New Zealand.

However, there are published examples of the successful eradication of other *Cervus* species from areas of up to 222km<sup>2</sup> in size. More widely, eradication programmes for other deer species and ungulates have relied on shooting and have been successful over large areas of up to 6,000km<sup>2</sup>. Globally, the cost-effectiveness of ungulate eradications has been improved through the use of helicopter shooting, judas animals to locate the last remaining individuals in the controlled populations, night shooting combined with infra-red cameras, fences and natural barriers to break larger areas into smaller components, and dogs to help locate animals. Acoustic sensors to detect the calls of particular species may also have applications. However, the use of these methods may be restricted in particular European member states and may attract opposition from the public and hunters on a case specific basis. Traps and toxins have been used as supporting methods in some eradication programmes. There are no toxins approved for use on deer in the EU.

The long-term management of deer populations is widespread in Europe, with established hunting traditions which value deer as a resource, and programmes to reduce impacts, such as local damage to crops and forestry, to acceptable levels. Current deer management practice relies on shooting and this is the primary method used to manage Sika deer. The potential use of contraceptives as a deer management tool attracts frequent public interest, but current approaches rely on catch and inject methods. There are no examples of contraceptives being used to achieve eradication, and only a small number of limited examples of their use on free-living populations of other deer. The use of fences, scaring methods and deterrents provide useful additional methods to reduce local damage.

One particular concern associated with introduced populations of Sika deer is hybridisation with native *Cervus* species, in particular Red Deer *Cervus elaphus*. The presence of hybrids complicates the prospects for management and programmes to support the selective culling of animals with hybrid characteristics may go some way to reducing rates of gene flow into the native populations. However, the frequency of hybridisation is highly variable between different populations, while many hybrids cannot reliably be determined from external examination in the field, reducing the effectiveness of selective culling. To date there are no effective methods available to prevent hybrids from an established stock eventually spreading and their genes introgressing into neighbouring red deer populations.

<b>Detailed assessment</b>			
	<b>Description of measures<sup>2</sup></b>	<b>Assessment of implementation cost and cost-effectiveness (per measure)<sup>3</sup></b>	<b>Level of confidence<sup>4</sup></b>
<b>Methods to achieve prevention of intentional and unintentional introduction<sup>5</sup></b>	Sika deer have been introduced to numerous Member States, primarily as an ornamental species from collections or escapes from deer farms, or as an addition for hunting. The adoption and enforcement of appropriate legislation and codes of best practice to reduce the risks posed by these pathways should reduce the probability of further introductions.	The enforcement of existing legislation to limit the introduction of this species will reduce the risk of further introductions into the EU. The costs of current enforcement measures are not known, However, the risk from new introductions must be considered in light of the already widespread distribution of this species in Europe.	High
	<b>Managing pathways</b>	<b>Managing pathways</b>	High

	<p>Spread from these initial introductions has been through a combination of natural dispersal, possibly assisted by the relocation of individuals by hunters, although there is little documented evidence.</p>	<p>Public education of the risks posed by this species together with the enforcement of existing legislation to limit the illegal transport of animals or relocations should help limit this risk. Natural spread from the existing populations is probably now the main pathway of spread</p>	
	<p><b>Raising awareness</b> Raising public awareness of the risks posed by invasive alien species in general and Sika deer in particular can reduce the risks of further intentional spread and increase support for control. This can include the production of targeted publicity and identification material.</p>	<p><b>Raising awareness</b> A number of information sources and sheets are available on-line which can assist with the production of new material to raise public awareness. Examples specific to Sika deer include: British Deer Society <a href="https://www.bds.org.uk/wp-content/uploads/2020/12/Sika-Deer_web.pdf">https://www.bds.org.uk/wp-content/uploads/2020/12/Sika-Deer_web.pdf</a> Scottish Natural Heritage (2018) <a href="https://www.bestpracticeguides.org.uk/wp-content/downloads/ecology_sika.pdf">https://www.bestpracticeguides.org.uk/wp-content/downloads/ecology_sika.pdf</a> Deer hunting and woodland conservation organisations exist in most European countries and provide a route for targeted information dissemination</p>	High
<p><b>Methods to achieve early detection<sup>6</sup></b></p>	<p><b>Effective surveillance and reporting of new incursions</b> Sika deer are a distinctive species. Encouraging rapid reporting of new incursions increases the likely success of rapid response before the species can become established. Citizen science provides a useful route for the reporting of IAS.</p>	<p><b>Effective surveillance and reporting of new incursions</b> Citizen-science species occurrence datasets are increasingly recognized as a useful tool for monitoring the occurrence and spread of invasive alien species across large spatial and temporal scale. They are dependent on citizen-scientists who collect and upload data, typically from 'opportunistic sampling' with no underlying scientific survey design which can limit the conclusions that can be drawn from these data. Most parts of north-west Europe have an extensive network of volunteer observers although this is less true of</p>	High

	<p>Deer are widely hunted and reports from the hunting community may be of particular value to detect new species in an area.</p> <p>The presence of native <i>Cervus</i> species and the possibility of hybrids may complicate the identification of Sika.</p>	<p>southern and especially eastern Europe. Nevertheless, the focus on native species may lead to disregard the presence of non-native species, and consequently to a delay in detecting a new presence of this non-native species. However, this naturalist community also provides an opportunity for developing an effective surveillance system. Unstructured citizen-science data do not reliably allow the estimation of species abundance or population trends, yet in an early-warning scenario it is likely sufficient to know where a species is present and these data limitations are thus of a lesser concern.</p> <p>For deer, reports from hunters can be an effective source of information on occurrence and distribution. Hunter records are often collated nationally to produce statistics on key species (Apollonio et al. 2010) although the methods and formats used vary between Member States. Updating this assessment and increasing standardisation of reporting would improve the usefulness of this approach.</p> <p>Sika deer are broadly similar in appearance to native red deer and the two species may be confused. Hybrids regularly occur in some parts of the risk assessment area with variable mixtures of characteristics from the two species. Many hybrids cannot reliably be determined as such from external examination in the field and genetic methods may be required (Senn and Pemberton 2009). Information of species identification is available through Wildlife On-Line</p> <p><a href="https://www.wildlifeonline.me.uk/animals/article/red-deer-genetic-diversity-hybridization">https://www.wildlifeonline.me.uk/animals/article/red-deer-genetic-diversity-hybridization</a></p>	
--	---	---	--

<p><b>Methods to achieve eradication<sup>7</sup></b></p>	<p>Overview of Eradication Programmes</p> <p>No accounts of the successful eradication of Sika deer have been reported. However, a proposed plan to eradicate them from a wooded area in New Zealand has been published (Latham 2020) and there are accounts of the successful eradication of other <i>Cervus</i> species, together with wider experience with other deer and ungulates.</p>	<p>There is only one reported eradication programme for Sika deer, work currently under consideration in New Zealand. Sika deer in the Russell Forest in New Zealand have been controlled since they were first established, but improved land access is thought necessary if eradication is to be achieved. Shooting would provide the main control method alongside supporting methods such as the use of trained dogs, infra-red cameras, Judas animals, faecal DNA surveillance and possibly acoustic sensors (Latham 2020).</p> <p>Considering all deer species, the DIISE (2018) database includes details of 10 successful eradications from islands. All of the cases that give details refer to shooting as the primary method used. These include a number of eradications of other <i>Cervus</i> species from various sites in New Zealand including from two islands (11.7 and 1.1km<sup>2</sup>) in Preservation Inlet (Brown 2013); Anchor (11.6km<sup>2</sup>) and Secretary (79.9km<sup>2</sup>) Islands (Crouchley et al 2011); and Lake Manapouri (2.5km<sup>2</sup>) (Whitehead 2009). A further example is of the eradication of <i>Cervus timorensis</i> from a 7.9km<sup>2</sup> island in New Caledonia (Genovesi and Carnevali 2011).</p> <p>The largest reported successful deer eradications are of Mule deer <i>Odocoileus hemionus</i> and Red deer <i>Cervus elaphus</i> from the Santa Rosa Channel Island off the Californian coast, an area of 222km<sup>2</sup> (Cruz et al 2009). No information on the costs of these deer eradications are available. However, Parkes (1990) and Carrion et al. (2011) describe the costs and methods of large-scale goat eradications from islands in some detail. These include successful removals from islands of up to 6000km<sup>2</sup> at a cost</p>	<p>Medium</p> <p>Eradications of similar species have been successfully achieved on increasingly large areas of land, mostly islands, of up to 6000km<sup>2</sup>. However, there are no published evidence accounts of the successful eradication of this species.</p>
--	--	--	---

		<p>of around US\$10,500,000 (US\$1,750 per km<sup>2</sup>) at 2011 prices, including the use of aerial hunting and Judas animals (Carrion et al. 2011). The costs per unit area are known to vary in relation to the size of the area managed (Robertson et al. 2017), the costs per unit area from smaller programmes will be substantially higher.</p>	
	<p><b>Shooting to achieve eradication</b> Shooting is the most widely used and effective method to control deer (Côté et al. 2004). This underpins most current management of deer populations in Europe (Apollonio et al. 2010) and is the most frequent method used for deer and other ungulate eradications worldwide (DIISE 2018). Deer are typically shot for sport with rifles by solitary hunters firing from a fixed position or by stalking the animals. Ungulate control programmes worldwide have used a wider variety of methods including the use of automatic weapons, night shooting, thermal imaging, use of fences and natural barriers to break up populations, dogs to locate animals, shooting from vehicles and from helicopters.</p>	<p><b>Shooting to achieve eradication</b> Sika deer are actively managed through shooting across most of their introduced range, using similar methods to those used to manage native Red deer. Shooting is typically carried out with centre-fire rifles with expanding ammunition. The use of shotguns for deer control is not recommended. Shooting with bows occurs in the USA, but is not lawful in the EU. Shooting is recognised as the main method used for the control of deer, including Sika (McCullough et al. 2008, Pérez-Espona et al. 2009). Guidelines for the management of deer populations, including Sika in their native (Takatsuki 2009, Kaji et al. 2010) and introduced ranges (Ratcliffe 1989, McCullough et al. 2008), are widely available. Eradication requires the removal of all individuals from an area, and this typically requires other methods to increase the effectiveness of control as densities are reduced, and specialised methods to remove the last few remaining individuals. Latham (2020) describes the potential use of automatic and semi-automatic firearms, night shooting, thermal imaging, together with shooting from vehicles and helicopters. The use of single shot rifles as used by sportsmen may be generally accepted, while the use of other these methods are likely to all raise public concern,</p>	<p>High.  Shooting is widely used for controlling deer species, including Sika deer. It has been the primary method used to support deer eradication programmes.</p>

		<p>including opposition from hunters who may normally be prohibited from their use. Although shooting is already widely used to control deer across Europe, its use in public places is likely to bring opposition and raise particular concerns. This is particularly the case for species with a high public profile, as can be the case for some deer populations.</p> <p>The use of different firearms, its calibre, number of cartridges and weight of ammunition together with the times of day and location where deer shooting is permitted is heavily regulated in Europe, and the details vary between Member States. These are likely to restrict the nature of the weapon, the requirements for the operator and the times and locations where they may be used. Many Member States require those using shooting to control deer to undertake a specialist training programme to ensure they are competent and safe before issuing a license. Local authorities in the Member State must be consulted before their use.</p> <p>The use of firearms brings risks to health and safety which need to be considered. The use of lead bullets has been restricted in some areas due to environmental concerns, although non-toxic alternatives are available.</p> <p>In some cases, Sika deer have been introduced to an area for hunting purposes. Attitudes to deer control also vary widely between stakeholders (Moriarty 2004a). Differing stakeholders may therefore present a barrier to eradication.</p>	
	<p><b>Use of Dogs</b> Trained dogs can be an effective tool to locate animals,</p>	<p><b>Use of Dogs</b> Dogs are widely used by hunters to help locate animals, and to assist with the retrieval of shot animals. The skills and</p>	<p>Medium</p>

	<p>particularly in habitats such as woodland which may otherwise provide concealment. This approach can be used to locate the animals themselves, or the presence of their signs, and can be particularly effective to assist with the removal of the last few remaining animals during an eradication, and to help confirm the absence of animals from an area.</p> <p>In some regions of the world, professional ground hunting with appropriately trained dogs may be used to control deer under conditions where conventional ground shooting would be difficult (Moriarty 2004b).</p>	<p>training required are widely available in many areas. Specialist training may be required to focus the dogs on a specific species, and to ensure that the dogs only locate and do not attack the animal.</p> <p>Dogs which bring an animal to bay rather than attack would allow humane management of deer in circumstances which would otherwise make eradication impossible (Moriarty 2004b).</p> <p>However, the use of dogs to kill prey is heavily restricted by law in many European countries. Local and national legislation would need to be consulted before considering the use of this method. This method has also been the focus of public protest in a number of countries and its use is likely to attract opposition. Deer hunting using trained dogs is less selective than shooting (Novak et al. 1991), while dogs can also cause greater disturbance which may decrease deer sighting rates (Godwin et al. 2013).</p>	<p>This method has been used for the control of other deer, but no published evidence for its use with this species or in areas where hybrids may be present</p>
	<p><b>Judas Animals</b></p> <p>Judas animals are marked individuals that are used to identify the locations of other of their species to assist with control by locating remaining groups or individuals. Judas animals are typically captured, radio-tagged, and then released to join a social group. This group</p>	<p><b>Judas Animals</b></p> <p>There are no published reports of the use of this method on Sika deer. However, Latham (2020) considers the use of Judas deer for the proposed eradication of Sika deer from Russell Forest in New Zealand.</p> <p>The Judas method for deer has only been trialled on red deer in New Zealand, suggesting it may be a useful tool for the latter stages of an eradication (Crouchley et al. 2011).</p> <p>The method is likely to have the greatest utility for deer species that are highly social, because they will be more</p>	<p>Medium</p> <p>Judas animals have been used successfully to assist the eradication of other ungulates, but no reports involve Sika deer or the use of this method in</p>

	<p>can then be followed using the radio-transmitter to assist with lethal control, typically by shooting. By sparing the Judas animal, it can then be left to locate and join another social group and the process repeated. The ability of Judas goats to attract conspecifics has also been enhanced through the use of chemically induced oestrous (Campbell et al. 2007), to lure otherwise wary males. Originally used to improve the efficiency of feral goat control (Parkes 1990, Taylor &amp; Katahira 1988, Campbell &amp; Donlan 2005), these approaches have now been used on a range of social mammals including deer (Crouchley et al. 2011) to improve the efficiency of eradication programmes.</p>	<p>likely to seek out conspecifics than solitary or species showing low social behaviour. However, Sika deer in New Zealand and elsewhere within their native and introduced ranges are considered only a moderately social species. Thus, it is debatable whether deploying Judas female Sika deer would be as useful as it has proven to be on more social species (Parkes 1990; Crouchley et al. 2011). However, Sika deer stags use a number of behavioural strategies to acquire mating opportunities during the rut. It may be possible to utilise this to help locate females during the rut.</p> <p>Latham (2020) concludes that using Judas Sika deer in Russell Forest would probably be expensive, and only achieve minor gains in terms of increased detection and kill rates. However, assessing the efficacy of this method before using it as a mop-up tool may be beneficial.</p> <p>The effectiveness of this method may be limited in areas where other <i>Cervus</i> species or their hybrids are present. No costs for the use of Judas deer are available. However, Campbell &amp; Donlan (2005) describe large improvements in the cost-effectiveness of goat eradications since the first application of this approach.</p> <p>This method has been predominantly used on uninhabited islands, although it is now also widely used in Scandinavia to assist the control of raccoon dogs (Kuczynski 2019). Little information is available on the public reaction to this approach. However, an adverse public reaction remains a possibility.</p>	<p>areas where hybrids are present.</p>
	<p><b>Traps</b></p>	<p><b>Traps</b> There are no accounts of deer eradication programmes</p>	<p>Medium</p>

	<p>A wide variety of traps and nets have been used to catch deer. However, these are typically used for live capture rather than as the primary control method during eradications. A variety of designs such as drop-nets (Ramsey 1968, Conner et al. 1987), Stephenson traps, clover traps, rocket nets and darting (Haulton et al. 2001) are all described in the literature, with information on their success and associated rates of injury. Deer may also be captured in corrals.</p>	<p>based on the use of traps as the primary control method. However, Crouchley et al. (2011) used traps as a subsidiary method during the eradication of red deer from an island of New Zealand. Trapping may also be a useful control method for use in areas where shooting is not feasible. Live capture is needed for the Judas animal method, and may form a useful part of eradication programmes based on this method. Given the wide variety of trap designs only general costs can be given, but most designs are likely to cost a few hundred Euros to construct.</p> <p>The live capture of deer risks stress and injury to the animals, requiring experienced personnel to reduce the risks. Conner et al. (1987) estimated White tailed deer (<i>Odocoileus virginianus</i>) mortality associated with drop traps to be between 1 and 7% within a week of capture. Haulton et al. (2001) reports between 2-20% trap related mortality.</p> <p>While trapping may remove deer, it is likely that remaining trap-shy individuals would still need to be removed by other means, for example shooting is likely to be required at some stage if complete eradication is the objective (Moriarty 2004b).</p>	<p>Traps have been used as a minor method to support deer eradication programmes and the live capture of Judas animals. However, no documented accounts of their use to manage Sika deer have been found.</p>
	<p><b>Toxins</b> Toxins have not been widely used for the management of deer in other parts of the world. The toxin 1080 (sodium monofluoroacetate) has been incorporated into a gel and</p>	<p><b>Toxins</b> No toxins are currently approved for use on deer in the EU. The use of toxins to manage deer in the EU could be expected to raise considerable public opposition and can be criticised for its likely impact on non-target species (Moriarty 2004b).</p>	<p>Medium</p> <p>Although toxins have been used for deer management, this has typically been to support other</p>

	<p>smear on leaves as a deer toxin in New Zealand (Batcheler &amp; Challies 1988). DIISE (2018) includes two New Zealand reports applying aerially based Brodifacoum baits as a secondary method to assist with deer eradication, but shooting forming the primary method in each case.</p>	<p>The New Zealand experience suggests that 1080 was expensive when applied over large areas, but it was used successfully to control localised populations of deer that could not be killed by other means (Moriarty 2004b) although actual costs are unavailable.</p>	<p>methods such as shooting. No data is available related to their use on Sika deer.</p>
	<p><b>Surveillance during eradication</b> Monitoring the reduction in population size and identifying the number of remaining animals is an important component of an eradication programme. Many programmes have used declines in catch, signs or sightings per unit effort to assess progress. More recently, programmes have collected DNA from culled animals and from faeces (pellet) found in the field to estimate the number of remaining animals in a population (Nugent et al. 2005, Crouchley et al. 2011). Thermal imaging (TI) cameras have been used for monitoring wildlife for over 20 years (Gill et al. 1997; Havens &amp; Sharp 1998).</p>	<p><b>Surveillance during eradication</b> <b>DNA</b> The use of DNA to estimate the size of any remaining population during eradication offers improvements in cost-effectiveness. However, animals need to be sufficiently genetically distinct for the method to be effective. Small populations derived from a limited founder stock may be too similar for the method to be effective (Crouchley et al. 2011). Latham (2020) discusses the potential use of this method to help achieve the eradication of Sika deer from Russell Forest, concluding that in that area information yielded by faecal DNA may marginally improve control efficacy, but he considers that it cannot currently help achieve eradication in this area. <b>Signs</b> Pellet counts are widely used to monitor ungulates but rely on the assumption that pellets of different species are correctly identified in the field. However recent eDNA studies revealed high rates of misidentification in diverse</p>	<p>Medium  Given the absence of successful sika deer eradications, the effectiveness of different surveillance methods to support that objective have not been assessed,.</p>

	<p>They offer improvements when determining the presence or absence of a species in an area, and can be used to help locate animals for control using methods such as shooting. TI relies on the differences in temperature between the animal and the surrounding habitat. Its use is therefore most effective when the habitat is cool, for example at night, in the early morning or in shaded habitats such as woodland.</p> <p>Acoustic devices are becoming increasingly used in wildlife ecology and management (Wall et al. 2014; Buxton et al. 2018). For example, they can provide 'real-time' directional tracking of animal sounds and gunshot detection, both of which have immediate application for wildlife management (Wall et al. 2014, Hill et al 2018).</p>	<p>European ungulate communities monitored through pellet counts (Spitzer et al. 2019).</p> <p><b>Thermal Imaging</b> Hand-held TI units and rifle scopes are increasingly being used for ground-based shooting of mammalian pests including Sika deer (Latham 2020). The use of thermal imaging equipment to assist with the control of Sika deer may be restricted in some countries. Proposals for its use may be opposed by existing hunter groups to whom this technology, or permission to shoot at night, may not be available, or on ethical grounds.</p> <p><b>Acoustic Sensors</b> Latham (2020) also discussed the potential utility of acoustic monitoring devices for Sika deer management in Russell Forest. Five devices were trialled for two weeks and were able to detect calls emitted by Sika deer. However, the utility of these devices was limited because data had to be downloaded from each device, rather than being retrieved remotely in real-time. Although this study confirmed that Sika deer calls could be detected using acoustic monitoring devices, the information was not received quickly enough to be useful for Sika deer control. Receiving data in real time would mean that control staff could respond immediately to a Sika deer call, thereby increasing the likelihood of locating and killing the individual detected by the device. There is also the potential to link acoustic monitoring devices to artificial intelligence (AI) systems that can learn to recognise the target species and then alert an appropriate person in real time when a deer is heard. This AI approach is at an early stage of development</p>	
--	---	--	--

		and would need to be developed specifically for detecting Sika deer.	
<b>Methods to achieve management<sup>8</sup></b>	All of the methods described to support eradication can also be used to manage existing deer populations.		
	<p><b>Shooting</b> Shooting is by far the most common and main control method used for the long-term management of Sika deer throughout its native and introduced range. This includes control to limit impacts on agriculture, forestry, biodiversity and to reduce hybridisation with native <i>Cervids</i>. While the situation varies widely dependent on Sika deer numbers and local conditions, there are frequent reports that current control efforts are insufficient to effectively limit the impacts of Sika and other deer species in many areas and their populations are generally increasing (McCullough et al. 2008, Takatsuki 2009, Kaji et al. 2010).</p>	<p><b>Shooting</b> Shooting is recognised as the main method used for the control of deer, including Sika (McCullough et al. 2008, Pérez-Espona et al. 2009). Guidelines for the management of deer populations, including Sika in their native (Takatsuki 2009, Kaji et al. 2010) and introduced ranges (Ratcliffe 1989 McCullough et al. 2008), are widely available.</p>	<p>High</p> <p>Shooting is widely used for the control of deer species, including Sika deer in a range of countries.</p>
	<b>Contraceptives</b>	<b>Contraceptives</b>	High

	<p>A wide variety of contraceptive agents have been considered for use on deer, including surgical implants, injectable contraceptives and orally delivered products. These can work through a number of different mechanisms, including supplementing or replacing natural hormones; inducing an immune response to elements of the reproductive system, such as sperm, egg surface proteins or particular hormones involved in reproduction.</p> <p>Two products have received particular attention. Injectable Porcine Zona Pallucida (PZP) raises an auto-immune response in the female to egg surface proteins, preventing fertilisation. GonaCon is another injectable product that raises an auto-immune response to GnRH, the hormone that provides high level regulation of other sex hormones; suppression of GnRH maintains the animal in a non-breeding or juvenile condition. The products and their potential</p>	<p>The use of contraceptives is of proven effectiveness for individual animals, but to reduce a population a significant proportion of the reproductive animals must be treated. This raises complex issues of scale, cost and practicality that have limited the widespread use of these products to date. There are currently few examples of the successful use of wildlife contraception beyond small, closed populations such as on islands, in suburbia or in fenced enclosures such as parks (IUCN 2017). There are also no examples of the use of contraceptives to eradicate an established population of deer or to reduce deer abundance over any significant area. Beyond surgical implants, currently the only commercially available immune-contraceptive products are PZP and GonaCon although their use is limited to particular species and this varies between countries. Neither is currently specifically licensed for use on Sika deer.</p> <p>There may be a variety of welfare consequences for the treated animal dependent on the product chosen. For example, females treated with PZP may undergo prolonged oestrus together with its associated behaviours. This can lead to stress and loss of body condition in the females from male harassment. Products such as GonaCon may interfere with the development of secondary sexual characters in males, such as antlers (Killian et al. 2005), with welfare implications. These can be avoided by the careful selection of products and their targeted delivery to only one sex, although these can increase the cost and limit the practicality of their use. The injection of immune-contraceptive products may be associated with the formation of abscesses at the injection site (Miller et al.</p>	<p>Despite the large volume of research on wildlife contraception, there are currently few examples of its practical use to control deer or examples of its use to achieve eradication.</p>
--	---	---	---

	<p>for use have been reviewed by Fagerstone et al. (2010) and in relation to the management of invasive alien species in Europe (IUCN 2017). The UK Deer Initiative have also reviewed the prospects of deer control using contraceptives in the UK.</p>	<p>2008). The welfare implications of these products are reviewed by IUCN (2017).  Proposals to use contraceptives and avoid lethal control are often welcomed by the public and many stakeholders.  Proposals for the use of contraceptives often receive opposition from deer hunting interests who are concerned about contamination of deer products from animals that they might subsequently hunt, the perceived impracticality of contraception for use at a large scale, and the lack of recognition for the traditional role of hunters in managing deer populations.  The practical costs of contraceptive use are currently high as they are typically based on the use of small numbers of implants or injectable products. These can involve the capture and surgical treatment of individual animals with associated costs and risks to animal welfare. If orally delivered contraceptive are developed, species specific delivery systems perfected and the appropriate licenses gained, then the costs may be dramatically reduced in future.  As reported by Gürtler et al. (2018) fertility reduction (contraception) and non-lethal removal have only played marginal roles for deer management, and was considered unsuitable for most situations in a review discussing the efficacy and cost-efficiency of deer management methods in Australia (Davis et al. 2016).</p>	
	<p><b>Management of Hybridisation</b>  Sika deer are known to hybridise with native deer, in particular Red deer <i>Cervus elaphus</i>. The</p>	<p><b>Management of Hybridisation</b>  One particular concern associated with introduced populations of Sika deer is hybridisation with native <i>Cervus</i> species (Swanson &amp; Putman 2009). At one level, the</p>	<p>Medium   Selective culling may help slow rates of</p>

	<p>potential loss of <i>C. elaphus</i> populations through hybridisation is a significant conservation concern.</p>	<p>geographical separation of allospecifics can help limit this risk. However, in areas where hybrids occur, programmes to support the selective culling of animals with hybrid characteristics has been used to reducing rates of gene flow into the native populations. However, the frequency of hybridisation is highly variable between different populations (Senn &amp; Pemberton 2009). Hybrids regularly occur with variable mixtures of characteristics from the two species. Many hybrids cannot reliably be determined as such from external examination in the field and genetic methods may be required. The lack of an effective method to identify hybrids reduces the effectiveness of selective culling (Pérez-Espona et al. 2009).  Management approaches based on the geographic separation of the two species offer some advantages (Wildlife On-Line), although the long-term sustainability of such approaches remains uncertain.  Pérez-Espona et al. (2009) conclude that a management policy on how to prevent hybrids from an established swarm eventually spreading and introgressing neighbouring red deer populations therefore cannot be proposed. although research to understand the processes behind swarm formation of red and sika hybrids continues (Smith et al 2018)</p>	<p>gene spread in native populations, however the difficulties in the identification of hybrids reduces its effectiveness.</p>
	<p><b>Fencing, Deterrence and Resource Protection</b>  Localised damage caused by deer can be managed by the use of deer proof fences. These are widely used in commercial</p>	<p><b>Fencing, Deterrence and Resource Protection</b>  Designs of deer proof fencing, both wire and electric, scaring methods and repellents are available on-line and from commercial companies.  Useful sites include:  The Internet Centre for Wildlife Damage Management:</p>	<p>High   Methods such as fencing are widely used to reduce local deer impacts.</p>

	<p>forestry to protect young plantations. However, they bring problems of reduced access for other purposes, reducing their use to protect agricultural crops or other resources. Individual trees can be protected during early growth through the use of covers or guards to prevent browsing. A wide variety of scaring and deterrent products have been proposed to limit local damage (Côté et al. 2004). The effectiveness of these methods is highly variable and local trails are required to assess the usefulness of each for a specific purpose.</p>	<p><a href="http://icwdm.org/handbook/mammals/Deer.asp">http://icwdm.org/handbook/mammals/Deer.asp</a></p> <p>There are a number of accounts of the use and consequences of fencing in relation to Sika deer, particularly in relation to forest management in their native range in Japan (Kumar et al. 2006, Honda et al. 2011, Tamura &amp; Nakajima 2017).</p>	
	<p><b>Biological control</b> Predation by feral and larger wild predators is believed to impact and possibly limit deer populations in some areas (Okarma et al. 1997, Ballard et al. 2001, Moriarty 2004b, Gürtler et al. 2018). However, the role of predators in controlling ungulate populations remains uncertain, particularly in the human-influenced habitats found across</p>	<p><b>Biological control</b> The main evidence for the limitation of deer populations by predation comes from relatively undisturbed habitats with a natural suite of predators. There is little evidence that predators currently limit deer numbers in many of the more human-influenced habitats common across Europe. While the reintroduction of predators may introduce some element of predation, the evidence that this will limit deer numbers in human-influenced habitats is limited, and there are significant conflicts associated with the reintroduction of predators. The reintroduction of predators would also potentially impact native as well as introduced deer, as</p>	<p>Low</p> <p>Although wild deer are impacted by predators, there is little evidence of the successful use of this approach to manage deer populations and no evidence to support their practical use to</p>

	most of Europe (Côté et al. 2004).	would the introduction of deer specific pathogens (Williams 2005). There are no other biological controls that appear useful as a control agent for deer (Moriarty 2004b).	manage Sika deer in Europe.

## Guidelines for Completing the Annex

1 Provide a brief summary description of the most cost-effective methods drawing on the reviews in the detailed assessments

2 Provide a description of the potential method. This should be based on the available key scientific evidence which should be gathered from sources including articles and reviews in technical and scientific journals, internet searches, online databases, grey literature and relevant books and personal communications from scientists, stakeholders, conservation practitioners and governmental bodies. This information should include a full bibliographic list detailing the literature and sources considered.

3 Provide an assessment of the likely cost and effectiveness of the method. Where information is available, consider the following range of questions, accepting that not all questions will be appropriate in all circumstances.

- How effective has this approach proven to be in the past or in an analogous situation?
- How publically acceptable is the approach likely to be?
- Over what period of time would this approach need to be applied to be effective?
- What is the direct cost of implementing this approach?
- How likely are the methods used in the approach to be available?
- How likely is it that relevant licences or other approvals to undertake the approach would be difficult to obtain?
- How likely is it that health and safety issues would prevent the use of this approach?
- How significant is the environmental harm caused by this approach?
- How significant is the economic harm caused by this approach?
- How significant is the social harm caused by this approach?
- How likely is it that the approach will be criticised on welfare grounds?
- How likely is it that the approach will be acceptable to other stakeholders?

Where available, factual information on the costs of specialist equipment, or case studies of management costs from across the Union or third countries should be provided. When describing case studies, if the information is available then provide both total cost and the area over which control was undertaken so that a cost per unit area might be derived. Where such quantitative information is not available, then any qualitative information from the literature is acceptable to help guide decision making. It is accepted that in the majority of cases the information required to assess the potential total cost of management at a member state level is unlikely to be available. This would normally require information on the extent and abundance of the species which is beyond the scope of this assessment. Assessors are not expected to extrapolate the potential total costs of management at a member state level, only to report on the information provided within the literature.

4 Provide an overall assessment of the confidence that can be applied to the information provided for this method. This confidence should relate to the quality of the available information using the guidance below. It should NOT relate to the confidence in the effectiveness of the method

The confidence scores are:

- **High:** Information comes from published material, or current practices based on expert experience applied in one of the EU countries or third country with similar environmental, economic and social conditions.
- **Medium:** Information comes from published data or expert opinion, but it is not commonly applied, or it is applied in regions that may be too different from Europe (e.g. tropical regions) to guarantee that the results will be transposable.
- **Low:** data are not published in reliable information sources and methods are not commonly practiced or are based solely on opinion; This is for example the case of a novel situation where there is little evidence on which to base an assessment.

If there are further factors beyond these that have determined the chosen level of confidence, then provide a brief written description to support the choice of the level of confidence.

5 Measures for preventing the species being introduced intentionally or unintentionally into the territory of a Member State (cf. Articles 7(1)(a), 7(2), 13, 15), i.e. preventing a species entering by blocking its pathways, including pre-border prevention and prevention of escape or release into the environment and secondary spread whenever relevant. Measures for preventing the species reproducing while in containment should be included, if appropriate. Consider all methods that might be applied, including any that have not proven useful. Provide a description of each method in turn, using separate rows to consider each method.

6 Measures to run an effective surveillance system for achieving an early detection of a new occurrence (cf. Article 16). This section assumes that the species is not currently present in a Member State, or part of a Member State's territory.

7 Measures to achieve eradication. Preferably, but not exclusively, used at an early stage of invasion, after an early detection of a new occurrence (cf. Article 17). Consider all methods that might be applied, including any that have not proven useful. Provide a description of each method in turn, using separate rows to consider each method.

8 Measures to achieve management of the species once it has become widely spread within a Member State territory (cf. Article 19). These measures can be aimed at eradication, population control or containment of a population of the species. Consider all methods that might be applied, including any that have not proven useful. Provide a description of each method in turn, using separate rows to consider each method.

The development and completion of this template forms part of the EU project **No 07.0202/2020/834529/ETU/ENV.D.2** Study on Invasive Alien Species – Development of risk assessments to tackle priority species and enhance prevention.

**Risk assessment template developed under the "Study on Invasive Alien Species – Development of risk assessments to tackle priority species and enhance prevention"  
Contract No 07.0202/2020/834529/ETU/ENV.D.2<sup>1</sup>**

**Name of organism:** *Cherax destructor* Clark, 1936

**Author(s) of the assessment:**

Elena Tricarico, Department of Biology, University of Florence, Italy

**Risk Assessment Area:** The risk assessment area is the territory of the European Union 27 and the United Kingdom, excluding the EU-outermost regions.

**Peer review 1:** Antonín Kouba, South Bohemian Research Center of Aquaculture and Biodiversity of Hydrocenoses, Faculty of Fisheries and Protection of Waters, University of South Bohemia in České Budějovice, Vodňany, Czech Republic

**Peer review 2:** Francisco J. Oficialdegui, Department of Wetland Ecology, Doñana Biological Station (EBD-CSIC), Seville, Spain

**Date of completion:** 15/10/2021

---

<sup>1</sup> This template is based on the Great Britain non-native species risk assessment scheme (GBNNRA). A number of amendments have been introduced to ensure compliance with Regulation (EU) 1143/2014 on IAS and relevant legislation, including the Delegated Regulation (EU) 2018/968 of 30 April 2018, supplementing Regulation (EU) No 1143/2014 of the European Parliament and of the Council with regard to risk assessments in relation to invasive alien species (see <https://eur-lex.europa.eu/legal-content/en/TXT/?uri=CELEX%3A32018R0968>).

ANNEX VIII Species Distribution Model ..... 67

## SECTION A – Organism Information and Screening

### **A1. Identify the organism. Is it clearly a single taxonomic entity and can it be adequately distinguished from other entities of the same rank?**

including the following elements:

- the taxonomic family, order and class to which the species belongs;
- the scientific name and author of the species, as well as a list of the most common synonym names;
- names used in commerce (if any)
- a list of the most common subspecies, lower taxa, varieties, breeds or hybrids

As a general rule, one risk assessment should be developed for a single species. However, there may be cases where it may be justified to develop one risk assessment covering more than one species (e.g. species belonging to the same genus with comparable or identical features and impact). It shall be clearly stated if the risk assessment covers more than one species, or if it excludes or only includes certain subspecies, lower taxa, hybrids, varieties or breeds (and if so, which subspecies, lower taxa, hybrids, varieties or breeds). Any such choice must be properly justified.

Response: The species is a single taxonomic entity, and it can be distinguished from other entities.

*Cherax destructor* Clark, 1936 (Malacostraca, Decapoda, Parastacidae)

Main synonyms: There are no formal synonyms<sup>2</sup>

Common names: common yabby, yabby, yabbies (EN), Australische kreeft; yabby (NL), ecrevisse bleue; ecrevisse de Murray; yabbie (FR); yabby (IT); Blauer Yabby (DE), rak ničivý (CZE), cangrejo australiano (ES), cranc australiá (Catalan), karramarro australiarra (Basque)

The species could hybridize with congeneric *Cherax albidus*, resulting in only male progeny: this can be used especially for controlling reproduction in ponds in Australia, limiting population size (Lawrence et al. 2000; Souty-Grosset et al. 2006). There is some debate about the presence of several subspecies belonging to *C. destructor*. There have been suggestions of a synonymy with *C. albidus*, but this has not been confirmed (Souty-Grosset et al. 2006). For the present Risk Assessment, *C. destructor* (and its different colour morphs in trade such as the blue one) is considered a unique species.

### **A2. Provide information on the existence of other species that look very similar [that may be detected in the risk assessment area, either in the environment, in confinement or associated with a pathway of introduction]**

Include both native and non-native species that could be confused with the species being assessed, including the following elements:

- other alien species with similar invasive characteristics, to be avoided as substitute species (in this case preparing a risk assessment for more than one species together may be considered);

<sup>2</sup> Crandall & De Grave (2017) reported *Cherax davisi* Clark, 1941a and *Cherax esculus* Riek, 1956 as possible synonyms but they were not mentioned in the current literature or other websites.

- other alien species without similar invasive characteristics, potential substitute species;
- native species, potential misidentification and mis-targeting

Response: Native and non-native crayfish species present in the risk assessment area can be distinguished based on morphological and colour characteristics (Souty-Grosset et al. 2006; Kouba et al. 2014). From Souty-Grosset et al. (2006), the species is described as follows: the colour body is green-beige to almost black, blue-grey being common in individuals kept in captivity or even orange in the yabby volcano<sup>3</sup>. Chelae dorsally showing the same colour as the body but with a marbled-like pattern, underside dirty-white or grey coloured. Colour shows a wide variability depending on the location, season and water conditions and may vary from individual to individual in a single location (Withnall 2000). The carapace is smooth with a single pair of post-orbital ridges forming two keels and no spines on shoulders. The rostrum is short, broad-based, triangular and smooth: no spines present along margins. Median carina indistinct. The chelae, usually robust and a peculiarity of the species, are smooth, elongated and large; there is a mat of setae along proximal cut edges of the chelar fingers. Eyes are relatively small. Membranous posterior half of telson.

Another typical features of *C. destructor*, as in other crayfish species native to the Southern Hemisphere (Parastacoidea: Parastacidae), are the morphological differences between sexes when compared with crayfish from the Northern Hemisphere (Astacoidea: Astacidae, Cambaridae, and Cambaroididae). Overall, in crayfish, females have gonopores located at the base of the third pairs of pereopods, while male genital papillae are at the base of the fifth pair of pereopods, nearest the abdomen. In Astacoidea, males have also the first and second pleopods (ventral appendages) modified in gonopods, while in Parastacoidea males lack of these modified gonopods: the first pleopod is vestigial or missing in both sexes. Moreover, in Cambaridae the females have also a seminal receptacle (*annulus ventralis*), absent in other Astacoidea and Parastacoidea (IUCN 2018). Thus, to identify the sex of *Cherax* individuals, the position of abovementioned gonopores and genital papillae should be assessed.

The congeneric *Cherax quadricarinatus* is also present in aquaculture facilities and internet trade in Europe (Haubrock et al. 2021), and in the wild in Slovenia (thermal waters: Kouba et al. 2014), Hungary (Weiperth et al. 2019), Malta (Deidun et al. 2018) and Spain (thermale waters: Arias & Torralba-Burrial 2021).

Several *Cherax* species, primarily of New Guinean origin, are sold in the European pet trade. Some of these have been already found introduced in the European wild, occupying thermal localities. Evidence on their establishment is, however, missing (Weiperth et al. 2020). Despite the generally similar morphological appearance, they can be usually distinguish from *C. destructor* for their diverse colouration. Moreover, the presence of the abovementioned two keels helps to distinguish *C. destructor* from *C. quadricarinatus*.

The identification of *C. destructor* juveniles could require the help of an expert or even the use of DNA barcoding.

---

<sup>3</sup> <https://www.pixtastock.com/photo/38959707>

**A3. Does a relevant earlier risk assessment exist? Give details of any previous risk assessment, including the final scores and its validity in relation to the risk assessment area.**

Response: For Europe, the species has been screened using FI-ISK, a tool for identifying potentially invasive freshwater invertebrates, considering as risk assessment area Italy (Tricarico et al. 2010); Czech Republic (Patoka et al. 2014); Greece (Papavlasopoulou et al. 2014); Germany (Chucholl 2013; Chucholl & Wendler 2017), Ukraine (Kotovska et al. 2016), Caspian region (Vodovsky et al. 2017) and Hungary (Weiperth et al. 2019). For all these RAs, the final outcome for *C. destructor* was high risk of invasiveness due to its potential negative impacts, feeding habits and adaptability to the local conditions.

A similar outcome (high risk) has been reported for Kazakhstan (Uderbayev et al. 2017) using FI-ISK, while for New Guinea with the EICAT (Environmental Impact Classification of Alien Taxa) the species has been ranked in the moderate category (Yonvitner et al. 2020).

For USA, the species has been screened by U.S. Fish and Wildlife Service (2019) with high risk as outcome again for its high climate match, potential impacts and history of invasiveness. The species was then officially listed as an injurious wildlife species by the U.S. Fish and Wildlife Service in 2016 under the Lacey Act (18.U.S.C.42) (U.S. Fish and Wildlife Service 2016). Many US states listed it as a prohibited species (U.S. Fish and Wildlife Service 2019).

**A4. Where is the organism native?**

including the following elements:

- an indication of the continent or part of a continent, climatic zone and habitat where the species is naturally occurring
- if applicable, indicate whether the species could naturally spread into the risk assessment area

Response: The species is native to central-eastern Australia (New South Wales, Victoria, eastern South Australia and southern parts of Northern Territory and Queensland) (Souty-Grosset et al. 2006), inhabiting areas with temperate and tropical climates (characterized by high summer temperatures and low annual rainfall). It can colonize a wide range of habitats (alpine streams, subtropical creeks, springs, billabongs, ephemeral lakes, swamps, irrigation ditches: Souty-Grosset et al. 2006). It can construct burrows (0.5 - 2 m deep) that help surviving during the drought (Withnall 2000; Kouba et al. 2016). It is adapted to a wide range of water temperatures (1 - 35 °C). It does not grow at water temperatures below 15 °C and above 34 °C; the optimal growth is around 28 °C (Souty-Grosset et al. 2006). It starts dying at 36 °C and with temperatures below 16 °C it can undergo to “hibernation” (i.e. metabolism and feeding cease) (Mills 1983; Morrissy et al. 1990; Merrick & Lambert 1991; Morrissy & Cassells 1992; Withnall 2000). However, Veselý et al. (2015) found that yabby can withstand low winter temperatures with foraging activities being observed even in the coldest period of the experiment (2 - 3 °C) with mentioned temperatures lasting for ~ 3 months. It can tolerate salinity (but growth stops at 8 ppt and mortality starts at 16 ppt: Mills & Geddes 1980) and hypoxic waters (oxygen concentration <1 mg L<sup>-1</sup>: Mills 1983; Morrissy & Cassells 1992). Optimal pH is comprised between 7.5 and 8.5 (with a tolerance up to 7 and 9) (CABI 2011). The species is usually found in turbid waters with muddy or silted bottoms (Withnall 2000).

It can naturally disperse within the same basin; anecdotal reports suggest that *C. destructor* emerges from hypoxic water and migrates between waterbodies (Morris & Callaghan 1998), but no studies confirmed this ability. A physiological study showed that the species appeared able to breathe air (Morris & Callaghan 1998) and this can be expected, being a drought resilience species such as *Procambarus* species (Kouba et al. 2016; Guo et al. 2019). Similar to its congeneric *C. quadricarinatus* (Haubrock et al. 2021), the species is omnivorous and opportunistic (Souty-Grosset et al. 2006), with plant material and detritus being the main component of its diet, followed by a low proportion of arthropods, algae and fungi (Lawrence & Jones 2002; Souty-Grosset et al. 2006; Linton et al. 2009). Predation on small fish has been documented as well (Beatty 2006).

**A5. What is the global non-native distribution of the organism outside the risk assessment area?**

Response: The species has been introduced in eastern drainages of the non-native range of New South Wales and in Western Australia (Coughran et al. 2009; McCormack 2014), where it became invasive. The species was also introduced in Tasmania, where it established and is spreading after an illegal introduction (Lynas et al. 2007).

**A6. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species been recorded and where is it established? The information needs to be given separately for recorded (including casual or transient occurrences) and established occurrences. “Established” means the process of an alien species successfully producing viable offspring with the likelihood of continued survival<sup>4</sup>.**

**A6a. Recorded: List regions**

**A6b. Established: List regions**

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

- Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea.

Comment on the sources of information on which the response is based and discuss any uncertainty in the response.

For delimitation of EU biogeographical regions please refer to <https://www.eea.europa.eu/data-and-maps/figures/biogeographical-regions-in-europe-2> (see also Annex VI).

<sup>4</sup> Convention on Biological Diversity, Decision VI/23

For delimitation of EU marine regions and subregions consider the Marine Strategy Framework Directive areas; please refer to <https://www.eea.europa.eu/data-and-maps/data/msfd-regions-and-subregions/technical-document/pdf> (see also Annex VI).

Response (6a): Mediterranean and Atlantic (Souty-Grosset et al. 2006; Kouba et al. 2014; Deidun et al. 2018; Vigneron et al. 2019; Collas 2020; Julian Reynolds, pers. comm.). The response is based on publications reporting the presence of the species in these biogeographic regions, so the level of confidence is high.

Response (6b): Mediterranean and Atlantic (Souty-Grosset et al. 2006; Kouba et al. 2014; Deidun et al. 2018; Vigneron et al. 2019; Collas 2020; Julian Reynolds, pers. comm.). The response is based on publications reporting the establishment of the species in these biogeographic regions, so the level of confidence is high.

**A7. In which biogeographic region(s) or marine subregion(s) in the risk assessment area could the species establish in the future under current climate and under foreseeable climate change? The information needs to be given separately for current climate and under foreseeable climate change conditions.**

**A7a. Current climate: List regions**

**A7b. Future climate: List regions**

With regard to EU biogeographic and marine (sub)regions, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

Response (7a): Atlantic, Black Sea (very few areas), Continental (very few areas), Mediterranean

Response (7b): 2070 RCP 2.6 Atlantic (increase), Black Sea (still very few areas), Continental (still very few areas), Mediterranean (small decrease); 2070 RCP 4.5 Atlantic (increase), Black Sea and Continental (still very few areas), Mediterranean (small decrease)

These responses are based on the Species Distribution Model (Annex VIII). The ensemble model suggested that suitability for *C. destructor* was most strongly determined by temperature seasonality, accounting for 36.1% of variation explained, followed by minimum temperature of the coldest month (-3°C; 23.2%), and maximum temperature of the warmest month (21 °C; 16.5%). The minimum

temperature of the coldest month is currently limiting the establishment in the northern and coldest biogeographic regions. The temperature increase will favour the species establishment in the future, even if the range increase forecasted under RCP 4.5 would decrease the percentage of suitable areas in the Mediterranean biogeographic region, probably becoming too dry for the species. The importance of temperature as predictor has also been confirmed by distribution models conducted on the species for Iberian Peninsula (Capinha & Anastácio 2011), with colder areas being less suitable. However, from a laboratory study, Veselý et al. (2015) showed that *C. destructor* can withstand low winter temperatures typical of lentic habitats in the European temperate zone, thus posing a risk of establishment also to these areas.

**A8. In which EU Member States has the species been recorded and in which EU Member States has it established? List them with an indication of the timeline of observations. The information needs be given separately for recorded and established occurrences.**

**A8a. Recorded: List Member States**

**A8b. Established: List Member States**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden

The description of the invasion history of the species shall include information on countries invaded and an indication of the timeline of the first observations, establishment and spread.

Response (8a): The first known introduction of the species (30 individuals from California) from California was in Catalonia, Spain, in 1983 for aquaculture purposes, although earlier or later introductions cannot be ruled out. Due to the lack of permits for aquaculture, these crayfish were released in an irrigation pond (Bolea 1996; Souty-Grosset et al. 2006). In Italy, the species was introduced at the end of 1980s in closed systems for aquaculture purposes (D'Agaro et al. 1999) and the first wild population was found in 2008 (Scalici et al. 2009). In France, the species has been found in the wild in 2018 (Vignon et al. 2019), probably introduced for aquaculture in ponds connected to open waters (Collas 2020). The species has also been reported for southern Ireland in 2018 where it was probably introduced in 2010 (Julian Reynolds, pers. comm.).

Response (8b): Spain, Italy, France, Ireland (Kouba et al. 2014; Deidun et al. 2018; Collas 2020; Julian Reynolds, pers. comm.). In Spain, the species became established in the autonomous communities Navarra and Aragón; then four populations were intentionally eradicated using crayfish plague (Souty-Grosset et al. 2006; Kouba et al. 2014), but at least another established population has been reported in a small irrigation pond close to Bagüés, province Zaragoza, Aragón, and the hypothesis that this population originated from individuals translocated within Spain cannot be discarded (Bolea 1996; Kouba et al. 2014). In Italy, the only established population in Latium disappeared, probably after the crayfish plague was transmitted by the red swamp crayfish *Procambarus clarkii* spreading in the area (Mazza et al. 2018). Still, another population has been reported in 2016 in Sicily in the province of Siracusa (Deidun et al. 2018). In France, the species is currently reported in a river in the north of Finstère (Brittany) (Collas 2020). The species has also been reported for southern Ireland in the county of Cork in a quarry pool (Julian Reynolds, pers. comm.).

**A9. In which EU Member States could the species establish in the future under current climate and under foreseeable climate change? The information needs be given separately for current climate and under foreseeable climate change conditions.**

**A9a. Current climate: List Member States**

**A9b. Future climate: List Member States**

With regard to EU Member States, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

Response (9a): Croatia (very few areas), France, Greece, Italy, Portugal, Spain, UK

Response (9b): 2070 RCP 2.6 Belgium, France (slight increase), Germany (very few areas), Greece (decrease), Ireland, Italy (decrease), Portugal (slight decrease), Spain (decrease), and the United Kingdom (increase); 2070 RCP 4.5: Belgium, France (similar), Germany (very few areas), Greece (decrease), Italy (decrease), Netherlands, Portugal (slight decrease), Spain (decrease), and the United Kingdom (increase).

These responses are based on the SDM (Annex VIII). The ensemble model suggested that suitability for *C. destructor* was most strongly determined by temperature seasonality (please see Annex VIII for details). The minimum temperature of the coldest month is currently limiting the establishment in the northern and coldest biogeographic regions. The temperature increase will favour the species establishment in the future, even if the rise forecasted under RCP 4.5 would decrease the percentage of suitable areas in the Member States of Mediterranean biogeographic region which probably would become too dry for the species, even if the species is rather drought tolerant. The importance of temperature as predictor has been confirmed also by distribution models conducted on the species for the Iberian Peninsula (Capinha & Anastácio 2011), with colder areas being the less suitable. However, from laboratory study, Veselý, et al. (2015) showed that *C. destructor* can withstand low winter temperatures typical of lentic habitats (and many lotic waters with temperatures that do not fall below 2.5 °C during the winter) in the European temperate zone, thus posing a severe threat also to these areas.

**A10. Is the organism known to be invasive (i.e. to threaten or adversely impact upon biodiversity and related ecosystem services) anywhere outside the risk assessment area?**

Response: In Australia, in the non-native range, it is reported to have destroyed macrophytes, caused siltation, and displaced the endemic crayfish *Euastacus dharawalus* (Coughran & Daily 2012). In addition, other potential impacts on fish, amphibians, freshwater turtles, dragonflies and other invertebrates have been suggested in the non-native Australian range (Bradsell et al. 2002; Lynas et al. 2004; Coughran & Daily 2012; Cerato et al. 2019).

**A11. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea

Response: Up to now, no impacts have been reported in the risk assessment area.

**A12. In which EU Member States has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden

Response: Up to now, no impacts have been reported in the risk assessment area.

**A13. Describe any known socio-economic benefits of the organism.**

including the following elements:

- Description of known uses for the species, including a list and description of known uses in the risk assessment area and third countries, if relevant.
- Description of social and economic benefits deriving from those uses, including a description of the environmental, social and economic relevance of each of those uses and an indication of

associated beneficiaries, quantitatively and/or qualitatively depending on what information is available.

If the information available is not sufficient to provide a description of those benefits for the entire risk assessment area, qualitative data or different case studies from across the risk assessment area or third countries shall be used, if available.

Response: In Australia, it has a relatively high commercial value as food. In its native central-eastern area, it represents about 90% of Australian crayfish production and from 2000 the majority of production derived from the translocated population in Western Australia (Piper 2000; CABI 2011). It is interesting to note that the production and value of the common yabby in aquaculture in Australia could have promoted the introduction of the species elsewhere outside the native range. Moreover, it is commonly used as bait by recreational fishers (Nguyen 2005). It is cultured in several countries in aquaculture facilities as a delicacy and also as ornamental species in aquaria being easy to maintain (CABI 2011).

In Europe, no recent detailed economic data have been found on the use of the species in aquaculture and ornamental pet trade, even though its presence in such activities has frequently been reported (D'Agaro et al. 1999; Chucholl 2013; Kouba et al. 2014; Chucholl & Wendler 2017; Deidun et al. 2018) as well its availability in several e-commerce sites (e.g. ebay for 10-30 € per specimen). D'Agaro et al. (1999) reported in 1995 a price of 8-14 US\$ per kg per *Cherax* sp. (without distinguishing *C. destructor* from *C. quadricarinatus*) sold in Italy and a rough estimate of production of *Cherax* spp. of 5 t per year. *Cherax* species (*C. destructor*, *C. quadricarinatus* and other New Guinean species) are currently becoming more important in the pet trade (Weiperth et al. 2020), considering also the ban of the red swamp crayfish *Procambarus clarkii* and marbled crayfish *P. virginalis*.

## SECTION B – Detailed assessment

### Important instructions:

- In the case of lack of information the assessors are requested to use a standardized answer: “No information has been found.” In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable).
- With regard to the scoring of the likelihood of events or the magnitude of impacts see Annexes I and II.
- With regard to the confidence levels, see Annex III.
- Highlight the selected response score and confidence level in **bold** but keep the other scores in normal text (so that the selected score is evident in the final document).

## 1 PROBABILITY OF INTRODUCTION AND ENTRY

### Important instructions:

- **Introduction** is the movement of the species into the risk assessment area (it may be either in captive conditions and/or in the environment, depending on the relevant pathways).
- **Entry** is the release/escape/arrival in the environment, i.e. occurrence in the wild
- Introduction and entry may coincide for species entering through pathways such as “corridor” or “unaided”, but it also may differ. If different, please consider all relevant pathways, both for the introduction into the risk assessment area and the entry in the environment.
- The classification of pathways developed by the Convention of Biological Diversity (CBD) should be used (see Annex IV). For detailed explanations of the CBD pathway classification scheme consult the IUCN/CEH guidance document<sup>5</sup> and the provided key to pathways<sup>6</sup>.
- For organisms which are already present (recorded or established) in the risk assessment area, the likelihood of introduction and entry should be scored as “very likely” by default.
- Repeated (independent) introductions and entries at separate locations in the risk assessment area should be considered here (see Qu. 1.7).

**Qu. 1.1. List relevant pathways through which the organism could be introduced into the risk assessment area and/or enter into the environment. Where possible give details about the specific origins and end points of the pathways as well as a description of any associated commodities.**

For each pathway answer questions 1.2 to 1.8 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 1.2a, 1.3a, etc. and then 1.2b, 1.3b etc. for the next pathway.

In this context a pathway is the route or mechanism of introduction and/or entry of the species.

<sup>5</sup> <https://circabc.europa.eu/sd/a/7e5f0bd4-34e8-4719-a2f7-c0cd7ec6a86e/2020-CBD-pathways-interpretation.pdf>

<sup>6</sup> <https://circabc.europa.eu/sd/a/0aeba7f1-c8c2-45a1-9ba3-bcb91a9f039d/TSSR-2016-010%20CBD%20pathways%20key%20full%20only.pdf>

The description of commodities with which the introduction of the species is generally associated shall include a list and description of commodities with an indication of associated risks (e.g. the volume of trade; the likelihood of a commodity being contaminated or acting as vector).

If there are no active pathways or potential future pathways this should be stated explicitly here, and there is no need to answer the questions 1.2-1.9.

Pathway name: Escape from confinement: **Aquaculture / mariculture; Pet/aquarium/terrarium species** (including live food for such species); **Live food and bait**.

The species has been introduced in Spain, France and Italy for aquaculture purposes (Bolea 1996; D’Agaro et al. 1999; Souty-Grosset et al. 2006; Scalici et al. 2009; Kouba et al. 2014; Collas 2020). The species is considered as a delicacy, being sold live for restaurants in Germany and other countries such as Switzerland and England (Souty-Grosset et al. 2006).

The “ornamental” trade became active after its first introduction in Europe (Chucholl 2013; Weiperth et al. 2019) and could lead to repeated introductions (as it probably happened for Ireland: Julian Reynolds, pers. comm) as the specimens for this purpose could be reproduced and sold within Europe. Indeed, hobbyists are always looking for new crayfish species/morphs to have in their aquaria, with the Czech Republic being the hub for freshwater ornamental animals in Europe (Patoka et al. 2015).

**Escape from confinement: Aquaculture / mariculture**

**Qu. 1.2a. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	<b>intentional</b>	<b>CONFIDENCE</b>	low
	unintentional		medium
			<b>high</b>

Response: The species was introduced into the risk assessment area for aquaculture purposes, and it is still farmed in some countries such as Italy (Kouba et al. 2014). The entry into the environment could have been intentional too, but unintentional escapes cannot be ruled out.

**Qu. 1.3a. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent

establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Even if the introduction of crayfish as food and bait in Europe has decreased in importance through the years (Kouba et al. 2014), the species is still farmed in some areas. Considering the possibility of repeated and independent introductions via this pathway, the probability of introducing a large number of individuals is moderately likely. However, we cannot discard the possibility that also few individuals would be sufficient to establish a new viable population, as happened in other invasive alien crayfish in Europe (e.g. *Faxonius immunis*; Kouba et al. 2014). Source of these repeated introductions could be individuals from Australia or other parts of the world where the species is farmed (e.g. Asia) or from individuals present in Europe (the last two situations happened for Spain; Souty-Grosset et al. 2006; Kouba et al. 2014). However, in Spain, this species is currently listed in the List of IAS of National Concern, thus, in theory, further introductions from and within this state should be very unlikely. According to Bolea (1996), 30 individuals were imported to Spain from Los Angeles in the introduction of 1983. No other data are available on numbers of crayfish introduced for aquaculture into other parts of the risk assessment area. The likelihood of reinvasion is also moderately likely because of the possible repeated use in aquaculture.

**Qu. 1.4a. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The species is established in the wild, proving that it can survive during the transport along this pathway (Kouba et al. 2014; Deidun et al. 2018). Reproduction and increase in number during the transport are unlikely, but it can reproduce once in the aquaculture facility.

**Qu. 1.5a. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely	<b>CONFIDENCE</b>	low medium
-----------------	---------------------------	-------------------	---------------

	moderately likely likely <b>very likely</b>		<b>high</b>
--	---	--	-------------

Response: No biosecurity measures target the species before and during the transport; on the contrary, there could be practices aimed at its long-term survival for further commercial exploitation. There could be border inspections for checking the introduction of crayfish already in the list of species of Union or Member States (e.g. Spain) concern, and possibly during these checks also *C. destructor* could be intercepted. But up to now no interceptions have been reported for this species. Also, there are no biosecurity measures for the entry, except for the procedures foreseen by the Regulation (EC) No 708/2007 when used in aquaculture.

**Qu. 1.6a. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: Theoretically, through this pathway, the introduction of the species into the risk assessment area should be detected as the final purpose is its breeding and trade. However, the species was previously detected in the wild only after its establishment (Bolea 1996; Scalici et al. 2009; Deidun et al. 2018), so there is high probability of being undetected in the wild in the first stages of the invasion process. It will be very likely to detect it only after establishing or when spreading. Its correct identification can also require an expert to confirm its presence.

**Qu. 1.7a. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated widespread ubiquitous	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--------------------------------------	-------------------	------------------------------

Response: Repeated introductions and entry are linked to aquaculture facilities, so possible introduction points and entry can be identified (see for example in Italy: D'Agaro et al. 1999).

**Qu. 1.8a. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The species entered the risk assessment area via this pathway, and it is still farmed in some areas (e.g. Italy), so we cannot completely discard the possibility that new escapes could be reported in the near future, as it already happened in Sicily in 2016 (Deidun et al. 2018).

**Escape from confinement: Pet/aquarium/terrarium species (including live food for such species)**

**Qu. 1.2b. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	intentional unintentional	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	------------------------------	-------------------	------------------------------

Response: For this pathway, as happened for other *Cherax* species and alien crayfish, we consider the possibility of repeated and independent introductions in the risk assessment area and entries into the wild, as the species is present in the European ornamental trade (Chucholl 2013; Weiperth et al. 2019; E. Tricarico, unpublished, 2021). The entry into the environment can be either intentional or unintentional, depending on whether it is the result of deliberate releases or accidental escapes.

**Qu. 1.3b. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely	<b>CONFIDENCE</b>	low <b>medium</b>
-----------------	---------------------------	-------------------	----------------------

	moderately likely <b>likely</b> very likely		high
--	---	--	------

Response: The species is used as an ornamental species in Europe (Chucholl 2013; Weiperth et al. 2019), and it is commonly offered in the internet trade being appreciated by the hobbyists (Chucholl & Wendler 2017). Source of these repeated introductions could be specimens from populations established in Europe or present in aquaculture and e-commerce. For introductions and entry, we can hypothesize few crayfish, as they are bought by a single person and then eventually released by them as unwanted pets. We cannot discard the possibility that few individuals can lead to a new viable population that could establish a new viable population as happened in other invasive alien crayfish in Europe (e.g. *Faxonius immunis*; Kouba et al. 2014). Likelihood of reinvasion is likely because of the use as pet and the possibility of owners dumping unwanted pets into the wild as probably happened in Ireland.

**Qu. 1.4b. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: As also testified by Irish introduction and other alien crayfish introduced for this purpose (and established in the wild) and the use of the species for ornamental reason (Kouba et al. 2014; Haubrock et al. 2021), it can survive during the transport along this pathway. There is no reproduction or increase in number during transport, but the species could reproduce during storage in aquaria under optimal conditions.

**Qu. 1.5b. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: No biosecurity measures target the species before and during the transport; on the contrary, there could be practices aimed at its long-term survival for further commercial exploitation. There could be border inspections for checking the introduction of crayfish already in the list of species of

Union or Member State (e.g. Spain) concern, and possibly during these checks also *C. destructor* could be intercepted. But up to now no interceptions have been reported for this species. Also, there are no biosecurity measures for the entry except for the code of conduct on IAS and pets.

**Qu. 1.6b. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: Pet owners can purchase the species online without previous indications on the hazards and potential implications of its invasiveness by sellers and can purposely release individuals into the wild, so the species is usually detected only once established. This has happened probably for the Irish introduction and also for many other invasive crayfish present in Europe (e.g. the marbled crayfish *Procambarus virginalis* Kouba et al. 2014, or redclaw crayfish *C. quadricarinatus* Haubrock et al. 2021). Its correct identification can also require an expert to confirm its presence.

**Qu. 1.7b. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: As there are no trade restrictions within the risk assessment area (except Spain and the UK) and it can be purchased online, its repeated introductions and entries could be widespread, being linked to release by private citizens potentially in all ponds, lakes, rivers and other suitable water bodies wherever they can have access. Urban and especially thermal waters are in general more prone to the disposal of unwanted pets (Chucholl 2015; Patoka et al. 2016; Weiperth et al. 2017).

**Qu. 1.8b. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

	very likely		
--	-------------	--	--

Response: The species is common in ornamental trade (see for example Italy, Czech Republic, Germany, Hungary: Chucholl & Wendler 2017; Weiperth et al. 2019), so the probability of repeated introductions is likely.

**Escape from confinement: Live food and bait**

**Qu. 1.2c. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	<b>intentional</b>	<b>CONFIDENCE</b>	low
	unintentional		medium
			<b>high</b>

Response: The species has been intentionally sold live for restaurants in Germany and other countries such as Switzerland and England (Souty-Grosset et al. 2006; Kouba et al. 2014). The entry into the environment could be intentional, but unintentional escapes are also possible.

**Qu. 1.3c. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
	unlikely		<b>medium</b>
	<b>moderately likely</b>		high
	likely		
	very likely		

Response: Even if the introduction of crayfish as live food and bait in Europe has decreased in importance through the years (Kouba et al. 2014), the species has been reported in fish markets. Considering the possibility of repeated and independent introductions via this pathway, the probability

of introducing a large number of individuals is moderately likely. However, we cannot discard the possibility that also few individuals would be sufficient to establish a new viable population, as happened in other invasive alien crayfish in Europe (e.g., *Faxonius immunis*; Kouba et al. 2014). The source of these repeated introductions could be individuals from aquaculture facilities in native and non-native range in Australia or other parts of the world where the species is farmed (e.g., Asia) or from individuals present in European aquaculture facilities (Souty-Grosset et al. 2006; Kouba et al. 2014). No data are available of numbers of crayfish introduced as live food into the risk assessment area. The likelihood of reinvasion is also moderately likely because of the possible repeated use in aquaculture.

**Qu. 1.4c. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The species has been reported live in fish markets, proving that it can survive during the transport along this pathway (Kouba et al. 2014). Moreover, other crayfish introduced for this purpose (e.g. the congeneric *Cherax quadricarinatus*) have been reported to survive along this pathway and arrive into the wild (Kouba et al. 2014). Reproduction and increase in number during transport are unlikely.

**Qu. 1.5c. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: No biosecurity measures are targeting the species before and during the transport; on the contrary, there could be practices aimed at its long-term survival for further human consumption and commercial exploitation. There could be border inspections for checking the introduction of crayfish already in the list of species of Union and Member State (e.g. Spain) concern, and possibly during these checks also *C. destructor* could be intercepted. But up to now no interceptions have been reported for this species. Also, there are no biosecurity measures for the entry except for eventual veterinary inspections for specimens coming from third countries.

**Qu. 1.6c. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: Other crayfish species introduced via this pathway (e.g. *Faxonius immunis*: Kouba et al. 2014; *Procambarus clarkii* in France, Oficialdegui et al. 2020) have been detected in the wild only after their establishment. So there is a high probability of the species being detected in the wild only after establishing or when spreading. Its correct identification can also require an expert to confirm its presence.

**Qu. 1.7c. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: Repeated introductions and entry are linked to fish markets and individuals released by sellers or fishermen, respectively. Possible points of introduction and entry can be widespread and often close to urban settlements as for unwanted pets (Weiperth et al. 2017).

**Qu. 1.8c. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: The species has already been reported in fish markets in the risk assessment area, so we cannot entirely discard the possibility of an introduction through this pathway, even if aquaculture and pet trade are more common pathways (Kouba et al. 2014).

**Qu. 1.9. Estimate the overall likelihood of introduction into the risk assessment area or entry into the environment based on all pathways and specify if different in relevant biogeographical regions in current conditions.**

Provide a thorough assessment of the risk of introduction in relevant biogeographical regions in current conditions: providing insight into the risk of introduction into the risk assessment area.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The species is already present in aquaculture facilities in the Mediterranean biogeographic region and sold in markets in Continental and Atlantic biogeographic regions (e.g., Kouba et al. 2014; Deidun et al. 2018; Collas 2020). Besides, being a species present in e-commerce, it could be sold all across the risk assessment area, hence all biogeographic regions are (potentially) affected regarding introduction and entry.

**Qu. 1.10. Estimate the overall likelihood of introduction into the risk assessment area or entry into the environment based on all pathways in foreseeable climate change conditions?**

Thorough assessment of the risk of introduction in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of introduction (e.g. change in trade or user preferences)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely introduction within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: It is a species adapted to a warm climate, we can expect that it could be still used in aquaculture and pet trade also in the future.

## 2 PROBABILITY OF ESTABLISHMENT

### Important instructions:

- For organisms which are already established in parts of the risk assessment area or have previously been eradicated, the likelihood of establishment should be scored as “very likely” by default.
- Discuss the risk also for those parts of the risk assessment area, where the species is not yet established.

**Qu. 2.1. How likely is it that the organism will be able to establish in the risk assessment area based on similarity of climatic and abiotic conditions in its distribution elsewhere in the world?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The species is already established in the risk assessment area (Kouba et al. 2014; Deidun et al. 2018; Collas 2020). In Australia it inhabits areas with temperate and tropical climates (characterized by high summer temperatures and low annual rainfall: Souty-Grosset et al. 2006). However, from a laboratory study, Veselý et al. (2015) showed that it can withstand low winter temperatures typical of lentic habitats in the European temperate zone, thus posing a risk of establishment also to these areas besides the Mediterranean one.

**Qu. 2.2. How widespread are habitats or species necessary for the survival, development and multiplication of the organism in the risk assessment area? Consider if the organism specifically requires another species to complete its life cycle.**

<b>RESPONSE</b>	very isolated isolated moderately widespread <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: The habitats required for survival and reproduction are widespread as the species can colonize a wide range of habitats (alpine streams, subtropical creeks, springs, billabongs, ephemeral lakes, swamps, irrigation ditches: Beatty et al. 2005; Souty-Grosset et al. 2006).

**Qu. 2.3. How likely is it that establishment will occur despite competition from existing species in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Interspecific aggressive interactions between *C. destructor* and other crayfish species have not yet been studied in the wild in the risk assessment area. However, recent laboratory studies showed that the species is dominant over the marbled crayfish *P. virginalis*, already proved to outcompete other alien crayfish present in Europe such as *P. clarkii*, *Faxonius limosus* and *F. immunis* (e.g. Hossain et al. 2019). Indeed, in interspecific agonistic encounters *C. destructor* won a significantly higher percentage of fights against *P. virginalis* (but not against signal crayfish *Pacifastacus leniusculus*: Fořt et al. 2019) and at 22°C, in mixed stocks of juveniles of *C. destructor* and *P. virginalis*, the former grew faster and reached higher survival rate (Kouba et al. 2021a). In any case, the species did manage to establish successfully in Italy, France, Ireland and Spain. *Cherax destructor* has chelae of considerable size (Austin & Knott 1996), and we can hypothesize that it could outcompete other European native and non-native crayfish.

**Qu. 2.4. How likely is it that establishment will occur despite predators, parasites or pathogens already present in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: North American crayfish species present in Europe can carry the crayfish plague caused by the oomycete *Aphanomyces astaci*: *C. destructor* is susceptible to the crayfish plague, and, if it comes in contact with them or water contaminated with spores, it can die, as happened in Italy (Mazza et al. 2018). Moreover, four populations in Spain were intentionally eradicated using this disease (Kouba et al. 2014). However, Mrugala et al. (2016) in laboratory experiments found that *C. destructor* individuals exposed to the least virulent *A. astaci* strain (genotype group A) can partly survive and that not all the individuals died after being infected with the two more virulent strains (genotype B and E). Furthermore, compared to the native noble crayfish *Astacus astacus* also tested in the study, the mortality of *C. destructor* was significantly delayed. Based on these results, the authors suggested that under favourable conditions (e.g. fluctuations of spore concentration), *C. destructor* may survive and contribute to crayfish plague spread in Central Europe.

As with other crayfish species, birds, fish, terrapins, and aquatic mammals can predate the species (Withnall 2000), but they do not significantly impact the establishment of populations, as they usually

do not cause its extinction. Eventually, the established populations in Spain, France, Ireland and Italy demonstrate that they can establish permanent populations despite resident fish and birds, or mammals (otters).

**Qu. 2.5. How likely is the organism to establish despite existing management practices in the risk assessment area? Explain if existing management practices could facilitate establishment.**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Management practices that promote the commercial use of alien crayfish as a product, e.g. for human consumption or pet trade, may facilitate establishment (Kouba et al. 2014). Management practices in the environment, e.g. ecosystem restoration via the creation of ecological corridors and connections between water bodies, can favour the spread and establishment of the species, as, for example, happened for the red swamp crayfish *Procambarus clarkii* in Italy (Mazza et al. 2018).

**Qu. 2.6. How likely is it that biological properties of the organism would allow it to survive eradication campaigns in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The likelihood of surviving eradication campaigns depends on the invaded habitat and the applied eradication methodology. As with all crayfish species, eradication is very challenging: this species is difficult to detect at low densities, it cannot be easily removed by only physical means, and the use of crayfish plague as mean of eradication could have several impacts on native crayfish (Gherardi et al. 2011). Moreover, the species digs burrows and moves overland that can allow it to survive some physical and chemical management actions (Souty-Grosset et al. 2006), and has a high reproductive rate (Lawrence & Jones 2002) that facilitates the recovery of the population in case of incomplete eradication. Eradication from complex natural habitats, in particular streams and rivers, is not feasible due to a lack of effective targeted methods and prohibitive collateral damage of non-selective methods (e.g., crayfish plague) (Gherardi et al. 2011), plus the risk of recolonisation.

**Qu. 2.7. How likely are the biological characteristics of the organism to facilitate its establishment in the risk assessment area?**

including the following elements:

- a list and description of the reproduction mechanisms of the species in relation to the environmental conditions in the risk assessment area
- an indication of the propagule pressure of the species (e.g. number of gametes, seeds, eggs or propagules, number of reproductive cycles per year) of each of those reproduction mechanisms in relation to the environmental conditions in the risk assessment area.
- If relevant, comment on the likelihood of establishment based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in establishment whereas for others high propagule pressure (many thousands of individuals) may not.
- If relevant, comment on the adaptability of the organism to facilitate its establishment and if low genetic diversity in the founder population would have an influence on establishment.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The species is omnivorous and opportunistic (Souty-Grosset et al. 2006). Plant material and detritus seem to be the main component of its diet, followed by a low proportion of arthropods, algae and fungi (Lawrence & Jones 2002; Souty-Grosset et al. 2006; Linton et al. 2009), but predation on small fish has been documented as well (Beatty 2006). It is an r-selected species: it has a high growth rate, with early maturity occurring also before one year of age (Lawrence & Jones 2002). The life span is three years, possibly up to six years (Souty-Grosset et al. 2006). In its native range in Australia, with water temperature above 15°C, the species reproduce from early spring to early summer: a female can produce from 30 to 450 eggs, for an average of 350 (Lawrence & Jones 2002). In case of constant water temperatures between 18°C and 20°C and artificial light of 14 hours, a female can spawn five times per year (Lawrence & Jones 2002; Souty-Grosset et al. 2006). It can construct burrows (0.5-2m deep) to survive during the drought (Withnall 2000). It is adapted to a wide range of water temperatures (1°C-35°C), and it can naturally disperse within the same basin (Souty-Grosset et al. 2006). Anecdotal reports suggest that *C. destructor* emerges from hypoxic water and migrates between waterbodies (Morris & Callaghan 1998). From laboratory study, Veselý, et al. (2015) showed that *C. destructor* can withstand low winter temperatures typical of lentic habitats in the European temperate zone, thus posing a serious threat to these areas. We do not have any data on propagule pressure. Still, we cannot discard the possibility that few individuals can establish viable populations. Thus, the founder's genetics could not influence its establishment as happened in other introduced crayfish in Europe (e.g. the parthenogenetic marbled crayfish *P. virginialis* and the spinycheek crayfish *F. limosus*: Kouba et al. 2014).

Beatty et al. (2005) studied the population and reproductive biology of a translocated Western Australian population of *C. destructor*: the species matured at the end of its first year of life, have a protracted spawning period (July-January), a high fecundity (210 eggs on average) and fast growth rate.

**Qu. 2.8. If the organism does not establish, then how likely is it that casual populations will continue to occur?**

Consider, for example, a species which cannot reproduce in the risk assessment area, because of unsuitable climatic conditions or host plants, but is present because of recurring introduction, entry and release events. This may also apply for long-living organisms.

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Continuous escape from aquaculture and/or escape/release of the species as unwanted pet in climatically unsuitable regions is likely to occur and may lead to casual populations in these areas as happened to the congeneric *Cherax quadricarinatus* (Kouba et al. 2014; Haubrock et al. 2021).

**Qu. 2.9. Estimate the overall likelihood of establishment in the risk assessment area under current climatic conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under current climatic conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in current conditions: providing insight in the risk of establishment in (new areas in) the risk assessment area.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The species is already established in the Mediterranean and Atlantic biogeographic region (Kouba et al. 2014). According to the model developed on current climate (Annex VIII), the species could find many suitable areas to establish permanent populations in the Atlantic and Mediterranean biogeographic regions, while very few suitable areas are present in the Black Sea and Continental biogeographic regions, even if the importance of thermal waters in these areas as sink/source of alien crayfish should not be discarded.

**Qu. 2.10. Estimate the overall likelihood of establishment in the risk assessment area under foreseeable climate change conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under foreseeable climate change conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of establishment (e.g. increase in average winter temperature, increase in drought periods)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely establishment within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: The species is adapted to a warm climate and, according to the SDM (2070 RCP 2.6/RCP 4.5; Annex VIII), the areas suitable for the species will increase in the Atlantic biogeographic region (while a small decrease could happen in the Mediterranean biogeographic region), while they will remain almost the same for the Black Sea and Continental biogeographic regions. The minimum temperature of the coldest month is currently limiting the establishment in the northern and coldest biogeographic regions (but apparently not in the coastal areas of some Member States such as Ireland and France), so with a warmer climate we can expect an increase in the establishment.

### 3 PROBABILITY OF SPREAD

**Important instructions:**

- Spread is defined as the expansion of the geographical distribution of an alien species within the risk assessment area.
- Repeated releases at separate locations do not represent continuous spread and should be considered in the probability of introduction and entry section (Qu. 1.7).

**Qu. 3.1. How important is the expected spread of this organism within the risk assessment area by natural means? (List and comment on each of the mechanisms for natural spread.)**

including the following elements:

- a list and description of the natural spread mechanisms of the species in relation to the environmental conditions in the risk assessment area.
- an indication of the rate of spread discussed in relation to the species biology and the environmental conditions in the risk assessment area.

The description of spread patterns here refers to the CBD pathway category “Unaided (Natural Spread)”. It should include elements of the species life history and behavioural traits able to explain its ability to spread, including: reproduction or growth strategy, dispersal capacity, longevity, dietary requirements, environmental and climatic requirements, specialist or generalist characteristics.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: Currently, the species is restricted to a few locations in the risk assessment area. There are no detailed studies on its locomotory activity, but it can naturally disperse within the same basin (Souty-Grosset et al. 2006). In the introduced range of Western Australia, it is reported that in 1982 it was found for the first time in the wild, and in three years colonized many sites, showing a continuous spread (Austin 1985; Lynas et al. 2004). Its current distribution occurs from Hutt River in the north to Esperance in the southeast of Australia (Morrissy & Cassells 1992; Horwitz & Knott 1995; Beatty et al. 2005). As reported, anecdotal reports suggest that *C. destructor* emerges from hypoxic water and migrates between waterbodies (Morris & Callaghan 1998), which may increase chances to spread across different water bodies.

The species can colonize a wide range of habitats (alpine streams, subtropical creeks, springs, billabongs, ephemeral lakes, swamps, irrigation ditches: Beatty et al. 2005; Souty-Grosset et al. 2006), digging burrows to survive during the drought and the winter (Withnall 2000; Veselý et al. 2015; Kouba et al. 2016). It is adapted to a wide range of water temperatures (1°C - 35°C). It can tolerate salinity (up to 8 ppt: Mills & Geddes 1980) and hypoxic waters (oxygen concentration <1 mg L<sup>-1</sup>: Morrissy & Cassells 1992). Optimal pH is comprised between 7.5 and 8.5 (CABI 2011). The species is omnivorous and opportunistic (Souty-Grosset et al. 2006); it has a high growth rate, with early maturity also occurring before one year of age (Lawrence & Jones 2002). The life span is three years,

possibly up to six years (Souty-Grosset et al. 2006), and a female can produce from 30 to 450 eggs, for an average of 350 (Lawrence & Jones 2002).

**Qu. 3.2a. List and describe relevant pathways of spread other than "unaided". For each pathway answer questions 3.3 to 3.9 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 3.3a, 3.4a, etc. and then 3.3b, 3.4b, etc. for the next pathway.**

including the following elements:

- a list and description of pathways of spread with an indication of their importance and associated risks (e.g. the likelihood of spread in the risk assessment area, based on these pathways; likelihood of survival, or reproduction, or increase during transport and storage; ability and likelihood of transfer from the pathway to a suitable habitat or host) in relation to the environmental conditions in the risk assessment area.
- an indication of the rate of spread for each pathway discussed in relation to the species biology and the environmental conditions in the risk assessment area.
- All relevant pathways of spread (except “Unaided (Natural Spread)”, which is assessed in Qu. 3.1) should be considered. The classification of pathways developed by the Convention of Biological Diversity shall be used (see Annex IV).

**Pathway name: Corridor (Interconnected waterways/basins/seas)**

**Qu. 3.3a. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional	<b>CONFIDENCE</b>	low
	<b>unintentional</b>		medium
			<b>high</b>

Response: There are interconnected rivers and basins in the risk assessment area throughout human infrastructures (e.g., canals) so we cannot discard the possibility of the species spreading through this pathway, as happened for other crayfish species (e.g. *Faxonius* and *Procambarus* spp. Kouba et al. 2014).

**Qu. 3.4a. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway

- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: There are no data on the propagule pressure, but, as shown by the natural spread of the species in the invaded range in Australia (Lynas et al. 2004), the species could also spread through this pathway. Some traits mentioned above – such as successful reproduction – could facilitate the spread. Reinvasion could happen, as the species seems capable to disperse also overland (Morris & Callaghan 1998).

**Qu. 3.5a. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: The species could survive along this pathway, as shown by its active dispersal in the invaded range in Australia (Lynas et al. 2004). It could even reproduce while spreading, as happened for other macroinvertebrates (Leuven et al. 2009).

**Qu. 3.6a. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Some barriers along the interconnected water bodies could slow the spread of species, but they would not affect its survival as showed in other alien crayfish (e.g., Krieg & Zenker 2020). Water drainage could potentially affect the survival of individuals, even if the species can withstand drought conditions remaining in the burrows..

**Qu. 3.7a. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Interconnected canals and rivers allowed the undetected spread of many invasive species in Europe (Panov et al. 2007, 2009); this could also happen for *C. destructor*.

**Qu. 3.8a. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: During natural dispersal in Australia (Lynas et al. 2004), the species usually arrives and settles in suitable habitats or moves on; the same could happen using this pathway.

**Qu. 3.9a. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area. (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: No quantitative data are available on the spread rate. Based on the situation observed in Australia (Lynas et al. 2004), we could hypothesise a moderate rate of dispersal using this pathway.

**Qu. 3.10. Within the risk assessment area, how difficult would it be to contain the organism in relation to these pathways of spread?**

<b>RESPONSE</b>	very easy easy <b>with some difficulty</b> difficult very difficult	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: Once in an aquatic system, it could be difficult to contain the species. Physical barriers have been tested on other alien crayfish, but they can also stop native species movement (Gherardi et al. 2011). Containment could be hypothesized for closed or almost confined systems: e.g. ponds or areas that could be fenced. The use of pyrethroids is not always feasible for their toxicity to other non-target species and to be effective against *C. destructor* a higher dose than other alien crayfish is required (Lidova et al. 2019).

**Qu. 3.11. Estimate the overall potential rate of spread in relevant biogeographical regions under current conditions for this organism in the risk assessment area (indicate any key issues and provide quantitative data where possible).**

Thorough assessment of the risk of spread in relevant biogeographical regions in current conditions, providing insight in the risk of spread into (new areas in) the risk assessment area.

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: According to what was reported for invaded areas in Australia (Lynas et al. 2004), we can hypothesize that species can moderately spread by natural means in the Mediterranean biogeographic region where it is currently present. Moreover, we should also consider that this area is occupied by North American crayfish species, especially *P. clarkii*, carrying highly virulent strains of *A. astaci* to which *C. destructor* is susceptible and that could act as a sort of barrier for the species dispersal.

**Qu. 3.12. Estimate the overall potential rate of spread in relevant biogeographical regions in foreseeable climate change conditions (provide quantitative data where possible).**

Thorough assessment of the risk of spread in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk, specifically if rates of spread are likely slowed down or accelerated.

<b>RESPONSE</b>	very slowly	<b>CONFIDENCE</b>	<b>low</b>
-----------------	-------------	-------------------	------------

	slowly <b>moderately</b> rapidly very rapidly		medium high
--	--	--	----------------

Response: As climate change will favour the species, we can hypothesize that in the future the species can spread by natural means at least similar to the current spread rates, considering also the presence of North American crayfish carrying highly virulent *A. astaci* strain.

## 4 MAGNITUDE OF IMPACT

Important instructions:

- Questions 4.1-4.5 relate to biodiversity and ecosystem impacts, 4.6-4.8 to impacts on ecosystem services, 4.9-4.13 to economic impact, 4.14-4.15 to social and human health impact, and 4.16-4.18 to other impacts. These impacts can be interlinked, for example, a disease may cause impacts on biodiversity and/or ecosystem functioning that leads to impacts on ecosystem services and finally economic impacts. In such cases the assessor should try to note the different impacts where most appropriate, cross-referencing between questions when needed.
- Each set of questions starts with the impact elsewhere in the world, then considers impacts in the risk assessment area (=EU27+UK excluding outermost regions) separating known impacts to date (i.e. past and current impacts) from potential future impacts (including foreseeable climate change).
- Only negative impacts are considered in this section (socio-economic benefits are considered in Qu. A.7)
- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable).

### Biodiversity and ecosystem impacts

**Qu. 4.1. How important is the impact of the organism on biodiversity at all levels of organisation caused by the organism in its non-native range excluding the risk assessment area?**

including the following elements:

- Biodiversity means the variability among living organisms from all sources, including terrestrial, marine and other aquatic ecosystems and the ecological complexes of which they are part; this includes diversity within species, between species and of ecosystems
- impacted chemical, physical or structural characteristics and functioning of ecosystems

RESPONSE		CONFIDENCE	
	minimal		low
	minor		medium
	moderate		<b>high</b>
	<b>major</b>		
	massive		

Response: In non-native range in Australia, it is reported to have destroyed macrophytes, caused siltation, displaced the endemic crayfish *Euastacus dharawalus* and threatened 11 endemic crayfish of Western Australia (Gherardi 2010; Coughran & Daily 2012). Other potential impacts on fish, amphibians, dragonflies, snails and other invertebrates have been suggested (Beatty 2006; Lynas et al. 2004; Coughran & Daily 2012; Cerato et al. 2019). Moreover, laboratory studies conducted in Australia showed its aggressive and predatory behaviour towards tortoise hatchlings, hypothesizing possible negative impact on native endangered freshwater turtles (Bradsell et al. 2002).

**Qu. 4.2. How important is the current known impact of the organism on biodiversity at all levels of organisation (e.g. decline in native species, changes in native species communities, hybridisation) in the risk assessment area (include any past impact in your response)?**

Discuss impacts that are currently occurring or are likely occurring or have occurred in the past in the risk assessment area. Where there is no direct evidence of impact in the risk assessment area (for example no studies have been conducted), evidence from outside of the risk assessment area can be used to infer impacts within the risk assessment area.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: In the risk assessment area, up to now, no impacts have been reported. The species is possibly resistant to crayfish plague in some cases, becoming an additional vector of this disease that is lethal for European native crayfish (Mrugala et al. 2016). Moreover, we cannot discard other potential impacts as possible competition with native crayfish, considering its bigger chelae, and possible negative impacts on macroinvertebrates and macrophytes, being an omnivorous species (Souty-Grosset et al. 2006).

**Qu. 4.3. How important is the potential future impact of the organism on biodiversity at all levels of organisation likely to be in the risk assessment area?**

See comment above. The potential future impact shall be assessed only for the risk assessment area. A potential increase in the distribution range due to climate change does not *per se* justify a higher impact score.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: According to the SDM (Annex VIII), the species will find more suitable climatic areas in the risk assessment area for its establishment in the future, especially in the Atlantic biogeographic region. Considering that the species is better adapted to warm climates, we cannot discard the hypothesis of a higher impact in the risk assessment area than under current conditions. Being an omnivorous species, it can cause a decrease in macrophyte cover, macroinvertebrates abundance and diversity, changing trophic interaction and community composition (Beatty 2006; Lynas et al. 2004; Coughran & Daily 2012; Cerato et al. 2019).

**Qu. 4.4. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism currently in the risk assessment area?**

including the following elements:

- native species impacted, including red list species, endemic species and species listed in the Birds and Habitats directives
- protected sites impacted, in particular Natura 2000
- habitats impacted, in particular habitats listed in the Habitats Directive, or red list habitats
- the ecological status of water bodies according to the Water Framework Directive and environmental status of the marine environment according to the Marine Strategy Framework Directive

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: In the risk assessment area, up to now, no impacts have been reported. The species is possibly resistant to crayfish plague in some cases, becoming an additional vector of this disease that is lethal for European native crayfish (Mrugala et al. 2016), listed in the Habitat Directive, such as the white-clawed crayfish, *Austropotamobius pallipes*, the stone crayfish *A. torrentium* and the noble crayfish *Astacus astacus*.

**Qu. 4.5. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.3. and 4.4.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: According to the SDM (Annex VIII), the species will find more suitable climatic areas in the risk assessment area in the future, so we can expect a major impact on conservation concern species and habitats as listed below.

Impact on native crayfish species listed in the Habitat Directive, such as the white-clawed crayfish, *Austropotamobius pallipes*, the stone crayfish *A. torrentium* and the noble crayfish *Astacus astacus*, could be significant through disease if *C. destructor* can survive and transmit the crayfish plague, lethally affecting native species (Mrugala et al. 2016). Moreover, several other diseases causing severe mortalities (specifically viruses) and other parasites are known mainly in aquaculture and pet trade of *Cherax* species, *C. destructor* included (e.g. Haubrock et al. 2021; Ložek et al. 2021) but their potential spillover on native crayfish has not yet been assessed and cannot be completely discarded.

Finally, *C. destructor* has chelae of considerable size (Austin & Knott 1996), and, based on laboratory experiments conducted on interspecific conditions with other alien crayfish (Fořt et al. 2019; Kouba et al. 2021a), we can hypothesize that it can outcompete native crayfish. The impact could also be significant on native macroinvertebrates (e.g. snails, odonates *Leucorrhinia caudalis*, *Ophiogomphus cecilia*, both species in the European Red List of Dragonflies and in the Habitat Directive), amphibians and reptiles (e.g. *Triturus* spp., *Rana* spp. in the Habitat Directive). All invaded habitats could be affected due to the species consumption of macroinvertebrates and macrophytes, in addition to burrowing and siltation. In this way, it could alter the ecological status of water bodies according to the Water Framework Directive. It could have negative effects on protected areas, potentially affecting habitats and species listed in the Habitat Directive (e.g. 3150 Natural eutrophic lakes with *Magnopotamion* or *Hydrocharition*; 3270 Rivers with muddy banks with *Chenopodion rubri* pp and *Bidention* pp vegetation; abovementioned dragonflies, reptiles and crayfish).

## Ecosystem Services impacts

**Qu. 4.6. How important is the impact of the organism on provisioning, regulating, and cultural services in its non-native range excluding the risk assessment area?**

- For a list of services use the CICES classification V5.1 provided in Annex V.
- Impacts on ecosystem services build on the observed impacts on biodiversity (habitat, species, genetic, functional) but focus exclusively on reflecting these changes in relation to their links with socio-economic well-being.
- Quantitative data should be provided whenever available and references duly reported.
- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”.

RESPONSE		CONFIDENCE	
	minimal		low
	minor		<b>medium</b>
	moderate		high
	<b>major</b>		
	massive		

Response: In the Australian introduced range, being a burrowing species, together with damage to riverbanks, siltation is reported together with destruction of macrophytes (Coughran & Daily 2012) with possible cascading effects on native species and ecosystem services (e.g. regulating services: baseline flows and extreme event regulation, water quality, soil quality regulation; provisioning services: wild plants and wild animals; cultural services: intellectual and representative interactions with natural environment considering the impact on local fauna and flora, and on native endangered crayfish species important for local people).

**Qu. 4.7. How important is the impact of the organism on provisioning, regulating, and cultural services currently in the different biogeographic regions or marine sub-regions where**

**the species has established in the risk assessment area (include any past impact in your response)?**

- See guidance to Qu. 4.6.

<b>RESPONSE</b>	N/A minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: No information has been found on the issue. In the risk assessment area, up to now no impacts on ecosystem services have been reported.

**Qu. 4.8. How important is the impact of the organism on provisioning, regulating, and cultural services likely to be in the different biogeographic regions or marine sub-regions where the species can establish in the risk assessment area in the future?**

- See guidance to Qu. 4.6.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: According to the predictive climatic models, the species will find more suitable climatic areas in the risk assessment area in the future (see Annex VIII), so we can expect major impacts on ecosystem services. Indeed, being a burrowing species, it can damage riverbanks leading to soil erosion and changes in sediments (regulating services: baseline flows and extreme event regulation; soil quality regulation), while the increase in turbidity can have a cascade effect on native species, primary production and trophic chains (provisioning services: wild plants and wild animals) and water quality (regulating services: water conditions, and provisioning services: water quality), as recorded for other invasive alien crayfish intensively burrowing in Europe (e.g. *Procambarus clarkii*; Souty-Grosset et al. 2016). Also, cultural services can be impacted because turbid ponds do not attract people (physical and experiential interactions with natural environment), and the species alters the pristine characteristics of the habitat and community composition (intellectual and representative interactions with natural environment).

## Economic impacts

**Qu. 4.9. How great is the overall economic cost caused by the organism within its current area of distribution (excluding the risk assessment area), including both costs of / loss due to damage and the cost of current management.**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the world these should be reported here. The assessment of the potential costs of / loss due to damage shall describe those costs quantitatively and/or qualitatively depending on what information is available. Cost of / loss due to damage within different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage. As far as possible, it would be useful to separate costs of / loss due to the organism from costs of current management.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: For Australia, Frost (1975) reported that “the burrows could destroy the integrity of dam walls” and Williams (1980) reported that “Many...construct burrows into which they retreat with the onset of unfavourable conditions. It is these burrows which are often so much of a nuisance in farm dams where they may cause the collapse of retaining walls and drainage canals”. “There are, however, indications that the reported damage to irrigation facilities occurs only under certain conditions” (de Moor 2002). No detailed information has been found for the costs of damaged banks and their management (see Kouba et al. 2021b). It is also considered a threat for the fishery of the congeneric *C. tenuimanus* and *C. cainii* (Souty-Grosset et al. 2006).

**Qu. 4.10. How great is the economic cost of / loss due to damage (excluding costs of management) of the organism currently in the risk assessment area (include any past costs in your response)?**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the EU these should be reported here. Assessment of the potential costs of damage on human health, safety, and the economy, including the cost of non-action. A full economic assessment at EU scale might not be possible, but qualitative data or different case studies from across the EU (or third countries if relevant) may provide useful information to inform decision making. In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable). Cost of / loss due to damage within different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>	N/A minimal	<b>CONFIDENCE</b>	low medium
-----------------	----------------	-------------------	---------------

	minor moderate major massive		high
--	---------------------------------------	--	------

Response: No information has been found on the issue. In the risk assessment area, up to now, no economic impacts have been reported.

**Qu. 4.11. How great is the economic cost of / loss due to damage (excluding costs of management) of the organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.10.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: This depends on the time elapsed between the first introduction and when (and if) action is taken to control the species. If action is taken immediately to mitigate its spread, then costs could be relatively low (for example damage to banks would be limited), but if left to spread the costs would potentially be major (the costs linked to riverbanks could increase; increase of turbidity could also affect fish populations with a potential consequence on fishing activities).

**Qu. 4.12. How great are the economic costs / losses associated with managing this organism currently in the risk assessment area (include any past costs in your response)?**

- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable).

<b>RESPONSE</b>	<b>minimal</b> minor moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: Even if no detailed costs have been found on the issue in the risk assessment area (Kouba et al. 2021b, we can hypothesize a minimal cost for the eradication of the species in Spain using crayfish plague: indeed, cages containing individuals of either *C. destructor* infected in the laboratory or signal crayfish *Pacifastacus leniusculus* with severe signs of infection were introduced into the invaded ponds (Gherardi et al. 2011).

**Qu. 4.13. How great are the economic costs / losses associated with managing this organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.12.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: If action is taken immediately to mitigate its spread, then costs could be relatively low, but if left to spread, the costs would potentially be major. Considering management activities on other invasive alien crayfish in Europe, intensive trapping an area of 10,000 m<sup>2</sup> with 120 traps for 171 trap days could cost approximately 30,000 euro to reduce species abundance by at least 70%. But intensive trapping should be permanently maintained through time. Eradication of crayfish from a water body of 19,000 m<sup>2</sup> could cost around 46,500 euro of biocides. Drainage at least once of a pond of approximately 400,000 m<sup>3</sup> could cost around 40-50,000 euro (E. Tricarico, unpublished, 2021). Costs are estimated based on the experience with measures targeting other invasive crayfish present in the risk assessment area. Costs of using crayfish plague could be lower, but with potentially adverse effects on native European crayfish.

## Social and human health impacts

**Qu. 4.14. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism for the risk assessment area and for third countries, if relevant (e.g. with similar eco-climatic conditions).**

The description of the known impact and the assessment of potential future impact on human health, safety and the economy, shall, if relevant, include information on

- illnesses, allergies or other affections to humans that may derive directly or indirectly from a species;
- damages provoked directly or indirectly by a species with consequences for the safety of people, property or infrastructure;
- direct or indirect disruption of, or other consequences for, an economic or social activity due to the presence of a species.

Social and human health impacts can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>	minimal minor moderate major	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---------------------------------------	-------------------	------------------------------

	massive		
--	---------	--	--

Response: No human health impacts have been reported up to now. The risk of flooding might increase if dykes are destabilized by crayfish burrowing (e.g. *Procambarus clarkii*: Haubrock et al. 2019). Possible risks could come from consumption of crayfish caught in contaminated waters by e.g. heavy metals as happened in other crayfish (e.g. the red swamp crayfish *P. clarkii*: Anandkumar et al. 2020).

**Qu. 4.15. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism in the future for the risk assessment area.**

- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable).

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: As in the future, the suitable areas for the species will increase we can hypothesize that risk of flooding might increase for crayfish burrowing because they actively dig, and this could lead to instability/collapse of banks, as already happened for a similar burrowing species *Procambarus clarkii* (Haubrock et al. 2019). The risk of consuming contaminated individuals could also persist similar to the current one.

## Other impacts

**Qu. 4.16. How important is the organism in facilitating other damaging organisms (e.g. diseases) as food source, a host, a symbiont or a vector etc.?**

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: If the species survives the crayfish plague, it could transmit it to European native crayfish (Mrugala et al. 2016). Moreover, we cannot discard the potential spillover of other diseases and parasites transmitted by the species.

**Qu. 4.17. How important might other impacts not already covered by previous questions be resulting from introduction of the organism?**

<b>RESPONSE</b>	N/A minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: No information has been found on the issue.

**Qu. 4.18. How important are the expected impacts of the organism despite any natural control by other organisms, such as predators, parasites or pathogens that may already be present in the risk assessment area?**

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: Even if fish and birds could predate on the species, they regulate the population to a low density level but do not cause extinction. Other invasive crayfish through the transmission of crayfish plague may slow the establishment and spread of the species, and maybe the impacts, but further studies are needed to assess this aspect (also because the species seems resistant to this disease in some cases).

**Qu. 4.19. Estimate the overall impact in the risk assessment area under current climate conditions. In addition, details of overall impact in relevant biogeographical regions should be provided.**

Thorough assessment of the overall impact on biodiversity and ecosystem services, with impacts on economy as well as social and human health as aggravating factors, in current conditions.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: No specific studies are available for the risk assessment area. However, studies from the Australian invaded range demonstrated potential and actual relevant ecological and economic impacts (reduction of macroinvertebrate abundance; decline of macrophytes; highly burrowing activity with damages to banks, impacts on fishery: Bradsell et al. 2002; Beatty 2006; Lynas et al. 2004; Coughran & Daily 2012; Cerato et al. 2019). Moreover, laboratory studies conducted in Europe showed the potential to withstand low temperatures and survival of crayfish plague, becoming an additional vector of the disease (Veselý et al. 2015; Kouba et al. 2016; Mrugala et al. 2016, 2019), and the possibility to outcompete native crayfish (e.g. Fořt et al. 2019; Kouba et al. 2021a). Thus, we can hypothesise moderate impacts under current climate in the Mediterranean and Atlantic biogeographic region.

**Qu. 4.20. Estimate the overall impact in the risk assessment area in foreseeable climate change conditions. In addition, details of overall impact in relevant biogeographical regions should be provided.**

Thorough assessment of the overall impact on biodiversity and ecosystem services, with impacts on economy as well as social and human health as aggravating factors, under future conditions.

- See also guidance to Qu. 4.3.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: As the species will find more suitable areas for establishment in the future (see Annex VIII), we can expect its impacts to be major in the future, especially in Atlantic and Mediterranean biogeographic regions.

<b>RISK SUMMARIES</b>			
	<b>RESPONSE</b>	<b>CONFIDENCE</b>	<b>COMMENT</b>
<b>Summarise Introduction and Entry*</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	low medium <b>high</b>	The species was already introduced in the risk assessment area via pet trade, aquaculture, and live food. It also entered into the wild intentionally and unintentionally. It is expected that in the future, due to its tolerance to warm climate and the increasing use of colourful crayfish species in aquaria, it could be still used in aquaculture and pet trade.
<b>Summarise Establishment*</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	low medium <b>high</b>	The species is already established in the Mediterranean and Atlantic biogeographic regions of the risk assessment area (France, Ireland, Spain and Italy since the late 1980s), and it is likely that under future climate it could establish also more in the Atlantic biogeographic region (and partly in few areas of the Black Sea and Continental biogeographic regions).
<b>Summarise Spread*</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	low <b>medium</b> high	The species is currently reported from few locations in the risk assessment area. Considering the favourable current and future climatic conditions and its capability to disperse unaided and via interconnected water basins, the species would be able to moderately spread as shown in the invaded range in Australia. In addition, their susceptibility (or not) to crayfish plague could interfere with the survival of individuals as they spread into other habitats already colonized by North American crayfish species.
<b>Summarise Impact*</b>	minimal minor moderate <b>major</b> massive	low <b>medium</b> high	No studies on impacts are available for the few locations of introduction in the risk assessment area. The studies on the impacts are from its Australian invaded range, but demonstrated ecological and economic impacts (reduction of macroinvertebrate abundance; decline of macrophytes; highly burrowing activity with damages to banks; impacts on fishery). A

			<p>study in Europe confirmed its susceptibility to crayfish plague with a certain resistance (that could allow the species to transmit it to European native crayfish with lethal consequences). The potential spillover of other lethal diseases and parasites carried by the species on native European crayfish cannot be completely discarded. Considering the current climate, we can expect moderate impacts in the risk assessment area, but even major impacts under the future climate.</p>
<p><b>Conclusion of the risk assessment (overall risk)</b></p>	<p>low moderate <b>high</b></p>	<p>low <b>medium</b> high</p>	<p>Based on the literature from Australia, its adaptability and the still active pathways (e.g. aquaculture and pet trade), we can expect that the species may establish wild populations and could pose a high risk to the biodiversity of the risk assessment area and cause also moderate economic damages in the future.</p>

\*in current climate conditions and in foreseeable future climate conditions

## Distribution Summary

Please answer as follows:

- Yes if recorded, established or invasive
- if not recorded, established or invasive
- ? Unknown; data deficient and/or?

The columns refer to the answers to Questions A5 to A12 under Section A.

For data on marine species at the Member State level, delete Member States that have no marine borders. In all other cases, provide answers for all columns.

### Member States and the United Kingdom

	Recorded	Established (currently)	Possible establishment (under current climate)	Possible establishment (under foreseeable climate)	Invasive (currently)
Austria	-	-			-
Belgium	-	-		YES	-

## **ANNEX I Scoring of Likelihoods of Events**

(taken from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

<b>Score</b>	<b>Description</b>	<b>Frequency</b>
Very unlikely	This sort of event is theoretically possible, but is never known to have occurred and is not expected to occur	1 in 10,000 years
Unlikely	This sort of event has occurred somewhere at least once in the last millenium	1 in 1,000 years
Moderately likely	This sort of event has occurred somewhere at least once in the last century	1 in 100 years
Likely	This sort of event has happened on several occasions elsewhere, or on at least once in the last decade	1 in 10 years
Very likely	This sort of event happens continually and would be expected to occur	Once a year

## ANNEX II Scoring of Magnitude of Impacts

(modified from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

Score	Biodiversity and ecosystem impact	Ecosystem Services impact	Economic impact (Monetary loss and response costs per year)	Social and human health impact, and other impacts
	<i>Question 5.1-5</i>	<i>Question 5.6-8</i>	<i>Question 5.9-13</i>	<i>Question 5.14-18</i>
Minimal	Local, short-term population loss, no significant ecosystem effect	No services affected <sup>7</sup>	Up to 10,000 Euro	No social disruption. Local, mild, short-term reversible effects to individuals.
Minor	Some ecosystem impact, reversible changes, localised	Local and temporary, reversible effects to one or few services	10,000-100,000 Euro	Significant concern expressed at local level. Mild short-term reversible effects to identifiable groups, localised.
Moderate	Measureable long-term damage to populations and ecosystem, but reversible; little spread, no extinction	Measureable, temporary, local and reversible effects on one or several services	100,000-1,000,000 Euro	Temporary changes to normal activities at local level. Minor irreversible effects and/or larger numbers covered by reversible effects, localised.
Major	Long-term irreversible ecosystem change, spreading beyond local area	Local and irreversible or widespread and reversible effects on one / several services	1,000,000-10,000,000 Euro	Some permanent change of activity locally, concern expressed over wider area. Significant irreversible effects locally or reversible effects over large area.
Massive	Widespread, long-term population loss or extinction, affecting several species with serious ecosystem effects	Widespread and irreversible effects on one / several services	Above 10,000,000 Euro	Long-term social change, significant loss of employment, migration from affected area. Widespread, severe, long-term, irreversible health effects.

<sup>7</sup> Not to be confused with “no impact”.

## ANNEX III Scoring of Confidence Levels

(modified from Bacher et al. 2017)

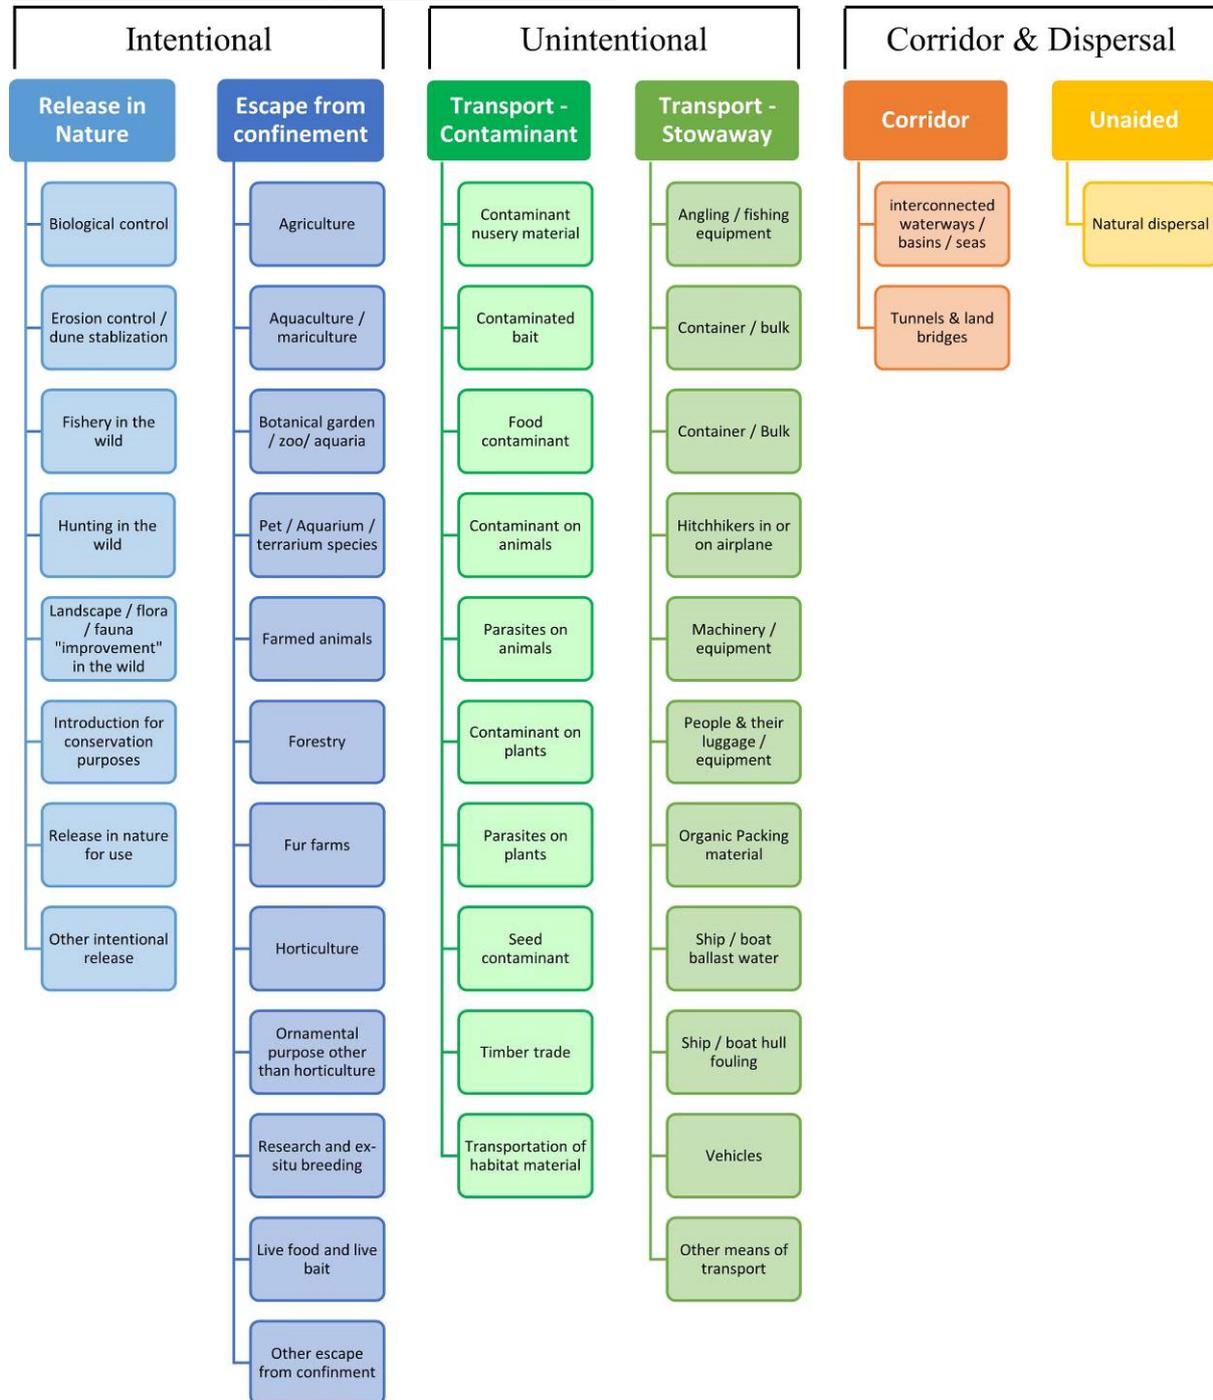

Each answer provided in the risk assessment must include an assessment of the level of confidence attached to that answer, reflecting the possibility that information needed for the answer is not available or is insufficient or available but conflicting.

The responses in the risk assessment should clearly support the choice of the confidence level.

<b>Confidence level</b>	<b>Description</b>
Low	There is no direct observational evidence to support the assessment, e.g. only inferred data have been used as supporting evidence <i>and/or</i> Impacts are recorded at a spatial scale which is unlikely to be relevant to the assessment area <i>and/or</i> Evidence is poor and difficult to interpret, e.g. because it is strongly ambiguous <i>and/or</i> The information sources are considered to be of low quality or contain information that is unreliable.
Medium	There is some direct observational evidence to support the assessment, but some information is inferred <i>and/or</i> Impacts are recorded at a small spatial scale, but rescaling of the data to relevant scales of the assessment area is considered reliable, or to embrace little uncertainty <i>and/or</i> The interpretation of the data is to some extent ambiguous or contradictory.
High	There is direct relevant observational evidence to support the assessment (including causality) <i>and</i> Impacts are recorded at a comparable scale <i>and/or</i> There are reliable/good quality data sources on impacts of the taxa <i>and</i> The interpretation of data/information is straightforward <i>and/or</i> Data/information are not controversial or contradictory.

## ANNEX IV CBD pathway categorisation scheme

Overview of CBD pathway categorisation scheme showing how the 44 pathways relate to the six main pathway categories. All of the pathways can be broadly classified into 1) those that involve intentional transport (blue), 2) those in which the taxa are unintentionally transported (green) and 3) those where taxa moved between regions without direct transportation by humans and/or via artificial corridors (orange and yellow). **Note that the pathways in the category “Escape from confinement” can be considered intentional for the introduction into the risk assessment area and unintentional for the entry into the environment.**

## ANNEX V Ecosystem services classification (CICES V5.1, simplified) and examples

For the purposes of this risk assessment, please feel free to use what seems as the most appropriate category / level / combination of impact (Section – Division – Group), reflecting information available.

Section	Division	Group	Examples (i.e. relevant CICES “classes”)
Provisioning	Biomass	<b>Cultivated terrestrial plants</b>	Cultivated terrestrial plants (including fungi, algae) grown for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from cultivated plants, fungi, algae and bacteria for direct use or processing (excluding genetic materials); Cultivated plants (including fungi, algae) grown as a <u>source of energy</u>  <i>Example: negative impacts of non-native organisms to crops, orchards, timber etc.</i>
		<b>Cultivated aquatic plants</b>	Plants cultivated by in- situ aquaculture grown for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from in-situ aquaculture for direct use or processing (excluding genetic materials); Plants cultivated by in- situ aquaculture grown as an <u>energy source</u> .  <i>Example: negative impacts of non-native organisms to aquatic plants cultivated for nutrition, gardening etc. purposes.</i>
		<b>Reared animals</b>	Animals reared for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from reared animals for direct use or processing (excluding genetic materials); Animals reared to provide <u>energy</u> (including mechanical)  <i>Example: negative impacts of non-native organisms to livestock</i>
		<b>Reared aquatic animals</b>	Animals reared by in-situ aquaculture for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from animals grown by in-situ aquaculture for direct use or processing (excluding genetic materials); Animals reared by in-situ aquaculture as an <u>energy source</u>  <i>Example: negative impacts of non-native organisms to fish farming</i>
		<b>Wild plants</b> (terrestrial and aquatic)	Wild plants (terrestrial and aquatic, including fungi, algae) used for <u>nutrition</u> ; <u>Fibres and other materials</u> from wild plants for direct use or processing (excluding genetic materials); Wild plants (terrestrial and aquatic, including fungi, algae) used as a <u>source of energy</u>  <i>Example: reduction in the availability of wild plants (e.g. wild berries, ornamentals) due to non-native organisms (competition, spread of disease etc.)</i>
		<b>Wild animals</b> (terrestrial and aquatic)	Wild animals (terrestrial and aquatic) used for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from wild animals for direct use or processing (excluding genetic materials); Wild animals (terrestrial and aquatic) used as a <u>source of energy</u>

			<i>Example: reduction in the availability of wild animals (e.g. fish stocks, game) due to non-native organisms (competition, predations, spread of disease etc.)</i>
	<b>Genetic material</b> from all biota	<b>Genetic material</b> from plants, algae or fungi	<p><u>Seeds, spores and other plant materials</u> collected for maintaining or establishing a population; Higher and lower plants (whole organisms) used to <u>breed new strains or varieties</u>; Individual genes extracted from higher and lower plants for the <u>design and construction of new biological entities</u></p> <p><i>Example: negative impacts of non-native organisms due to interbreeding</i></p>
		<b>Genetic material</b> from animals	<p>Animal material collected for the purposes of maintaining or establishing a population; Wild animals (whole organisms) used to breed new strains or varieties; Individual genes extracted from organisms for the design and construction of new biological entities</p> <p><i>Example: negative impacts of non-native organisms due to interbreeding</i></p>
	<b>Water</b> <sup>8</sup>	<b>Surface water</b> used for nutrition, materials or energy	<p>Surface water for <u>drinking</u>; Surface water used as a material (<u>non-drinking purposes</u>); Freshwater surface water, coastal and marine water used as an <u>energy source</u></p> <p><i>Example: loss of access to surface water due to spread of non-native organisms</i></p>
		<b>Ground water</b> for used for nutrition, materials or energy	<p>Ground (and subsurface) water for <u>drinking</u>; Ground water (and subsurface) used as a material (<u>non-drinking purposes</u>); Ground water (and subsurface) used as an <u>energy source</u></p> <p><i>Example: reduced availability of ground water due to spread of non-native organisms and associated increase of ground water consumption by vegetation.</i></p>
<b>Regulation &amp; Maintenance</b>	Transformation of biochemical or physical inputs to ecosystems	<b>Mediation of wastes or toxic substances</b> of anthropogenic origin by living processes	<p><u>Bio-remediation</u> by micro-organisms, algae, plants, and animals; <u>Filtration/sequestration/storage/accumulation</u> by micro-organisms, algae, plants, and animals</p> <p><i>Example: changes caused by non-native organisms to ecosystem functioning and ability to filtrate etc. waste or toxics</i></p>
		<b>Mediation of nuisances</b> of anthropogenic origin	<p><u>Smell reduction</u>; <u>noise attenuation</u>; <u>visual screening</u> (e.g. by means of green infrastructure)</p> <p><i>Example: changes caused by non-native organisms to ecosystem structure, leading to reduced ability to mediate nuisances.</i></p>
	Regulation of physical, chemical, biological conditions	<b>Baseline flows and extreme event</b> regulation	<p>Control of <u>erosion</u> rates; Buffering and attenuation of <u>mass movement</u>; <u>Hydrological cycle and water flow regulation</u> (Including flood control, and coastal protection); <u>Wind</u> protection; <u>Fire</u> protection</p> <p><i>Example: changes caused by non-native organisms to ecosystem functioning or structure leading to, for example,</i></p>

<sup>8</sup> Note: in the CICES classification provisioning of water is considered as an abiotic service whereas the rest of ecosystem services listed here are considered biotic.

			<p><i>destabilisation of soil, increased risk or intensity of wild fires etc.</i></p>
		<p><b>Lifecycle maintenance</b>, habitat and gene pool protection</p>	<p><u>Pollination</u> (or 'gamete' dispersal in a marine context); <u>Seed dispersal</u>; Maintaining <u>nursery populations and habitats</u> (Including gene pool protection)</p> <p><i>Example: changes caused by non-native organisms to the abundance and/or distribution of wild pollinators; changes to the availability / quality of nursery habitats for fisheries</i></p>
		<p><b>Pest and disease control</b></p>	<p>Pest control; Disease control</p> <p><i>Example: changes caused by non-native organisms to the abundance and/or distribution of pests</i></p>
		<p><b>Soil quality regulation</b></p>	<p><u>Weathering processes</u> and their effect on soil quality; <u>Decomposition and fixing processes</u> and their effect on soil quality</p> <p><i>Example: changes caused by non-native organisms to vegetation structure and/or soil fauna leading to reduced soil quality</i></p>
		<p><b>Water conditions</b></p>	<p>Regulation of the <u>chemical condition</u> of freshwaters by living processes; Regulation of the chemical condition of salt waters by living processes</p> <p><i>Example: changes caused by non-native organisms to buffer strips along water courses that remove nutrients in runoff and/or fish communities that regulate the resilience and resistance of water bodies to eutrophication</i></p>
		<p><b>Atmospheric composition and conditions</b></p>	<p>Regulation of <u>chemical composition</u> of atmosphere and oceans; Regulation of <u>temperature and humidity</u>, including ventilation and transpiration</p> <p><i>Example: changes caused by non-native organisms to ecosystems' ability to sequester carbon and/or evaporative cooling (e.g. by urban trees)</i></p>
<p><b>Cultural</b></p>	<p><b>Direct, in-situ and outdoor interactions</b> with living systems that depend on presence in the environmental setting</p>	<p><b>Physical and experiential</b> interactions with natural environment</p>	<p>Characteristics of living systems that that enable activities promoting health, recuperation or enjoyment through <u>active or immersive interactions</u>;</p> <p>Characteristics of living systems that enable activities promoting health, recuperation or enjoyment through <u>passive or observational interactions</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that make it attractive for recreation, wild life watching etc.</i></p>
		<p><b>Intellectual and representative</b> interactions with natural environment</p>	<p>Characteristics of living systems that enable <u>scientific investigation</u> or the creation of traditional ecological knowledge;</p> <p>Characteristics of living systems that enable <u>education and training</u>;</p> <p>Characteristics of living systems that are resonant in terms of <u>culture or heritage</u>;</p> <p>Characteristics of living systems that enable <u>aesthetic experiences</u></p>

			<i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have cultural importance</i>
	<b>Indirect, remote, often indoor interactions</b> with living systems that do not require presence in the environmental setting	<b>Spiritual, symbolic</b> and other interactions with natural environment	Elements of living systems that have <u>symbolic meaning</u> ; Elements of living systems that have <u>sacred or religious meaning</u> ; Elements of living systems used for <u>entertainment or representation</u>  <i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have sacred or religious meaning</i>
		Other biotic characteristics that have a <b>non-use value</b>	Characteristics or features of living systems that have an <u>existence value</u> ; Characteristics or features of living systems that have an <u>option or bequest value</u>  <i>Example: changes caused by non-native organisms to ecosystems designated as wilderness areas, habitats of endangered species etc.</i>

## **ANNEX VIII Species Distribution Model**

### **Projection of environmental suitability for *Cherax destructor* establishment in Europe**

Björn Beckmann, Elena Tricarico and Dan Chapman

23 September 2021

#### ***Aim***

To project the suitability for potential establishment of *Cherax destructor* in Europe, under current and predicted future climatic conditions.

#### ***Data for modelling***

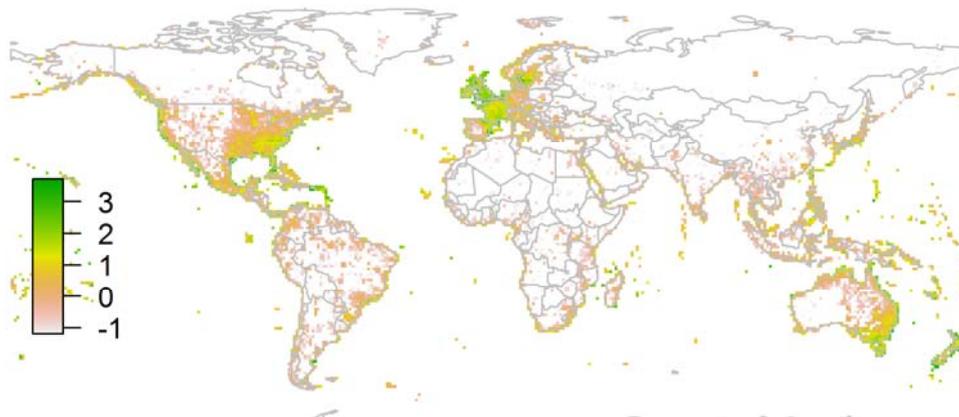

Species occurrence data were obtained from the Global Biodiversity Information Facility (GBIF) (3995 records), the Atlas of Living Australia (976 records), iNaturalist (64 records), the Integrated Digitized Biocollections (iDigBio) (1 records), and additional records from the risk assessment team. We scrutinised occurrence records from regions where the species is not known to be established and removed any dubious records or where the georeferencing was too imprecise (e.g. records referenced to a country or island centroid) or outside of the coverage of the predictor layers (e.g. small island or coastal occurrences). The remaining records were gridded at a 0.25 x 0.25 degree resolution for modelling, yielding 348 grid cells with occurrences (Figure 1a). As a proxy for recording effort, the density of terrestrial Decapoda records held by GBIF was also compiled on the same grid (Figure 1b).

**Figure 1.** (a) Occurrence records obtained for *Cherax destructor* and used in the modelling, showing native and invaded distributions. (b) The recording density of terrestrial Decapoda on GBIF, which was used as a proxy for recording effort.

(a) Species distribution used in modelling

(b) Estimated recording effort (log<sub>10</sub>-scaled)

Climate data were selected from the ‘Bioclim’ variables contained within the WorldClim database (Hijmans et al. 2005), originally at 5 arcminute resolution (0.083 x 0.083 degrees of longitude/latitude) and aggregated to a 0.25 x 0.25 degree grid for use in the model.

Based on the biology of *Cherax destructor*, the following climate variables were used in the modelling:

- Temperature seasonality (Bio4)
- Maximum temperature of the warmest month (Bio5)
- Minimum temperature of the coldest month (Bio6)
- Mean temperature of the wettest quarter (Bio8)
- Annual precipitation (Bio12)
- Precipitation of the wettest month (Bio13)
- Precipitation seasonality (Bio15)

To estimate the effect of climate change on the potential distribution, equivalent modelled future climate conditions for the 2070s under the Representative Concentration Pathways (RCP) 2.6 and 4.5 were also obtained. These represent low and medium emissions scenarios, respectively. The above variables were obtained as averages of outputs of eight Global Climate Models (BCC-CSM1-1, CCSM4, GISS-E2-R, HadGEM2-AO, IPSL-CM5A-LR, MIROC-ESM, MRI-CGCM3, NorESM1-M), downscaled and calibrated against the WorldClim baseline (see [http://www.worldclim.org/cmip5\\_5m](http://www.worldclim.org/cmip5_5m)).

### *Species distribution model*

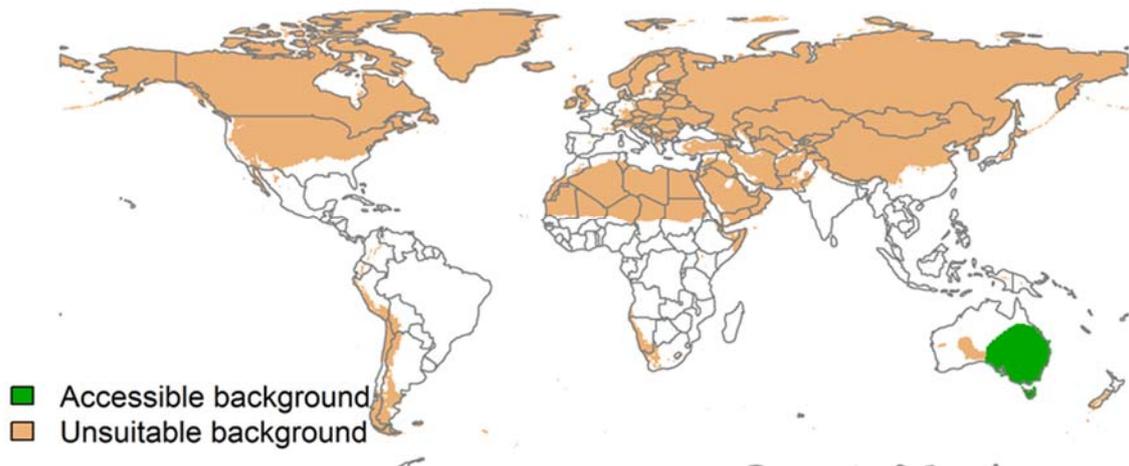

A presence-background (presence-only) ensemble modelling strategy was employed using the BIOMOD2 R package version 3.4.6 (Thuiller et al. 2020; Thuiller et al. 2009). These models contrast the environment at the species' occurrence locations against a random sample of the global background environmental conditions (often termed 'pseudo-absences') in order to characterise and project suitability for occurrence. This approach has been developed for distributions that are in equilibrium with the environment. Because invasive species' distributions are not at equilibrium and subject to dispersal constraints at a global scale, we took care to minimise the inclusion of locations suitable for the species but where it has not been able to disperse to (Chapman et al. 2019). Therefore the background sampling region included:

- The area accessible by native *Cherax destructor* populations, in which the species is likely to have had sufficient time to disperse to all locations. Based on presumed maximum dispersal distances, the accessible region was defined as a 400km buffer around the native range occurrences; AND
- A 30km buffer around the non-native occurrences, encompassing regions likely to have had high propagule pressure for introduction by humans and/or natural dispersal of the species; AND
- Regions where we have an *a priori* expectation of high unsuitability for the species so that absence is assumed irrespective of dispersal constraints (see Figure 2). The following rules were applied to define a region expected to be highly unsuitable for *Cherax destructor* at the spatial scale of the model:
  - Minimum temperature of the coldest month (Bio6) < -3°C
  - Maximum temperature of the warmest month (Bio5) < 20°C
  - Annual precipitation (Bio12) < 200mm

Altogether, 1.1% of occurrence grid cells were located in the unsuitable background region.

Within the unsuitable background region, 10 samples of 5000 randomly sampled grid cells were obtained. In the accessible background (comprising the accessible areas around native and non-native occurrences as detailed above), the same number of pseudo-absence samples were drawn as there were presence records (348), weighting the sampling by a proxy for recording effort (Figure 2).

**Figure 2.** The background from which pseudo-absence samples were taken in the modelling of *Cherax destructor*. Samples were taken from a 400km buffer around the native range and a 30km buffer around non-native occurrences (together forming the accessible background), and from areas expected to be highly unsuitable for the species (the unsuitable background region). Samples from the accessible background were weighted by a proxy for recording effort (Figure 1(b)).

Each dataset (i.e. combination of the presences and the individual background samples) was randomly split into 80% for model training and 20% for model evaluation. With each training dataset, seven statistical algorithms were fitted with the default BIOMOD2 settings and rescaled using logistic regression, except where specified below:

- Generalised linear model (GLM)
- Generalised boosting model (GBM)
- Generalised additive model (GAM) with a maximum of four degrees of freedom per smoothing spline
- Artificial neural network (ANN)
- Multivariate adaptive regression splines (MARS)
- Random forest (RF)
- Maxent

Since the total background sample was larger than the number of occurrences, prevalence fitting weights were applied to give equal overall importance to the occurrences and the background. Normalised variable importance was assessed and variable response functions were produced using BIOMOD2's default procedure.

Model predictive performance was assessed by the following three measures:

- AUC, the area under the receiver operating characteristic curve (Fielding & Bell 1997). Predictions of presence-absence models can be compared with a subset of records set aside for model evaluation (here 20%) by constructing a confusion matrix with the number of true positive, false positive, false negative and true negative cases. For models generating non-

dichotomous scores (as here) a threshold can be applied to transform the scores into a dichotomous set of presence-absence predictions. Two measures that can be derived from the confusion matrix are sensitivity (the proportion of observed presences that are predicted as such, quantifying omission errors), and specificity (the proportion of observed absences that are predicted as such, quantifying commission errors). A receiver operating characteristic (ROC) curve can be constructed by using all possible thresholds to classify the scores into confusion matrices, obtaining sensitivity and specificity for each matrix, and plotting sensitivity against the corresponding proportion of false positives (equal to 1 - specificity). The use of all possible thresholds avoids the need for a selection of a single threshold, which is often arbitrary, and allows appreciation of the trade-off between sensitivity and specificity. The area under the ROC curve (AUC) is often used as a single threshold-independent measure for model performance (Manel et al. 2001). AUC is the probability that a randomly selected presence has a higher model-predicted suitability than a randomly selected absence (Allouche et al. 2006).

- Cohen's Kappa (Cohen 1960). This measure corrects the overall accuracy of model predictions (ratio of the sum of true presences plus true absences to the total number of records) by the accuracy expected to occur by chance. The kappa statistic ranges from -1 to +1, where +1 indicates perfect agreement and values of zero or less indicate a performance no better than random. Advantages of kappa are its simplicity, the fact that both commission and omission errors are accounted for in one parameter, and its relative tolerance to zero values in the confusion matrix (Manel et al. 2001). However, Kappa has been criticised for being sensitive to prevalence (the proportion of sites in which the species was recorded as present) and may therefore be inappropriate for comparisons of model accuracy between species or regions (McPherson et al. 2004; Allouche et al. 2006).
- TSS, the true skill statistic (Allouche et al. 2006). TSS is defined as sensitivity + specificity - 1, and corrects for Kappa's dependency on prevalence. TSS compares the number of correct forecasts, minus those attributable to random guessing, to that of a hypothetical set of perfect forecasts. Like kappa, TSS takes into account both omission and commission errors, and success as a result of random guessing, and ranges from -1 to +1, where +1 indicates perfect agreement and values of zero or less indicate a performance no better than random (Allouche et al. 2006).

An ensemble model was created by first rejecting poorly performing algorithms with relatively extreme low AUC values and then averaging the predictions of the remaining algorithms, weighted by their AUC. To identify poorly performing algorithms, AUC values were converted into modified z-scores based on their difference to the median and the median absolute deviation across all algorithms (Iglewicz & Hoaglin 1993). Algorithms with  $z < -2$  were rejected. In this way, ensemble projections were made for each dataset and then averaged to give an overall suitability, as well as its standard deviation. The projections were then classified into suitable and unsuitable regions using a "minimum presence threshold", setting the cut-off as the lowest value at which 98% of all presence records are classified correctly.

Projections were classified into suitable and unsuitable regions using a "lowest presence threshold" (Pearson et al. 2007), setting the cut-off as the lowest value at which 98% of all presence records are classified correctly under the current climate (here 0.68). In order to express the sensitivity of classifications to the choice of this threshold, thresholds at which 95% and 99% of records are classified correctly (here 0.81 and 0.55 respectively) were used in the calculation of error bars in Figs. 9 and 10 below in addition to taking account of uncertainty in the projections themselves.

We also produced limiting factor maps for Europe following Elith et al. (2010). For this, projections were made separately with each individual variable fixed at a near-optimal value. These were chosen as the median values at the occurrence grid cells. Then, the most strongly limiting factors were identified as the one resulting in the highest increase in suitability in each grid cell.

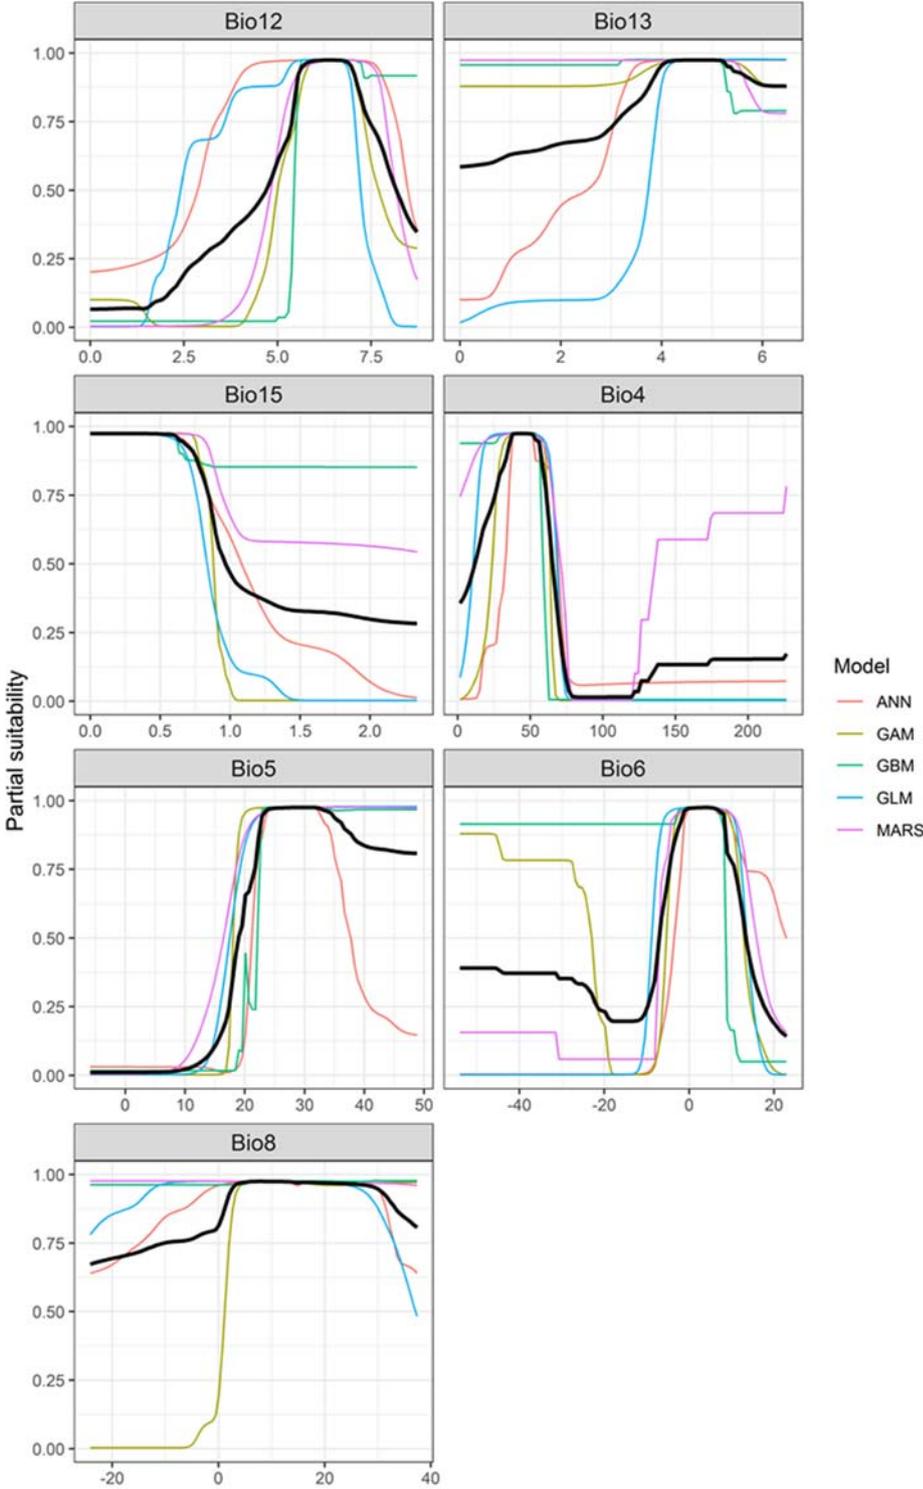

## Results

The ensemble model suggested that suitability for *Cherax destructor* was most strongly determined by Temperature seasonality (Bio4), accounting for 36.1% of variation explained, followed by Minimum temperature of the coldest month (Bio6) (23.2%), Maximum temperature of the warmest month (Bio5) (16.5%), Annual precipitation (Bio12) (11.3%), Precipitation of the wettest month (Bio13) (5.7%), Precipitation seasonality (Bio15) (4.7%) and Mean temperature of the wettest quarter (Bio8) (2.6%) (Table 1, Figure 3).

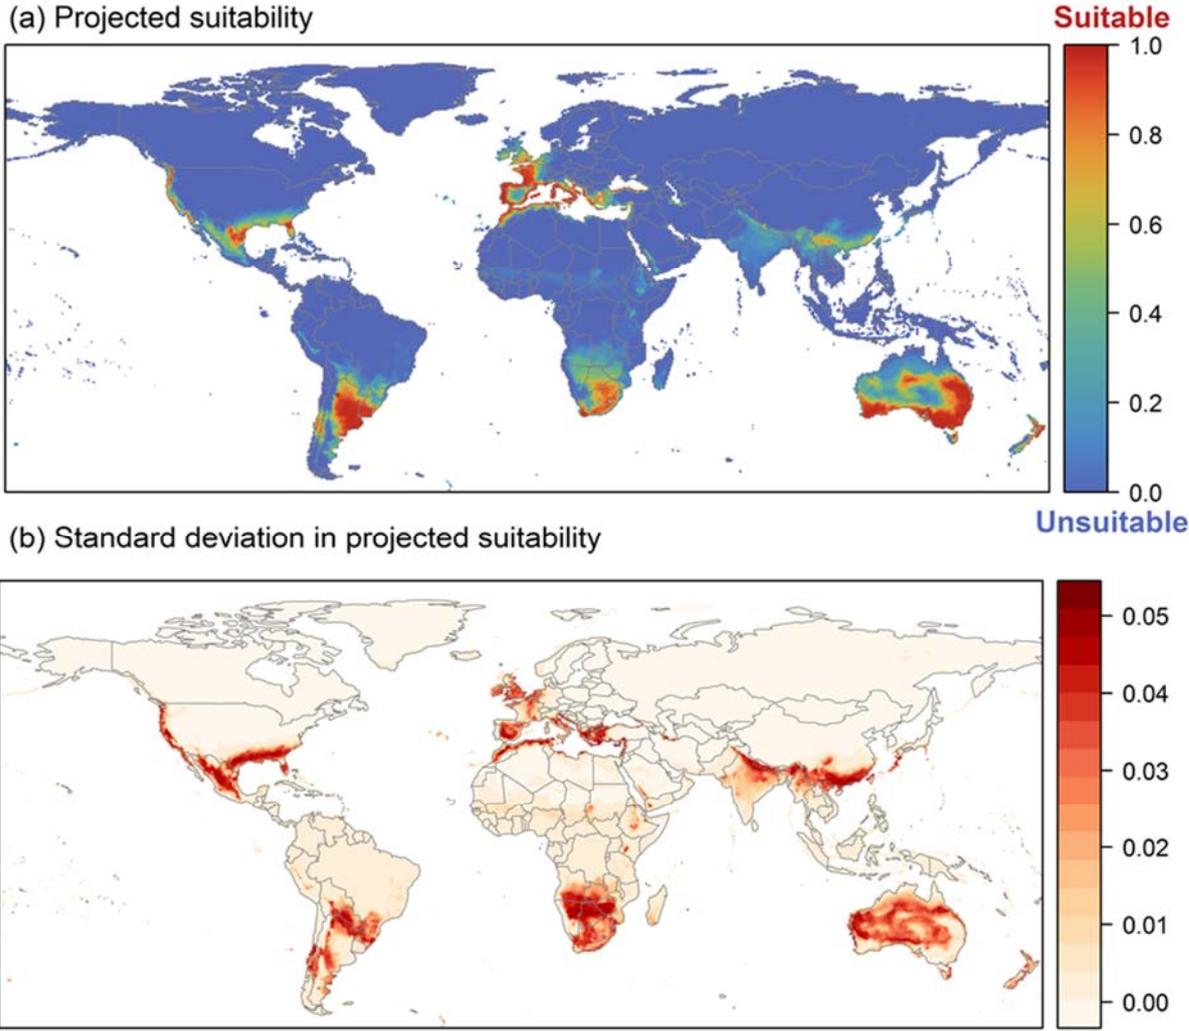

**Table 1.** Summary of the cross-validation predictive performance (AUC, Kappa, TSS) and variable importance of the fitted model algorithms and the ensemble (AUC-weighted average of the best performing algorithms). Results are the average from models fitted to 10 different background samples of the data.

Algorithm	AUC	Kappa	TSS	Used in the ensemble	Variable importance (%)						
					Temperature seasonality (Bio4)	Minimum temperature of the coldest month (Bio6)	Maximum temperature of the warmest month	Annual precipitation (Bio12)	Precipitation of the wettest month (Bio13)	Precipitation seasonality (Bio15)	Mean temperature of the wettest quarter (Bio8)

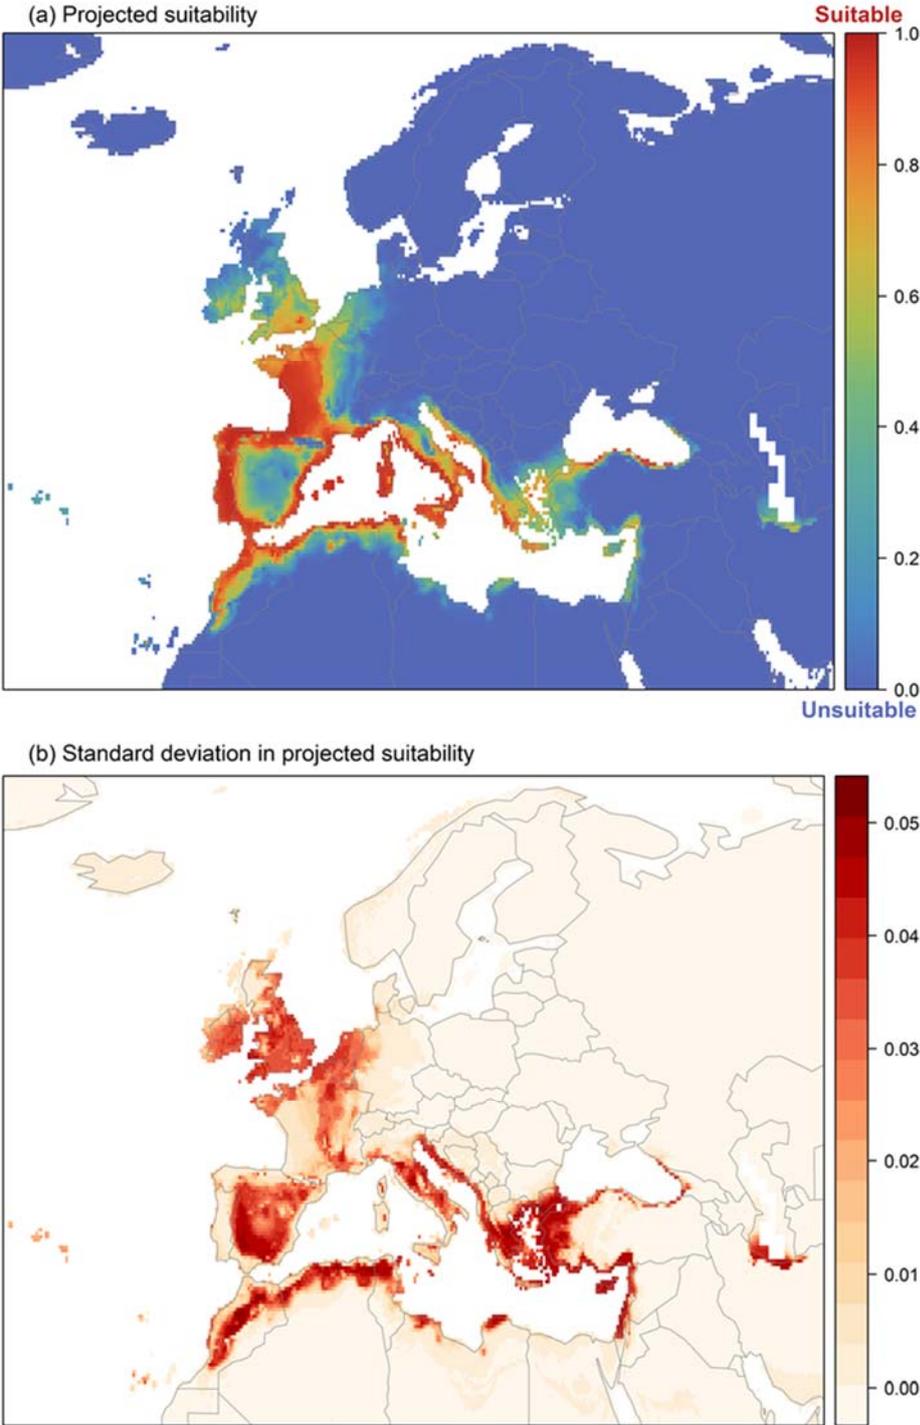

**Figure 3.** Partial response plots from the fitted models. Thin coloured lines show responses from the algorithms in the ensemble, while the thick black line is their ensemble. In each plot, other model variables are held at their median value in the training data. Some of the divergence among algorithms is because of their different treatment of interactions among variables.

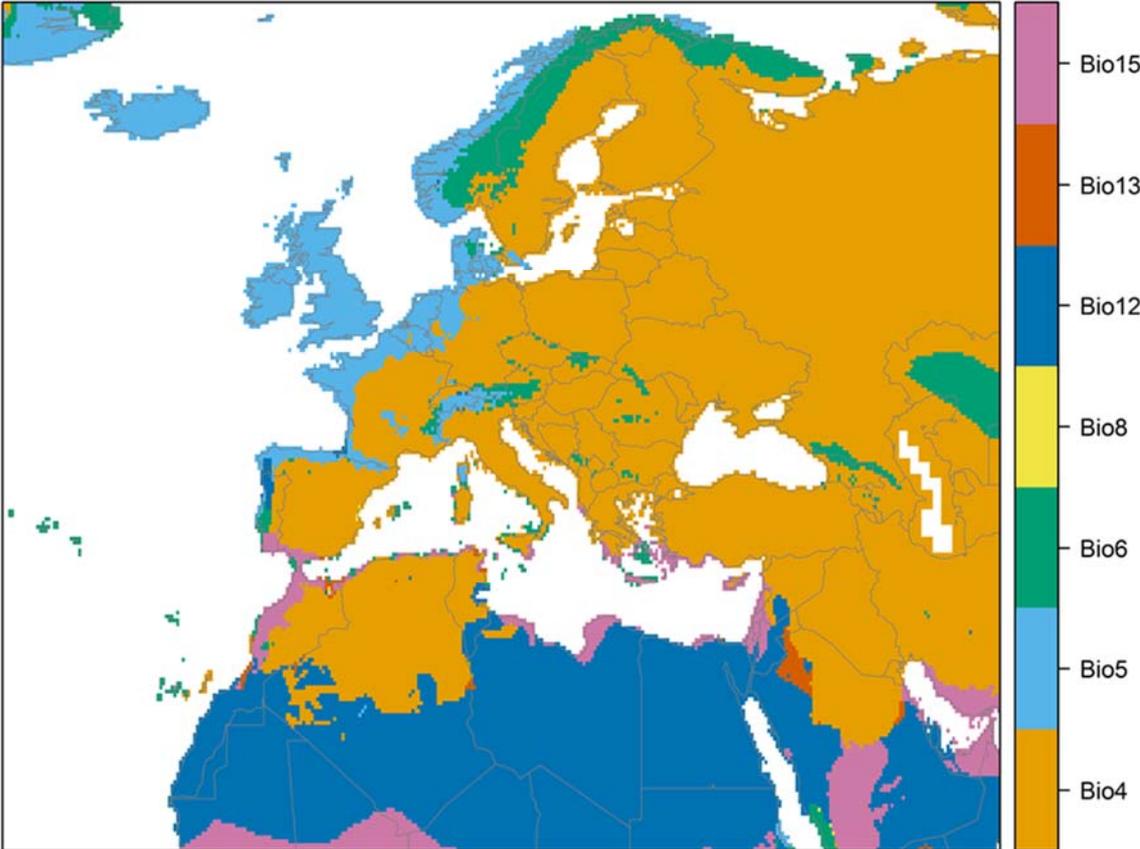

**Figure 4.** (a) Projected global suitability for *Cherax destructor* establishment in the current climate. For visualisation, the projection has been aggregated to a 0.5 x 0.5 degree resolution, by taking the maximum suitability of constituent higher resolution grid cells. Values > 0.68 are suitable for the species, with 98% of global presence records above this threshold. Values below 0.68 indicate lower relative suitability. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

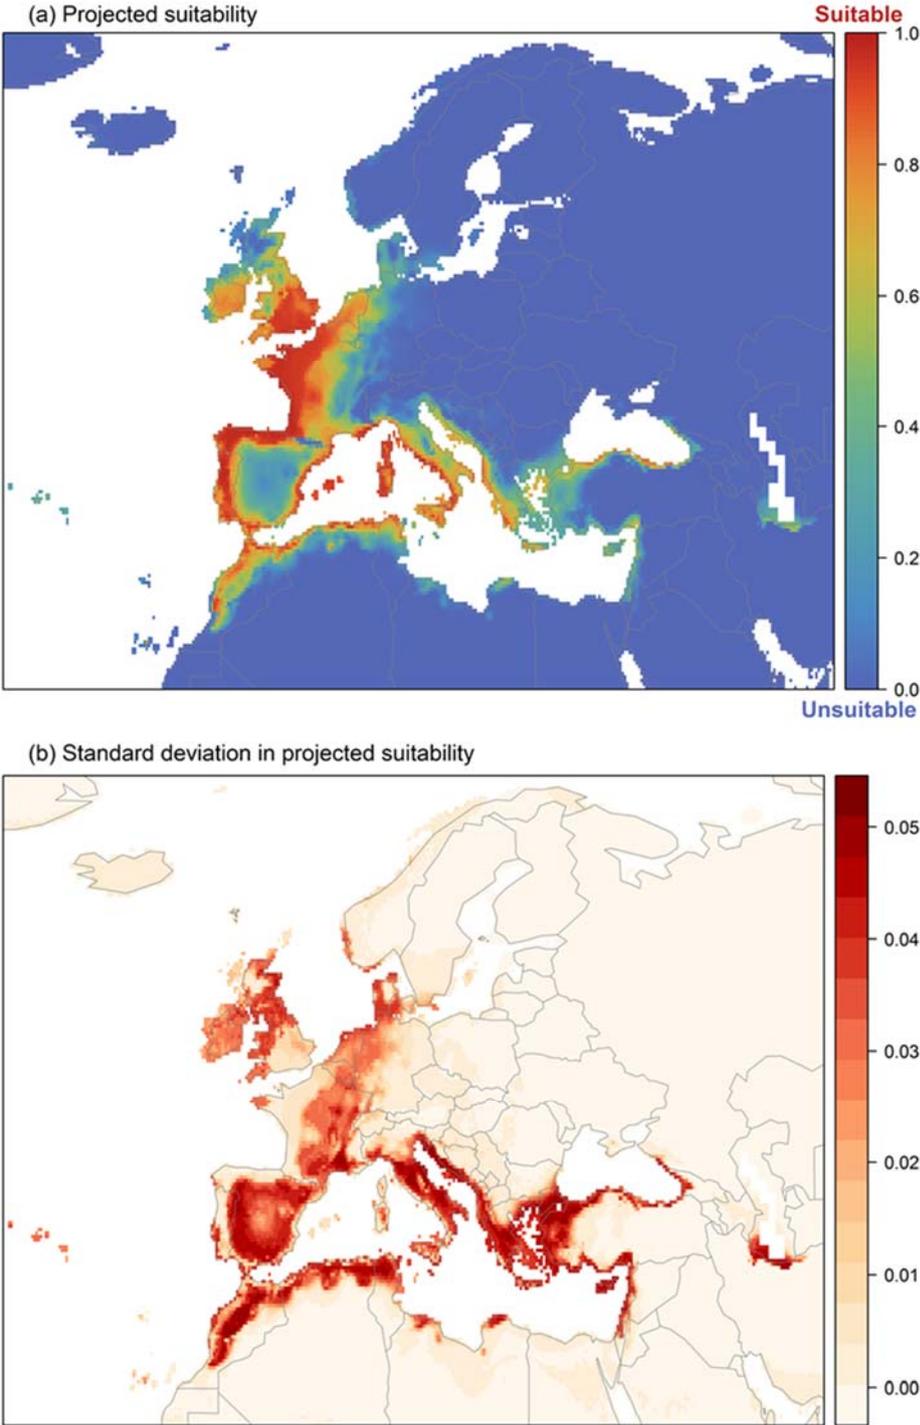

**Figure 5.** (a) Projected current suitability for *Cherax destructor* establishment in Europe and the Mediterranean region. Values > 0.68 are suitable for the species, with 98% of global presence records above this threshold. Values below 0.68 indicate lower relative suitability. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

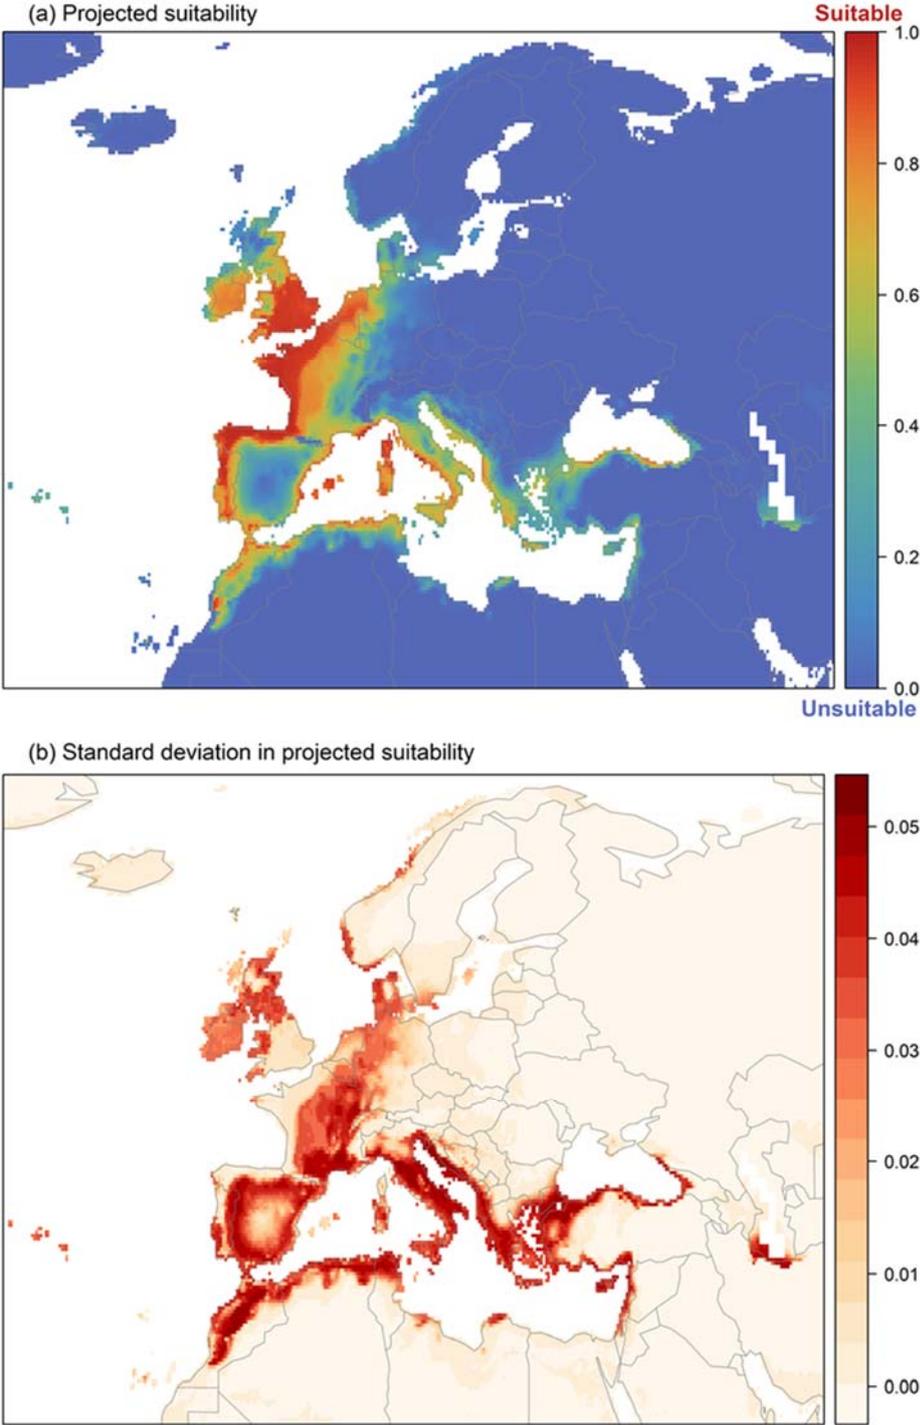

**Figure 6.** The most strongly limiting factors for *Cherax destructor* establishment estimated by the model in Europe and the Mediterranean region in current climatic conditions.

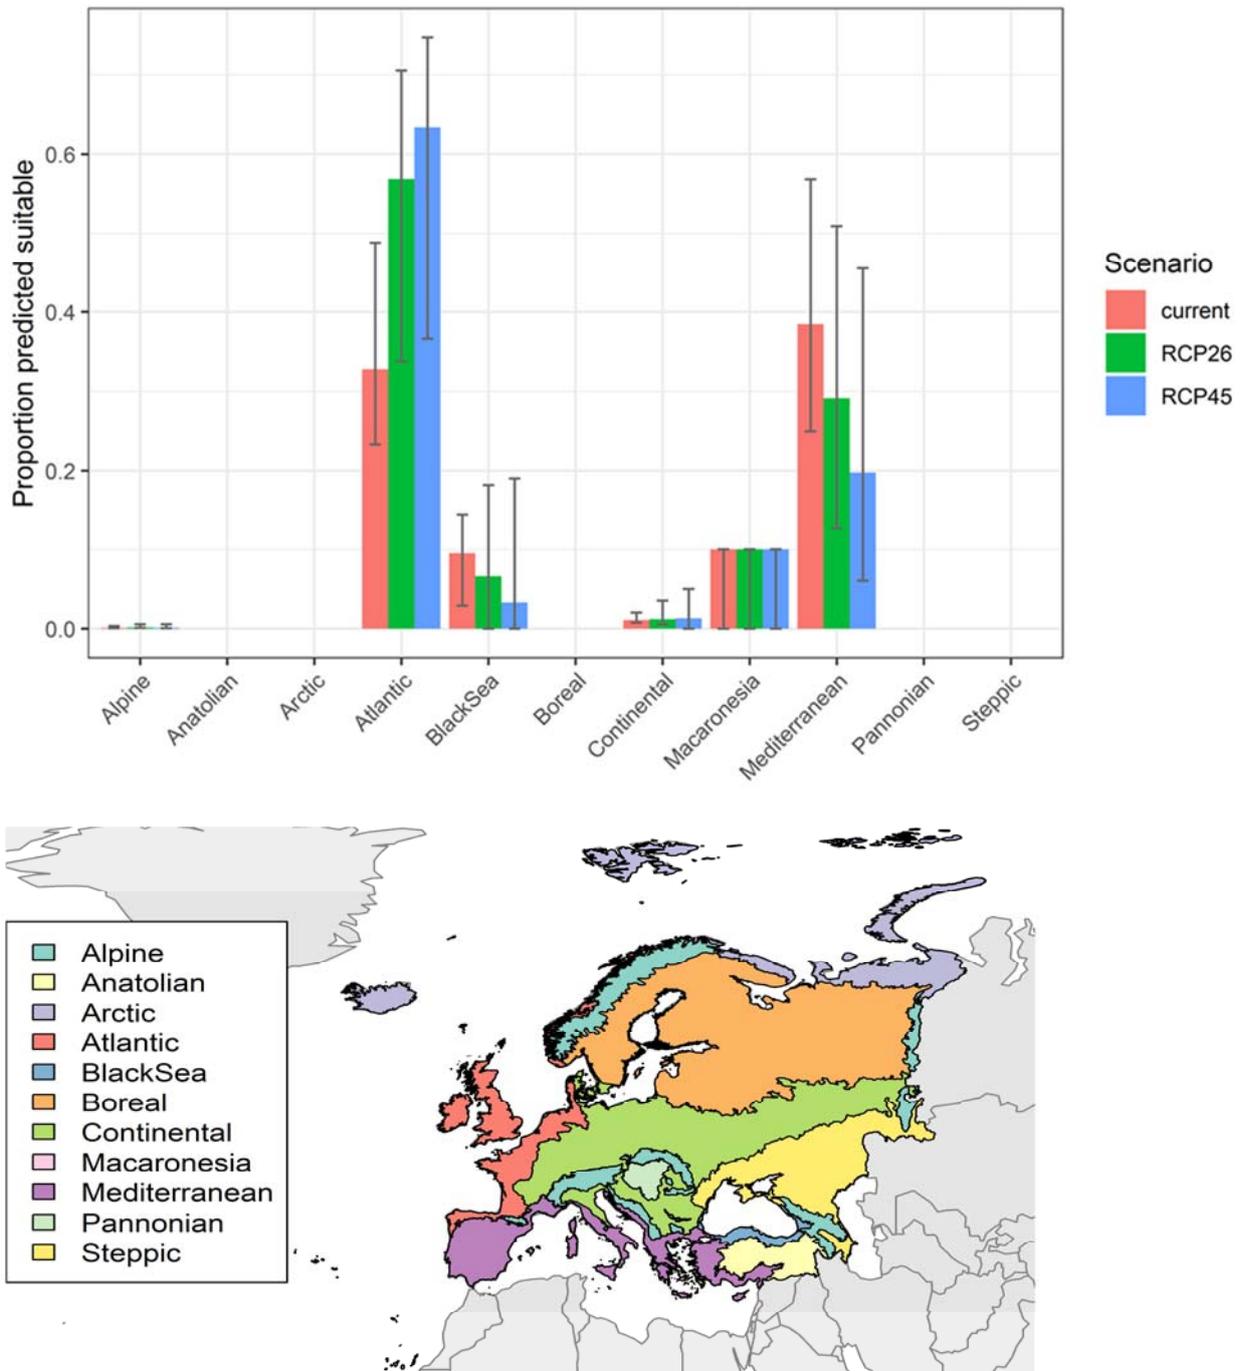

**Figure 7.** (a) Projected suitability for *Cherax destructor* establishment in Europe and the Mediterranean region in the 2070s under climate change scenario RCP2.6. Values > 0.68 are suitable for the species, with 98% of global presence records above this threshold under current climate. Values below 0.68 indicate lower relative suitability. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

**Figure 8.** (a) Projected suitability for *Cherax destructor* establishment in Europe and the Mediterranean region in the 2070s under climate change scenario RCP4.5. Values > 0.68 are suitable for the species, with 98% of global presence records above this threshold under current climate. Values below 0.68 indicate lower relative suitability. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

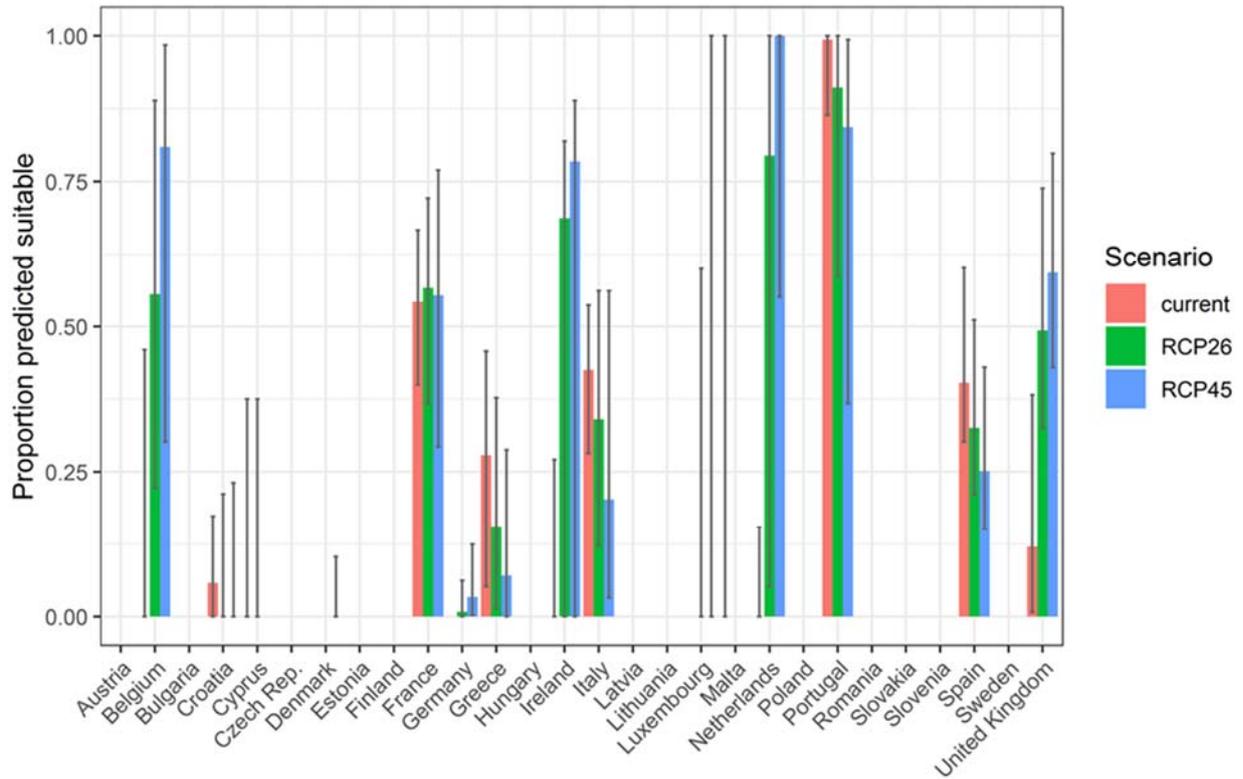

**Figure 9.** Variation in projected suitability for *Cherax destructor* establishment among Biogeographical Regions of Europe (<https://www.eea.europa.eu/data-and-maps/data/biogeographical-regions-europe-3>). The bar plots show the proportion of grid cells in each region classified as suitable (with values > 0.68) in the current climate and projected climate for the 2070s under two RCP emissions scenarios. Error bars indicate uncertainty due to both the choice of classification threshold (cf. p.5/6) and uncertainty in the projections themselves (cf. part (b) of Figures 5, 7 and 8). The location of each region is also shown. The Arctic and Macaronesian regions are not part of the study area, but are included for completeness.

**Table 2.** Variation in projected suitability for *Cherax destructor* establishment among Biogeographical regions of Europe (numerical values of Figure 9 above). The numbers are the proportion of grid cells in each region classified as suitable in the current climate and projected climate for the 2070s under two RCP emissions scenarios. The Arctic and Macaronesian biogeographical regions are not part of the study area, but are included for completeness.

## ***Caveats to the modelling***

To remove spatial recording biases, the selection of the background sample from the accessible background was weighted by the density of Decapoda records on the Global Biodiversity Information Facility (GBIF). While this is preferable to not accounting for recording bias at all, it may not provide the perfect measure of recording bias.

There was substantial variation among modelling algorithms in the partial response plots (Figure 3). In part this will reflect their different treatment of interactions among variables. Since partial plots are made with other variables held at their median, there may be values of a particular variable at which this does not provide a realistic combination of variables to predict from.

Other variables potentially affecting the distribution of the species, such as types of land cover were not included in the model.

<b>Date completed</b>	<b>15/10/2021</b>

### Summary<sup>1</sup>

Highlight of measures that provide the most cost-effective options to prevent the introduction, achieve early detection, rapidly eradicate and manage the species, including significant gaps in information or knowledge to identify cost-effective measures.

*Cherax destructor* is an Australian crayfish species reported in Europe in the wild in Spain, France, Ireland and Italy. In general, eradication and management of aquatic invasive species are very challenging. Prevention remains the best approach, which also applies to this species. The measures reported in this Annex also consider the European experience on other invasive alien crayfish. A combination of techniques is recommended to manage the species as there is no single “silver bullet” for every situation.

**Prevention** can be achieved by implementing the legislation (banning the species for the pathways of introduction: aquaculture and e-commerce) coupled with powerful and effective public awareness campaigns.

**Early detection** foresees effective surveillance and reporting by monitoring areas using environmental DNA, or citizen science. Traps can be used for surveillance and monitoring, even if less effective than eDNA, when the species is at low population densities.

**Eradication and management practices** can be more effective at the early stage of invasion in closed water bodies (timescale of the intervention depends on the situation), but not in open (connected) systems. An Integrated Pest Management approach is the most recommended method, being the best and most effective way to target different crayfish life stages. Chemical control can be used to rapidly eradicate a population in closed waterbodies. Chemical eradication of already established populations in the catchment scale is usually unfeasible. Only non-selective products are available, causing environmental damage and problems with public opinion. These are not approved for use in all Member States and can only be applied in very particular situations (their use in protected areas should be rigorously evaluated, for example). As the species is a burrowing crayfish, like the red swamp crayfish (*Procambarus clarkii*), biocides should be applied to the water using a method that reaches the individuals in the burrows, possibly with more than one application.

The combined use of intensive trapping and native predators has been proved to be effective in tackling invasive crayfish, so it applies to *C. destructor* as well. It almost eradicated (reduction of 99%) the rusty crayfish (*Faxonius rusticus*) in a US lake after eight years of activities

(without a population recovery for the subsequent four years). Moreover, in two years, the combined use of intensive trapping and sterile male techniques has led to a decrease of 87% in a red swamp crayfish population inhabiting an Italian lake, without a complete eradication. Drainage of closed waterbodies may be used in the case of confined populations, but to be effective, waterbodies should be left dried for a prolonged time (at least one year). Habitat destruction/modification (i.e. filling of ponds) and subsequent restoration could be considered for very specific cases.

The use of crayfish plague to eradicate *C. destructor* has been proven effective, but it can lead to significant risks for native European crayfish (and also a chronically infected population of *C. destructor* can establish, serving as a reservoir of the pathogen).

Besides managing the pathways and increasing public awareness, if the species is established, physical barriers can halt or slow down the spread of the species. However, as a side effect, they can also impede the movement of native species.

For management, the same listed measures for eradication (chemical, trapping) can be used, plus the construction of barriers that may be used in the case of confined populations. Barriers can be costly and impede the movement of native species.

Recently, new autocidal techniques, such as the creation of monosex populations, silencing of key hormones through RNA interference and oral delivery of neuropeptides, have also been suggested as promising methods to control crayfish populations. However, they have not proven entirely effective in practice yet, except in aquaculture.

Detailed assessment			
	Description of measures <sup>2</sup>	Assessment of implementation cost and cost-effectiveness (per measure) <sup>3</sup>	Level of confidence <sup>4</sup>
<b>Methods to achieve prevention of intentional and unintentional introduction<sup>5</sup></b>	<b>Managing the pathways:</b> Common yabby is already present in Europe (Spain, France, Ireland and Italy) where it was introduced for aquaculture purposes (Bolea 1996; D'Agaro et al. 1999). The species also became an ornamental species in the European online trade, which is another potential pathway of its introduction (Chucholl 2013). The species has been reported to be sold live in markets (i.e. Germany).	Legislation can be a very effective method of limiting the risk of introduction but requires sufficient sustained enforcement effort. A ban on trade would be an effective means of limiting the risk of introducing the species through the pathways identified (aquaculture, pet trade and use as live food). Still, it is necessary to properly educate and communicate with the wider public (Patoka et al. 2018). Bans are an accepted tool to limit trade and are already used worldwide for this and other species. <i>Cherax destructor</i> is a common species in the ornamental trade (e.g. Chucholl 2013; Chucholl & Wendler 2017) and is still	High

	<p>The adoption and enforcement of appropriate legislation and codes of best practice could reduce the likelihood of introduction in other EU countries.</p>	<p>farmed, so some opposition by stakeholders can be expected, even if other colourful <i>Cherax</i> spp. would still be sold/exchanged online as replacement species. Costs of implementation could be kept to a minimum by utilising existing enforcement processes, for example, those in place for the other crayfish (up to now five species) already present in the list of Invasive Alien Species of Union concern of the EU Regulation 1143/2014. Some specific training for relevant authorities would be necessary to recognise the species. Implementation of legislation should be coupled with a targeted public awareness campaign and spread of codes of conduct to be more effective, involving the most relevant stakeholders (e.g. pet retailers, farmers, and online marketplaces).</p>	
	<p><b>Increasing public awareness:</b> Dumping from citizens can cause the introduction of this species as already recorded for other crayfish sold for ornamental purposes (e.g. the marbled crayfish; Kouba et al. 2014, and the common yabby in Ireland). Information campaigns are necessary to increase public awareness and avoid new introductions. Guidance material can be produced and distributed for species identification (e.g. IUCN 2018).</p>	<p>Campaigns to educate and increase awareness on invasive alien species (IAS) are an effective way to curb illegal introductions, especially those targeted at specific sectors (e.g. pet retailers and owners). Public awareness campaigns, however, do need to be maintained, so they do not drop out of the collective consciousness, but are also renewed periodically to avoid fatigue. Implementing public campaigns as a preventative measure for the introduction of IAS is generally well accepted by stakeholders and the general public. The costs are possibly related to labour costs and of the production of communication materials and of communication campaigns. They can vary a lot, depending on the communication channel (radio, depending on how the information newspapers, websites or TV, or field</p>	<p>High</p>

		campaigns) <sup>1</sup> . Despite being a highly recommended measure, up to now, the effectiveness in reducing introductions of crayfish has not been measured and detailed costs are not available. No strong opposition by stakeholders is expected.	
<b>Methods to achieve early detection<sup>6</sup></b>	<p><b>Effective surveillance and reporting:</b> there are other <i>Cherax</i> species already present in Europe, especially in internet trade (Kouba et al. 2014; Chucholl &amp; Wendler 2017), and the congeneric <i>C. quadricarinatus</i> is already reported in the wild for Slovenia, Malta, Spain, and Hungary (Kouba et al. 2014; Deidun et al. 2018; Weiperth et al. 2019; Arias &amp; Torralba-Burrial 2021).</p> <p>There are different methods that can be used for surveillance, such as eDNA, citizen science, traps.</p> <p>1) eDNA has been used to successfully detect other alien crayfish in USA and Europe, also at low population densities (Mauvisseau et al. 2018, 2019; Manfrin et al. 2019; Rusch et al. 2020).</p> <p>2) Citizen science could be promoted to monitor the possible introduction and spread of the species and has been proved to be effective in detecting the arrival of IAS (e.g. involving anglers:</p>	<p>Usually, these methods do not elicit any problems with acceptance by the public and stakeholders. The costs vary.</p> <p>1) For eDNA, its development and testing have high initial costs, but its regular use can reduce the total costs considerably (Manfrin et al. 2019; Rusch et al. 2020). According to Zogaris (2017), “setting up the lab (PCR equipment etc.) would cost a minimum of € 20,000, while c. €30,000 could be estimated for annual operational costs (€24,000 personnel and travel + €6,000 lab consumables), referring to six months development, 12 months sampling campaign and six months for analysis. The method requires collecting water samples (1 to 10 L of water) from strategically placed sampling sites to search for the targeted species”.</p> <p>2) For citizen science, costs are related to individual training of citizens, validating data and maintaining the e-platform where data are collected. For example, as Adriaens et al. (2015) reported, an app developed by the RINSE project cost € 20,262, so a rough estimate of maintenance costs could be between € 3,000 and 4,000 per year. Already existing apps could also be used. Costs of people screening, validating and managing the collected data should be included: a part-time position could be sufficient, with</p>	High

<sup>1</sup> <https://www.shropshirewildlifetrust.org.uk/shropshire-invasive-non-native-species-initiative>

	<p>Zukowski et al. 2018). A simple and clear identification sheet could be also drafted and distributed to different stakeholders (e.g. anglers, aquarists) to increase the probability of an early detection and rapid response (e.g. IUCN 2018)<sup>2</sup>.</p> <p>3) Traps can be used for surveillance and monitoring, even if not always effective when the species is at low densities (Gherardi et al. 2011).</p>	<p>personnel managing data also collected on other species targeted by the citizen science initiative (the cost of the position depends on labour costs of Member States<sup>3</sup>: in 2020, in the EU, the average hourly labour cost was € 28.5). eDNA may have advantages over citizen science for use in areas where both native and alien crayfish co-occur, due to the risk of accidentally spreading crayfish plague by untrained citizens (so strict biosecurity protocols should be enforced or activities be limited).</p> <p>3) For surveillance trapping, the costs depend on the number of traps used (anglers and other stakeholders could be involved to check them). The cost of one trap can vary between € 8 and 15, cat food used in the traps as bait costs € 0.25 per can. Trapped animals should be disposed of according to the national legislation. Moreover, there could be associated environmental costs if non-target species are captured in the traps (e.g., reptiles, amphibians, fishes,...), so they should be set semi-submerged and frequently checked.</p> <p>All the three listed methods are already used for other aquatic IAS (thus, costs can be reduced). No relevant health and safety issues for personnel involved in citizen science and eDNA procedures, while all health and safety procedures should be strictly followed for trapping, including, e.g. wearing protective clothing and life jackets, especially if using boats.</p>

<p><b>Methods to achieve eradication<sup>7</sup></b></p>	<p><b>Eradication of aquatic species is very challenging</b> and is usually only feasible in small, enclosed water bodies. This places the emphasis on prevention as the most effective management tool. Management practices can be more effective at the early stage of invasion in closed but not in open waterbodies. An <b>integrated approach</b> is recommended (Gherardi et al. 2011; Stebbing et al. 2014; Stebbing 2016; Manfrin et al. 2019).</p>	<p>The suggested methods are those developed from European experience on other invasive alien crayfish.</p>	<p>High</p>
	<p><b>Mechanical removal:</b> the use of baited traps of various designs (Swedish traps, Evo-traps, collapsible traps, fyke nets, seine nets, etc. <a href="https://picclick.co.uk/Swedish-Crayfish-Trap-Otter-Friendly-UK-123356021888.html">https://picclick.co.uk/Swedish-Crayfish-Trap-Otter-Friendly-UK-123356021888.html</a>), ART (Artificial Refuge Traps consisting of a series of tubes of different diameters and lengths that are attached to a metal baseplate and that mimic the burrows; Green et al. 2018) or by electrofishing can reduce the density of the populations.</p>	<p>Traps are very simple and user friendly, and the public and stakeholders generally accept their use. Traps should be set semi-submerged to avoid the capture or harm of non-target organisms (such as amphibians, grass snakes, turtles). Frequent emptying of traps can increase capture rates since previously captured crayfish prevent other crayfish from entering the trap (Gherardi et al. 2011; Stebbing 2016). However, juveniles and ovigerous females can be trap shy and thus less trapped. The use of ART should be considered (Green et al. 2018) together with traditional traps. Trapping over extended periods is often required, which brings significant man-power costs. Setting traps when crayfish are most active (usually in summer and at night) increases trapping efficiency and therefore reduces costs for sampling effort in periods where the catch rate is very low (Dana et al. 2011a). The scale of this is dependent on the type of water body: e.g. in Italy two people on a boat in three hours covered a lake of 10,000 m<sup>2</sup> with 120 traps to manage the</p>	<p>High</p>

		<p>red swamp crayfish. The costs referred of trap checking over 171 days was around € 8,000 for traps and baits, and € 20,000 for manpower. Usually, mechanical removal (e.g. trapping) is coupled with other techniques to achieve the eradication (or near eradication). Autocidal methods such as sterilisation and biological methods (see descriptions below) can enhance the effectiveness of physical removal (Gherardi et al. 2011; Stebbing et al. 2014; Manfrin et al. 2019). Sex pheromones could be used in the traps, even if their identification is still far from being completed. Traps, if properly set, usually do not elicit any public concern. Electrofishing is seldom used and limited in its application to certain habitats (e.g. shallow, clear water; small water systems; Stebbing 2016). Costs are related to the equipment (between € 6,000 and 12,000) and manpower (this depends on labour costs of Member States, see above).</p> <p>Animals caught in traps or by electrofishing should be disposed of according to the national legislation.</p> <p>All health and safety procedures should be strictly followed when trapping and electrofishing, including e.g. wearing protective clothing and life jackets, especially if using boats. Special training and permission are required for electrofishing to prevent any damages to operators and species.</p>	
	<p><b>Biocides:</b> chemicals (BETAMAX VET, Pyblast) can be used in certain cases. Many effective maintenance management projects employ</p>	<p>The synthetic pyrethroid BETAMAX VET was used in Europe to successfully eradicate the signal crayfish from some ponds (five small ponds, the largest measuring approximately 2000 m<sup>2</sup> surface area; Sandodden &amp; Johnsen 2010). Similarly, the natural pyrethrum Pyblast was used</p>	<p>High</p>

	<p>chemicals, alone or in concert with mechanical or physical methods.</p>	<p>with varying success to eradicate the signal crayfish and the red swamp crayfish in different areas of Europe (Gherardi et al. 2011). For example, in Scotland, signal crayfish were treated in an isolated gravel-pit, c. 9,000 m<sup>3</sup>; three dammed ponds, c. 5,000 m<sup>3</sup> and a leaking, offline pond, c. 6,000 m<sup>3</sup> (Peay et al. 2006), and then in a quarry pond of 18,776 m<sup>2</sup> (Ballantyne et al. 2019), while in Italy the red swamp crayfish was treated from a small part of a ditch (c 700 m<sup>2</sup>) (Cecchinelli et al. 2011). Other chemicals have been tested and suggested to control invasive alien crayfish (Gherardi et al. 2011), but no chemicals have been used on <i>C. destructor</i> in the wild. However, laboratory trials on the species using Cyperkill 25 EC (active compound 250 g/l cypermethrin) and Decis Mega (active compound 50 g/l deltamethrin) showed that the values of Cyperkill 25 EC and Decis Mega inducing a 50% mortality after 96 hrs were 0.30 µg/l and 0.27 µg/l, respectively, higher than those required for other alien crayfish (Lidova et al 2019). However, these chemicals are not aquatic species selective, can be expensive and application protocols according to species biology and recipient environments are not established. Moreover, they can cause environmental damage and problems with public opinion; they are not approved for use in all the Member States and can only be applied in very particular situations. Pyblast could be better perceived, being natural and less toxic. Non-target species (e.g. fish, amphibians, reptiles) should be removed before their application, following strict and detailed protocols to recover them. As the species is a burrowing crayfish, like the red swamp crayfish, biocides should be applied in the water so that it also reaches the</p>	
--	--	--	--

		<p>individuals in the burrows (Cecchinelli et al. 2011), possibly requiring more than one application.</p> <p>Chemicals have been proved to be successful in closed small water bodies (&lt; 25,000 m<sup>2</sup>: Peay et al. 2019) or confined systems. Costs are related to the chemicals (1 l of Pyblast costs € 75; Ballantyne et al. 2019 used 620 l; synthetic pyrethroids containing cypermethrin or deltamethrin should be cheaper, e.g. 250 ml of Decis mega costs € 8-9), boat (estimate of € 200-440 per day) and manpower (this depends on labour costs of Member States, see above). All health and safety procedures should be strictly followed when applying chemicals.</p>	
	<p><b>Physical methods:</b> drainage of closed waterbodies may be used in the case of confined populations. Habitat destruction/modification (e.g., filling the waterbody) and restoration could also be considered for small, isolated ponds, which cannot be drained.</p>	<p>In cases where a single closed pond has been invaded, it may be possible to drain the pond, destroying the population, but also the habitat (Poulet 2014). Moreover, repeated draining could be necessary before achieving the eradication (Poulet 2014) and water should be released in a safe place (e.g. pasture, arable land) far away from other waterbodies. Sieving could be considered only in very special and rare cases (very low water volumes). However, drying out cannot be effective to eradicate some species, especially those that burrow like common yabby (Gherardi et al. 2011). So, the water body should be left dry for at least one year to achieve the eradication. This may not always be possible, depending on the use/destination of the water body (e.g. if used for irrigation or fisheries, there would be an interest to restore as soon as possible).</p> <p>Draining a pond of approximately 400,000 m<sup>3</sup> could cost around € 40-50,000 (E. Tricarico, unpublished). Costs could</p>	<p>High</p>

		<p>be lower in case of planned draining for other reasons (e.g. fish harvesting).</p> <p>Habitat destruction/modification and restoration might work for small, isolated ponds, which cannot be drained and where the species tends to cause severe ecological damage. Re-invasion after restoration can be prevented with fencing or using tree-trunks (C. Chucholl, pers. comm. 2020). In Germany, a combination of techniques (traps, nets, bricks, gravel covering the ground to avoid burrowing and tree trunks as fence around the pond to avoid species dispersion) was used to manage <i>Faxonius immunis</i> in a pond of 763 m<sup>2</sup> (A. Martens, pers. comm. 2020). No details are available of the results and the costs.</p> <p>Depending on the use of the pond (e.g. fishing, aquaculture), stakeholders could have concerns about complete destroying the pond, and compensatory measures should be considered (e.g. creating a new pond in another area).</p> <p>Caught animals when draining a pond should be disposed of according to the national legislation. Health and safety procedures should be followed when draining a pond (e.g. protective clothing).</p>	
	<p><b>Autocidal methods:</b> they include the sterile male release technique (SMRT) and the use of sex pheromones. SMRT is based on capturing or rearing, sterilising, and releasing large numbers of males into the wild to mate with females, who will then produce non-viable eggs. It has been successful in the</p>	<p>In a pond (70,000 m<sup>2</sup>) located in North Italy, a two-year SMRT programme using males sterilised with X-rays coupled with intensive trapping led to a reduction of 87% in the abundance of red swamp crayfish (Aquiloni &amp; Zanetti 2014). The SMRT technique has the advantage of being species-specific, not harmful to the environment and generally acceptable to the public and stakeholders. Costs depend on the number of animals to be sterilised but are usually low,</p>	<p>Medium</p>

	<p>control of some insect pests and aquatic vertebrates, such as sea lamprey <i>Petromyzon marinus</i>. Up to now, SMRT in crayfish has been successfully used only in the red swamp crayfish. Sex pheromones are widely used to control insect pests and research is in progress to identify them in crayfish.</p>	<p>depending on the cost of manpower (labour costs vary according to the different Member States). Its use is more effective in relatively small, closed systems. However, manual removal of gonopods (i.e. modified appendages in males used for reproduction) cannot be considered for <i>Cherax destructor</i>, lacking typical male gonopods present in members of other crayfish families. Moreover, even if intersex individuals (with both male and female genital openings) are present (and thus the identification of only males could be more difficult), SMRT could work on common yabby (but no studies have been conducted so far).</p> <p>The presence of sex pheromones has been proved in crayfish (Gherardi et al. 2011; Stebbing 2016). However, their purification and identification have not yet been achieved, even if their use in managing invasive alien crayfish could be very successful. Sex pheromones can be used in the traps to attract and kill reproductive individuals (El-Sayed et al. 2009). Caught animals should be disposed of according to the national legislation.</p> <p>The public and stakeholders accept both methods, and there are no relevant health and safety procedures to follow (except when using traps).</p>	
	<p><b>Autocidal methods: novel methods</b> There are other promising methods (monosex populations, silencing of key hormones through RNA interference, oral delivery of neuropeptides) successfully tested in the laboratory on</p>	<p>These methods are species-specific and should not harm any other species; they should be generally accepted, even if the genetic modification could elicit some concerns in public opinion. Their effectiveness in the field should be assessed. Costs are related to manpower (this depends on the labour costs of Member States) and genetics/chemical consumables (no detailed info). For <i>C. destructor</i>, hybrids</p>	<p>Medium</p>

	red swamp crayfish but not yet verified in the field (Manfrin et al. 2019).	with the congeneric <i>C. albidus</i> result in only male progeny (Lawrence et al. 2000). This technique has been used to control the reproduction in stocked ponds in Australia.	
	<b>Biological control methods: predators.</b> Several studies have shown that fish predation has an impact on crayfish populations. Fish usually predate juveniles, soft molted and small-sized crayfish, being complementary to trapping. In Europe, native fish as the eel <i>Anguilla anguilla</i> , the pike <i>Esox lucius</i> , the perch <i>Perca fluviatilis</i> and the pikeperch <i>Stizostedion lucioperca</i> have been observed to prey on invasive alien crayfish (Gherardi et al. 2011; Stebbing 2016; Manfrin et al. 2019).	In the USA, in an isolated lake in Wisconsin, Sparkling Lake (1,000,000 m <sup>2</sup> ), during a long-term management action (8 years) involving the combination of intensive trapping and the protection of local smallmouth bass from fishing pressure led to a 99% decline in crayfish abundance with no population recovery in the subsequent four years (Hein et al. 2006, 2007; Hansen et al. 2013). This method is generally acceptable to the public or does not cause environmental damage, although moving fish between waterbodies would also require certification of fish health and maintenance of biosecurity protocols. There could be a potential conflict with anglers who want to catch and remove the fish, but a catch and release approach can be promoted in these cases. The cost is related mainly to traps (see above for mechanical methods) and manpower (this depends on labor costs of Member States). Native European fish should be used to control crayfish. They can be reintroduced or restocked (after having assessed the feasibility, i.e. potential effects on non-target species should be considered). There are no relevant health and safety procedures to follow.	High
	<b>Biological control methods: pathogens.</b> The species is susceptible to crayfish plague caused by the oomycete <i>Aphanomyces astaci</i> . Four populations of the species have been eradicated with this method in Spain (Souty-Grosset et al. 2006).	<i>Cherax destructor</i> infected in the laboratory or chronically infected signal crayfish <i>Pacifastacus leniusculus</i> were introduced into the invaded ponds and the entire <i>C. destructor</i> invasive populations died after 30 days and 120 days, respectively (Souty-Grosset et al. 2006). There are no relevant health and safety procedures to follow, and the method is not costly. However, its use might generate the	High

		risk of its indirect spreading to the native crayfish populations, that are all protected, elicited major concerns by public and stakeholders. Similarly, a chronically infected population can establish, serving as a source of the pathogen. Moreover, legal requirements (including a risk assessment) could be necessary to use pathogens as a control method in the wild in some Member States.	
<b>Methods to achieve management<sup>8</sup></b>	All the methods described above for spread and eradication can also be used to manage established populations of common yabby. An integrated approach is always recommended.	See above	See above
	<b>Physical methods:</b> diversion of rivers, and construction of barriers (e.g. weirs, small dams) may be used in the case of confined populations or to exclude the invasive alien species from habitats of protected or imperilled native species.	In some cases, exclusion barriers have been effective to contain invasive crayfish populations (e.g. preventing them from spreading into headwater reaches; Dana et al. 2011b; Frings et al. 2013). However, they can also impede the dispersal of native species like fish (thus eliciting some concerns in some stakeholders, such as anglers and conservationists) and be costly. Dams can also be effective, because they halt the spread of the species, but they should be maintained, and their cost could be high. No health and safety issues for personnel involved.	Medium

## Guidelines for Completing the Annex

1 Provide a brief summary description of the most cost-effective methods drawing on the reviews in the detailed assessments

2 Provide a description of the potential method. This should be based on the available key scientific evidence which should be gathered from sources including articles and reviews in technical and scientific journals, internet searches, online databases, grey literature and relevant books and personal communications from scientists, stakeholders, conservation practitioners and governmental bodies. This information should include a full bibliographic list detailing the literature and sources considered.

3 Provide an assessment of the likely cost and effectiveness of the method. Where information is available, consider the following range of questions, accepting that not all questions will be appropriate in all circumstances.

- How effective has this approach proven to be in the past or in an analogous situation?
- How publically acceptable is the approach likely to be?
- Over what period of time would this approach need to be applied to be effective?
- What is the direct cost of implementing this approach?
- How likely are the methods used in the approach to be available?
- How likely is it that relevant licences or other approvals to undertake the approach would be difficult to obtain?
- How likely is it that health and safety issues would prevent the use of this approach?
- How significant is the environmental harm caused by this approach?
- How significant is the economic harm caused by this approach?
- How significant is the social harm caused by this approach?
- How likely is it that the approach will be criticised on welfare grounds?
- How likely is it that the approach will be acceptable to other stakeholders?

Where available, factual information on the costs of specialist equipment, or case studies of management costs from across the Union or third countries should be provided. When describing case studies, if the information is available then provide both total cost and the area over which control was undertaken so that a cost per unit area might be derived. Where such quantitative information is not available, then any qualitative information from the literature is acceptable to help guide decision making. It is accepted that in the majority of cases the information required to assess the potential total cost of management at a member state level is unlikely to be available. This would normally require information on the extent and abundance of the species which is beyond the scope of this assessment. Assessors are not expected to extrapolate the potential total costs of management at a member state level, only to report on the information provided within the literature.

4 Provide an overall assessment of the confidence that can be applied to the information provided for this method. This confidence should relate to the quality of the available information using the guidance below. It should NOT relate to the confidence in the effectiveness of the method

The confidence scores are:

- **High:** Information comes from published material, or current practices based on expert experience applied in one of the EU countries or third country with similar environmental, economic and social conditions.
- **Medium:** Information comes from published data or expert opinion, but it is not commonly applied, or it is applied in regions that may be too different from Europe (e.g. tropical regions) to guarantee that the results will be transposable.
- **Low:** data are not published in reliable information sources and methods are not commonly practiced or are based solely on opinion; This is for example the case of a novel situation where there is little evidence on which to base an assessment.

If there are further factors beyond these that have determined the chosen level of confidence, then provide a brief written description to support the choice of the level of confidence.

5 Measures for preventing the species being introduced intentionally or unintentionally into the territory of a Member State (cf. Articles 7(1)(a), 7(2), 13, 15), i.e. preventing a species entering by blocking its pathways, including pre-border prevention and prevention of escape or release into the environment and secondary spread whenever relevant. Measures for preventing the species reproducing while in containment should be included, if appropriate. Consider all methods that might be applied, including any that have not proven useful. Provide a description of each method in turn, using separate rows to consider each method.

6 Measures to run an effective surveillance system for achieving an early detection of a new occurrence (cf. Article 16). This section assumes that the species is not currently present in a Member State, or part of a Member State's territory.

7 Measures to achieve eradication. Preferably, but not exclusively, used at an early stage of invasion, after an early detection of a new occurrence (cf. Article 17). Consider all methods that might be applied, including any that have not proven useful. Provide a description of each method in turn, using separate rows to consider each method.

8 Measures to achieve management of the species once it has become widely spread within a Member State territory (cf. Article 19). These measures can be aimed at eradication, population control or containment of a population of the species. Consider all methods that might be applied, including any that have not proven useful. Provide a description of each method in turn, using separate rows to consider each method.

The development and completion of this template forms part of the EU project **No 07.0202/2020/834529/ETU/ENV.D.2** Study on Invasive Alien Species – Development of risk assessments to tackle priority species and enhance prevention.

**Risk assessment template developed under the "Study on Invasive Alien Species – Development of risk assessments to tackle priority species and enhance prevention"  
Contract No 07.0202/2020/834529/ETU/ENV.D.2<sup>1</sup>**

**Name of organism:** *Delawarea odorata* Lem.

**Author(s) of the assessment:**

## SECTION A – Organism Information and Screening

**A1. Identify the organism. Is it clearly a single taxonomic entity and can it be adequately distinguished from other entities of the same rank?**

including the following elements:

- the taxonomic family, order and class to which the species belongs;
- the scientific name and author of the species, as well as a list of the most common synonym names;
- names used in commerce (if any)
- a list of the most common subspecies, lower taxa, varieties, breeds or hybrids

As a general rule, one risk assessment should be developed for a single species. However, there may be cases where it may be justified to develop one risk assessment covering more than one species (e.g. species belonging to the same genus with comparable or identical features and impact). It shall be clearly stated if the risk assessment covers more than one species, or if it excludes or only includes certain subspecies, lower taxa, hybrids, varieties or breeds (and if so, which subspecies, lower taxa, hybrids, varieties or breeds). Any such choice must be properly justified.

Response: This risk assessment covers one species, the Cape ivy *Delairea odorata* Lem.

### Taxonomy

<b>Kingdom</b>	<i>Plantae</i>
<b>Phylum</b>	<i>Tracheophyta</i>
<b>Class</b>	<i>Magnoliopsida</i>
<b>Order</b>	<i>Asterales</i>
<b>Family</b>	<i>Asteraceae</i> Dumort.
<b>Subfamily</b>	<i>Asteroideae</i> (Cass.) Lindl.
<b>Genus</b>	<i>Delairea</i> Lem.
<b>Species</b>	<i>Delairea odorata</i> Lem.

*Delairea odorata* Lem., in Ann. Sci. Nat., Bot. 1: 379 (1844), is the valid name of the species with an origin in the Cape region of South Africa in the genus *Delairea* (family *Asteraceae*) (Euro+Med 2006-; IPNI 2021; Plants of the World Online 2021; Roskov et al. 2021; The Plant List 2013). This vine was first described by Lemaire (1844) as *Delairea odorata*, but transferred to *Senecio* (as *S. mikanioides*) by

Harvey (1865) and returned to the original *D. odorata* by Jeffrey (1986). For a long period, the genus *Delairea* was considered monospecific. Recently, Funez et al. (2021) newly described *Delairea aparadensis*, an endemic species in the highlands of southern Brazil.

### Synonyms

After cross-checking the information available at IPNI (2021), Plants of the World Online (2021), Euro+Med (2006-), Roskov et al. (2021), Iamónico (2017), and the African Plant Database (2021) it can be concluded that main synonyms for the species are:

- *Delairea scandens* (DC.) Lem.;
- *Mikania scandens* Lem. [*non* (L.) W.];
- *Senecio mikanioides* Otto ex Walp., in C.F.Otto & A.Dietrich, Allg. Gartenzeitung 13: 42. 1845;
- *Senecio scandens* Juss. ex DC. *non* Buch.-Ham. ex D.Don, *nom. illeg., p.p.*];
- *Breonia palmata* Hort. [*non* A.Rich.];
- *Ipomoea hederacea* Hort.

### Common names

According to CABI (2021), EPPO (2021), Euro+Med (2006-), FinBIF (2021) and Roskov et al. (2021) common names in the European region are:

- Croatian: staračac
- English: Cape ivy, German ivy, climbing senecio, parlor-ivy
- Finnish: murattivillakko
- French: lierre d'Allemagne
- German: Kap-Efeu, Efeugreiskraut, Salonefeu
- Italian: Senecione profumato, Senecione mikanioide
- Portuguese: erva-de-são-tiago
- Russian: крестовник миканиевидный
- Spanish: yedra alemana
- Swedish: sommarmurgröna
- Welsh: Creulys Dail Eiddew

According to Cal-IPC (2021a), Italian ivy, ivy groundsel, parlor ivy and water ivy are additional common names in the USA.

### Most common subspecies, lower taxa, varieties, breeds or hybrids

Subspecies, lower taxa, breeds or hybrids are not known. Two morphological varieties (stipulate and exstipulate) of Cape-ivy exist in the native region in South Africa as well in the invaded regions of California and Oregon (Reddy & Mehelis 2015). The stipulate variety has ear-like, flattened auricles at the base of the leaf petioles, whereas the exstipulate variety lacks auricles. The stipulate variety is the most common variety reported in all collections of Cape-ivy in South Africa (Robison & DiTomaso, 2010). In contrast, the exstipulate variety is the most common variety in California (Robison & DiTomaso, 2010).

#### **Assumptions made by the authors on the reproductive mechanisms of *D. odorata* in the risk assessment area**

*Delairea odorata* is an obligate outcrossing species that can reproduce sexually by seed which are wind dispersed and spreads vegetatively from stem fragments that readily root at nodes (Robison, 2006) and by the extension of the plant through stolons (Alvarez 1998). Viable seed has only been reported from the plants' native range (South Africa) and from Australia (Rolando 2000) and the USA (Hawaii, California and Oregon) (Robison 2006, Alvarez, 1998, Rolando, 2000).

It is interesting to note that viable seed was not reported in the USA before 2000, despite relevant studies. Bossard (2000) and Bossard et al. (2000) tested thousands of seeds from 26 populations in the USA and did not find any viable seeds. Additionally, Young (2000) tested 100 seeds at temperatures between 5 and 40 °C using various treatments and only one seed germinated. However, Robison (2006) showed that *D. odorata* was self-incompatible and able to produce viable seed throughout California. Over a three-year period, seed from a wide geographic range of populations was sampled and 66% of 104 locations produced viable seed. In addition, viable seed is reported from Oregon (Robison 2006).

Robison (2006) suggests that this indicates, at least in California, viable seed was not produced in populations in the natural environment prior to 2001. The author suggests that this could be due to two reasons:

1. Because the flowers of *D. odorata* are self-incompatible, only a few genetic lines have been introduced, which inhibits viable seed production. But potentially, additional genetic lines have been introduced.
2. A factor inhibiting viable seed production occurs in the risk assessment area.

Robison (2006) does however highlight that it is not known whether sexual or asexual reproduction contributes more to the spread of *D. odorata* in North America. Robison (2006) notes that although viable seed is produced in some populations in the USA, most populations are sterile and clonal expansions.

In the risk assessment area, vegetative reproduction is considered the main, if not the only reproductive mechanism. Vegetative reproduction can occur at any time when the nodes of the stem, stolon, or leaf petiole are in contact with the soil. Small fragments of 1.3 cm can root easily and quickly.

Seed production has been observed in the risk assessment area (for example, pers. obs. E. Marchante, Portugal), but scientific studies are lacking to confirm seed viability.

The authors of this risk assessment have assumed that at the current time in the risk assessment area, *D. odorata* does not produce:

- (1) viable seed, or
- (2) Seedlings are not produced in the natural environment, or
- (3) Seedlings do not persist to grow into mature plants.

The authors base these assumptions on two main arguments. Firstly, there is no scientific evidence to suggest one or more of the above occur in the risk assessment area. Secondly, although the species is established in the risk assessment area, evidence of high spread rates and establishment of satellite populations, as would be expected from a wind dispersed species, is lacking.

Therefore, throughout the risk assessment, only vegetative reproduction is considered when answering and scoring the questions (with the exception of some questions on entry when potentially viable seed could be imported). However, when providing the overall score for the risk assessment and the associated confidence, the uncertainty of viable seeds has been taken into consideration.

If point 1, 2 and 3 occur in the future this may increase the scores in the spread sections. This may require a revision of the spread scores. The authors do not consider that the lack of seed production in itself is a limitation to invasiveness.

**A2. Provide information on the existence of other species that look very similar [that may be detected in the risk assessment area, either in the environment, in confinement or associated with a pathway of introduction]**

Include both native and non-native species that could be confused with the species being assessed, including the following elements:

- other alien species with similar invasive characteristics, to be avoided as substitute species (in this case preparing a risk assessment for more than one species together may be considered);
- other alien species without similar invasive characteristics, potential substitute species;
- native species, potential misidentification and mis-targeting

Response: *Delairea odorata* is a fleshy, perennial, evergreen vine with a woody base. Roots arise from the nodes of stolons and rhizomes, and are simple and shallow, frequently scarcely penetrating the loose surface layer of organic material. Stolons and rhizomes are shiny, with thick cuticles, and the latter frequently have dark purple blotches, or are entirely purple. Stems are twining and can ascend to 8 m. Leaves are green, glabrous, alternate, broadly deltate to “ivy-shaped”, 3-10 cm long, 3.6 cm wide with 3 to 10 lobes. Both leaves and stems store water. Capitula with yellow florets, grouped on terminal and axillary cymes, disk florets 4-5 mm long arranged in clusters, ray flowers absent. Fruits are cypselas about 2 mm long, pappus 5–6 mm long, readily falling or fragile, white; bristles minutely scabrid-barbellate (CABI 2021a; EPPO 2012; Manning, & Goldblatt 2012).

**Existence of other non-native species that look very similar**

*Senecio angulatus* (*Asteraceae*; creeping groundsel, climbing groundsel) is a vigorous fast-growing climber with semi-succulent stems and leaves native to South Africa. Its form is a dense tangled shrub 2 meters tall or a climber that can reach 6 meters high. The leaves are rhombic to ovate, 3.7 to 22

centimeters long and 1 to 14 centimeters wide and occur in 1-4 pairs. They are thick, glossy, fleshy and coarsely toothed (but not entirely), with one to three teeth each side and bluntly lobed, with upper leaves becoming smaller with fewer teeth or none at all. Flower heads radiate, in branched corymbs or panicles, yellow, involucre calyced (Manning, & Goldblatt 2012). According to Euro+Med (2006- b) and CABI (2021b), the species is present in the following European countries: Albania, Croatia, France, Italy, Malta, Portugal and Spain.

*Senecio tamoides* (*Asteraceae*; Canary creeper, parlor ivy) is a climbing *Asteraceae* species native to Southern Africa. It is a fast-growing, scrambling, mostly evergreen perennial climber with semi-succulent stems and leaves that creeps along the ground or climbs several meters into the trees. It grows up to a height of 4 metres. The light green, shiny, fleshy leaves resemble those of ivy in that they are roughly triangle-shaped with unequal lobes. According to CABI (2021c), the species is present in Portugal.

*Roldana petasitis* (*Asteraceae*; Velvet groundsel) is an erect perennial *Asteraceae* shrub native to Southern Africa. Leaves with lamina are  $\pm$  circular to broad-ovate, 10–20 cm long and wide, margins palmately lobed with 9–13 lobes, softly hairy,; petiole at least half as long as lamina, except on leaves near heads. According to Euro+Med (2006- c) and CABI (2021d), the species is present in France, Italy, Portugal and Spain.

#### **Existence of other native species that look very similar**

No information about native species looking very similar are found.

**A3. Does a relevant earlier risk assessment exist? Give details of any previous risk assessment, including the final scores and its validity in relation to the risk assessment area.**

Response: No.

*Delairea odorata* was added to the EPPO Alert List in 2009 and transferred to the List of Invasive Alien Plants in 2012 (EPPO 2012).

#### Inside of the risk assessment area

##### **Cyprus**

In 2019, a workshop of experts on invasive alien species, prioritised species that may cause a threat to Cyprus. Experts were asked to score each potential IAS within their thematic group for their separate likelihoods of: (i) arrival, (ii) establishment, (iii) magnitude of the potential negative impact on human health or economies. *Delairea odorata* was considered a high threat as this species can negatively impact on both human health and economies. The plant species has a high likelihood of arrival, establishment and human health impacts within Cyprus (Peyton et al. 2020).

#### Outside of the risk assessment area

##### **United States of America (USA)**

USDA (2013) used a PPQ weed risk assessment model (Koop et al. 2012) to evaluate the risk potential of *Delairea odorata*. The species was first introduced into the USA in the 1850s as an ornamental houseplant (Robison et al. 2011). It was first collected from California in 1892 (Robison & DiTomaso, 2010) and naturalized there by the 1960s (Bossard et al. 2000). Since then, this species has become naturalized in all coastal counties in California, one coastal county in Oregon, and much of Hawaii (Kartesz 2021; Robison & DiTomaso 2010). In Hawaii, it was first collected in 1910 and is now considered naturalized (Wagner et al. 1999). In California, it occurs in riparian forest, coastal scrub, salt marsh, oak woodland, conifer forest, agricultural, and non-native forests (Robison & DiTomaso 2010). In California, it readily establishes in riparian areas and then spreads into drier sites (CABI 2021). In Hawaii, it encompasses an elevation range of 1600 to 8200 feet (487 m – 2500 m) (Jacobi & Warschauer 1992). *Delairea odorata* is managed in California and Hawaii (Bossard et al. 2000; Elliott 1994; Motooka et al. 2003). It is commercially grown and sold in the USA, but it does not appear to be sold by any of the major distributors (e.g., Monrovia, Green Leaf, Bailey). It is sold as both Cape ivy and German ivy (CABI 2021). It primarily impacts natural systems. As with other vine species, *D. odorata* forms dense mats that blanket and smother vegetation (Elliott 1994), including small trees (Bossard et al. 2000), and reduces native species diversity (Alvarez & Cushman 2002). It prefers shady disturbed sites with ample year-round moisture (Bossard et al. 2000). In habitats without year-round moisture, it dies back during dry seasons and then regrows during wet seasons (Bossard et al. 2000). *Delairea odorata* is particularly troublesome because of its ability to root at stem nodes (Bossard et al. 2000; Elliott 1994). This species reproduces and spreads vegetatively from stem fragments that readily root at nodes (Robison 2006) and by the extension of the plant through stolons (Alvarez 1998). In summary, the result of the weed risk assessment for *Delairea odorata* is scored as **High Risk**.

Parts of the USA West coast may have similar climatic conditions as well as habitat conditions like some regions in the EU, basic information of e.g. biology, habitat preferences, invasiveness given in this risk assessment can be taken into account.

**USA - Hawaii**

According to the Hawaiian Ecosystems at Risk project (HEAR 2021) *Delairea odorata* is assessed as **High Risk** by a score of **14**. The relevant scores are:

Question	Score
Has the species become naturalized where grown?	
Species suited to tropical or subtropical climate(s) (0-low; 1-intermediate; 2-high)	2
Quality of climate match data (0-low; 1-intermediate; 2-high)	
Broad climate suitability (environmental versatility)	Yes
Native or naturalized in regions with tropical or subtropical climates	Yes
Does the species have a history of repeated introductions outside its natural range?	Yes

Question	Score
Naturalized beyond native range	Yes
Environmental weed	Yes
Toxic to animals	Yes
Causes allergies or is otherwise toxic to humans	Yes
Climbing or smothering growth habit	Yes
Geophyte (herbaceous with underground storage organs -- bulbs, corms, or tubers)	Yes
Produces viable seed	yes
Reproduction by vegetative fragmentation	Yes
Propagules likely to be dispersed unintentionally (plants growing in heavily trafficked areas)	Yes
Propagules dispersed intentionally by people	Yes
Propagules adapted to wind dispersal	Yes
Tolerates, or benefits from, mutilation, cultivation, or fire	Yes

Hawaii has different climatic conditions than regions in the EU, though basic information on e.g. biology, habitat preferences, given in this risk assessment can be taken into account, though the assessment of e.g. invasiveness has to be reviewed accordingly to different climate conditions.

#### USA - Oregon

*Delairea odorata* meets the criteria of an “A” listed noxious weed as defined by the Oregon Department of Agriculture Noxious Weed Policy and Classification System (ODA 2014). *Delairea odorata* scored **58** out of a potential score of 90 using an adapted USDA-APHIS PPQ rating system. Using the ODA Noxious Weed Rating system, the species scored **19**, indicating an “A” listing. Noxious weeds are non-native plants with scores of 11 points or higher. The determination is based on two independent risk assessments.

Issue	Answer and score

Invasive in other areas.	Known to be invasive in geographically similar areas (California Coastal Riparian Areas) - 6
Habitat availability: Are there susceptible habitats for this species and how common or widespread are they?	<b>High</b> - 6
Environmental factors: Do abiotic (non-living) factors in the environment effect establishment and spread of the species? (e.g., precipitation, drought, temperature, nutrient availability, soil type, slope, aspect, soil moisture, standing or moving water).	<b>Medium</b> – Moderately confined by environmental factors (Needs moisture year round to become established, can survive drought once established) - 2
Reproductive traits: How does this species reproduce? Traits that may allow rapid population increase both on and off site.	<b>Medium</b> – Reproduction is vegetative (e.g., by root fragments, rhizomes, bulbs, stolons) - 3
Biological factors: Do biotic (living) factors restrict or aid establishment and spread of the species?	<b>High</b> – Few biotic interactions restrict growth and reproduction. Species expresses full growth and reproductive potential (No evidence indicating biotic factors limiting spread on the west coast.) - 4
Reproductive potential and spread after establishment - Non-human Factors.	<b>Medium</b> - Moderate potential for natural spread with either high reproductive potential or highly mobile propagules (Can be moved in waterways during flood events, seeds can be wind blown via wispy pappus on achenes) - 3
Economic Impact: What impact does/can the species have on Oregon's agriculture and economy?	<b>Medium</b> – Potential to, or causes moderate impacts to urban areas, right-of-way maintenance, property values, recreational activities, reduces rangeland productivity (Similar impacts to that of English Ivy, which include additional right of way maintenance costs, forest regeneration costs, and control costs to public and private landowners. These impacts are most likely to occur in the coastal zones. Leaves are toxic to livestock, animals) - 5
Environmental Impact: What risks or harm to the environment does this species pose? Plant may cause negative impacts on ecosystem function, structure, and biodiversity of plant or fish and wildlife habitat; may put desired species at risk.	<b>High</b> - Species can or does cause significant impacts in several of the above categories. Plant causes severe impacts to limited or priority habitats (Significant impacts to riparian and some inland habitats, alters entire canopy and understory diversity.) - 6

Parts of Oregon may have similar climatic conditions as well as habitat conditions like some regions in the EU, basic information of e.g. biology, habitat preferences, invasiveness given in this risk assessment can be taken into account.

## USA - California

Cal-IPC (2021a) assesses *D. odorata* as a perennial vine found along the coast of California and in the San Gabriel Mountains. *Delawarea odorata* is especially problematic in coastal riparian areas, though it may also invade inland riparian areas, moist forests, and oak woodlands. Vines are known to form dense mats of vegetation over trees and shrubs, killing plants underneath. It is toxic to animals and fish can be killed when plant materials are soaking in waterways. Stem, rhizome and stolon fragments resprout if left in the ground after treatment. Can occasionally reproduce by seeds in some areas. The Cal-IPC rating is **high**. These species have severe ecological impacts on physical processes, plant and animal communities, and vegetation structure. Their reproductive biology and other attributes are conducive to moderate to high rates of dispersal and establishment. The California Department of Food and Agriculture (CDFA) Rating is **B\***. A pest with rating B is of known economic or environmental detriment and, if present in California, it is of limited distribution and is included in the CCR Section 4500 list of California State Noxious Weeds Cal-IPC (2021a). The impact on abiotic ecosystem processes, plant communities and on higher trophic levels are assessed as severe. Role of anthropogenic and natural disturbance in establishment is assessed as severe as well. *Delawarea odorata* takes over habitats regardless of anthropogenic or natural disturbance. *Delawarea odorata* on the US west coast grows vigorously in physically challenging environments such as streamside thickets, willows and poison oak (*Toxicodendron diversilobum*). Severe invasive potential. This species can establish independently of natural or anthropogenic disturbance. The distribution of *D. odorata* ranges along the entire Californian coast and some mesic areas of the Central Valley. Over 500,000 acres (202342 ha) are infested in California, and on Catalina Island, 13 populations were detected with six in riparian habitats and one in island scrub oak chaparral near a riparian area. *Delawarea odorata* spreads primarily by vegetative means, breaks apart easily and both stem nodes and leaf petioles are capable of rooting. Seeds disperse with wind, water, and soil movement. If there is a *D. odorata* source upstream, high water flows in the winter can be expected to transport pieces of plants down-stream, which can begin new colonies (2021b).

Parts of California may have similar climatic conditions as well as habitat conditions like some regions in the EU, basic information of e.g. biology, habitat preferences, invasiveness given in this risk assessment can be taken into account.

**Australia - Victoria**

The Weed Risk Assessment (WRA) developed by the Biosciences Research Division of the Department of Primary Industries, Victoria, is a prioritisation process or risk assessment, based on the Analytic Hierarchy Process (AHP), which ranks weeds by (1) assessing the plant’s invasiveness, (2) comparing the plant’s present and potential distribution and (3) determining the impacts of the plant on social, economic, and environmental values. Accordingly Agriculture Victoria (2021a) conducted an invasiveness (2021b) and impact (2021c) assessment of *Delawarea odorata* and modelled the species’ distribution (2021d). During the assessment of biological data, criteria are assigned intensity ratings (criteria ratings) of high (H), medium-high (MH), medium (M), medium-low (ML), and low (L), to score each species.

Relevant high respectively medium-high rated criterions regarding biological characteristics of *D. odorata* in the invasiveness assessment (2021b) are:

Establishment
---------------

Germination requirements	Germination is reported to be rare, occurring in autumn. However vegetative propagules (pieces of stem and stolons) which is the main form of reproduction can root and grow when conditions are suitable (Blood 2001) - <b>High</b>
Establishment requirements	Reported to invade rainforest (Carr et al. 1992). Therefore it can establish under low light conditions. Cut stems can survive months, then set roots and grow when exposed to suitable conditions (Blood 2001). Therefore it has some requirements for establishment. – <b>Medium-High</b>
How much disturbance is required?	Establishes in undisturbed /minor disturbed natural ecosystems: heath land: sclerophyll forest and woodland: riparian vegetation: rainforest (Carr et al. 1992). - <b>High</b>
Growth/Competitive	
Tolerates herb pressure?	Contains pyrrolizidine alkaloids and xanthenes that make it unsuitable forage for most fauna and if slashed to ground level, plants can regrow from rootstock (Bossard et al. 2000). Bio-Control agents have been researched in South Africa and a program has been developed in California, however no such efforts are reported in Australia (Bossard et al. 2000). - <b>High</b>
Normal growth rate?	Reported to be a fast growing vine (Weber 2003). In California it has been reported as spreading more rapidly than any other weed species. Average growth rates of plants around San Francisco have been calculated to one foot of growth per month. (Alvarez 1998). - <b>High</b>
Stress tolerance to frost, drought, w/logg, sal. etc?	Tolerates some salinity (recorded on salt exposed bluffs) (Alvarez 1998). Drought tolerant (Blood 2001). Reported in seasonal wetlands, therefore tolerant of waterlogging (Bossard et al. 2000). Frost tender (Blood 2001), however hard frosts appear to stimulate seed set, therefore while frost may damage the plant, it may not kill it. Foliage has high moisture content and therefore resistant to burning also plants can regrow from rootstock (Bossard et al. 2000). - <b>High</b>
Reproduction	
Reproductive system	Produces seed, however primary mode of reproduction is vegetative, through stolons and stem fragments (Bossard et al. 2000 and Muyt 2001). - <b>High</b>
Number of propagules produced?	Large plants can produce more than 40,000 seeds annually (Muyt 2001). - <b>High</b>

Reproductive period?	Long lived, can form monocultures (Bossard et al. 2000). - <b>High</b>
Time to reproductive maturity?	Reach sexual maturity within two years (Muyt 2001) – <b>Medium-High</b>
Dispersal	
Number of mechanisms?	Seeds are 2 mm with hairs attached, spread by wind and water (Muyt 2001). Vegetative propagules spread by water and deliberate human actions (Alvarez 1998). - <b>High</b>
How far do they disperse?	Wind dispersed seed can travel distances of more than 1 km. - <b>High</b>

Relevant high or medium-high rated criteria regarding recreation, abiotic characteristics, habitat and fauna in the impact assessment (2021c) are:

Recreation	
Restrict human access?	Can form dense tangled curtains of vegetation, including in riparian areas (Muyt 2001). Access would be difficult and would require significant work to control the species to maintain access due to the species rapid growth. – <b>Medium-High</b>
Injurious to people?	Toxic to people. Toxins include pyrrolizidine alkaloids and xanthones, which are contained in the leaves and present all year (Bossard et al. 2000). No reported fatalities. – <b>Medium-High</b>
Abiotic	
Increase soil erosion?	Can contribute to soil erosion on hillsides (Bossard et al. 2000). – <b>Medium-High</b>
Reduce biomass?	The weight of the ivy can cause trees to fall, and dense canopy of the vine can smother species of the lower strata and reduce growth (Bossard et al. 2000). – <b>Medium-High</b>
Community Habitat	
Impact on composition  (a) high value Ecological Vegetation Class (EVC): Riparian Forest	The weight of the ivy can cause trees to fall, the dense canopy of the vine can smother species of the lower strata and reduce growth and regeneration of species and can form monocultures (Bossard et al. 2000). All EVCs - <b>High</b>

(b) medium value EVC: Lowland Forest	
(c) low value EVC: Wet Forest	
Impact on structure?	The weight of the ivy can cause trees to fall, and the dense canopy of the vine can smother species of the lower strata and reduce growth and regeneration of species (Bossard et al. 2000). – <b>Medium-High</b>
Effect on threatened flora?	Can significantly reduce the species richness and diversity of an area, and render habitat in protected reserves for plant species worthless (Bossard et al. 2000). – <b>Medium-High</b>
Fauna	
Effect on threatened fauna?	Can render habitat in protected reserves for animal species worthless (Bossard et al. 2000). – <b>Medium-High</b>
Effect on non-threatened fauna?	Significant alteration of habitat; reducing plant species richness and diversity and therefore diversity of food and shelter available. Invasion by cape ivy can render habitat in protected reserves for animal species worthless (Bossard et al. 2000). – <b>Medium-High</b>
Benefits fauna?	Nothing reported. Insects may visit flowers, dense foliage may provide some shelter. - <b>High</b>
Injurious to fauna?	Foliage contains compounds toxic to mammals, spiders and fish (Bossard et al. 2000). Compounds toxic but not necessarily lethal to rats. - <b>High</b>

In summary, *Delairea odorata* is assessed as **Highly Invasive** (Score 0.6-0.79) by its invasiveness index of 0.72 and a **risk rating V - very serious threat to one or more vegetation formation in Victoria**.

Parts of Victoria may have similar climatic conditions as well as habitat conditions like some regions in the risk assessment, basic information of e.g. biology, habitat preferences, invasiveness given in this risk assessment can be taken into account.

#### **A4. Where is the organism native?**

including the following elements:

- an indication of the continent or part of a continent, climatic zone and habitat where the species is naturally occurring
- if applicable, indicate whether the species could naturally spread into the risk assessment area

Response: *Delairea odorata* is native to southern Africa from Uitenhage to KwaZulu-Natal (CABI 2021; Manning & Goldblatt 2012; Red List of South African Plants 2021), i.e. Lesotho and (Eastern and Western) Cape Province and KwaZulu-Natal in South Africa (GRIN-Global 2021; Grobbelaar et al. 1999; Queensland Government 2021; Roskov et al. 2021; USDA 2013).

Hilliard (1977) describes the native distribution as: “*Widespread, but not much collected, from the Cape peninsula through the southern and eastern Cape to Natal as far north as Nkandia, Nhlazatsche Mt. and the Biggarsberg north of Ladysmith; also recorded from Mhaleshoek in Lesotho. Grows on forest margins or in the forest, in Natal between ca. 800 and 1900 m above sea level.*” In its native region, *D. odorata* appears to have originally been confined to 'mist-veldt' regions, such as those in the Drakensberg Mountains, where it is found along forest edges and as an opportunistic vine exploiting openings in the native forest. Its occurrence at more coastal sites in South Africa may be more recent (Balciunas et al. 2004). Some of the coastal sites are quite arid, to less than 100 mm/yr (CABI 2021). According to EPPO (2012), Cape ivy grows in moist mountain forests.

Since the native distribution center in southern Africa and the European continent are separated by a large distance, natural spread into the risk assessment area is very unlikely.

<b>A5. What is the global non-native distribution of the organism outside the risk assessment area?</b>
---

Response: Table 1 and Figure 1 give an overview about global non-native distribution outside the risk assessment area. Considering the native range in the Cape region of Southern Africa, available spatial and non-spatial data describe the non-native distribution of *Delairea odorata* covering parts of North, Middle and South America, Northern Africa, Asia and Oceania. Occurrence information provided in literature without coordinates are listed in the table, but are not shown in the map.

## Delairea odorata

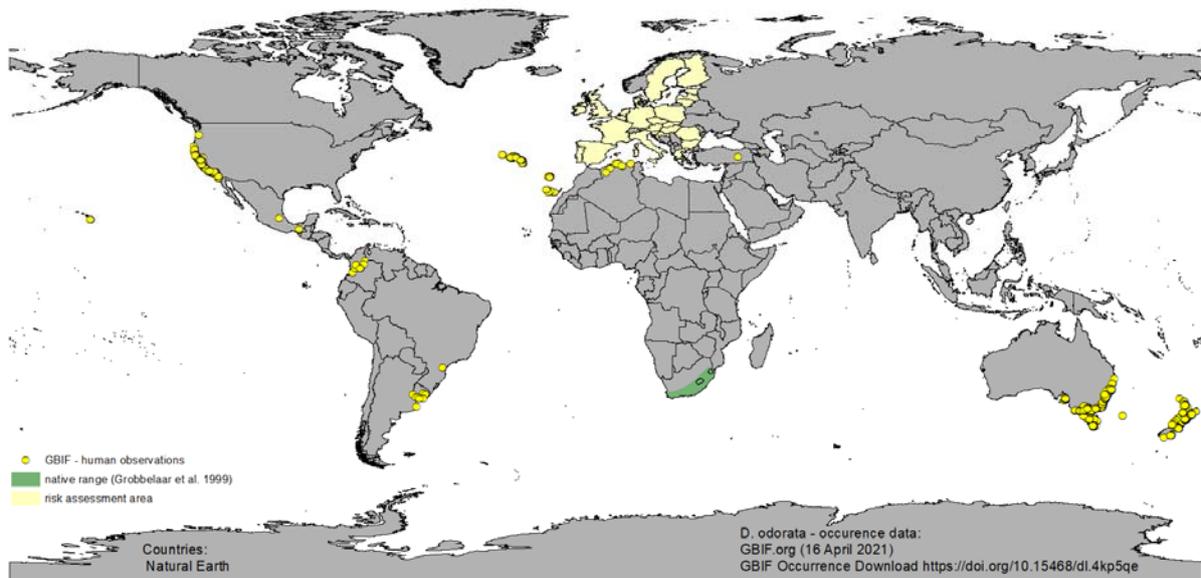

Figure 1 Global non-native occurrence records of *Delairea odorata* outside the risk assessment area (map designed by Umweltbundesamt/Environment Agency Austria - 2021/04/19)

Table 1 countries with *Delairea odorata* occurrences mentioned in references and databases (\* references without coordinates not shown in map)

**A6. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species been recorded and where is it established? The information needs to be given separately for recorded (including casual or transient occurrences) and established occurrences. “Established” means the process of an alien species successfully producing viable offspring with the likelihood of continued survival<sup>2</sup>.**

**A6a. Recorded: List regions**

**A6b. Established: List regions**

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

- Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea.

Comment on the sources of information on which the response is based and discuss any uncertainty in the response.

For delimitation of EU biogeographical regions please refer to <https://www.eea.europa.eu/data-and-maps/figures/biogeographical-regions-in-europe-2> (see also Annex VI).

<sup>2</sup> Convention on Biological Diversity, Decision VI/23

For delimitation of EU marine regions and subregions consider the Marine Strategy Framework Directive areas; please refer to <https://www.eea.europa.eu/data-and-maps/data/msfd-regions-and-subregions/technical-document/pdf> (see also Annex VI).

Response: The Arctic, Anatolian and Macaronesian biogeographical regions are not part of the risk assessment area, but included for completeness. Table 2 and Figure 2 give an overview about occurrences of the species in the biogeographical regions. In the Steppic region, no occurrence information is available.

Source of human observation data is GBIF (2021), European wide overviews like Euro+Med PlantBase (providing an on-line database and information system for the vascular plants of Europe and the Mediterranean region, against an up-to-date and critically evaluated consensus taxonomic core of the species concerned) as well as national floristic or invasive species references.

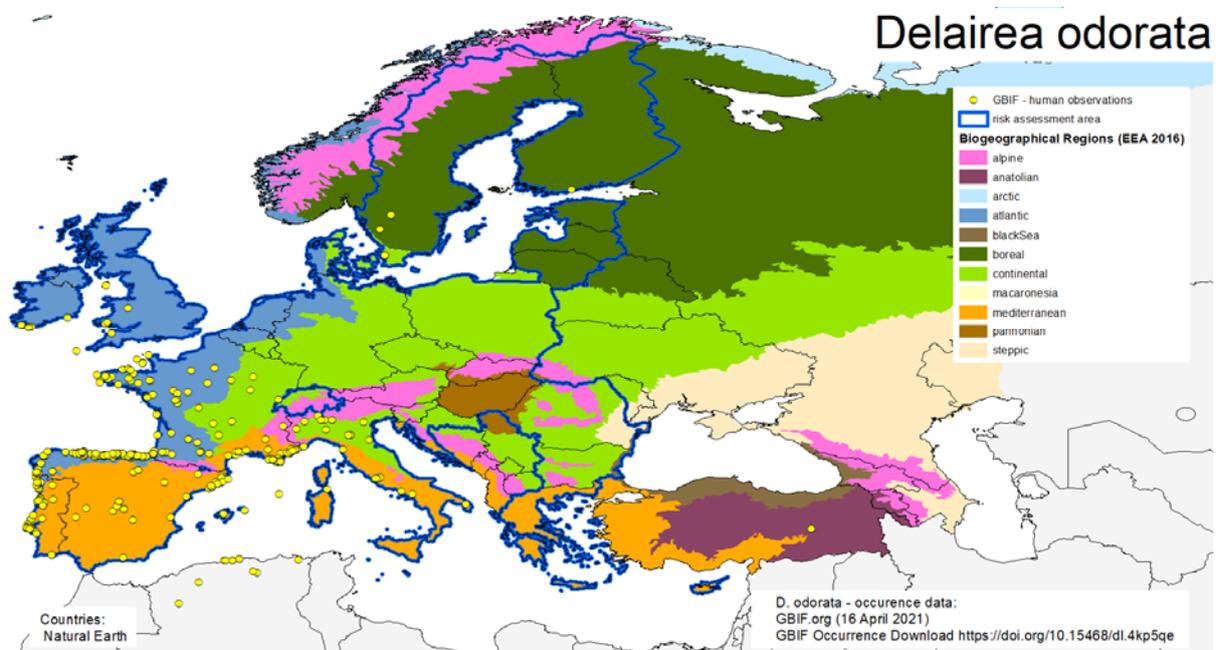

Figure 2 Occurrence records of *Delairea odorata* in the biogeographical regions (map designed by Umweltbundesamt/Environment Agency Austria – 2021/04/19)

(2005), EPPO (2012), EPPO (2021), Euro+Med (2006- a), GISD (2021), GRIN-Global (2021), Plants of the World online (2021), Roskov et al. 2021, Royal Botanic Garden Edinburgh (2003), Sampaio (1947), Tutin et al. (1976)
Pannonian	No	No		
Steppic	No	No		

Response (6a): *Delairea odorata* is recorded in the Alpine, Atlantic, Boreal, Continental and Mediterranean biogeographical regions. No recorded occurrence data is available for the Black Sea, Pannonian and Steppic biogeographical regions.

Response (6b): According to the available information, *D. odorata* can be considered as “established” in the Atlantic, Continental and Mediterranean biogeographical regions.

“Established” means the process of an alien species successfully producing viable offspring with the likelihood of continued survival. In the available references (mainly Euro+Med PlantBase), the term “naturalized” is used. In order to answer question 6b, “naturalized” is used as a synonym for “established”. The assessment of established occurrences in biogeographical regions is mainly deduced from the data available on national level (compare Table 3).

**A7. In which biogeographic region(s) or marine subregion(s) in the risk assessment area could the species establish in the future under current climate and under foreseeable climate change? The information needs be given separately for current climate and under foreseeable climate change conditions.**

**A7a. Current climate: List regions**

**A7b. Future climate: List regions**

With regard to EU biogeographic and marine (sub)regions, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

According to SDM results (see also Annex IX) the biogeographical regions *D. odorata* could establish in are as follows:

Response (7a):

<b>Biogeographic region</b>	<b>likeliness</b>	<b>confidence</b>
Alpine	unlikely	high
Anatolian	unlikely	high
Arctic	unlikely	high

**A8. In which EU Member States has the species been recorded and in which EU Member States has it established? List them with an indication of the timeline of observations. The information needs be given separately for recorded and established occurrences.**

**A8a. Recorded: List Member States**

**A8b. Established: List Member States**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden

The description of the invasion history of the species shall include information on countries invaded and an indication of the timeline of the first observations, establishment and spread.

Response: Figure 2 and Table 3 give an overview about occurrences of the species in the EU Member States and the United Kingdom. Sources of information are observational data (GBIF 2021), European wide overviews like Euro+Med PlantBase as well as national floristic or invasive species references. An indication of the first observation is not possible for every member state but given if possible.

Response (8a): *Delairea odorata* is recorded in 8 out of 27 Member States (Croatia, Finland, France, Ireland, Italy, Portugal, Spain, Sweden) and in the United Kingdom.

Response (8b): Based upon the available data, *Delairea odorata* can be assessed as established in 6 Member States (Croatia, France, Ireland, Italy, Portugal, Spain) and in the United Kingdom.

By using a subset of GBIF records with a spatial accuracy  $\leq 250$  m, the EUNIS habitat classes at Level 2 (EEA 2019) can be spatially retrieved from the Ecosystem types of Europe 2012 raster data set. *Delairea odorata* in its native distribution seems to underlie some oceanic climate conditions. Therefore, the parameter “distance to sea” is used in the species distribution model (SDM; see Annex VIII). In its non-native range in the Western USA (California, Oregon), the species is described with most occurrences in coastal areas. In order to get some impressions whether there may be differences in EUNIS ecosystems at actual European occurrences, these are roughly classified as directly along coast-line respectively as countryside (Figure 3).

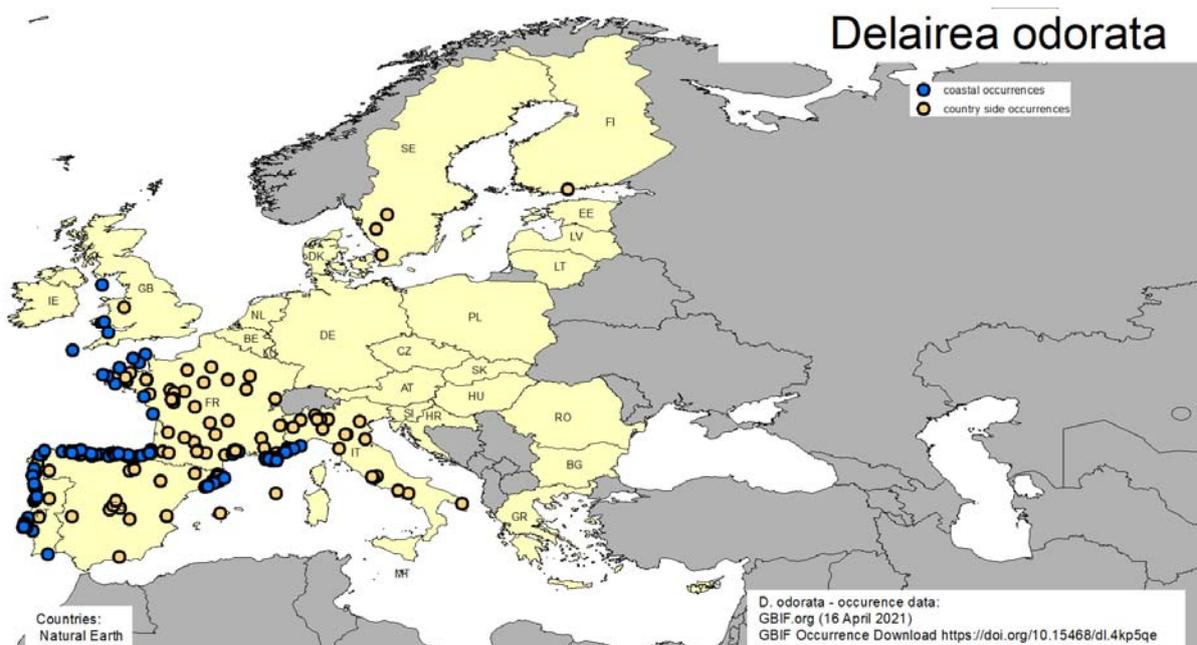

Figure 3 coastal/countryside classified occurrences of *Delairea odorata* (map designed by Umweltbundesamt/Environment Agency Austria – 2021/04/19)

Based upon the available data, there is enough evidence that the used data covers several ecosystem categories from anthropogenic/urban to more natural types (Table 4) in coastal as well as in countryside classified occurrences.

Anthropogenic types are for example *Buildings of cities, towns and villages* or *Low density buildings*; more natural types are woodland (*Broadleaved deciduous woodland* or *Mixed deciduous and coniferous woodland*) and grassland (*Mesic grassland*).

Table 4 *Delairea odorata* GBIF occurrences with coordinate accuracy < 250 m classified as coastal or countryside, and related EUNIS habitat classes at level 2 (EEA 2019)

EUNIS ecosystem level 2	coastal occurrences	countryside occurrences
E2 - Mesic grasslands	18	10
F3 - Temperate and Mediterranean-montane scrub	3	
F5 - Maquis, arborescent matorral and thermo-Mediterranean brushes	1	
FB - Shrub plantations		1
G1 - Broadleaved deciduous woodland	8	8

<b>EUNIS ecosystem level 2</b>	<b>coastal occurrences</b>	<b>countryside occurrences</b>
G2 - Broadleaved evergreen woodland	1	
G3 - Coniferous woodland	4	
G4 - Mixed deciduous and coniferous woodland	5	
G5 - Lines of trees, small anthropogenic woodlands, recently felled woodland, early-stage woodland and coppice	1

**A9. In which EU Member States could the species establish in the future under current climate and under foreseeable climate change? The information needs be given separately for current climate and under foreseeable climate change conditions.**

**A9a. Current climate: List Member States**

**A9b. Future climate: List Member States**

With regard to EU Member States, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

The ensemble model (see Annex IX) suggested that suitability for *D. odorata* was most strongly determined by Minimum temperature of the coldest month (Bio6), accounting for 50.2% of variation explained, followed by Human influence index (HII) (24.8%), Mean temperature of the warmest quarter (Bio10) (10.4%), Distance to the sea (dist\_to\_sea) (8.6%), Climatic moisture index (CMI) (5.6%) and Global tree cover (Tree) (0.4%)

**A10. Is the organism known to be invasive (i.e. to threaten or adversely impact upon biodiversity and related ecosystem services) anywhere outside the risk assessment area?**

Response: *Delairea odorata* is invasive in North America (California, Hawaii and Oregon), Australia (New South Wales, Northern Territory, South Australia, Tasmania, Victoria) and New Zealand.

Table 1 gives an overview about invasiveness outside of the risk assessment area. Well-documented invasive behavior of *Delairea odorata* is reported for Australia, New Zealand, and the United States.

In California, it occurs in riparian forest, coastal scrub, salt marsh, oak woodland, conifer forest, agricultural, and non-native forests (Robison & DiTomaso 2010). *Delairea odorata* forms dense mats that blanket and smother vegetation (Elliott 1994), including small trees (Bossard et al. 2000), and reduces native plant species diversity (Alvarez & Cushman 2002). Cape ivy can invade different habitat types ranging from disturbed to native ecosystems and occurs in both dry to moist conditions. Due to a shallow root system, Cape ivy can contribute to soil erosion problems on hillsides and impact flood control functions along streams (Bossard 2000).

In southern Australia, Cape Ivy is a highly invasive environmental weed. It invades waterways, moist gullies, closed forests and margins, open woodlands, roadsides, waste areas and coastal areas and is also commonly found in gardens and along fences and urban areas parks (Weeds Australia 2021).

In New Zealand, Cape Ivy can be found in coastal and lowland regions. The plant occurs in coastal ecosystems as well as in scrub and forest margin communities, shrublands, rocklands, roadsides, quarries, farm hedges, wasteland and house gardens (New Zealand Plant Conservation Network 2021).

**A11. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea

Response: *Delairea odorata* exhibits a widespread distribution in parts of the Atlantic and Mediterranean biogeographical regions (compare Figure 2). There are documented signs of invasiveness in these regions, especially along the coastlines. In Portugal, Cape Ivy frequently invades banks of watercourses, hedgerows and slopes, ruderal environments and communities of thorny shrubs (Plantas invasoras em Portugal 2020). *Delairea odorata* is reported as established in Tuscany (including the Tuscan Archipelago, see Lazzaro et al., 2014) and in Sardinia (Italy) (Iamónico 2017), where it occurs in ruderal habitats only, and in few localities with low density, so that at the time being no significant ecological impacts have been recorded (Bacchetta et al. 2009, Camarda et al. 2016, Portale della Flora d'Italia 2021).

**A12. In which EU Member States has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden

Response: There are documented signs of invasiveness in Portugal and Italy. In Portugal, Cape Ivy frequently invades banks of watercourses, hedgerows and slopes, ruderal environments and communities of thorny shrubs (Plantas invasoras em Portugal 2020). *Delairea odorata* is reported as established in Tuscany and in Sardinia (Italy) (Iamónico 2017), where it occurs in ruderal habitats only, and in few localities with low density, so that at the time being no significant ecological impacts have been recorded (Bacchetta et al. 2009, Camarda et al. 2016, Portale della Flora d'Italia 2021).

For the United Kingdom, invasiveness is mentioned in a few references (e.g. CABI 2021a), though no further and detailed information could be found.

**A13. Describe any known socio-economic benefits of the organism.**

including the following elements:

- Description of known uses for the species, including a list and description of known uses in the risk assessment area and third countries, if relevant.
- Description of social and economic benefits deriving from those uses, including a description of the environmental, social and economic relevance of each of those uses and an indication of associated beneficiaries, quantitatively and/or qualitatively depending on what information is available.

If the information available is not sufficient to provide a description of those benefits for the entire risk assessment area, qualitative data or different case studies from across the risk assessment area or third countries shall be used, if available.

Response: *Delairea odorata* is a popular ornamental climbing vine used in landscaping and gardening (Cal-IPC 2021a, EPPO 2012, ISSG 2021). *Delairea odorata* is traded and used as an ornamental species

in the RA area. However, there is no quantitative data on its value to the horticulture trade and it is not considered to be a popular species in horticulture. This may also be due to the fact that the species can easily be propagated by its ramets. Ornamental use includes the use as a ground cover and also for covering structures; additionally, the species is used as an indoor ornamental.

## SECTION B – Detailed assessment

### Important instructions:

- In the case of lack of information the assessors are requested to use a standardized answer: “No information has been found.” In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable).
- With regard to the scoring of the likelihood of events or the magnitude of impacts see Annexes I and II.
- With regard to the confidence levels, see Annex III.
- Highlight the selected response score and confidence level in **bold** but keep the other scores in normal text (so that the selected score is evident in the final document).

## 1 PROBABILITY OF INTRODUCTION AND ENTRY

### Important instructions:

- **Introduction** is the movement of the species into the risk assessment area (it may be either in captive conditions and/or in the environment, depending on the relevant pathways).
- **Entry** is the release/escape/arrival in the environment, i.e. occurrence in the wild
- Introduction and entry may coincide for species entering through pathways such as “corridor” or “unaided”, but it also may differ. If different, please consider all relevant pathways, both for the introduction into the risk assessment area and the entry in the environment.
- The classification of pathways developed by the Convention of Biological Diversity (CBD) should be used (see Annex IV). For detailed explanations of the CBD pathway classification scheme consult the IUCN/CEH guidance document<sup>3</sup> and the provided key to pathways<sup>4</sup>.
- For organisms which are already present (recorded or established) in the risk assessment area, the likelihood of introduction and entry should be scored as “very likely” by default.
- Repeated (independent) introductions and entries at separate locations in the risk assessment area should be considered here (see Qu. 1.7).

**Qu. 1.1. List relevant pathways through which the organism could be introduced into the risk assessment area and/or enter into the environment. Where possible give details about the specific origins and end points of the pathways as well as a description of any associated commodities.**

For each pathway answer questions 1.2 to 1.8 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 1.2a, 1.3a, etc. and then 1.2b, 1.3b etc. for the next pathway.

In this context a pathway is the route or mechanism of introduction and/or entry of the species.

<sup>3</sup> <https://circabc.europa.eu/sd/a/7e5f0bd4-34e8-4719-a2f7-c0cd7ec6a86e/2020-CBD-pathways-interpretation.pdf>

<sup>4</sup> <https://circabc.europa.eu/sd/a/0aeba7f1-c8c2-45a1-9ba3-bcb91a9f039d/TSSR-2016-010%20CBD%20pathways%20key%20full%20only.pdf>

The description of commodities with which the introduction of the species is generally associated shall include a list and description of commodities with an indication of associated risks (e.g. the volume of trade; the likelihood of a commodity being contaminated or acting as vector).

If there are no active pathways or potential future pathways this should be stated explicitly here, and there is no need to answer the questions 1.2-1.9.

**(1): Horticulture (escape from confinement)**

**(2): Ornamental purpose other than horticulture (escape from confinement)**

**(3): Transport of habitat material (soil, vegetation) (transport – contaminant)**

Pathways considered but excluded from the risk assessment.

The pathway people and their luggage/equipment in particular tourism (transport - stowaway) was considered when writing this risk assessment. However, the authors consider it is very unlikely that *D. odorata* will enter along this pathway. There is no evidence in the literature that tourism is an active pathway, and it is unlikely that the seeds will be moved by this pathway. Seeds do not have barbs or spines which can attach to clothes or recreation equipment.

The authors considered the pathway Landscape / flora / fauna improvement in the wild and concluded that this pathway did not need to be detailed as the species is generally described as growing poorly in full sunlight (Robison et al., 2011). The pathway is not considered further in the risk assessment.

Pathway name: **Horticulture (escape from confinement)**

**Qu. 1.2a. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	<b>intentional</b>	<b>CONFIDENCE</b>	low
	unintentional		medium
			<b>high</b>

Response: Horticulture is the intentional introduction of the species into the risk assessment area for commercial culturing. *Delairea odorata* has been utilized as a garden ornamental species in the risk assessment area since the early 1900s (Bollettino 1902).

The pathway includes the movement of plant material via e-commerce.

The Horticulture pathway should be applied to plants escaping from commercial culturing facilities (nurseries, greenhouses) (including the deliberate dumping of plant material) or during transport to/from the nursery trade. Therefore, this pathway includes the bulk shipment of live plants for nurseries and gardens centres, and the intentional introduction of seeds for planting.

García Gallo et al. (2008) detail that *D. odorata* has been intentionally introduced as an ornamental species into the Azores, Madeira and the Canary Islands, most likely from stock in Portugal.

**Qu. 1.3a. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: The species is an ornamental species and grown in the risk assessment area. There are a number of suppliers listed throughout EU Member states.

The pathway ‘Horticulture’ is the deliberate movement of the plant into the risk assessment area for use as an ornamental species. However, it should be noted that the frequency and volume of individuals entering the risk assessment area is potentially low as much of the material sold in nurseries and garden centers is likely to be propagated within the risk assessment area.

The species is available for sale via a limited number of e-commerce sites (often under the name *Senecio mikanioides*) such as: [eBay](#) and others, e.g. [https://www.arafloora.nl/p4042/senecio\\_mikanioides](https://www.arafloora.nl/p4042/senecio_mikanioides)

It is moderately likely that the species will enter the natural environment via this pathway. Potentially, if planted in nurseries and garden centers, plant material may escape from confined areas into the natural environment. Additionally, dumping of material into the natural environment may occur though unlikely with good horticulture industry practice. Dumped waste, containing seeds (though not relevant for the risk assessment area) and stem pieces, has been reported as contributing to its spread in Australia (Northcote City Council & Duggan 1994).

If eradication measures are taken following dumping, there is the potential that the species can re-establish if it is dumped again or if some small shoot or root material is left behind. Plants can regenerate from a small piece of stem, stolon or rhizome as long as a node is included (DiTomaso and Healy 2004).

**Qu. 1.4a. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The pathway ‘Horticulture’ is the deliberate movement of plant material into the risk assessment area and as such plant material would be maintained and moved to ensure survival.

*Delairea odorata* is utilized as an ornamental plant in landscaping and gardening (Cal-IPC 2021a, EPPO 2012, ISSG 2021) and also as a houseplant (Robison & DiTomaso2010).

Three types of material can potentially enter the risk assessment area via this pathway (1) seed, (2) live plants and (3) cuttings (including rhizomes and stems).

**Seed**

Although seed import cannot be ruled out, it is very unlikely seeds of this species will be part of the horticulture pathway for the commercial production of the species.

Seed may survive along the pathway but there is no period of dormancy of the seed. It would not be possible for the species to reproduce or increase during transport and storage along this pathway. There is no detailed analysis on the viability of seed when stored or transported.

**Live plants**

Live plants will be moved along the pathway and packaged to promote their survival. It is unlikely the plants will reproduce or increase during their transport along this pathway. The end result of the pathway is the planting of the species in a suitable area (garden) to promote its growth.

**Shoot or root material**

Shoot or root material may be moved along the pathway and packaged to promote survival. There is no data on the survival of this material, but it is likely that it will survive during transportation as industry will ensure they are packaged appropriately to ensure survival. Roots are robust and if placed near the soil surface, this can increase the chances of growth after they are dumped. If plant material is placed in areas where there is disturbance, there may be a greater chance that the species can survive in these habitats. Often dumping of plant material takes place in ruderal habitats.

**Qu. 1.5a. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely	<b>CONFIDENCE</b>	low medium
-----------------	---------------------------	-------------------	---------------

	moderately likely likely <b>very likely</b>		<b>high</b>
--	---	--	-------------

Response: Plant material (most likely live plants or cuttings) is the commodity itself and it is deliberately moved for sale within the risk assessment area. Therefore, management practices before and during transport are not considered in this question. Management practices during storage at the end point (nursery and garden centre) may affect the survival of the species for example cleaning, temperature storage etc. However, the species is likely to survive.

**Qu. 1.6a. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: It is moderately likely that the organism will enter the risk assessment area undetected via this pathway as this concerns the intentional movement of plant material into the risk assessment area. USDA (2013) found no evidence that propagules are likely to be dispersed in trade as contaminants or hitchhikers.

The species could enter the environment undetected as the species may escape from garden centers and nurseries via seed or the dumping of plant material. Robison & DiTomaso (2010) highlight that the species may have been established in California from discarded houseplants. A moderate score has been given with a medium confidence due to potential dumping of the species.

**Qu. 1.7a. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: For live plant imports in the risk assessment area (introduction), each EU Member country has official entry points where plant material can be imported into. Therefore, these introduction points are widespread in the risk assessment area.

For the introduction of plant material via e-commerce, the entry points are widespread as anyone with an internet connection and a postal address can obtain seeds of the species from outside the risk assessment area. Therefore, introduction points are widespread within the risk assessment area.

*Delaria odorata* can enter the environment from nurseries and garden centers (the end point of this pathway) which are widespread within the risk assessment area. This does not mean the species is widely propagated but implies these possible points of introduction are widespread.

**Qu. 1.8a. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The pathway ‘Horticulture’ involves the movement of plant material for planting from outside of the risk assessment area via nurseries and garden centres.

This pathway is active though it is unlikely that the species is being moved along the pathway from outside the risk assessment area into the risk assessment area. However, the species is sold within the risk assessment area and nurseries will propagate the species and it is moderately likely for the species to enter the natural environment from these types of facilities.

Live plant material may be imported into the risk assessment area for sale in the horticulture industry. However, it should be noted that this is probably more of a historic pathway as the species is likely to be propagated within the risk assessment area as the species can be easily grown from root fragments.

**Pathway name: (2) Ornamental purposes other than horticulture (escape from confinement)**

**Qu. 1.2b. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	Unintentional <b>intentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response: This pathway involves the intentional introduction of the species for ornamental purposes, though entry into the natural environment would be unintentional. This pathway includes the movement of all potential plant parts (live plants, seed and rhizomes) into the risk assessment area. However, it should be noted that there is only evidence of live plants being moved along this pathway.

In Spain, *D. odorata* is an ornamental escape in waste places, abandoned gardens and along paths (Perez 2002).

For escape/entry into the environment, this pathway includes the dumping of plant material into the natural environment. Dumping of garden waste, containing seed, shoots or roots, has been reported as contributing to its spread in Australia (Northcote City Council & Duggan 1994).

*Delairea odorata* has been utilized as a garden ornamental species for a number of decades in the risk assessment area since the early 1900s (Bollettino SBI 1902, p. 141).

**Qu. 1.3b. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: There is no information on frequency or volumes entering the risk assessment area or the environment.

Entry into the natural environment is likely as the species will be planted in gardens, sometimes in close proximity to the natural environment. Shoots can spread into the natural environment from planting in gardens.

If eradication measures are taken following planting, there is the potential that the species can re-establish if replanted. The number of potential areas where the species can escape from increases the difficulty of eradication at a large scale.

**Qu. 1.4b. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Plant material is the commodity itself and it is deliberately moved for sale within the risk assessment area. Therefore, plant parts or whole parts are likely to survive along the pathway to the end point where it is planted in a garden.

The following section lists the plant parts of concern:

**Seed (low concern)**

There are no reports of seed in the Risk assessment area.

**Live plants (high concern)**

Live plants may be dumped into the natural environment and it is likely that these can survive during transport. *D. odorata* can grow in a range of habitats from disturbed to natural areas and occurs in both dry to moist conditions. It also can tolerate a wide range of soil conditions. Robison & DiTomaso (2010) highlight that the species may have been established in California from discarded houseplants.

**Shoot and root material (high concern)**

Shoot material and to a lesser extent, root material may spread outside the confines of a garden where it is deliberately planted. Additionally, if garden waste is placed on a suitable substrate, it will be able to survive.

**Qu. 1.5b. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: Management practices before and during transport are very likely to facilitate the survival of the species as it is the commodity itself..

Management practices, i.e. removal and waste disposal may increase the propagule pressure of the species in the environment and facilitate the reproduction of the species. Therefore, management practices such as physical removal or cutting above and below ground material may lead to fragmentation of plant material.

Other management practices (e.g. chemical control of weeds in gardens), may have an impact on the survival and reproduction of the species.

**Qu. 1.6b. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response. It is moderately likely the species can enter the environment via the dumping of garden waste. The score is based on the worst case scenario. A moderately likely overall score has been given based on the potential of it entering the natural environment.

**Qu. 1.7b. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: Private gardens associated with households are high. For example, data from 2014 shows that 58% of houses have a garden or outside space in France, 81% in the United Kingdom, 80.3% in Poland and 27% in Spain (Statista 2020).

**Qu. 1.8b. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Through management practices or dumping of plant material, plant material can enter into the natural environment.

This introduction pathway is active and there is evidence that the species is being moved along the pathway into the risk assessment area. Based on this, a score of likely with medium confidence has been given.

**Pathway name (3): Transport – Contaminant (transport of habitat material (soil, vegetation))**

**Qu. 1.2c. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response: Entry via this pathway is unintentional movement of the species via the contamination of habitat material (soil and vegetation).

**Qu. 1.3c. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**  
including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: There is no information available on the volumes of movement along this pathway. The transport of topsoil, sand or other contaminated habitat material with shoot or root material could facilitate entry into the RA area. However, the pathway is mainly closed within the RA as there are prohibitions of the movement of soil into the EU from many countries.

Such material is likely to be placed in suitable habitats in the risk assessment area for the establishment of the species.

*Delairea odorata* can produce a large biomass of shoot material which may regenerate into viable plants if broken from the parent plant. Shoot material can become incorporated into soil and included in habitat material which is then transported both into the risk assessment area and within the risk assessment area.

**Qu. 1.4c. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Shoot and root material can survive transport along the pathway, especially as it would be moved with habitat material that is likely to retain moisture. It is unlikely that plant material will reproduce or increase along the pathway.

**Qu. 1.5c. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: The species is moderately likely to survive existing management practices along this pathway. However, there is no information available for this pathway.

**Qu. 1.6c. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: Shoots and root material can be viable at a small size and buried in soil and other material, making them difficult to detect.

**Qu. 1.7c. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: There are no specific data on the points of introduction or entry.

Points of introduction can include road routes which join countries and other international transportation hubs. These are widespread throughout the risk assessment area. Urbanization and the management of land is increasing through the risk assessment area.

**Qu. 1.8c. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Root and shoot material may be able to move along this pathway, and the commodity is placed within the environment where the propagules have the opportunity to establish. However, there is no direct evidence that the species has moved along this pathway and therefore it is scored moderately likely with medium confidence.

**Qu. 1.9. Estimate the overall likelihood of introduction into the risk assessment area or entry into the environment based on all pathways and specify if different in relevant biogeographical regions in current conditions.**

Provide a thorough assessment of the risk of introduction in relevant biogeographical regions in current conditions: providing insight in to the risk of introduction into the risk assessment area.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The overall likelihood of *D. odorata* being introduced into the risk assessment area is very likely with a high confidence especially because the species is already present (recorded or established) in the risk assessment area, hence the likelihood of introduction and entry should be scored as “very likely” by default. The species has been known to be introduced into the risk assessment area by ‘Horticulture’ (escape from confinement), and ‘Ornamental purpose other than horticulture’ (e.g. planting by private gardeners). *Delairea odorata* has the potential of being dumped in the environment as the species produces a lot of above ground biomass which can be difficult to dispose of in the proper means.

As the highest occurrences of the species in the environment are in the Atlantic and Mediterranean biogeographical regions, it is these regions that would potentially see a higher likelihood of entry into the environment. The species distribution modelling shows that the Alpine, Boreal, Pannonian and Steppic biogeographical regions are currently largely unsuitable for the establishment of the species (compare SDM in Annex IX) and therefore the likelihood of the species traded for horticultural purposes in these regions is low.

**Qu. 1.10. Estimate the overall likelihood of introduction into the risk assessment area or entry into the environment based on all pathways in foreseeable climate change conditions?**

Thorough assessment of the risk of introduction in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of introduction (e.g. change in trade or user preferences)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely introduction within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6 °C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0 °C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: The main aspects of climatic change which will influence the entry of *D. odorata* into the risk assessment area include increased minimum temperature of winter months, increased spring and summer temperatures.

Climate change (RCP 2.6 2070) will expand the potential distribution the species can establish in, making the species more available to gardeners. For example, more inland areas in the Atlantic and Continental biogeographical regions may become more suitable for growing the species and the horticulture pathway may expand in this area to meet further demand. Ornamental plants traded for private gardens and landscape improvements may also see a higher volume and frequency. A high rating has been given with a medium confidence (due to the fact that this is a projection).

## 2 PROBABILITY OF ESTABLISHMENT

### Important instructions:

- For organisms which are already established in parts of the risk assessment area or have previously been eradicated, the likelihood of establishment should be scored as “very likely” by default.
- Discuss the risk also for those parts of the risk assessment area, where the species is not yet established.

**Qu. 2.1. How likely is it that the organism will be able to establish in the risk assessment area based on similarity of climatic and abiotic conditions in its distribution elsewhere in the world?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: *Delairea odorata* is already established in the natural environment in the risk assessment area (Croatia, France, Ireland, Italy, Portugal, Spain, United Kingdom) (see Qu. A8b). It is likely that further countries where the species could potentially establish are present within the RA area (see Qu. A9a).

The SDM (Annex VIII) shows the potential distribution of the species based on the current occurrences of the species both in the risk assessment area and elsewhere in the world. The model shows that there is a large area of the EU that is suitable for the establishment of *D. odorata*.

In the native and introduced ranges (outside of the EU), *D. odorata* occurs predominantly in the Köppen-Geiger climate classifications of Cfb (Temperate [oceanic climate](#)), Csb ([Warm-summer Mediterranean climate](#)), Csa ([Hot-summer Mediterranean climate](#)) and BSk ([Cold semi-arid climate](#)). MacLeod and Korycinska (2019) estimate that the percentage of 5-minute grid cells for each aforementioned climate category occurring in the EU are as follows: Cfb 48.62 %, Csb 3.8% Csa 10.13 and BSk 1.46. Based on this almost 60% of the EU plus the United Kingdom is currently climatically suitable.

**Qu. 2.2. How widespread are habitats or species necessary for the survival, development and multiplication of the organism in the risk assessment area? Consider if the organism specifically requires another species to complete its life cycle.**

<b>RESPONSE</b>	very isolated isolated	<b>CONFIDENCE</b>	low medium
-----------------	---------------------------	-------------------	---------------

	moderately widespread <b>widespread</b> ubiquitous		<b>high</b>
--	--	--	-------------

Response: *Delairea odorata* can invade different habitats ranging from disturbed to natural and occurs in both dry to moist conditions. It can form dense vegetative ground cover mats that can prevent seeding of native plants.

In South Africa, *D. odorata* grows in moist mountain forests. Where it naturalized, it extended its habitat range and is found in coastal areas, riparian zones and wetlands, dry forests and moist forests, shrublands and ruderal habitats, and grows very well in early successional forests. Typically found below 200 m elevation, it prefers shady, disturbed sites with year-round moisture.

According to the CORINE Land Cover nomenclature, these habitats correspond to: natural grassland, mixed forests, broad-leaved forests, sclerophyllous vegetation (e.g. garrigue, maquis), inland wetlands (marshes, EPPO, 2012 peat bogs), continental waters (water courses, water bodies), banks of continental water, riverbanks/canal sides (dry river beds), road and rail networks and associated land, and other artificial surfaces (wastelands).

CABI (2021) lists potential habitats as managed forests, plantations and orchards, managed grasslands, disturbed areas, rail/roadsides, urban/per-urban areas, natural forests, natural grasslands, riverbanks, wetlands and coastal areas.

García Gallo et al. (2008) detail habitats for *D. odorata* in Azores, Madeira and the Canary Islands to be: Waste places, hedgerows, walls, ravines, *Pittosporum* and *Morella* scrubland, Cliffs, heath substituting *Apollonias* laurel forest, heath substituting *Ocotea* laurel forest, *Apollonias* laurel forest (Mediterranean laurel forest), *Ocotea* laurel forest (temperate laurel forest), riparian laurel forest (*Sambucus* woodland, *Persea* laurel forest, *Salix* woodland), cultivated land, anthropogenic vegetation, mountain humid woodlands and urban areas.

According to Iamónico (2017), *D. odorata* is recorded in Sardinia (Italy) in ruderal habitats only. According to Viciani et al. (2020), *D. odorata* communities can be included in the vegetation class *Artemisietea vulgaris* Lohmeyer, Preising & Tüxen ex Von Rochow 1951.

When taking into consideration all of the habitats detailed above, within the EU, habitats that can facilitate the survival, development and multiplication of the *D. odorata* are widespread. However, it should be noted that many of the areas where the species is currently clustered in the risk assessment area are close to the coast and/or at lower altitudes.

*Delairea odorata* is commonly found in high pH soils characterized by high fertility (Baars et al. 1998) and the species has some tolerance to salt as in the US it has been known to establish on salt exposed bluffs (Starr et al. 2003)

**Qu. 2.3. How likely is it that establishment will occur despite competition from existing species in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Competition with native vegetation is unlikely to limit the establishment of *D. odorata* in the risk assessment area. Although there is no scientific information on competition with native species, *D. odorata* can form dense ground cover which can prevent the formation of native vegetation. It can use ground cover vegetation as a support to grow up into the canopy and climb over other species.

Competition may occur with native lianas in managed forests in the risk assessment area; other liana species in Europe, with the exception of *Hedera helix* and *Clematis vitalba*, are limited, but a higher diversity of lianas is present in Mediterranean shrublands and forests.

**Qu. 2.4. How likely is it that establishment will occur despite predators, parasites or pathogens already present in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: CABI (2021) detail a number of biological control agents including two insect species, the Cape ivy gall fly (*Parafreutreta regalis* Munro) and the Cape ivy stem moth (*Digitivalva delaireae* Gaedike & Kruger). However, these species are not present in the EU. It is very likely that establishment will occur despite predators, parasites or pathogens already present in the risk assessment area. *D. odorata* does not have any host specific natural enemies in the risk assessment area and there is no evidence that native organisms feed or infect the species in substantial levels to inflict any damage on the species.

**Qu. 2.5. How likely is the organism to establish despite existing management practices in the risk assessment area? Explain if existing management practices could facilitate establishment.**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: As detailed in section (2.2), the establishment of *D. odorata* is suited to a number of different habitat types, including disturbed habitats. Management of urban and semi-urban habitats is likely to increase disturbance of the habitat, which can act to break the shoots of the plant and resprouting of these parts can occur if they have contact with the ground (Starr et al. 2003).

**Qu. 2.6. How likely is it that biological properties of the organism would allow it to survive eradication campaigns in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: In the risk assessment area, vegetative reproduction is considered the main, if not the only reproductive mechanism. Vegetative reproduction can occur at any time when the nodes of the stem, stolon, or leaf petiole are in contact with the soil. Small fragments of 1.3 cm can root easily and quickly. Seed production has been observed in the risk assessment area (for example, pers. obs. E. Marchante, Portugal), but scientific studies are lacking to confirm seed viability. These biological properties do not allow survival from eradication campaigns, but the fact that small pieces of shoot and root material can form viable plants increases the likelihood. In addition, the stems are brittle and easily broken, thus this can further complicate eradication. *D. odorata* uses other plants to support its growth and can climb over structures.

Therefore, unless eradication campaigns are thorough and remove all reproductive material, it is likely that the species can survive during eradication campaigns. A medium confidence is given as there is no published information for the risk assessment area on eradication campaigns.

**Qu. 2.7. How likely are the biological characteristics of the organism to facilitate its establishment in the risk assessment area?**

including the following elements:

- a list and description of the reproduction mechanisms of the species in relation to the environmental conditions in the risk assessment area
- an indication of the propagule pressure of the species (e.g. number of gametes, seeds, eggs or propagules, number of reproductive cycles per year) of each of those reproduction mechanisms in relation to the environmental conditions in the risk assessment area.
- If relevant, comment on the likelihood of establishment based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in establishment whereas for others high propagule pressure (many thousands of individuals) may not.
- If relevant, comment on the adaptability of the organism to facilitate its establishment and if low genetic diversity in the founder population would have an influence on establishment.

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low medium high
-----------------	--	-------------------	-----------------------

In the risk assessment area, vegetative reproduction is considered the main, if not the only reproductive mechanism. Vegetative reproduction can occur at any time when the nodes of the stem, stolon, or leaf petiole are in contact with the soil. Small fragmented pieces of 1.3 cm can root easily and quickly. Parts of the plant can also disperse along water courses. Nelson (1999) reports that pieces of *D. odorata* are transported via flooding along the coast of Big Sur river in California.

The growth habit of *D. odorata* can facilitate its establishment, the species climbs over most other vegetation, forming a solid cover that blocks light and smothers other vegetation.

**Qu. 2.8. If the organism does not establish, then how likely is it that casual populations will continue to occur?**

Consider, for example, a species which cannot reproduce in the risk assessment area, because of unsuitable climatic conditions or host plants, but is present because of recurring introduction, entry and release events. This may also apply for long-living organisms.

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

	very likely		
--	-------------	--	--

Response: In areas, where *D. odorata* is not present, casual populations may occur in urban habitats or semi-urban habitats. Casual populations may occur in surrounding habitats. Casual populations are likely to occur in areas outside the optimum climatic conditions. For example, this may include areas in Figure 5 of Appendix 4 at the margin of suitable and unsuitable areas. Countries where casual populations may occur include those in central and eastern Europe (see Qu. A8a).

**Qu. 2.9. Estimate the overall likelihood of establishment in the risk assessment area under current climatic conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under current climatic conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in current conditions: providing insight in the risk of establishment in (new areas in) the risk assessment area.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The overall likelihood of *D. odorata* establishing in the risk assessment area is very likely with high confidence. The species is already established in the Mediterranean and Atlantic biogeographical regions. Countries where the species is established include: Croatia, France, Ireland, Italy, Portugal, Spain, and the United Kingdom. The Mediterranean and Atlantic biogeographical regions have a high proportion of area suitable for the establishment of the species and thus further establishment is likely in these areas under the current climatic conditions.

**Qu. 2.10. Estimate the overall likelihood of establishment in the risk assessment area under foreseeable climate change conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under foreseeable climate change conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of establishment (e.g. increase in average winter temperature, increase in drought periods)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely establishment within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: The overall likelihood of establishing in the risk assessment area under future climatic conditions (2070 RCP. 2.6) is very likely with medium confidence. The species is already established in the Mediterranean, Continental and Atlantic biogeographical regions. The Continental and Atlantic biogeographical regions see a slight increase in establishment potential with future climate change whereas the Mediterranean region shows a slight decrease. The Pannonian region shows a steep increase in suitability. Southern areas of the Boreal biogeographical region show potential for establishment and small coastal areas of Norway (Alpine biogeographical region) under future climatic conditions (see Annex IX).

### 3 PROBABILITY OF SPREAD

**Important instructions:**

- Spread is defined as the expansion of the geographical distribution of an alien species within the risk assessment area.
- Repeated releases at separate locations do not represent continuous spread and should be considered in the probability of introduction and entry section (Qu. 1.7).

**Qu. 3.1. How important is the expected spread of this organism within the risk assessment area by natural means? (List and comment on each of the mechanisms for natural spread.)**

including the following elements:

- a list and description of the natural spread mechanisms of the species in relation to the environmental conditions in the risk assessment area.
- an indication of the rate of spread discussed in relation to the species biology and the environmental conditions in the risk assessment area.

The description of spread patterns here refers to the CBD pathway category “Unaided (Natural Spread)”. It should include elements of the species life history and behavioural traits able to explain its ability to spread, including: reproduction or growth strategy, dispersal capacity, longevity, dietary requirements, environmental and climatic requirements, specialist or generalist characteristics.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: In the USA, *D. odorata* reproduces vegetatively from stem fragments that readily root at nodes (Robison 2006) and by the extension of the plant through stolons (Alvarez 1998). There is no scientific information on the spread rates of this species for the risk assessment area.

In California, *D. odorata* has readily established in riparian areas and then subsequently spread into drier sites (CABI 2013). One California infestation expanded from 9 acres (3.6 ha) to 67 acres (27.1 ha) in nine years (Alvarez 1998). Alvarez & Cushman (2002) stated that rapid growth (0.35 to 1.35 m per month), clonal reproduction, and pronounced tolerance to environmental conditions have contributed to its invasiveness.

Vegetative reproduction can occur at any time when the nodes of the stem, stolon, or leaf petiole are in contact with the soil. Small fragmented pieces of 1.3 cm can root easily and quickly. Parts of the plant can also disperse along water courses. Nelson (1999) reports that pieces of *D. odorata* are transported via flooding along the coast of Big Sur river in California.

**Qu. 3.2a. List and describe relevant pathways of spread other than "unaided". For each pathway answer questions 3.3 to 3.9 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 3.3a, 3.4a, etc. and then 3.3b, 3.4b etc. for the next pathway.**

including the following elements:

- a list and description of pathways of spread with an indication of their importance and associated risks (e.g. the likelihood of spread in the risk assessment area, based on these pathways; likelihood of survival, or reproduction, or increase during transport and storage; ability and likelihood of transfer from the pathway to a suitable habitat or host) in relation to the environmental conditions in the risk assessment area.
- an indication of the rate of spread for each pathway discussed in relation to the species biology and the environmental conditions in the risk assessment area.
- All relevant pathways of spread (except "Unaided (Natural Spread)", which is assessed in Qu. 3.1) should be considered. The classification of pathways developed by the Convention of Biological Diversity shall be used (see Annex IV).

Starr et al. (2013) state: 'Long distance dispersal is currently mostly by humans spreading the plant in landscaping.

### **Spread pathways are detailed in order of importance**

#### **Ornamental purposes other than horticulture (escape from confinement)**

This spread pathway is the intentional spread of the species from private gardening and urban and semi-urban plantings (roadsides and roundabouts for example). This pathway would be the most relevant for spread and include the highest movement of plant propagules.

#### **Transport – Contaminant (transport of habitat material (soil, vegetation))**

This spread pathway deals with the potential spread of contaminated habitat material. There is no quantitative evidence/ interceptions to support the movement of the species along this spread pathway but where urbanization has occurred in the Mediterranean region the species has shown significant spread.

#### **Transport – stowaway: Machinery/ equipment**

This pathway details the potential spread of contaminated machinery and equipment. There is no quantitative evidence/ interceptions to support the movement of the species along this spread pathway but the potential for the pathway is highlighted in the USA (Alvarez 1997; USDA 2013).

### **Pathway name: (1) Ornamental purposes other than horticulture (escape from confinement)**

**Qu. 3.3a. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	Unintentional <b>intentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response: *Delairea odorata* is present in the risk assessment area as an ornamental species. Additionally, the species may be planted in urban and semi-urban habitats (for example on roundabouts). In Spain, *D. odorata* is an ornamental escape in waste places, abandoned gardens and along paths (Perez 2002).

**Qu. 3.4a. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: There is no quantitative information on the number of sales of the species in the risk assessment area or the numbers of sites where the species has been planted. Sales of the species within the risk assessment area will be mainly whole plants as seeds have variable viability in non-optimal conditions. However, plants that can be very easily vegetatively propagated and are sometimes not so interesting for professional breeders and garden centers, as everyone can very easily propagate the species (by ramets) and plant it in his/her garden, without buying it and paying for it.

Plants can be purchased from garden centers within the risk assessment area and moved to gardens where they are planted. However, *D. odorata* is not a popular ornamental species. The species may also be dumped from waste garden material into the natural environment, though again, there are no details and the volume of movement or frequency.

**Qu. 3.5a. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: It is very likely that *D. odorata* plant material will survive during transport and storage along this pathway.

Live plants will be moved along the pathway and packaged to promote their survival. It is unlikely the plants will reproduce or increase during their transport along this pathway.

**Qu. 3.6a. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: *Delairea odorata* is likely to survive existing management practises during spread. Management of urban and semi-urban habitats is likely to increase disturbance of the habitat, which can act to break the shoots of the plant and resprouting of these parts can occur if they have contact with the ground (Starr et al. 2003).

Although there is no data on the effect of urbanisation on the spread of the species, small fragments of the plant may be moved which can facilitate spread. If dumped, the species is likely to be deposited in ruderal habitats and potentially on waste ground where management practices may be minimal and the native vegetation sparse, this may make the survival of the species in these areas more likely.

**Qu. 3.7a. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: Small root fragments (e.g. 2-3 cm in length with a node) can produce a viable plant. These fragments may be spread via dumping of garden waste and therefore may be spread in the risk assessment area undetected.

**Qu. 3.8a. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>low</b> <b>medium</b> high
-----------------	--	-------------------	-------------------------------------

Response: The species has been shown to spread to ruderal habitats and natural habitats. The presence of the species in urban and semi-urban habitats in the risk assessment area, including waste/abandoned lands highlights the species spread. In Spain, *D. odorata* is an ornamental escape in waste places, abandoned gardens and along paths (Perez 2002).

**Qu. 3.9a. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area. (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: *Delairea odorata* is a garden ornamental species which is sold in the risk assessment area. It has also been planted in urban and semi-urban habitats. There is no quantitative analysis on the spread of the species in the risk assessment area.

**Pathway name: (2) Transport – Contaminant (transport of habitat material (soil, vegetation))**

**Qu. 3.3b. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response: The spread of *D. odorata* via transport of habitat material (soil, vegetation) is the unintentional spread of the species within the risk assessment area. Both seed material and plant fragments can be spread via this pathway, though seed is unlikely to be viable in the risk assessment area.

**Qu. 3.4b. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: There is no information available on the volumes of movement along this pathway. Shoot and root material can be present on/in the soil, in potentially large amounts if such material is taken from an area where the species is present.

**Qu. 3.5b. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: There is no quantitative evidence for *D. odorata*, for the survival, reproduction or increase as a contaminant of habitat material. Viable shoot and root material can be small and therefore it could

survive during transport along this spread pathway. Habitat material would be suitable for the survival of the species over short periods. Shoot and root material can remain viable within soil material.

**Qu. 3.6b. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Careful methodical management practices coupled with inspection would be needed to ensure that the species did not spread with contaminated soil and vegetation. This is often not feasible with such small shoot or root fragments.

**Qu. 3.7b. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Soil and other habitat material can be moved throughout the RA area and can be spread within such material. Shoot and root material may be small and buried in soil and other material, making them difficult to detect.

**Qu. 3.8b. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: It would be very likely that *D. odorata* can transfer to a suitable habitat if shoot and root material of the species is incorporated in soil. Topsoil and habitat material is often physically transferred and deposited in suitable habitats. This fact that the species is recorded in urban development areas further supports the hypothesis that the species can be moved by soil and habitat material.

**Qu. 3.9b. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area. (provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: There is no quantitative data on the spread of the species in relation to habitat material.

Habitat material can move freely within the single market in the EU enabling contaminated material to spread over long distances. Shoot or root material may be included as a contaminant. Because of the lack of quantitative data, confidence is medium.

**Pathway name: (3) Transport – stowaway: Machinery / equipment**

**Qu. 3.3c. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response: This pathway details the potential spread of the species with contaminated machinery and equipment. There is no quantitative evidence / interceptions to support the movement of the species along this spread pathway but the potential for the pathway is highlighted in the USA (Alvarez 1997; USDA 2013).

**Qu. 3.4c. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: There is no information available on the volumes of movement along this pathway. However, any mechanisms involving equipment and vehicles could act to break shoot or root material into smaller fragments and therefore the number of viable stem or root pieces can be high. Only small shoot/root pieces are needed to form a viable plant.

**Qu. 3.5c. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Root and shoot material could survive during transport along this spread pathway. The species is unlikely to increase along the pathway until it finds a suitable habitat.

**Qu. 3.6c. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Root and shoot material can also remain hidden within crevices of machinery and equipment. ISPM 41 (IPPC 2017) 'Intentional movement of machinery and equipment' provides international measures for cleaning, which can be applied to local level movement also.

**Qu. 3.7c. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Shoot and root fragments are relatively small, are easily broken from the main stem or root and potentially can remain hidden in soil in cracks and crevices in machinery and equipment. Such machinery can be moved within the RA area transporting the seed to new areas.

**Qu. 3.8c. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: It would be moderately likely that *D. odorata* can transfer to a suitable habitat if the species is a stowaway on machinery/ equipment. Landscaping machinery and construction machinery is used in suitable habitats of the species.

**Qu. 3.9c. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area. (provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: Used machinery and equipment can be moved within the RA area at a local and long distances scale. Any seed and root/shoot material attached could be spread at a fast rate. However, it is scored moderately as a number of measures can be adopted against this spread pathway to reduce the spread of the species. Inspections of used machinery and equipment coupled with cleaning will reduce the potential of spread of the species. A low confidence has been given as there is no quantitative data.

**Qu. 3.10. Within the risk assessment area, how difficult would it be to contain the organism in relation to these pathways of spread?**

<b>RESPONSE</b>	very easy easy <b>with some difficulty</b> difficult very difficult	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: Natural spread would be relatively easy to control within the risk assessment area. Though some habitats where the species grows may present more difficulties - e.g. coastal habitats.

As the species can spread as a contaminant of soil and habitat material, machinery and equipment and recreational equipment, biosecurity measures and inspections would need to be adopted where these spread pathways are active, and the species is present. This would involve multiple stakeholders and communication and awareness raising to reduce the spread pathways. A ban on sale could act to prevent further spread of the species within the risk assessment area.

Preventing the spread from already established populations, including those in private gardens will be difficult.

**Qu. 3.11. Estimate the overall potential rate of spread in relevant biogeographical regions under current conditions for this organism in the risk assessment area (indicate any key issues and provide quantitative data where possible).**

Thorough assessment of the risk of spread in relevant biogeographical regions in current conditions, providing insight in the risk of spread into (new areas in) the risk assessment area.

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: In the risk assessment area, *D. odorata* reproduces and spreads by vegetative reproduction. Therefore, spread by natural means can be assessed as moderately.

Human mediated spread includes intentional movement of the species through horticulture and unintentional movement through contamination of habitat material and used machinery and equipment). For human mediated spread, the rate of spread can be estimated as moderately. Spread would be highest in biogeographical regions where the species is already present, such as Alpine, Atlantic, Boreal, Continental and Mediterranean biogeographical regions. A higher rate of spread may be seen in biogeographical regions where *D. odorata* can be considered as established, e.g. Atlantic, Continental and Mediterranean biogeographical regions.

**Qu. 3.12. Estimate the overall potential rate of spread in relevant biogeographical regions in foreseeable climate change conditions (provide quantitative data where possible).**

Thorough assessment of the risk of spread in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk, specifically if rates of spread are likely slowed down or accelerated.

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: The overall potential rate of spread in the risk assessment area under future climatic conditions (2070 RCP. 2.6) is moderately with a low confidence. Spread would maintain in the areas where the species is already established: Mediterranean, Continental and Atlantic biogeographical regions. The Continental and Atlantic biogeographical regions see a slight increase in establishment potential with future climate change whereas the Mediterranean region shows a slight decrease. The Pannonian region shows a steep increase in suitability. Southern areas of the Boreal biogeographical region show potential for establishment and small coastal areas of Norway (Alpine biogeographical

region) under future climatic conditions (see Annex VIII). All this might also increase the likelihood of human-mediated spread in these regions.

## 4 MAGNITUDE OF IMPACT

Important instructions:

- Questions 4.1-4.5 relate to biodiversity and ecosystem impacts, 4.6-4.8 to impacts on ecosystem services, 4.9-4.13 to economic impact, 4.14-4.15 to social and human health impact, and 4.16-4.18 to other impacts. These impacts can be interlinked, for example, a disease may cause impacts on biodiversity and/or ecosystem functioning that leads to impacts on ecosystem services and finally economic impacts. In such cases the assessor should try to note the different impacts where most appropriate, cross-referencing between questions when needed.
- Each set of questions starts with the impact elsewhere in the world, then considers impacts in the risk assessment area (=EU excluding outermost regions) separating known impacts to date (i.e. past and current impacts) from potential future impacts (including foreseeable climate change).
- Only negative impacts are considered in this section (socio-economic benefits are considered in Qu. A.7)
- In absence of specific studies or other direct evidence this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable).

### Biodiversity and ecosystem impacts

**Qu. 4.1. How important is the impact of the organism on biodiversity at all levels of organisation caused by the organism in its non-native range excluding the risk assessment area?**

including the following elements:

- Biodiversity means the variability among living organisms from all sources, including terrestrial, marine and other aquatic ecosystems and the ecological complexes of which they are part; this includes diversity within species, between species and of ecosystems
- impacted chemical, physical or structural characteristics and functioning of ecosystems

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: *Delawarea odorata* has caused considerable biodiversity and ecosystem impacts in its invasive range particularly on the west coast of the USA. The California Invasive Plant Council (Cal-IPC) lists Cape ivy on its High List as a "Species with severe ecological impacts on ecosystems, plant and animal communities, and vegetational structure" (Cal-IPC 2005). Its impacts are broad and Brunel et al. (2010) summed it up as follows: “*D. odorata* can invade different habitats ranging from disturbed to natural and occurs in both dry to moist conditions. It can form dense vegetative ground-cover mats that can prevent seeding of native plants. It can also smother native vegetation and affect regeneration, forming

stands of over 75% cover and competing with other plants for water and nutrients. Native plant species richness can be reduced by about 50 percent, with greater impact on annual than on woody perennial species. The weight of large masses of climbing vines can bring down trees. Higher trophic levels can also be affected, such as several sensitive species of insects and predators.”

In the Golden Gate National Recreation Area, California, USA, Alvarez (1997) found that native plant species richness was significantly lower with increasing cover of Cape ivy, but this was not the case for non-native species. In addition, invasion by Cape ivy was associated with a 31% decrease in species diversity as well as an 88% decrease in the abundance of native seedlings and a 92% decrease in non-native seedlings compared to uninvaded areas. This impact was found to be somewhat reversible in that a 2 yr Cape-ivy reduction experiment resulted in a 10% increase in the richness of native species compared to control plots, but also a 43% increase in the richness of nonnative taxa. Forb species richness increased significantly when Cape-ivy cover was reduced, whereas shrub richness decreased slightly and no effects were detected for ferns and grasses. They also found that Cape-ivy reduction led to a 32% increase in plant species diversity, and importantly an 86% increase in the abundance of native seedlings, and an 85% increase for nonnative seedlings. Lab studies also show the production of biotoxic and bioactive compounds which can inhibit seed germination and root growth as well as having significant impacts on copepod populations (Kozsiz 2013).

According to the US Fish and Wildlife Service (2009a; 2009b) *D. odorata* contributes to the threat posed to two threatened and endangered plant species namely *Thysanocarpus conchuliferus* and *Zanthoxylum dipetalum* var. *tomentosum*

*Delairea odorata* has been shown to change soil mycobiota to its benefit by increasing functional diversity (Oclaman & Case 2017). There is also some preliminary evidence that there is less microbial metabolic diversity in native coastal scrub soil than in soil under *D. odorata* (Khalil & Case 2013).

Though not a direct impact on species at risk, Robison & DiTomaso (2010) observed that in California three animals vulnerable to Cape Ivy invasion and five vulnerable plants were expected to have 40% reduction of their occurrences within a 500 m buffer to Cape ivy infestations.

Given the wide range of impacts from pulling down trees and shrubs to competing for space and water as well as altering the soil to its benefit across quite a large area, the impact is scored as major with medium confidence.

**Qu. 4.2. How important is the current known impact of the organism on biodiversity at all levels of organisation (e.g. decline in native species, changes in native species communities, hybridisation) in the risk assessment area (include any past impact in your response)?**

Discuss impacts that are currently occurring or are likely occurring or have occurred in the past in the risk assessment area. Where there is no direct evidence of impact in the risk assessment area (for example no studies have been conducted), evidence from outside of the risk assessment area can be used to infer impacts within the risk assessment area.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: *Delairea odorata* is reported as established in Tuscany and in Sardinia (Italy) (Iamónico 2017), where it occurs in ruderal habitats only, and in few localities with low density, so that at the time being no significant ecological impacts have been recorded (Bacchetta et al. 2009, Camarda et al. 2016). However, in Portugal, Cape Ivy frequently invades banks of watercourses, hedgerows and slopes, ruderal environments and communities of thorny shrubs (Plantas invasoras em Portugal 2020). There is a lack of published information so the score is minor with a low confidence.

<b>Qu. 4.3. How important is the potential future impact of the organism on biodiversity at all levels of organisation likely to be in the risk assessment area?</b>			
See comment above. The potential future impact shall be assessed only for the risk assessment area. A potential increase in the distribution range due to climate change does not <i>per se</i> justify a higher impact score.			

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: If its behaviour in other invaded regions is replicated then the impacts on biodiversity could be major but without any evidence of impact at this stage it is hard to place a high potential impact estimate in the medium term. It is expected that the impacts will increase so a moderate score with low confidence is given.

<b>Qu. 4.4. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism currently in the risk assessment area?</b>			
including the following elements:			
<ul style="list-style-type: none"> <li>● native species impacted, including red list species, endemic species and species listed in the Birds and Habitats directives</li> <li>● protected sites impacted, in particular Natura 2000</li> <li>● habitats impacted, in particular habitats listed in the Habitats Directive, or red list habitats</li> </ul>			

- the ecological status of water bodies according to the Water Framework Directive and environmental status of the marine environment according to the Marine Strategy Framework Directive

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: *D. odorata* is certainly found in areas with high conservation value and there is good evidence of impact in Macaronesian islands which is not included in the risk assessment area. Its recorded presence is likely to devalue status and require management as was the case in the Natura 200 site Cabo Busto-Luanco; where removal of the species was carried out under the LIFE+ project [ARCOS \(2021\)](#).

By overlaying Natura 2000 sites with human observations (GBIF coordinate accuracy <250m), 18 Natura 2000 sites are recorded namely

FR2601012 Gîtes et habitats à chauves-souris en Bourgogne;

ES7020073 Los Acantilados de la Culata;

ES0000143 Marismas de Santoña, Victoria y Joyel y Ría de Ajo;

ES1300007 Marismas de Santoña, Victoria y Joyel; confirmed in Laiseca (2017)

PTCON0061 Ria de Aveiro;

PTZPE0004 Ria de Aveiro;

PTCON0055 Dunas de Mira, Gândara e Gafanhas;

PTZPE0011 Estuário do Sado;

PTCON0011 Estuário do Sado;

ES0000106 Teno;

ES7020096 Teno;

ES1200009 Ponga-Amieva;

ES1200016 Ría del Eo;

ES1200055 Cabo Busto-Luanco;

ES0000318 Cabo Busto-Luanco; where removal of the species was carried out under the LIFE+ project [ARCOS](#)

PTCON0008 Sintra / Cascais;

PTCON0017 Litoral Norte

*D. odorata* is also recorded as present in the Urdaibai Biosphere Reserve of Biscay, Basque Country, Spain (world species reserve [dataset](#)) [accessed 28.04.2021]

There is some inferred evidence of impact in the risk assessment area and given the multiple sites harbouring the plant and evidence of control measures implemented in at least one Natura 2000 site a score of moderate is given but with a low confidence due to the lack of peer reviewed evidence.

**Qu. 4.5. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.3. and 4.4.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: as above the score is kept the same as it is unlikely that major impacts would occur in the time frame considered but confidence remains low.

## Ecosystem Services impacts

**Qu. 4.6. How important is the impact of the organism on provisioning, regulating, and cultural services in its non-native range excluding the risk assessment area?**

- For a list of services use the CICES classification V5.1 provided in Annex V.
- Impacts on ecosystem services build on the observed impacts on biodiversity (habitat, species, genetic, functional) but focus exclusively on reflecting these changes in relation to their links with socio-economic well-being.
- Quantitative data should be provided whenever available and references duly reported.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major	<b>CONFIDENCE</b>	<b>low</b> <b>medium</b> high
-----------------	--	-------------------	-------------------------------------

	massive		
--	---------	--	--

Response: Various ecosystem service impacts are associated with *D. odorata* invasions outside of the risk assessment area and much evidence comes from the USA.

Regulation & Maintenance - Regulation of physical, chemical, biological conditions - Baseline flows and extreme event regulation: In riparian communities, *D. odorata* can increase soil erosion along watercourses due to its shallow root system not capable of holding soil (Brunel et al 2010). It can also contribute to soil erosion on hillsides (Bossard et al. 2000).

Regulation & Maintenance - Regulation of physical, chemical, biological conditions - Water conditions: *Delairea odorata* contains pyrrolizidine alkaloids (liver toxins) and xanthone (Catalano et al, 1996) and can be toxic to animals when ingested; fish can be killed when plant materials are soaking in waterways. It is possible that chemicals could enter the food chain through honey and milk derivatives in the same way as is reported with *Senecio* spp. (see Gottschalk et al, 2020; de Nijs et al, 2017) but no evidence was found of this for *D. odorata*. Flood control function along streams is impacted by *D. odorata* (Bossard et al. 2000).

Regulation & Maintenance - Regulation of physical, chemical, biological conditions - Soil quality regulation: Biotoxicity and bioactive compounds shown to inhibit seed germination and root growth using EPA bioassays as well as having significant impacts on copepod populations (Kozsiz 2013).

Cultural - Direct, in-situ and outdoor interactions with living systems that depend on presence in the environmental setting - natural environment: Can significantly reduce the species richness and diversity of an area, and render habitat in protected reserves for plant species worthless (Bossard et al. 2000). *Delairea odorata* dominates plant communities altering vegetation structure and topples oaks (Knapp 2010). The weight of the ivy can cause trees to fall, and dense canopy of the vine can smother species of the lower strata and reduce growth (Bossard et al. 2000).

**Qu. 4.7. How important is the impact of the organism on provisioning, regulating, and cultural services currently in the different biogeographic regions or marine sub-regions where the species has established in the risk assessment area (include any past impact in your response)?**

- See guidance to Qu. 4.6.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: The presence of *D. odorata* in vulnerable and/or protected sites and areas of eco-tourism interest across the risk assessment area, coupled with its known behaviour allows us to conclude that it

is likely to be having an effect on multiple ecosystem services but with no direct evidence of ecosystem service impacts in the RA area, a minor score is given with low confidence.

**Qu. 4.8. How important is the impact of the organism on provisioning, regulating, and cultural services likely to be in the different biogeographic regions or marine sub-regions where the species can establish in the risk assessment area in the future?**

- See guidance to Qu. 4.6.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: No information has been found on the issue but as above an expert judgment suggests that a minor score with low confidence would remain in the timescale considered.

### Economic impacts

**Qu. 4.9. How great is the overall economic cost caused by the organism within its current area of distribution (excluding the risk assessment area), including both costs of / loss due to damage and the cost of current management.**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the world these should be reported here. The assessment of the potential costs of / loss due to damage shall describe those costs quantitatively and/or qualitatively depending on what information is available. Cost of / loss due to damage within different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage. As far as possible, it would be useful to separate costs of / loss due to the organism from costs of current management.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: There are references to economic impacts such as reducing forage quality when present in pastures (Weber 2003; GISD 2007) and cattle poisoning in New Zealand (Verdcourt & Trump 1969). However, there are no estimates of financial cost.

In the case of management costs there is reference to Golden Gate National Recreation Area, California, USA which spent over US\$600,000 over three years trying to eradicate this vine (CABI 2021a) This figure justifies the moderate score but it is quite probable that higher costs are incurred by other land owners.

**Qu. 4.10. How great is the economic cost of / loss due to damage (excluding costs of management) of the organism currently in the risk assessment area (include any past costs in your response)?**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the EU these should be reported here. Assessment of the potential costs of damage on human health, safety, and the economy, including the cost of non-action. A full economic assessment at EU scale might not be possible, but qualitative data or different case studies from across the EU (or third countries if relevant) may provide useful information to inform decision making. In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable). Cost of / loss due to damage within different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>	N/A minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: No information has been found on the issue. The question has not been scored.

**Qu. 4.11. How great is the economic cost of / loss due to damage (excluding costs of management) of the organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.10.

<b>RESPONSE</b>	N/A minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: No information has been found on the issue. The question has not been scored.

**Qu. 4.12. How great are the economic costs / losses associated with managing this organism currently in the risk assessment area (include any past costs in your response)?**

- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable).

<b>RESPONSE</b>	minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	--	-------------------	-----------------------

Response: The control measures referred to in the ARCOS Life+ project (<https://www.arcoslife.eu/arcosweb/>) are not costed in the report and the control was also applied to species other than *D. odorata* so it is not possible to estimate costs beyond minimal with low confidence because multiple small scale management efforts would soon exceed the threshold for a minor or even moderate score. Other examples include:

<https://www.gavarres.cat/uploads/imagenes/22-url-1575553537.pdf>

<http://www.comunidadism.es/wp-content/uploads/downloads/2012/07/gestion-de-la-biodiversidad-desde-el-ambito-local.pdf>

[https://www.miteco.gob.es/es/ceneam/grupos-de-trabajo-y-seminarios/red-parques-nacionales/Plan%20de%20control%20y%20eliminaci%C3%B3n%20de%20especies%20vegetales%20invasoras%20dunas\\_tcm30-169318.pdf](https://www.miteco.gob.es/es/ceneam/grupos-de-trabajo-y-seminarios/red-parques-nacionales/Plan%20de%20control%20y%20eliminaci%C3%B3n%20de%20especies%20vegetales%20invasoras%20dunas_tcm30-169318.pdf)

**Qu. 4.13. How great are the economic costs / losses associated with managing this organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.12.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: In the absence of evidence for current annual costs associated with the management of the species it is difficult to estimate future costs but it is highly likely that across the risk assessment area the costs would exceed 10,000 euros per year in the near future if not already, so a minor score is given with a low confidence.

**Social and human health impacts**

**Qu. 4.14. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism for the risk assessment area and for third countries, if relevant (e.g. with similar eco-climatic conditions).**

The description of the known impact and the assessment of potential future impact on human health, safety and the economy, shall, if relevant, include information on

- illnesses, allergies or other affections to humans that may derive directly or indirectly from a species;
- damages provoked directly or indirectly by a species with consequences for the safety of people, property or infrastructure;
- direct or indirect disruption of, or other consequences for, an economic or social activity due to the presence of a species.

Social and human health impacts can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: *Delairea odorata* contains pyrrolizidine alkaloids (liver toxins) and xanthone (Catalano et al, 1996) and can be toxic to animals when ingested (Bossard 2000). Balciunas (2004) reports that *D. odorata* is considered to be poisonous to pets that consume it with the Dog’s Trust citing gastrointestinal tract and dermatitis as potential areas of concern (<https://www.dogstrust.org.uk/help-advice/factsheets-downloads/factsheetpoisonoussubstances09.pdf>) No evidence of such impacts were found in the risk assessment area and it is assumed that the impacts are potential rather than common. The fact that park managers in Western USA spend their limited resources managing the plant suggests that the visitor experience would be reduced if such management were not carried out but this is difficult to quantify.

**Qu. 4.15. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism in the future for the risk assessment area.**

- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable).

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: It is not anticipated that any significant change in the importance is caused in the future.

### Other impacts

**Qu. 4.16. How important is the organism in facilitating other damaging organisms (e.g. diseases) as food source, a host, a symbiont or a vector etc.?**

<b>RESPONSE</b>	N/A minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: No information has been found on the issue.

**Qu. 4.17. How important might other impacts not already covered by previous questions be resulting from introduction of the organism?**

<b>RESPONSE</b>	N/A minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: No information has been found on the issue.

**Qu. 4.18. How important are the expected impacts of the organism despite any natural control by other organisms, such as predators, parasites or pathogens that may already be present in the risk assessment area?**

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: *Delairea odorata* does not have any host specific natural enemies in the risk assessment area and there is no evidence that native organisms feed or infect the species in substantial levels to inflict any damage on the species. Given the impacts seen elsewhere in its exotic range, *D. odorata* can be expected to have at least a moderate impact should it replicate its behaviour in California for example but confidence remains low due to lack of current evidence of impact in the risk assessment area.

**Qu. 4.19. Estimate the overall impact in the risk assessment area under current climate conditions. In addition, details of overall impact in relevant biogeographical regions should be provided.**

Thorough assessment of the overall impact on biodiversity and ecosystem services, with impacts on economy as well as social and human health as aggravating factors, in current conditions.

<b>RESPONSE</b>	<b>minimal</b> minor moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: The overall current impact in the risk assessment area can only be scored as minimal due to the limited amount of reliable evidence but confidence in this score is low. In other, more thoroughly researched and reported regions such as California the overall impact of the species is major on various levels of community structure and ecosystem services and it could be considered an ecosystem engineer given the transformations it can achieve through smothering competing vegetation permanently.

**Qu. 4.20. Estimate the overall impact in the risk assessment area in foreseeable climate change conditions. In addition, details of overall impact in relevant biogeographical regions should be provided.**

Thorough assessment of the overall impact on biodiversity and ecosystem services, with impacts on economy as well as social and human health as aggravating factors, under future conditions.

- See also guidance to Qu. 4.3.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: Under future climate conditions *D. odorata* is likely to exert more impact on habitats and ecosystem services in the risk assessment area but the speed at which this will happen is unclear given the doubts over current and future spread by seed so a slightly elevated score of minor with low confidence is given.

## RISK SUMMARIES

	RESPONSE	CONFIDENCE	COMMENT
<b>Summarise Introduction and Entry*</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	low medium <b>high</b>	The species has been introduced and entered the risk assessment area in the past. A number of active pathways exist (e.g. horticulture, ornamental purposes other than horticulture and contaminant of habitat material). The plant is not a very popular ornamental species in the risk assessment area. The very likely score is given by default as the species is already established in the risk assessment area.
<b>Summarise Establishment*</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	low <b>medium</b> high	The species is established in the risk assessment area and further establishment is likely in both current and future climatic conditions. The species has a wide tolerance of habitats and other abiotic parameters which promotes its establishment.
<b>Summarise Spread*</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	low <b>medium</b> high	Natural spread by vegetative reproduction. There is no scientific evidence to suggest the species spreads by seed in the risk assessment area. Human assisted spread can act to move the species within the RA area.
<b>Summarise Impact*</b>	minimal minor <b>moderate</b> major massive	<b>low</b> medium high	The species has shown significant and extensive impact on biodiversity and ecosystem services in its invaded range outside of the risk assessment area but this has not yet been realised in the risk assessment area yet. However, the significant number of control projects in the risk assessment area means this moderate score could be higher so a low confidence is given
<b>Conclusion of the risk assessment (overall risk)</b>	low <b>moderate</b> high	<b>low</b> medium high	Overall, <i>D. odorata</i> has a moderate risk to the EU with a low confidence. This score takes into account the moderate impact score but also the high likelihood of entry and establishment, coupled with a moderate spread. The low confidence

			score incorporates uncertainty in seed reproduction in the risk assessment area and the potential implications of seed reproduction in the future.
--	--	--	--

\*in current climate conditions and in foreseeable future climate conditions

## Distribution Summary

Please answer as follows:

- Yes if recorded, established or invasive
- if not recorded, established or invasive
- ? Unknown; data deficient

The columns refer to the answers to Questions A5 to A12 under Section A.

For data on marine species at the Member State level, delete Member States that have no marine borders.

In all other cases, provide answers for all columns.

Member States, and the United Kingdom

	Recorded	Established (currently)	Possible establishment (under current climate)	Possible establishment (under foreseeable climate)	Invasive (currently)
Austria	NO	NO	YES	YES	NO
Belgium	NO	NO	YES	YES	NO

## ANNEX I Scoring of Likelihoods of Events

(taken from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

Score	Description	Frequency
Very unlikely	This sort of event is theoretically possible, but is never known to have occurred and is not expected to occur	1 in 10,000 years
Unlikely	This sort of event has occurred somewhere at least once in the last millenium	1 in 1,000 years
Moderately likely	This sort of event has occurred somewhere at least once in the last century	1 in 100 years
Likely	This sort of event has happened on several occasions elsewhere, or on at least once in the last decade	1 in 10 years
Very likely	This sort of event happens continually and would be expected to occur	Once a year

## ANNEX II Scoring of Magnitude of Impacts

(modified from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

Score	Biodiversity and ecosystem impact	Ecosystem Services impact	Economic impact (Monetary loss and response costs per year)	Social and human health impact, and other impacts
	<i>Question 5.1-5</i>	<i>Question 5.6-8</i>	<i>Question 5.9-13</i>	<i>Question 5.14-18</i>
Minimal	Local, short-term population loss, no significant ecosystem effect	No services affected <sup>5</sup>	Up to 10,000 Euro	No social disruption. Local, mild, short-term reversible effects to individuals.
Minor	Some ecosystem impact, reversible changes, localised	Local and temporary, reversible effects to one or few services	10,000-100,000 Euro	Significant concern expressed at local level. Mild short-term reversible effects to identifiable groups, localised.
Moderate	Measureable long-term damage to populations and ecosystem, but reversible; little spread, no extinction	Measureable, temporary, local and reversible effects on one or several services	100,000-1,000,000 Euro	Temporary changes to normal activities at local level. Minor irreversible effects and/or larger numbers covered by reversible effects, localised.
Major	Long-term irreversible ecosystem change, spreading beyond local area	Local and irreversible or widespread and reversible effects on one / several services	1,000,000-10,000,000 Euro	Some permanent change of activity locally, concern expressed over wider area. Significant irreversible effects locally or reversible effects over large area.
Massive	Widespread, long-term population loss or extinction, affecting several species with serious ecosystem effects	Widespread and irreversible effects on one / several services	Above 10,000,000 Euro	Long-term social change, significant loss of employment, migration from affected area. Widespread, severe, long-term, irreversible health effects.

<sup>5</sup> Not to be confused with “no impact”.

## ANNEX III Scoring of Confidence Levels

(modified from Bacher et al. 2017)

Each answer provided in the risk assessment must include an assessment of the level of confidence attached to that answer, reflecting the possibility that information needed for the answer is not available or is insufficient or available but conflicting.

The responses in the risk assessment should clearly support the choice of the confidence level.

Confidence level	Description
Low	There is no direct observational evidence to support the assessment, e.g. only inferred data have been used as supporting evidence <i>and/or</i> Impacts are recorded at a spatial scale which is unlikely to be relevant to the assessment area <i>and/or</i> Evidence is poor and difficult to interpret, e.g. because it is strongly ambiguous <i>and/or</i> The information sources are considered to be of low quality or contain information that is unreliable.
Medium	There is some direct observational evidence to support the assessment, but some information is inferred <i>and/or</i> Impacts are recorded at a small spatial scale, but rescaling of the data to relevant scales of the assessment area is considered reliable, or to embrace little uncertainty <i>and/or</i> The interpretation of the data is to some extent ambiguous or contradictory.
High	There is direct relevant observational evidence to support the assessment (including causality) <i>and</i> Impacts are recorded at a comparable scale <i>and/or</i> There are reliable/good quality data sources on impacts of the taxa <i>and</i> The interpretation of data/information is straightforward <i>and/or</i> Data/information are not controversial or contradictory.

## ANNEX IV CBD pathway categorisation scheme

Overview of CBD pathway categorisation scheme showing how the 44 pathways relate to the six main pathway categories. All of the pathways can be broadly classified into 1) those that involve intentional transport (blue), 2) those in which the taxa are unintentionally transported (green) and 3) those where taxa moved between regions without direct transportation by humans and/or via artificial corridors (orange and yellow). **Note that the pathways in the category “Escape from confinement” can be considered intentional for the introduction into the risk assessment area and unintentional for the entry into the environment.**

## ANNEX V Ecosystem services classification (CICES V5.1, simplified) and examples

For the purposes of this risk assessment, please feel free to use what seems as the most appropriate category / level / combination of impact (Section – Division – Group), reflecting information available.

Section	Division	Group	Examples (i.e. relevant CICES “classes”)
Provisioning	Biomass	<b>Cultivated <i>terrestrial</i> plants</b>	<p>Cultivated terrestrial plants (including fungi, algae) grown for <u>nutritional purposes</u>;</p> <p>Fibres and other materials from cultivated plants, fungi, algae and bacteria for direct use or processing (excluding genetic materials);</p> <p>Cultivated plants (including fungi, algae) grown as a <u>source of energy</u></p> <p><i>Example: negative impacts of non-native organisms to crops, orchards, timber etc.</i></p>
		<b>Cultivated <i>aquatic</i> plants</b>	<p>Plants cultivated by in- situ aquaculture grown for <u>nutritional purposes</u>;</p> <p>Fibres and other materials from in-situ aquaculture for direct use or processing (excluding genetic materials);</p> <p>Plants cultivated by in- situ aquaculture grown as an <u>energy source</u>.</p> <p><i>Example: negative impacts of non-native organisms to aquatic plants cultivated for nutrition, gardening etc. purposes.</i></p>
		<b>Reared animals</b>	<p>Animals reared for <u>nutritional purposes</u>;</p> <p>Fibres and other materials from reared animals for direct use or processing (excluding genetic materials);</p> <p>Animals reared to provide <u>energy</u> (including mechanical)</p> <p><i>Example: negative impacts of non-native organisms to livestock</i></p>
		<b>Reared <i>aquatic</i> animals</b>	<p>Animals reared by in-situ aquaculture for <u>nutritional purposes</u>;</p> <p>Fibres and other materials from animals grown by in-situ aquaculture for direct use or processing (excluding genetic materials);</p> <p>Animals reared by in-situ aquaculture as an <u>energy source</u></p> <p><i>Example: negative impacts of non-native organisms to fish farming</i></p>
		<b>Wild plants</b> (terrestrial and aquatic)	<p>Wild plants (terrestrial and aquatic, including fungi, algae) used for <u>nutrition</u>;</p> <p>Fibres and other materials from wild plants for direct use or processing (excluding genetic materials);</p> <p>Wild plants (terrestrial and aquatic, including fungi, algae) used as a <u>source of energy</u></p> <p><i>Example: reduction in the availability of wild plants (e.g. wild berries, ornamentals) due to non-native organisms (competition, spread of disease etc.)</i></p>
		<b>Wild animals</b> (terrestrial and aquatic)	<p>Wild animals (terrestrial and aquatic) used for <u>nutritional purposes</u>;</p>

			<p>Fibres and other <u>materials</u> from wild animals for direct use or processing (excluding genetic materials); Wild animals (terrestrial and aquatic) used as a <u>source of energy</u></p> <p><i>Example: reduction in the availability of wild animals (e.g. fish stocks, game) due to non-native organisms (competition, predations, spread of disease etc.)</i></p>
	Genetic material from all biota	Genetic material from plants, algae or fungi	<p><u>Seeds, spores and other plant materials</u> collected for maintaining or establishing a population; Higher and lower plants (whole organisms) used to <u>breed new strains or varieties</u>; Individual genes extracted from higher and lower plants for the <u>design and construction of new biological entities</u></p> <p><i>Example: negative impacts of non-native organisms due to interbreeding</i></p>
		Genetic material from animals	<p>Animal material collected for the purposes of maintaining or establishing a population; Wild animals (whole organisms) used to breed new strains or varieties; Individual genes extracted from organisms for the design and construction of new biological entities</p> <p><i>Example: negative impacts of non-native organisms due to interbreeding</i></p>
	Water <sup>6</sup>	Surface water used for nutrition, materials or energy	<p>Surface water for <u>drinking</u>; Surface water used as a material (<u>non-drinking purposes</u>); Freshwater surface water, coastal and marine water used as an <u>energy source</u></p> <p><i>Example: loss of access to surface water due to spread of non-native organisms</i></p>
		Ground water for used for nutrition, materials or energy	<p>Ground (and subsurface) water for <u>drinking</u>; Ground water (and subsurface) used as a material (<u>non-drinking purposes</u>); Ground water (and subsurface) used as an <u>energy source</u></p> <p><i>Example: reduced availability of ground water due to spread of non-native organisms and associated increase of ground water consumption by vegetation.</i></p>
Regulation & Maintenance	Transformation of biochemical or physical inputs to ecosystems	Mediation of wastes or toxic substances of anthropogenic origin by living processes	<p>Bio-remediation by micro-organisms, algae, plants, and animals; <u>Filtration/sequestration/storage/accumulation</u> by micro-organisms, algae, plants, and animals</p> <p><i>Example: changes caused by non-native organisms to ecosystem functioning and ability to filtrate etc. waste or toxics</i></p>
		Mediation of nuisances of anthropogenic origin	<p>Smell reduction; noise attenuation; visual screening (e.g. by means of green infrastructure)</p> <p><i>Example: changes caused by non-native organisms to ecosystem structure, leading to reduced ability to mediate nuisances.</i></p>

<sup>6</sup> Note: in the CICES classification provisioning of water is considered as an abiotic service whereas the rest of ecosystem services listed here are considered biotic.

	Regulation of physical, chemical, biological conditions	Baseline flows and extreme event regulation	Control of <u>erosion</u> rates; Buffering and attenuation of <u>mass movement</u> ; <u>Hydrological cycle and water flow regulation</u> (Including flood control, and coastal protection); <u>Wind</u> protection; <u>Fire</u> protection  <i>Example: changes caused by non-native organisms to ecosystem functioning or structure leading to, for example, destabilisation of soil, increased risk or intensity of wild fires etc.</i>
		Lifecycle maintenance, habitat and gene pool protection	<u>Pollination</u> (or 'gamete' dispersal in a marine context); <u>Seed dispersal</u> ; <u>Maintaining nursery populations and habitats</u> (Including gene pool protection)  <i>Example: changes caused by non-native organisms to the abundance and/or distribution of wild pollinators; changes to the availability / quality of nursery habitats for fisheries</i>
		Pest and disease control	Pest control; Disease control  <i>Example: changes caused by non-native organisms to the abundance and/or distribution of pests</i>
		Soil quality regulation	<u>Weathering processes</u> and their effect on soil quality; <u>Decomposition and fixing processes</u> and their effect on soil quality  <i>Example: changes caused by non-native organisms to vegetation structure and/or soil fauna leading to reduced soil quality</i>
		Water conditions	Regulation of the <u>chemical condition</u> of freshwaters by living processes; Regulation of the chemical condition of salt waters by living processes  <i>Example: changes caused by non-native organisms to buffer strips along water courses that remove nutrients in runoff and/or fish communities that regulate the resilience and resistance of water bodies to eutrophication</i>
		Atmospheric composition and conditions	Regulation of <u>chemical composition</u> of atmosphere and oceans; Regulation of <u>temperature and humidity</u> , including ventilation and transpiration  <i>Example: changes caused by non-native organisms to ecosystems' ability to sequester carbon and/or evaporative cooling (e.g. by urban trees)</i>
Cultural	Direct, in-situ and outdoor interactions with living systems that depend on presence in the environmental setting	Physical and experiential interactions with natural environment	Characteristics of living systems that that enable activities promoting health, recuperation or enjoyment through <u>active or immersive interactions</u> ; Characteristics of living systems that enable activities promoting health, recuperation or enjoyment through <u>passive or observational interactions</u>  <i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that make it attractive for recreation, wild life watching etc.</i>

		<p><b>Intellectual and representative</b> interactions with natural environment</p>	<p>Characteristics of living systems that enable <u>scientific investigation</u> or the creation of traditional ecological knowledge;  Characteristics of living systems that enable <u>education and training</u>;  Characteristics of living systems that are resonant in terms of <u>culture or heritage</u>;  Characteristics of living systems that enable <u>aesthetic experiences</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have cultural importance</i></p>
	<p><b>Indirect, remote, often indoor interactions</b> with living systems that do not require presence in the environmental setting</p>	<p><b>Spiritual, symbolic</b> and other interactions with natural environment</p>	<p>Elements of living systems that have <u>symbolic meaning</u>;  Elements of living systems that have <u>sacred or religious meaning</u>;  Elements of living systems used for <u>entertainment or representation</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have sacred or religious meaning</i></p>
		<p>Other biotic characteristics that have a <b>non-use value</b></p>	<p>Characteristics or features of living systems that have an <u>existence value</u>;  Characteristics or features of living systems that have an <u>option or bequest value</u></p> <p><i>Example: changes caused by non-native organisms to ecosystems designated as wilderness areas, habitats of endangered species etc.</i></p>

## **ANNEX VIII Projection of environmental suitability for *Delairea odorata* establishment in Europe**

Björn Beckmann, Helmut Kudrnovsky, Rob Tanner, Richard Shaw and Dan Chapman

15 June 2021

### ***Aim***

To project the suitability for potential establishment of *Delairea odorata* in Europe, under current and predicted future climatic conditions.

### ***Data for modelling***

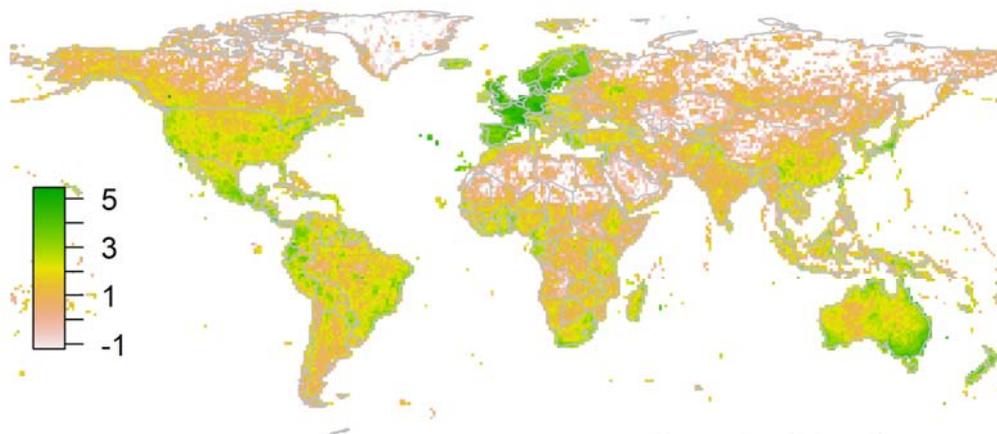

Species occurrence data were obtained from the Global Biodiversity Information Facility (GBIF) (4253 records), iNaturalist (2214 records), the Atlas of Living Australia (1356 records), the Biodiversity Information Serving Our Nation database (BISON) (400 records), and additional records from the risk assessment team. We scrutinised occurrence records from regions where the species is not known to be established and removed any dubious records or where the georeferencing was too imprecise (e.g. records referenced to a country or island centroid) or outside of the coverage of the predictor layers (e.g. small island or coastal occurrences). We removed records dated pre-1950, as these might refer to populations no longer in existence. The remaining records were gridded at a 0.25 x 0.25 degree resolution for modelling, yielding 535 grid cells with occurrences (Figure 1a). As a proxy for recording effort, the density of Tracheophyta records held by GBIF was also compiled on the same grid (Figure 1b).

**Figure 1.** (a) Occurrence records obtained for *Delairea odorata* and used in the modelling, showing native and invaded distributions. (b) The recording density of Tracheophyta on GBIF, which was used as a proxy for recording effort.

(a) Species distribution used in modelling

(b) Estimated recording effort (log<sub>10</sub>-scaled)

Climate data were selected from the 'Bioclim' variables contained within the WorldClim database (Hijmans et al., 2005), originally at 5 arcminute resolution (0.083 x 0.083 degrees of longitude/latitude) and aggregated to a 0.25 x 0.25 degree grid for use in the model.

Based on the biology of *Delairea odorata*, the following climate variables were used in the modelling:

- Minimum temperature of the coldest month (Bio6)
- Mean temperature of the warmest quarter (Bio10)
- Climatic moisture index (CMI): ratio of mean annual precipitation to potential evapotranspiration, log+1 transformed. For its calculation, monthly potential evapotranspirations were estimated from the WorldClim monthly temperature data and solar radiation using the simple method of Zomer et al. (2008) which is based on the Hargreaves evapotranspiration equation (Hargreaves, 1994).

To estimate the effect of climate change on the potential distribution, equivalent modelled future climate conditions for the 2070s under the Representative Concentration Pathways (RCP) 2.6 and 4.5 were also obtained. These represent low and medium emissions scenarios, respectively. The above variables were obtained as averages of outputs of eight Global Climate Models (BCC-CSM1-1, CCSM4, GISS-E2-R, HadGEM2-AO, IPSL-CM5A-LR, MIROC-ESM, MRI-CGCM3, NorESM1-M), downscaled and calibrated against the WorldClim baseline (see [http://www.worldclim.org/cmip5\\_5m](http://www.worldclim.org/cmip5_5m)).

The following habitat layers were also used:

- Tree cover (Tree): This was estimated from the MODerate-resolution Imaging Spectroradiometer (MODIS) satellite continuous tree cover raster product, produced by the Global Land Cover Facility (<http://glcf.umd.edu/data/vcf/>). The raw product contains the percentage cover by trees in each 0.002083 x 0.002083 degree grid cell. We aggregated this to the mean cover in our 0.25 x 0.25 degree grid cells.
- Human influence index (HII): As many non-native invasive species associate with anthropogenically disturbed habitats. We used the Global Human Influence Index Dataset of the Last of the Wild Project (Wildlife Conservation Society - WCS & Center for International Earth Science Information Network - CIESIN - Columbia University, 2005), which is developed from nine global data layers covering human population pressure (population density), human land use and infrastructure (built-up areas, nighttime lights, land use/land cover) and human access (coastlines, roads, railroads, navigable rivers). The index ranges between 0 and 1 and was ln+1 transformed for the modelling to improve normality.
- Distance to the sea (dist\_to\_sea): As some species require oceanic climates, we calculated distance to the sea as a proxy. Distances are in meters and were ln+1 transformed for modelling to improve normality.

### ***Species distribution model***

A presence-background (presence-only) ensemble modelling strategy was employed using the BIOMOD2 R package version 3.4.6 (Thuiller et al., 2020, Thuiller et al., 2009). These models contrast the environment at the species' occurrence locations against a random sample of the global background environmental conditions (often termed 'pseudo-absences') in order to characterise and project suitability for occurrence. This approach has been developed for distributions that are in equilibrium with the environment. Because invasive species' distributions are not at equilibrium and subject to dispersal constraints at a global scale, we took care to minimise the inclusion of locations suitable for the species but where it has not been able to disperse to (Chapman et al. 2019).

Therefore the background sampling region included:

- The area accessible by native *Delairea odorata* populations, in which the species is likely to have had sufficient time to disperse to all locations. Based on presumed maximum dispersal distances, the accessible region was defined as a 400km buffer around the native range occurrences; AND
- A 30km buffer around the non-native occurrences, encompassing regions likely to have had high propagule pressure for introduction by humans and/or dispersal of the species; AND
- Regions where we have an *a priori* expectation of high unsuitability for the species so that absence is assumed irrespective of dispersal constraints (see Figure 2). The following rules were applied to define a region expected to be highly unsuitable for *Delairea odorata* at the spatial scale of the model:

- Minimum temperature of the coldest month (Bio6) < -7.5°C
- Mean temperature of the warmest quarter (Bio10) < 11°C
- Climatic moisture index (CMI) < 0.20

Altogether, only 0.9% of occurrence grid cells were located in the unsuitable background region.

Within the unsuitable background region, 10 samples of 5000 randomly sampled grid cells were obtained. In the accessible background (comprising the accessible areas around native and non-native occurrences as detailed above), the same number of pseudo-absence samples were drawn as there were presence records (535), weighting the sampling by a proxy for recording effort (Figure 2).

**Figure 2.** The background from which pseudo-absence samples were taken in the modelling of *Delairea odorata*. Samples were taken from a 400km buffer around the native range and a 30km buffer around non-native occurrences (together forming the accessible background), and from areas expected to be highly unsuitable for the species (the unsuitable background region). Samples from the accessible background were weighted by a proxy for recording effort (Figure 1(b)).

Each dataset (i.e. combination of the presences and the individual background samples) was randomly split into 80% for model training and 20% for model evaluation. With each training dataset, seven statistical algorithms were fitted with the default BIOMOD2 settings and rescaled using logistic regression, except where specified below:

- Generalised linear model (GLM)
- Generalised boosting model (GBM)
- Generalised additive model (GAM) with a maximum of four degrees of freedom per smoothing spline
- Artificial neural network (ANN)
- Multivariate adaptive regression splines (MARS)

- Random forest (RF)
- Maxent

Since the total background sample was larger than the number of occurrences, prevalence fitting weights were applied to give equal overall importance to the occurrences and the background. Normalised variable importance was assessed and variable response functions were produced using BIOMOD2's default procedure.

Model predictive performance was assessed by the following three measures:

- AUC, the area under the receiver operating characteristic curve (Fielding & Bell 1997). Predictions of presence-absence models can be compared with a subset of records set aside for model evaluation (here 20%) by constructing a confusion matrix with the number of true positive, false positive, false negative and true negative cases. For models generating non-dichotomous scores (as here) a threshold can be applied to transform the scores into a dichotomous set of presence-absence predictions. Two measures that can be derived from the confusion matrix are sensitivity (the proportion of observed presences that are predicted as such, quantifying omission errors), and specificity (the proportion of observed absences that are predicted as such, quantifying commission errors). A receiver operating characteristic (ROC) curve can be constructed by using all possible thresholds to classify the scores into confusion matrices, obtaining sensitivity and specificity for each matrix, and plotting sensitivity against the corresponding proportion of false positives (equal to  $1 - \text{specificity}$ ). The use of all possible thresholds avoids the need for a selection of a single threshold, which is often arbitrary, and allows appreciation of the trade-off between sensitivity and specificity. The area under the ROC curve (AUC) is often used as a single threshold-independent measure for model performance (Manel, Williams & Ormerod 2001). AUC is the probability that a randomly selected presence has a higher model-predicted suitability than a randomly selected absence (Allouche et al. 2006).
- Cohen's Kappa (Cohen 1960). This measure corrects the overall accuracy of model predictions (ratio of the sum of true presences plus true absences to the total number of records) by the accuracy expected to occur by chance. The kappa statistic ranges from -1 to +1, where +1 indicates perfect agreement and values of zero or less indicate a performance no better than random. Advantages of kappa are its simplicity, the fact that both commission and omission errors are accounted for in one parameter, and its relative tolerance to zero values in the confusion matrix (Manel, Williams & Ormerod 2001). However, Kappa has been criticised for being sensitive to prevalence (the proportion of sites in which the species was recorded as present) and may therefore be inappropriate for comparisons of model accuracy between species or regions (McPherson, Jetz & Rogers 2004, Allouche et al. 2006).
- TSS, the true skill statistic (Allouche et al. 2006). TSS is defined as sensitivity + specificity - 1, and corrects for Kappa's dependency on prevalence. TSS compares the number of correct forecasts, minus those attributable to random guessing, to that of a hypothetical set of perfect forecasts. Like kappa, TSS takes into account both omission and commission errors, and success as a result of random guessing, and ranges from -1 to +1, where +1 indicates perfect agreement and values of zero or less indicate a performance no better than random (Allouche et al. 2006).

An ensemble model was created by first rejecting poorly performing algorithms with relatively extreme low AUC values and then averaging the predictions of the remaining algorithms, weighted by their AUC. To identify poorly performing algorithms, AUC values were converted into modified z-scores based on their difference to the median and the median absolute deviation across all

algorithms (Iglewicz & Hoaglin 1993). Algorithms with  $z < -2$  were rejected. In this way, ensemble projections were made for each dataset and then averaged to give an overall suitability, as well as its standard deviation.

Projections were classified into suitable and unsuitable regions using a “lowest presence threshold” (Pearson et al. 2007), setting the cut-off as the lowest value at which 98% of all presence records are classified correctly under the current climate (here 0.61). In order to express the sensitivity of classifications to the choice of this threshold, thresholds at which 95% and 99% of records are classified correctly (here 0.77 and 0.36 respectively) were used in the calculation of error bars in Figs. 9 and 10 below in addition to taking account of uncertainty in the projections themselves.

We also produced a limiting factor map for Europe following Elith et al. (2010). For this, projections were made separately with each individual variable fixed at a near-optimal value. These were chosen as the median values at the occurrence grid cells. Then, the most strongly limiting factors were identified as the ones resulting in the highest increase in suitability in each grid cell.

## Page Break

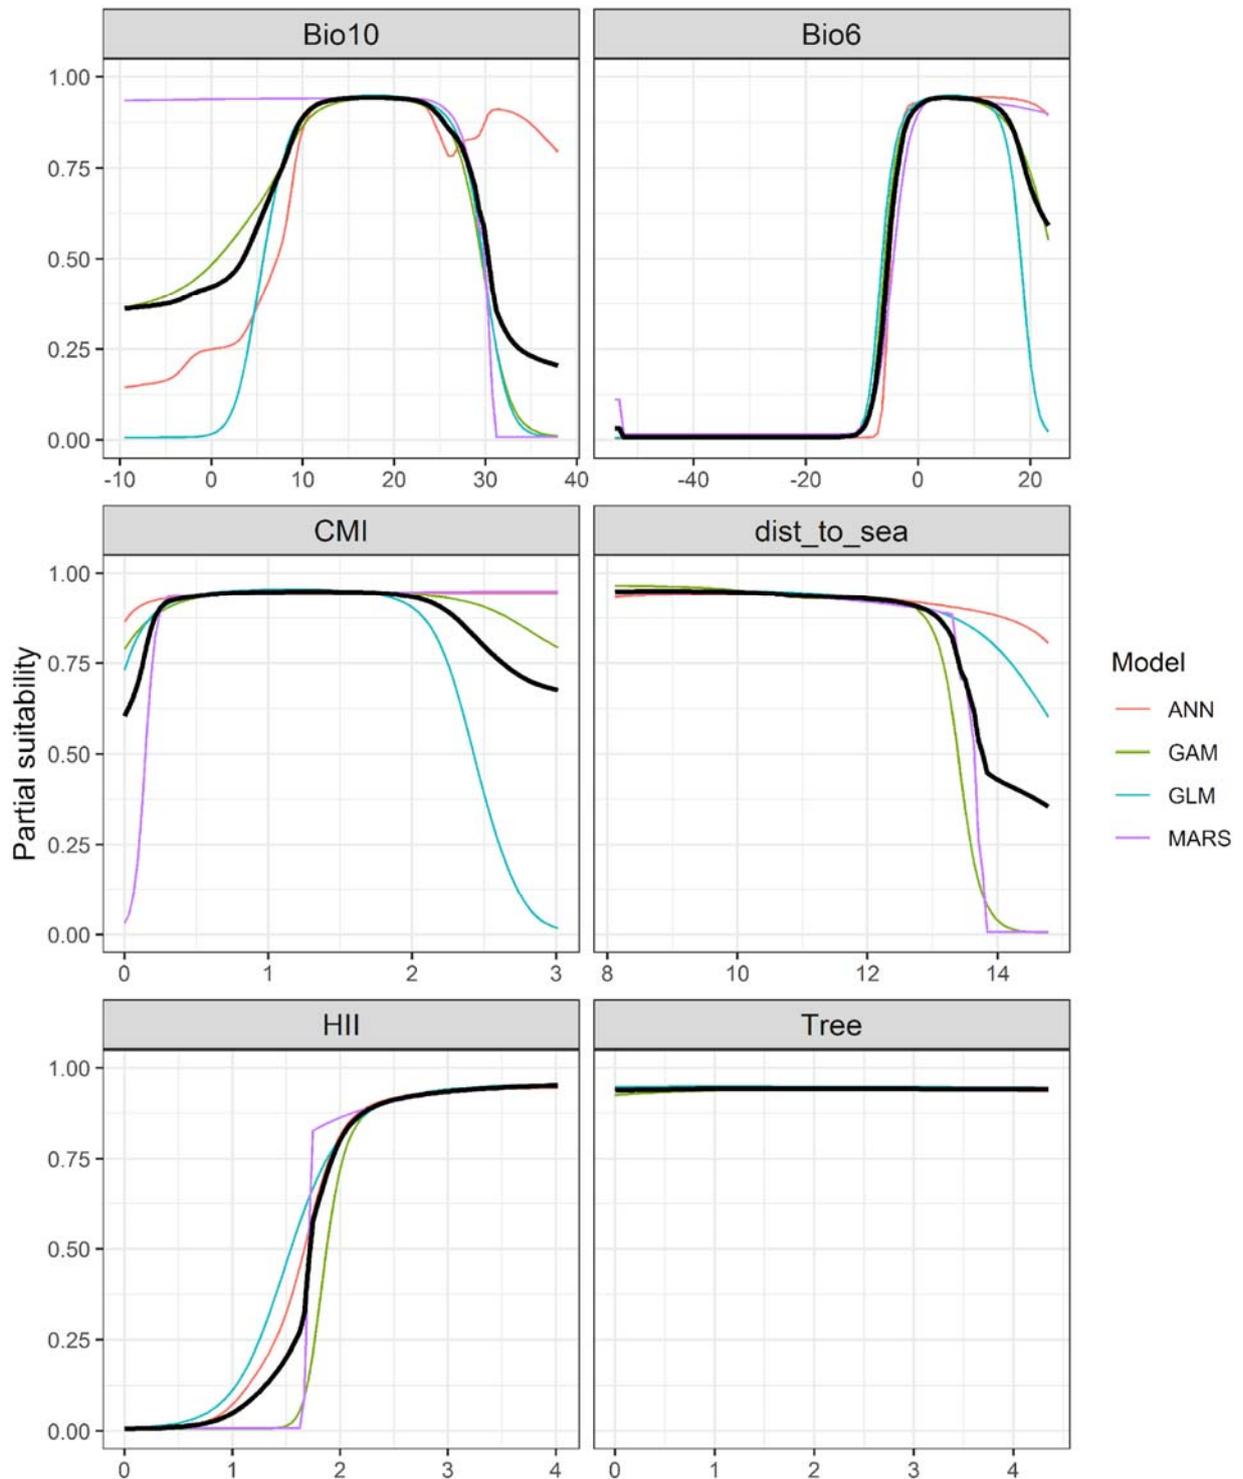

## Results

The ensemble model suggested that suitability for *Delairea odorata* was most strongly determined by Minimum temperature of the coldest month (Bio6), accounting for 50.9% of variation explained, followed by Human influence index (HII) (24.1%), Mean temperature of the warmest quarter (Bio10) (9.9%), Distance to the sea (dist\_to\_sea) (8.6%), Climatic moisture index (CMI) (6%) and Global tree cover (Tree) (0.5%) (Table 1, Figure 3).

**Table 1.** Summary of the cross-validation predictive performance (AUC, Kappa, TSS) and variable importance of the fitted model algorithms and the ensemble (AUC-weighted average of the best performing algorithms). Results are the average from models fitted to 10 different background samples of the data.

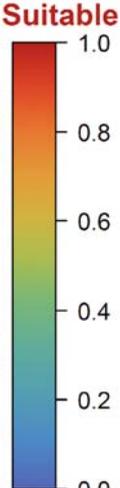

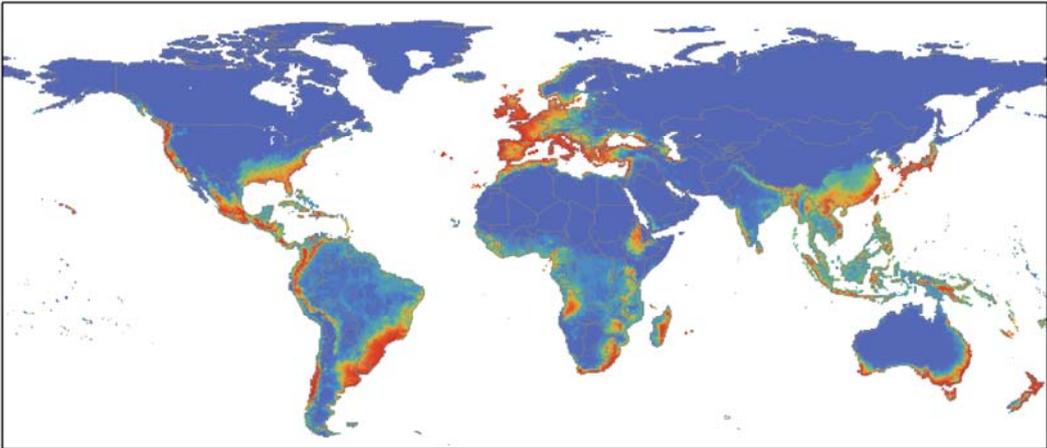

Algorithm	AUC	Kappa	TSS	Used in the ensemble	Variable importance (%)					
					Minimum temperature of the coldest month (Bio6)	Human influence index (HII)	Mean temperature of the warmest quarter (Bio10)	Distance to the sea (dist_to_sea)	Climatic moisture index (CMI)	Global tree cover (Tree)
GLM	0.962	0.644	0.895	yes	56	22	15	3	4	0
GAM	0.962	0.640	0.895	yes	47	27	9	15	2	0
GBM	0.959	0.643	0.893	no	51	3	13	12	21	0
ANN	0.963	0.651	0.897	yes	53	24	11	4	7	2
MARS	0.963	0.653	0.896	yes	48	23	5	12	11	0
RF	0.942	0.611	0.882	no	61	7	4	8	16	3
Maxent	0.954	0.638	0.885	no	36	13	13	11	23	4
<b>Ensemble</b>	<b>0.963</b>	<b>0.652</b>	<b>0.897</b>		<b>51</b>	<b>24</b>	<b>10</b>	<b>9</b>	<b>6</b>	<b>1</b>

**Figure 3.** Partial response plots from the fitted models. Thin coloured lines show responses from the algorithms in the ensemble, while the thick black line is their ensemble. In each plot, other model variables are held at their median value in the training data. Some of the divergence among algorithms is because of their different treatment of interactions among variables.

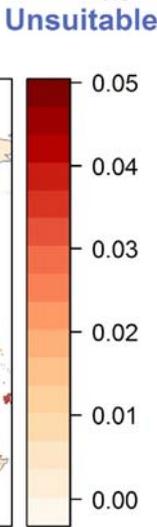

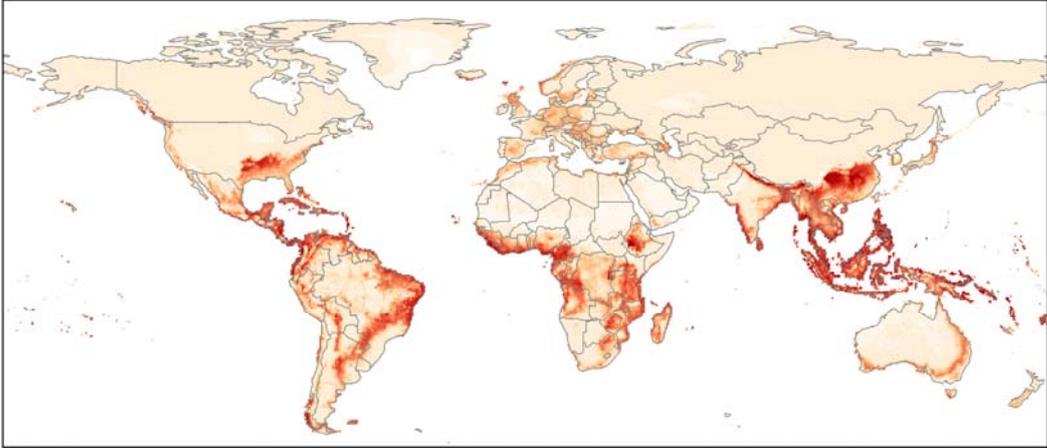

**Figure 4.** (a) Projected global suitability for *Delairea odorata* establishment in the current climate. For visualisation, the projection has been aggregated to a 0.5 x 0.5 degree resolution, by taking the maximum suitability of constituent higher resolution grid cells. Values > 0.61 are suitable for the species, with 98% of global presence records above this threshold. Values below 0.61 indicate lower relative suitability. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

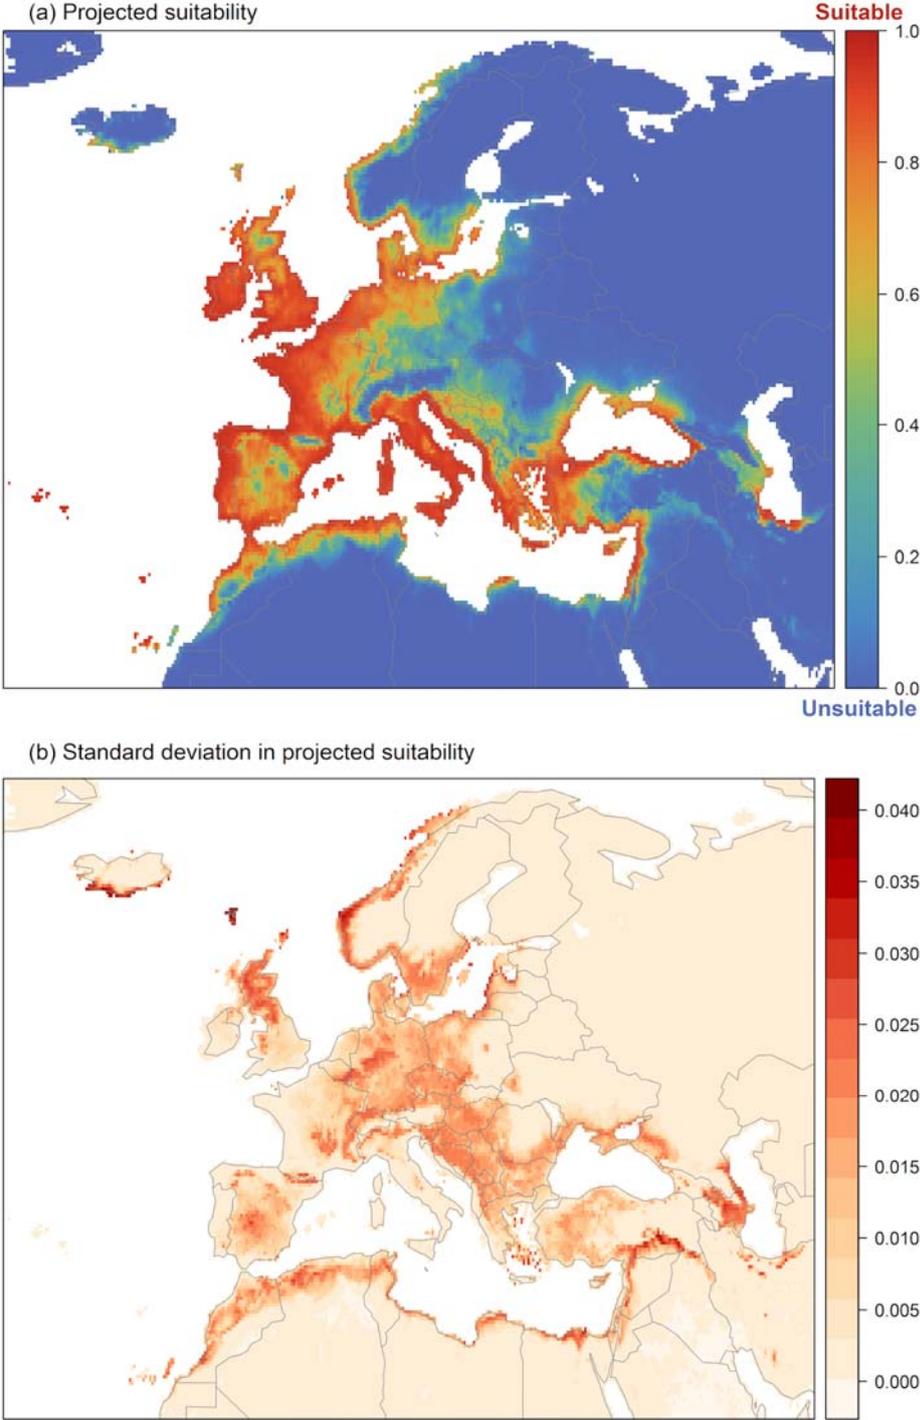

(a) Projected suitability

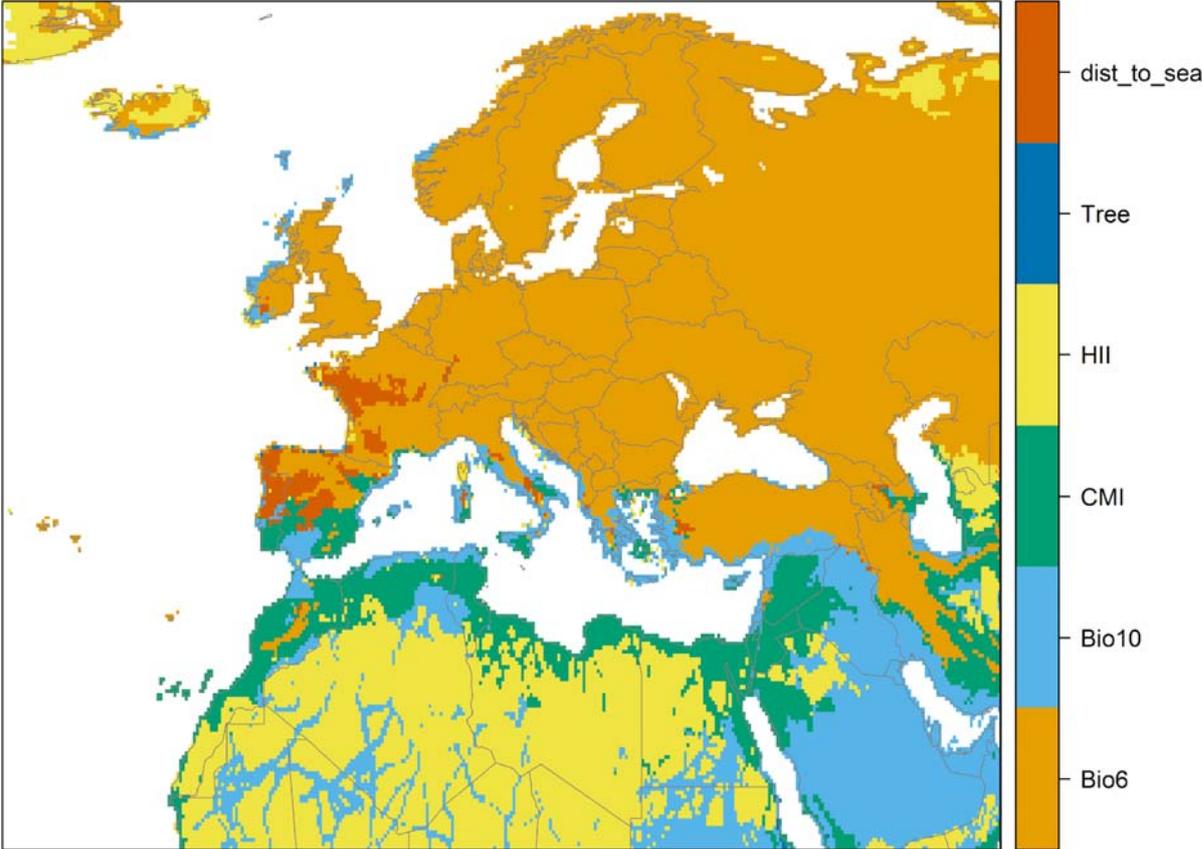

(b) Standard deviation in projected suitability

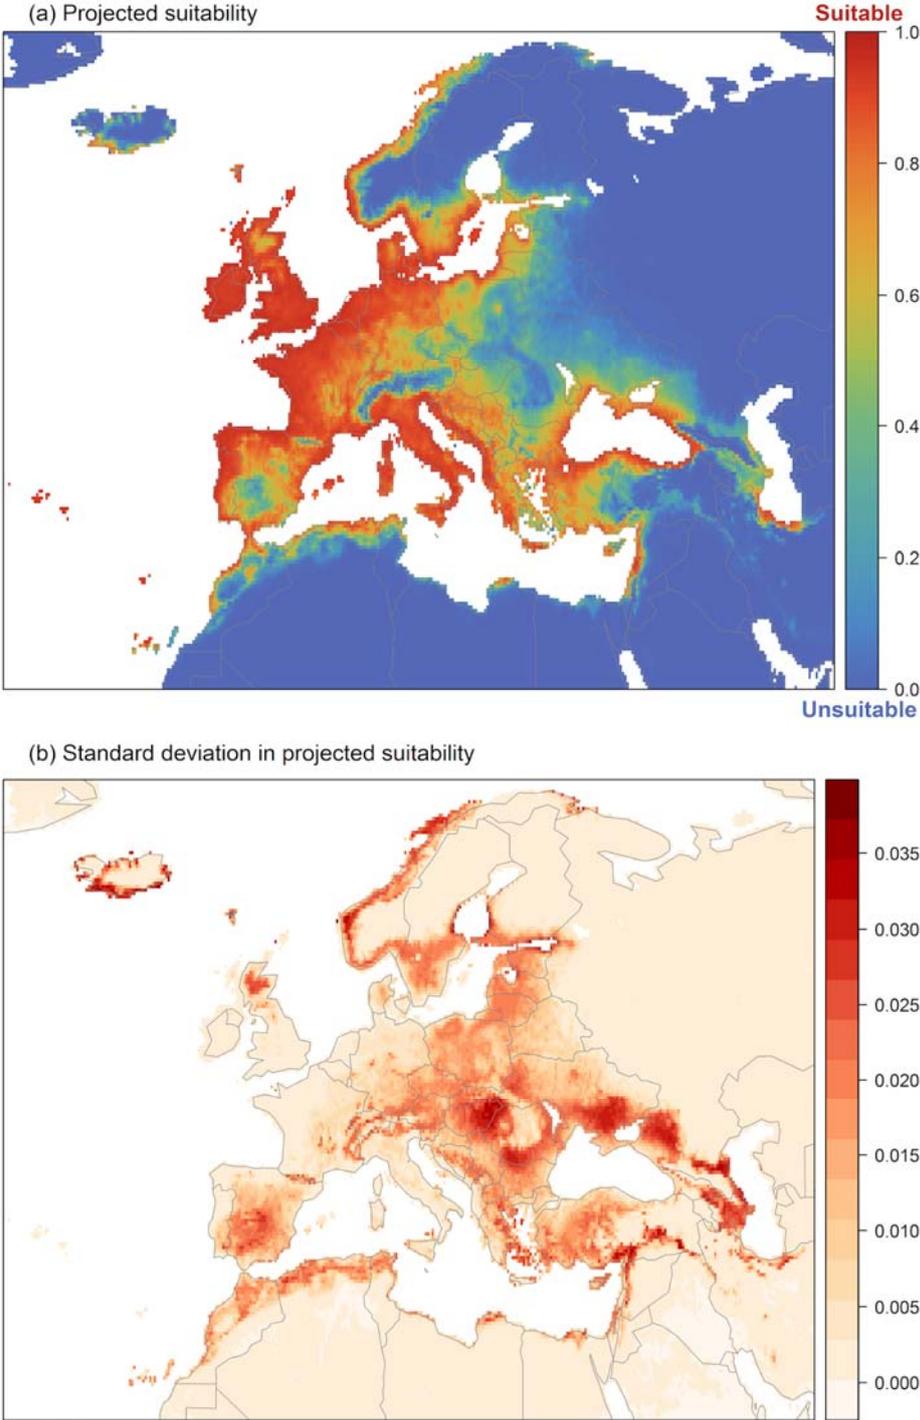

**Figure 5.** (a) Projected current suitability for *Delairea odorata* establishment in Europe and the Mediterranean region. Values > 0.61 are suitable for the species, with 98% of global presence records above this threshold. Values below 0.61 indicate lower relative suitability. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

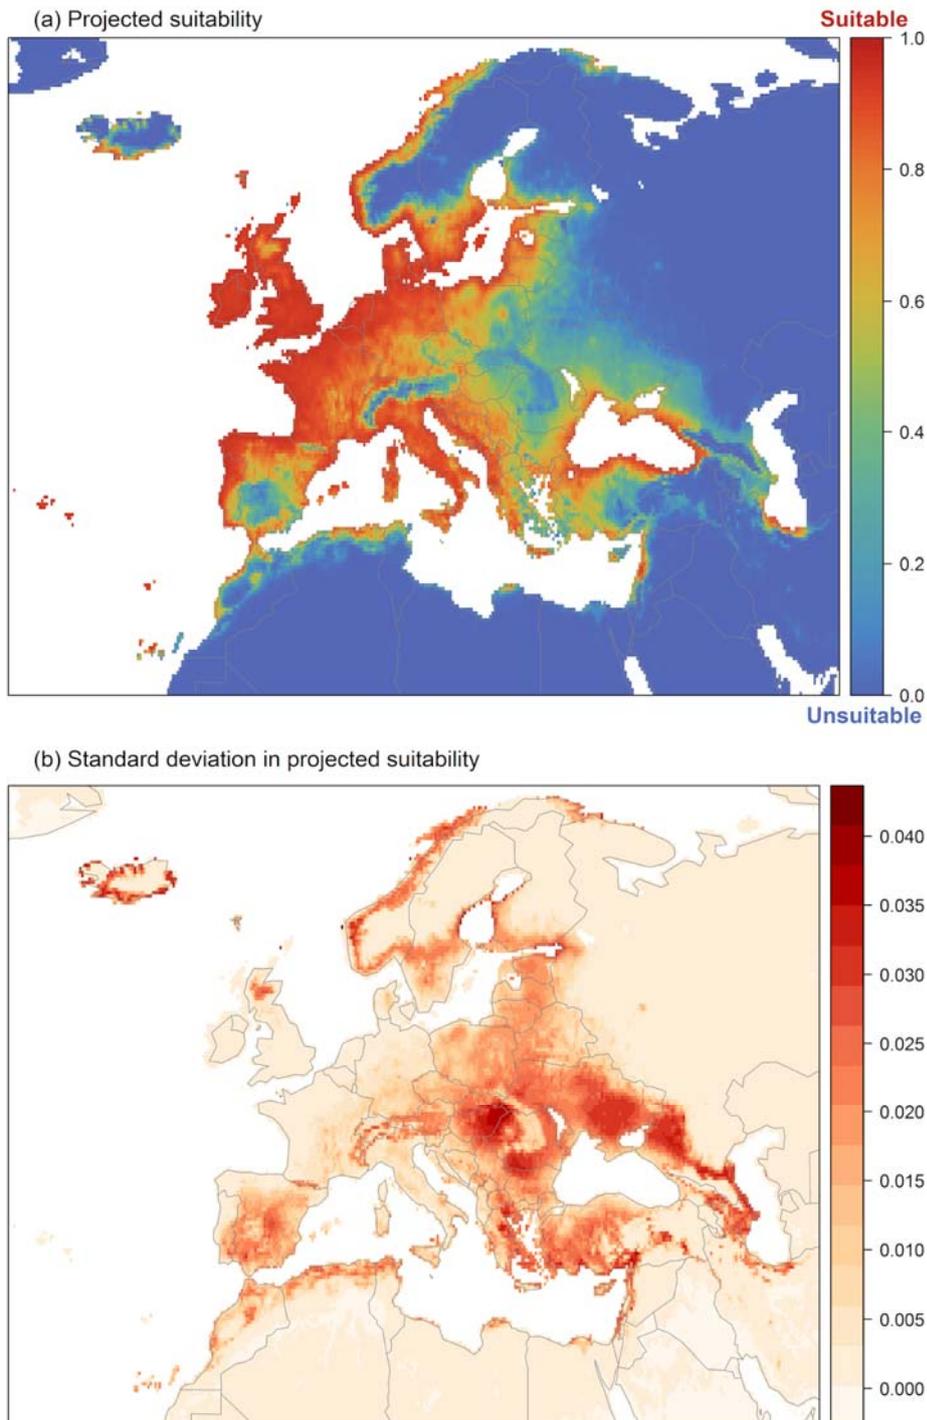

**Figure 6.** The most strongly limiting factors for *Delairea odorata* establishment estimated by the model in Europe and the Mediterranean region in current climatic conditions.

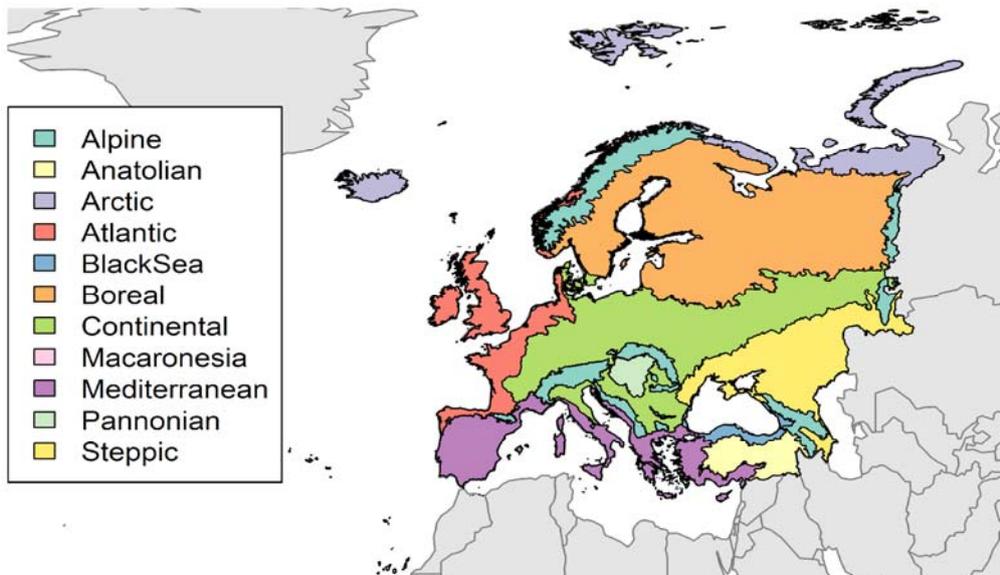

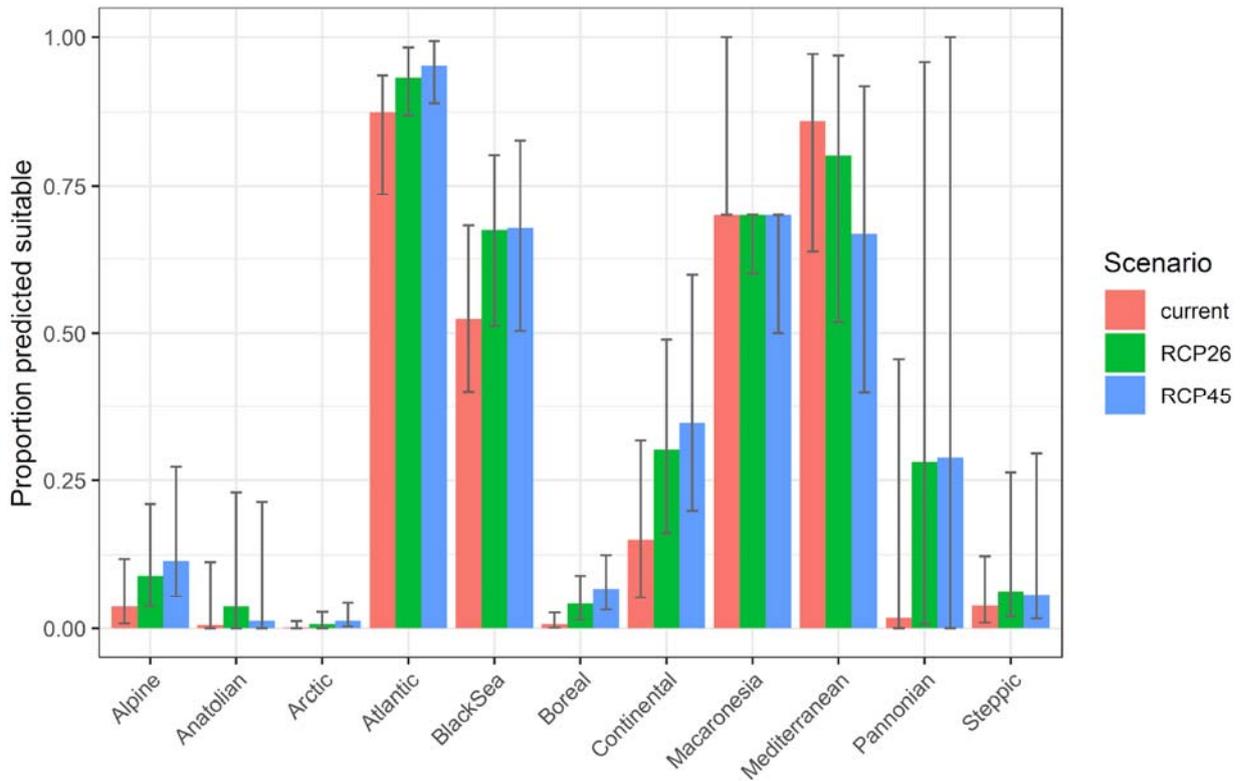

**Figure 7.** (a) Projected suitability for *Delairea odorata* establishment in Europe and the Mediterranean region in the 2070s under climate change scenario RCP2.6. Values > 0.61 are suitable for the species, with 98% of global presence records above this threshold under current climate. Values below 0.61 indicate lower relative suitability. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

**Figure 8.** (a) Projected suitability for *Delairea odorata* establishment in Europe and the Mediterranean region in the 2070s under climate change scenario RCP4.5. Values > 0.61 are suitable for the species, with 98% of global presence records above this threshold under current climate. Values below 0.61 indicate lower relative suitability. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

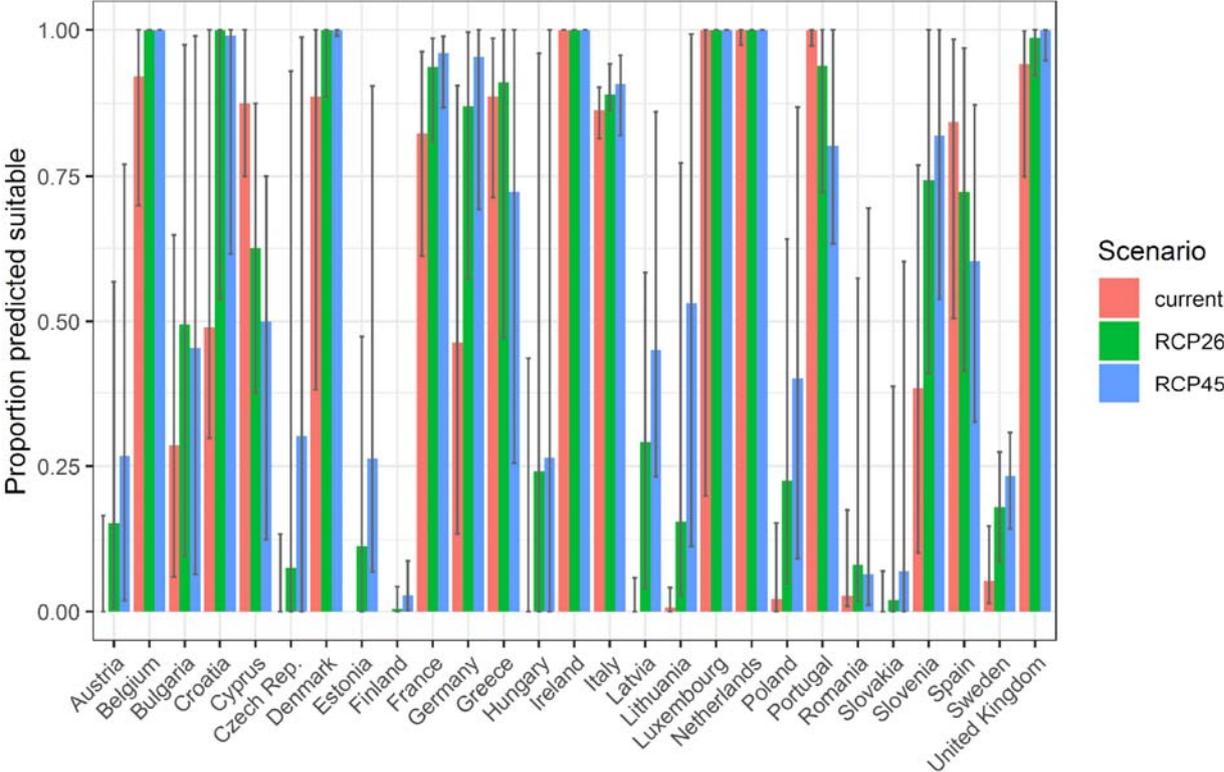

**Figure 9.** Variation in projected suitability for *Delairea odorata* establishment among Biogeographical Regions of Europe (<https://www.eea.europa.eu/data-and-maps/data/biogeographical-regions-europe-3>). The bar plots show the proportion of grid cells in each region classified as suitable (with values > 0.61) in the current climate and projected climate for the 2070s under two RCP emissions scenarios. Error bars indicate uncertainty due to both the choice of classification threshold (cf. p.5/6) and uncertainty in the projections themselves (cf. part (b) of Figs. 5,7,8). The location of each region is also shown. The Arctic and Macaronesian regions are not part of the study area, but are included for completeness.

**Table 2.** Variation in projected suitability for *Delairea odorata* establishment among Biogeographical regions of Europe (numerical values of Figure 9 above). The numbers are the proportion of grid cells in each region classified as suitable in the current climate and projected climate for the 2070s under two RCP emissions scenarios. The Arctic and Macaronesian biogeographical regions are not part of the study area, but are included for completeness.

**Figure 10.** Variation in projected suitability for *Delairea odorata* establishment among European Union countries and the UK. The bar plots show the proportion of grid cells in each country classified as suitable (with values > 0.61) in the current climate and projected climate for the 2070s under two RCP emissions scenarios. Error bars indicate uncertainty due to both the choice of classification threshold (cf. p.5/6) and uncertainty in the projections themselves (cf. part (b) of Figs. 5,7,8). Malta has been excluded because the Human Influence Index dataset lacks coverage for Malta.

**Table 3.** Variation in projected suitability for *Delairea odorata* establishment among European Union countries and the UK (numerical values of Figure 10 above). The numbers are the proportion of grid cells in each country classified as suitable in the current climate and projected climate for the 2070s under two RCP emissions scenarios.

## ***Caveats to the modelling***

To remove spatial recording biases, the selection of the background sample from the accessible background was weighted by the density of Tracheophyta records on the Global Biodiversity Information Facility (GBIF). While this is preferable to not accounting for recording bias at all, it may not provide the perfect measure of recording bias.

There was substantial variation among modelling algorithms in the partial response plots (Figure 3). In part this will reflect their different treatment of interactions among variables. Since partial plots are made with other variables held at their median, there may be values of a particular variable at which this does not provide a realistic combination of variables to predict from.

Other variables potentially affecting the distribution of the species, such as types of land cover other than trees were not included in the model.

<b>Reviewer</b>	<b>Johan van Valkenburg and Giuseppe Brundu</b>
<b>Date completed</b>	<b>15/10/2021</b>

### Summary<sup>1</sup>

Highlight of measures that provide the most cost-effective options to prevent the introduction, achieve early detection, rapidly eradicate and manage the species, including significant gaps in information or knowledge to identify cost-effective measures.

*Delairea odorata* is already established within the risk assessment area. It is recorded in eight EU Member States where it is established in six. The species is recorded in the Alpine, Atlantic, Boreal, Continental and Mediterranean biogeographical regions and can be assessed as “established” in the Atlantic and Mediterranean biogeographical regions. The main introduction and entry pathways are *Horticulture (escape from confinement)*, *Ornamental purpose other than horticulture: (escape from confinement)* and *Landscape / flora / fauna (improvement in the wild) (cover for walls buildings etc.)*. The overall potential rate of spread under current conditions is assessed as moderate. Thus, to mitigate the impact of this species within the risk assessment area, measures should focus on:

- early detection and eradication of the species where it occurs in new outbreaks,
- limiting spread into new areas,
- suppressing populations where this is still feasible.

The best form of management is the prevention of the introduction of an invasive species into new areas of Member States. Cape ivy is traded within the risk assessment area. A ban from sale requires resources including financial resources, staff time and the development of communication material from several sectors, including governmental, regulators, horticulture and horticulture suppliers, the general public and environmental NGOs. Phytosanitary inspections can be implemented on commodities coming into the EU from outside, but the risk of *D. odorata* entering as a contaminant is low. Biosecurity campaigns have been shown to have a significant effect on awareness raising of negative impacts of invasive alien species. This method is expected to be generally acceptable to the public as it acts to engage stakeholders and put the responsibility into their hands. Early detection could be achieved by surveying the most likely areas of disturbed habitats in urban and peri-urban areas and natural and semi natural areas, especially in coastal regions. If prevention is no longer possible, it is best to treat the weed infestations when they are small to prevent them from establishing (early detection and rapid response). Alvarez (1997) suggested for the Golden Gate National Recreation Area (California) following containment strategy: (1) Achieve parkwide

containment; (2) Remove highest priority infestations, and remove all small or remote Cape-ivy patches; (3) Improve control methods to secure long-term control; (4) Expand community-based involvement in long-term control program. NPS (2021) reports of 80ha Cape ivy removal at the Golden Gate National Recreation Area in 2015. Control is generally best applied to the least infested areas before dense infestations are tackled. Consistent follow-ups are required for effective management. Cape ivy can be managed by traditional physical, mechanical and chemical control methods. However, the latter should be used with caution as chemical application is often non-selective and the plant often climbs over other non-target vegetation.

Management on several levels may be:

- Preventive: Do not plant Cape ivy. Educate homeowners and others on its invasive nature.
- Cultural: Recommend alternative native plants that can be planted after Cape ivy has been removed.
- Mechanical: hand-pulling of Cape ivy in small infestations; repeating as necessary to control any re-growth from sprouts.
- Biological: There are fully researched biocontrol agents in use against Cape ivy but these are not available or tested for the risk assessment area.
- Chemical: application of chemicals can reduce the population of Cape ivy.

CABI (2021) provides some indications related to management but these may not yet be suitable for application in the risk assessment area:

- Although very labour intensive, hand-pulling of *D. odorata* is usually the preferred control method. To prevent new infestations in other areas, the plant material that has been removed, must be disposed of carefully.
- Clopyralid has been used successfully in Australia (Fagg, 1989). In California, glyphosate alone provided only very temporary control, but when a mixture of glyphosate + triclopyr + silicone surfactant in water was used, it provided successful control after two applications (Bossard, 2000). Damage to non-target vegetation is likely, and care should be taken to minimize this.
- There are no approved biological control agents available to manage *D. odorata* in the risk assessment area. However, under a project to develop such agents from South Africa by USDA-ARS in 1998 (Balciunas and Archbald, 1999), a shoot tip-galling fly (*Parafreutreta regalis* Munro) has been released in California and is becoming established (ARS 2020) In addition, a moth, *Secusio extensa* (Lepidoptera: Erebidae), has been released in Hawaii and is recorded as causing heavy damage on the Cape ivy as well as its primary target *Senecio madagascariensis* in Hawaii (Krushelnyckya et al., 2018).
- Whatever control method is used, careful monitoring and removal of any resprouts and seedlings is essential, or within a matter of months the treated area will become indistinguishable from adjacent untreated areas.

Effective management should be supported by a dedicated Action Plan. There is a need to map the distribution, identify management priorities and areas and integrated control strategy (i.e. combination of different methods).

Detailed assessment			
	Description of measures <sup>2</sup>	Assessment of implementation cost and cost-effectiveness (per measure) <sup>3</sup>	Level of confidence <sup>4</sup>
<b>Methods to achieve prevention of intentional and unintentional introduction<sup>5</sup></b>	<p><b>Ban from sale</b></p> <p>One potential pathway for entry or spread of <i>Delairea odorata</i> into the EU, or between Member States, is through the purchase of material (plants and seeds) through the horticultural trade. A ban from sale would help to regulate this pathway for Cape ivy.</p>	<p><i>Delairea odorata</i> is already traded within the risk assessment area and sold as a garden ornamental, and a houseplant. A ban on the sale of the species would be a reasonably cost-effective measure to prevent the movement into and within the risk assessment area. A ban on sale requires resources including financial resources, staff time and the development of communication material from a number of sectors, including governmental, regulators, horticulture and horticultural suppliers, the general public, and environmental NGOs. A ban on sale may be relatively easy to achieve with limited opposition as the species is not popular or widely available via the horticulture industry or e-commerce sites and many alternative species exist. Costs may be saved by being part of a broader effort covering other invasive alien species. The method is likely to be effective if all stakeholders are convinced of the risk of the species to biodiversity and ecosystems in the risk assessment area. Stakeholder acceptance can be achieved if the risk assessment shows a high risk. However, where the species has low likelihood of establishment outdoors, Member States may question the need for a ban. The general public may find the approach acceptable if supporting information is provided to justify the risk. Health and safety considerations are not appropriate for this measure.</p>	High
	<p><b>Public awareness campaigns</b></p> <p>Communication material detailing the negative impacts of the species would be essential to educate the public and support a ban on sale.</p>	<p>Public awareness campaigns may highlight the risk of the species and prevent further spread of the species from existing populations. Public awareness campaigns should highlight that fragments of the species should not be collected and planted or dumped in waste piles or natural areas. Where possible campaigns should highlight alternative species that could be planted. It is estimated that the cost for an awareness raising campaign could be up to EUR 10,000 per year (which would include the cost to</p>	High

		<p>produce and disseminate information material along with associated staff costs) for each Member State which is already affected by the invasive species. An alternative approach may be an European wide awareness campaign with information material prepared by the European Commission and translated into Member States languages. Public awareness campaigns should highlight that following management, plant material should be disposed of according to national regulations. Where possible, campaigns should highlight alternative species that could be used as ornamentals. Health and safety considerations are not appropriate for this measure.</p>	
	<p><b>Phytosanitary inspections</b>  The transport of stem material as a contaminant of habitat material (soil and vegetation) may facilitate its entry and spread within the EU. Phytosanitary inspections along with associated phytosanitary measures can act to prevent the entry of the species into specific countries/regions. Preventing the spread of <i>D. odorata</i> should also be regarded as a priority for national phytosanitary inspection services</p>	<p>Phytosanitary inspections can be implemented on commodities coming into the EU from outside but the risk of <i>D. odorata</i> entering as a contaminant is, depending on the commodity, moderately low as the seed is often not viable and stem material would be visible. The authors could not find any examples where stem or root material has been intercepted as a containment. It is difficult to implement phytosanitary measures within the EU due to freedom of movement of commodities between countries. Therefore, this limits the effectiveness of inspections regarding the repeated introduction and spread of the species within the EU. At the Member State level, national phytosanitary authorities are responsible for raising awareness of such inspections. If measures are not implemented by all countries, they will not be effective since the species could enter a country or spread within a country or from one country to another. National measures should be combined with international measures, and international coordination of management of the species between countries is recommended. The cost of such a measure is likely to be relatively low in preparation but key identification information would need to be supplied to inspectors (e.g. 5-10,000 Euros). The cost for implementation may be higher as training for inspectors may be needed. Inspectors will be well trained in health and safety</p>	<p>Medium</p>

		procedures, although there are no specific concerns relating to this species.	
	<b>Awareness raising material</b>	To prevent the movement of contaminated material between EU Member States, management plans for habitat material, identification guides, factsheets, Codes of conduct (e.g. Queensland Government 2016) should be developed. These materials would support staff training. Costs to develop awareness raising material can vary depending on the types and format it is disseminated. Online factsheets and management documents can be developed at a low cost i.e. 500-1000 euros. Health and safety considerations are not appropriate for this measure.	Medium
<b>Methods to achieve early detection<sup>6</sup></b>	<b>Awareness raising campaigns combined with citizen science projects</b> Communication material detailing the characteristics and negative impacts of the species would be essential to educate the public. Public awareness campaigns (combined with citizen science projects to detect new occurrences) may highlight the risk of the species and prevent further spread of the species from existing populations.	Citizen science and public participation have emerged as powerful techniques to engage the public in the content and practices of applied science. Citizen science programs need to attract and retain participants with clear goals and motivations. It is useful to identify and acknowledge the contributions that individual stakeholders can bring to project efforts. By doing so, the program can build on known strengths and target where additional capacity needs to be developed. Involving partners and other stakeholders early in the process of project design can increase investment and enhance outcomes. Where possible it is worth adopting standardized and vetted protocols used by others after adaptation for local or regional conditions. Plans should be made early on for the infrastructure necessary to capture, manage, store, and share project data, where appropriate. Many existing citizen science projects can provide the core infrastructure around which a regional or topical effort can be developed (e.g., iNaturalist). An increasing number of technology platforms and tools are also arising to facilitate custom citizen science project design (Rückert-John et al. 2017). There may be a spatial imbalance in data collection due to differences in participation in the different regions and countries.	Medium

		Costs: The costs could be minimal if technology (e.g. apps) and the framework (citizen scientists) are already in place. Resources would involve IT-costs, staff time. The staff involved could come from government agencies and/or citizen scientists. Some regional training workshops could be conducted to train stakeholders in identification; it is estimated that each training workshop may cost approx. EUR 3,000. Health and safety considerations are not appropriate for this measure.	
	<p><b>Surveillance by experts</b></p> <p>This type of surveillance includes involvement of experts e.g. in field surveys (e.g. habitat mapping or dedicated invasive alien species mapping).</p>	<p>Habitat mapping has become the standard technique of site related inventories for nature conservation and landscape planning (EEA 2014). Often, habitat mapping is not an area-wide but a selective survey of natural or semi-natural high value biotopes. Collection of invasive alien species data is a by-product in most cases. Dedicated invasive alien species surveillance is not yet a common tool. Field surveys, especially in larger areas, are cost intensive.</p> <p>Costs: It is estimated that the cost for an annual surveillance could be from about EUR 10,000 per year in smaller Member States to much larger figures in larger Member States. This could incorporate multiple species and widespread surveillance. Costs could significantly increase if novel technologies are added (drones, computer software). Health and safety considerations are not appropriate for this measure.</p>	Medium
<p><b>Methods to achieve eradication<sup>7</sup></b></p> <p>There are a number of methods that can potentially achieve eradication of discrete populations. However, if the population occurs</p>	<p><b>Control using mechanical or manual removal</b></p> <p>Manual measures assisted by mechanical tools (cutting and excavating) and in combination with chemicals. Due to the vigorous regrowth from cut stumps, vegetative root regeneration and seed dispersal, control using traditional methods is both labour intensive and costly with repeated applications needed to achieve a</p>	<p>In many types of invaded sites mechanical and chemical control for Cape ivy are more effective when used in combination, therefore the two methods are often combined and are here treated as a single management measure. Cape ivy is very difficult or impossible to control by simple cutting or by other mechanical means alone.</p> <p>The resources required will be related to the extent of the invaded area, the land accessibility, the need to repeat the interventions. The resources needed for an integrated control strategy within a dedicated management plan will be dependent upon specific</p>	Medium

<p>over a large area, eradication attempts may be limited or will require investment over a number of years. It is also important to note that any eradication method may need to be used in combination, e.g. removal of the above-ground stem will not achieve eradication alone and will need to be used in combination with excavation of the below-ground roots or repeated chemical application to deplete the below-ground biomass. Eradication methods can be applied on a local scale. Methods would depend on the habitat where the species is invasive and the</p>	<p>restored habitat. Manual removal (uprooting) and cutting coupled with an application of systemic herbicides have been shown to be effective in controlling shrub forms of the plant (Stern 2011). Manual removal of plants including roots and rhizomes, before viable seed develops can help control infestations in areas where plants are accessible. Removing all plant materials from the site will help prevent re-rooting of rhizomes, stolons, or stem fragments. Follow-up removal of resprouts is essential. In some large patches, all stems can be cut at ground level and Cape ivy rolled up like a rug. Although the below-ground reproductive tissues will resprout, this strategy makes it possible to detect and spot-treat new sprouts avoiding contact with desirable vegetation. Because Cape ivy can resprout and establish from stem fragments, mowing is not recommended. Cutting Cape ivy before it flowers will reduce seed production and deplete the plant's energy reserves. Resprouts are common after treatment. Cutting should be combined with a herbicide treatment or with multiple cuttings over a period of years. All plant parts should be bagged and properly disposed of (DiTomaso et al. 2013). Small plants can be uprooted but it is important to remove the roots completely as <i>Delairea odorata</i> reproduces vegetatively from roots and stolons. Effective removal of</p>	<p>circumstances, but in general will include trained staff, access to necessary tools and equipment to undertake mechanical or manual control, the purchasing and application of plant protection products (PPP), and the disposal costs for the removed plants. Staff should be trained in health and safety aspects for applying chemicals. Costs will vary depending on the area infested and the type of habitat. If plant material is on a discrete piece of land (e.g. removing a single patch, legal disposal and recovering the soil), control costs could be as little as 2,000-5,000 EUR. However, attention to detail is needed as leaving just a little part of the plant may regenerate (Bossard, 2000). Stern (2011) indicates for areas in California with less than 50% Cape ivy cover an average annual hand removal cost about \$6,160 per acre per year (13500 euro per Ha per year).). These costs were based on volunteer crews; with appropriate training, these labor costs can be reduced. Costs can also be substantially reduced by using volunteers. Hiring a part-time volunteer coordinator for \$20 to \$25/hour to coordinate volunteer days if existing staff is not available is also an option. Using volunteers is an option not only for cost reasons, but to engage the community in stewardship, and provide education to prevent future introduction of invasive species. However, where the species invades a site with multiple landownerships and/or if the species is growing over native vegetation, costs may be increased. Costs also include the disposal of plant material in an authorized site and soil replacement. No monetary figures have been found on the manual control of larger populations. Depending on the size of the infestation and the habitat costs may be substantial to eradicate the species. For example, Golden Gate National Recreation Area near San Francisco, California, USA has spent over US\$600,000 over three years trying to eradicate this vine across an area of up to 162 acres</p>	
---	---	--	--

extent of the infestation.	the above and belowground plant material is essential for the eradication of the species and this can be labour intensive.	(65.5 Ha) (Alvarez, 1997). More recent estimate of the invasion suggests 76 ha.	
	<b>Excavation of the roots from the soil</b>	Excavating soil contaminated with root material or seed material could potentially assist in eradication attempts but may be costly as heavy machinery may be needed and the contaminated soil may need to be removed to a licensed landfill which will incur additional costs. Health and safety precautions should be employed as this method can involve the use of machinery and equipment. Some disturbance to the environment is likely, though this is unlikely to be long-lived. Restoration activities can minimize environmental disturbance.	Medium
	<b>Chemical application (herbicides)</b> As a general disclaimer, plant protection products are subject to national restrictions and regulations of the EU Member States. Furthermore, there may be legal constraints as well as low public acceptance to use chemicals in larger or in protected areas. Chemical control methods should be used with caution as substances often are non-selective. In addition, time of the year/season, day time and especially weather conditions can make a difference.	Growth regulators: <i>Clopyralid</i> is a selective herbicide for broadleaf species. This compound has been shown to be successful in controlling Cape ivy in Australia (Fagg 1989). Timing: postemergence when plants are growing rapidly. <i>Triclopyr</i> is a selective herbicide for broadleaf species. In areas where desirable grasses are growing under or around Cape ivy, triclopyr can be used without non-target damage. Timing: postemergence when plants are growing rapidly. Aromatic amino-acid inhibitors: <i>Glyphosate</i> is a nonselective systemic herbicide. It gives good control with some resprouts. In many situations, it may be more appropriate to use a wiper application to achieve selectivity. Glyphosate can be combined with triclopyr for more effective control (and using a surfactant when applying this combination). Timing: postemergence when plants are growing rapidly. Best results when treated in late summer or early fall (DiTomaso et al. 2013; Weedbusters 2021). Health and safety precautions should be employed as this method involves the use of chemical application. Some disturbance to the environment is likely, when applying chemicals. These can be minimized with direct application on the target species.	Medium

		<p>Acceptability of chemical control in natural areas is generally low within the EU.</p> <p>Costs: Stern (2011) estimates the first-year costs of \$11,893 per acre per year (29 375 euros per hectare per year) for areas with greater than 50% Cape ivy cover and high native plant cover. This would probably need to be repeated over a number of years to achieve eradication.</p>	
<p><b>Methods to achieve management<sup>8</sup></b></p> <p>Management methods can be applied on a local scale. Methods would depend on the habitat where the species is invasive and the extent of the infestation.</p>	<p><b>Manual removal</b></p> <p>Manual removal can be used to control the spread of the species, in particular of small populations. Further, manual removal of incremental spread from the edge of established stocks is worth for consideration.</p>	<p>Manual removal (uprooting) and cutting coupled with an application of systemic herbicides have been shown to be effective in controlling shrub forms of the plant (Stern 2011). Small plants can be uprooted but it is important to remove the roots completely as <i>Delairea odorata</i> reproduces vegetatively from the roots. Mechanical removal of <i>D. odorata</i> (using machinery or larger equipment) is difficult and time consuming since the vine can resprout from any node that is not disposed off properly. When using mechanical control, the species has to be dug out, a containment zone should be established to prevent further spread and all plant debris has to be removed according to national legislations (EPPO 2021). Small infestations of Cape Ivy can be removed completely. Climbing stems can be severed at the base and left to dry out in the canopy. Broken stem pieces must be collected and removed from the site to prevent them from taking root (Weeds Australia 2021). Health and safety precautions should be employed as this method can involve the use of equipment (e.g. secateurs, saws). Some disturbance to the environment is likely. Acceptability of this method may vary depending on the habitat quality (natural versus ruderal) and the level of disturbance, but is likely to be more acceptable than chemical application.</p> <p>This can be minimized with precaution and restoration activities. Costs: Stern (2011) indicates for areas in California with less than 50% Cape ivy cover an average annual hand removal cost about \$6,160 per acre per year (13500 euro per Ha per year).</p>	Medium

	<p><b>Excavation of the roots from the soil</b></p>	<p>Excavation of roots from the soil, and contaminated soil, may be cost effective over a long period of time but the initial outlay of costs can be high and include costs of heavy machinery and costs of disposal of contaminated soil. Further complications can arise depending on the habitat type invaded, where for example invasions into natural habitats may act to increase the costs associated with management. Removing a small number of plants from a limited area may be feasible and relatively inexpensive. However, at larger scales and in more complex environments, feasibility of eradication is likely to drop rapidly with significant increases in cost. However, little evidence is available on which to base further assessments. Health and safety precautions should be employed, as this method can involve the use of equipment.</p> <p>Acceptability of this method may vary depending on the habitat quality (natural versus ruderal) and the level of disturbance, but is likely to be more acceptable than chemical application.</p> <p>Costs: there are no specific costs estimates for the management with excavation of roots and seeds from the soil.</p>	<p>Medium</p>
	<p><b>Chemical control</b></p>	<p>Chemical control is probably not a cost-effective method for this species over a large area but it could be useful when controlling small populations of the species. Repeated and targeted applications may be needed to maintain suppression of the population. Staff should be trained in health and safety aspects for applying chemicals.</p> <p>Chemical control of <i>D. odorata</i> depends on location of the infestation, sensitivity of the associated species, and the surface area covered by the plant (EPPO 2021). Some disturbance to the environment is likely, when applying chemicals. These can be minimized with direct application on the target species.</p>	<p>Medium</p>

		<p>Acceptability of chemical control in natural areas is generally low within the EU.</p> <p>Costs: Stern (2011) estimates the first year costs with \$11,893 per acre per year (29 375 euros per hectare per year) for areas with greater than 50% Cape ivy cover and high native plant cover.</p>	
	<b>Biological control</b>	<p>There are no approved biological control agents available to manage <i>D. odorata</i> in the risk assessment area. However, under a project to develop such agents from South Africa by USDA-ARS in 1998 (Balciunas &amp; Archbald 1999), a shoot tip-galling fly (<i>Parafreutreta regalis</i> Munro) has been released in California and is becoming established (ARS 2020). In addition, a moth, <i>Secusio extensa</i> (Lepidoptera: Erebidae) has been released in Hawaii and is recorded as causing heavy damage on the cape ivy as well as its primary target <i>Senecio madagascariensis</i> in Hawaii (Krushelnyckya et al. 2018; Cal-IPC 2021a/b).</p> <p>Acceptability of biological control is increasing within Europe as the acceptability of chemical applications is decreasing. With awareness raising and information dissemination, acceptability can be increased.</p> <p>Costs: there are no specific costs estimates for the management by biological control, but once releases have been successful there is no on-going cost to such control programs other than for monitoring. Initially, a biological control programme could cost in the region of 200 - 600 000 Euros to implement and costs are lower for those targets for which successful biocontrol has been demonstrated elsewhere as the R&amp;D input is very much lower. Health and safety considerations are not appropriate for this measure.</p>	High
	<b>Action plan</b>	<p>Effective management should be supported by a dedicated Action Plan. There is a need to map the distribution, identify management priorities and areas and integrated control strategy (i.e.</p>	Medium

		<p>combination of different methods). Health and safety considerations are not appropriate for this measure.</p> <p>Costs: an action plan can vary in potential costs dependent on the coverage of the plan. A plan that includes several habitats for example may be greater than one that focuses on a specific area/habitat. An action plan can be produced at a cost of 500 -2 000 euros.</p>

## Guidelines for Completing the Annex

1 Provide a brief summary description of the most cost-effective methods drawing on the reviews in the detailed assessments

2 Provide a description of the potential method. This should be based on the available key scientific evidence which should be gathered from sources including articles and reviews in technical and scientific journals, internet searches, online databases, grey literature and relevant books and personal communications from scientists, stakeholders, conservation practitioners and governmental bodies. This information should include a full bibliographic list detailing the literature and sources considered.

3 Provide an assessment of the likely cost and effectiveness of the method. Where information is available, consider the following range of questions, accepting that not all questions will be appropriate in all circumstances.

- How effective has this approach proven to be in the past or in an analogous situation?
- How publically acceptable is the approach likely to be?
- Over what period of time would this approach need to be applied to be effective?
- What is the direct cost of implementing this approach?
- How likely are the methods used in the approach to be available?
- How likely is it that relevant licences or other approvals to undertake the approach would be difficult to obtain?
- How likely is it that health and safety issues would prevent the use of this approach?
- How significant is the environmental harm caused by this approach?
- How significant is the economic harm caused by this approach?
- How significant is the social harm caused by this approach?
- How likely is it that the approach will be criticised on welfare grounds?
- How likely is it that the approach will be acceptable to other stakeholders?

Where available, factual information on the costs of specialist equipment, or case studies of management costs from across the Union or third countries should be provided. When describing case studies, if the information is available then provide both total cost and the area over which control was undertaken so that a cost per unit area might be derived. Where such quantitative information is not available, then any qualitative information from the literature is acceptable to help guide decision making. It is accepted that in the majority of cases the information required to assess the potential total cost of management at a member state level is unlikely to be available. This would normally require information on the extent and abundance of the species which is beyond the scope of this assessment. Assessors are not expected to extrapolate the potential total costs of management at a member state level, only to report on the information provided within the literature.

4 Provide an overall assessment of the confidence that can be applied to the information provided for this method. This confidence should relate to the quality of the available information using the guidance below. It should NOT relate to the confidence in the effectiveness of the method

The confidence scores are:

- **High:** Information comes from published material, or current practices based on expert experience applied in one of the EU countries or third country with similar environmental, economic and social conditions.
- **Medium:** Information comes from published data or expert opinion, but it is not commonly applied, or it is applied in regions that may be too different from Europe (e.g. tropical regions) to guarantee that the results will be transposable.
- **Low:** data are not published in reliable information sources and methods are not commonly practiced or are based solely on opinion; This is for example the case of a novel situation where there is little evidence on which to base an assessment.

If there are further factors beyond these that have determined the chosen level of confidence, then provide a brief written description to support the choice of the level of confidence.

5 Measures for preventing the species being introduced intentionally or unintentionally into the territory of a Member State (cf. Articles 7(1)(a), 7(2), 13, 15), i.e. preventing a species entering by blocking its pathways, including pre-border prevention and prevention of escape or release into the environment and secondary spread whenever relevant. Measures for preventing the species reproducing while in containment should be included, if appropriate. Consider all methods that might be applied, including any that have not proven useful. Provide a description of each method in turn, using separate rows to consider each method.

6 Measures to run an effective surveillance system for achieving an early detection of a new occurrence (cf. Article 16). This section assumes that the species is not currently present in a Member State, or part of a Member State's territory.

7 Measures to achieve eradication. Preferably, but not exclusively, used at an early stage of invasion, after an early detection of a new occurrence (cf. Article 17). Consider all methods that might be applied, including any that have not proven useful. Provide a description of each method in turn, using separate rows to consider each method.

8 Measures to achieve management of the species once it has become widely spread within a Member State territory (cf. Article 19). These measures can be aimed at eradication, population control or containment of a population of the species. Consider all methods that might be applied, including any that have not proven useful. Provide a description of each method in turn, using separate rows to consider each method.

The development and completion of this template forms part of the EU project **No 07.0202/2020/834529/ETU/ENV.D.2** Study on Invasive Alien Species – Development of risk assessments to tackle priority species and enhance prevention.

**Risk assessment template developed under the "Study on Invasive Alien Species – Development of risk assessments to tackle priority species and enhance prevention"  
Contract No 07.0202/2020/834529/ETU/ENV.D.2<sup>1</sup>**

**Name of organism:** *Marisa cornuarietis* (Linnaeus 1758)

**Author(s) of the assessment:**

Frances Lucy, IT Sligo, Sligo, Ireland and Darren Garland, IT Sligo, Sligo, Ireland

**Risk Assessment Area:** The risk assessment area is the territory of the European Union 27 and the United Kingdom, excluding the EU-outermost regions.

**Peer review 1:** *Elena Tricarico, Department of Biology, University of Florence, Sesto Fiorentino (FI), Italy*

**Peer review 2** *Hugo Verreycken, INBO, Brussels, Belgium*

**Date of completion:** 15/10/2021

---

<sup>1</sup> This template is based on the Great Britain non-native species risk assessment scheme (GBNNRA). A number of amendments have been introduced to ensure compliance with Regulation (EU) 1143/2014 on IAS and relevant legislation, including the Delegated Regulation (EU) 2018/968 of 30 April 2018, supplementing Regulation (EU) No 1143/2014 of the European Parliament and of the Council with regard to risk assessments in relation to invasive alien species (see <https://eur-lex.europa.eu/legal-content/en/TXT/?uri=CELEX%3A32018R0968>).

## SECTION A – Organism Information and Screening

**A1. Identify the organism. Is it clearly a single taxonomic entity and can it be adequately distinguished from other entities of the same rank?**

including the following elements:

- the taxonomic family, order and class to which the species belongs;
- the scientific name and author of the species, as well as a list of the most common synonym names;
- names used in commerce (if any)
- a list of the most common subspecies, lower taxa, varieties, breeds or hybrids

As a general rule, one risk assessment should be developed for a single species. However, there may be cases where it may be justified to develop one risk assessment covering more than one species (e.g. species belonging to the same genus with comparable or identical features and impact). It shall be clearly stated if the risk assessment covers more than one species, or if it excludes or only includes certain subspecies, lower taxa, hybrids, varieties or breeds (and if so, which subspecies, lower taxa, hybrids, varieties or breeds). Any such choice must be properly justified.

Response: *Marisa cornuarietis* (Linnaeus 1758) is the species for which this risk assessment has been conducted, it is a single species (no lower taxa or hybrids) belonging to the genus *Marisa* which is part of the Ampullariidae family, commonly known as the apple snails (Barker 2019).

Domain: Eukaryota

Kingdom: Metazoa

Phylum: Mollusca

Class: Gastropoda

Subclass: Caenogastropoda

Order: Architaenioglossa

Family: Ampullariidae

Genus: *Marisa*

Species: *Marisa cornuarietis*

The Ampullariidae family consists of 9 genera and 120 species (Arias & Torralba-Burrial 2014). The genus *Marisa* consists of two species: *M. cornuarietis* and *M. planogyra* (Pilsbry 1933). According to the Integrated Taxonomic Information System ([www.itis.org](http://www.itis.org)) *Marisa cornuarietis* is commonly referred to as the giant ramshorn snail or golden horn marisa. In the RA area, the common English name for *M. cornuarietis* is giant ramshorn snail (Arias & Torralba-Burrial 2014). Other common names are: Paradiesschnecke, Brasilianische Streifenschnecke (DE).

**A2. Provide information on the existence of other species that look very similar [that may be detected in the risk assessment area, either in the environment, in confinement or associated with a pathway of introduction]**

Include both native and non-native species that could be confused with the species being assessed, including the following elements:

- other alien species with similar invasive characteristics, to be avoided as substitute species (in this case preparing a risk assessment for more than one species together may be considered);
- other alien species without similar invasive characteristics, potential substitute species;
- native species, potential misidentification and mis-targeting

Response: Barker (2019) details two species similar in appearance to *M. cornuarietis*, these include *M. planogyra* and *Planorbarius corneus*. *M. planogyra* is nonnative to the EU while *Planorbarius corneus* occurs throughout Europe. The general morphological features of adult *Marisa cornuarietis* according to Barker (2019) include: a dextrally coiled shell, shell in adults 18-22 mm in height, 48-56 mm in diameter, more-or-less glossy but with growth lines that are most prominent near the aperture *M. cornuarietis* is differentiated from *M. planogyra* as the latter has a smaller shell size which is about 30mm, is more strongly planispiral, with both dorsal and ventral (umbilical) aspects strongly concave and openly perspective. *Planorbarius corneus* is distinguished from *M. cornuarietis* as it only grows to a shell size of 35-40 mm, the shell is sinistral lacking spiral colour bands and the mantle cavity is sealed except for a small contractile opening (*pneumostome*). Furthermore, juveniles of *P. corneus* lack an elevated spire.

**A3. Does a relevant earlier risk assessment exist? Give details of any previous risk assessment, including the final scores and its validity in relation to the risk assessment area.**

Response: No risk assessment specific only to *M. cornuarietis* has previously been carried out for the RA area. However, a risk assessment of incidental molluscs associated with aquarium trade was carried out for the EU region in 2017 (Patoka *et al.* 2017). This risk assessment included *M. cornuarietis* and utilised the Freshwater Invertebrate Invasiveness Scoring Kit (FI-ISK). A scoring kit based on 49 questions focused on zoogeography, biology, and ecology (e.g. has the species established beyond its native range? Is the species' reproductive tolerance suited to climates in the risk assessment area? Is the species unpalatable to predators? Does the species tolerate a wide range of salinity regimes?). After processing, the FI-ISK distinguishes potentially invasive and non-invasive species by invasiveness score.

Patoka *et al.* (2017) concluded that *M. cornuarietis* was established in the European Union, its temperature suitability was 25.25% (based on proportion of all meteorological stations monitored within the EU), its potential invasiveness score was 15, which deemed to be of medium invasiveness in the EU (low-risk: score <1, medium-risk: score >1 and <16, and high-risk: score >16). This risk assessment is valid for the RA area of this current risk assessment for *M. cornuarietis*.

**A4. Where is the organism native?**

including the following elements:

- an indication of the continent or part of a continent, climatic zone and habitat where the species is naturally occurring
- if applicable, indicate whether the species could naturally spread into the risk assessment area

Response: The species native range extends from the northern part of South America (from Brazil and Bolivia to Venezuela, Colombia) to Central America (Panama, Costa Rica) (Arias & Torralba-Burrial 2014). It must be noted that its native range may only encompass Venezuela and Columbia but it is unknown if its wide ranging occurrence in the other aforementioned areas is natural or a result of introductions (Cowie *et al.* 2017). It primarily inhabits freshwater lotic and lentic systems including lakes, river, ponds, irrigation channels, swamps and wetlands where it occurs at depths of less than 1 metre (Arias & Torralba-Burrial 2014). *Marisa cornuarietis* is an omnivore renowned for its voracious appetite feeding on live or decaying plants, fish, snail eggs and juveniles (Benson *et al.* 2021). Climatic conditions have been cited as a factor limiting the establishment of this snail species as per its temperature requirements. Another limiting factor in its ability to establish new areas are physiochemical parameters of potential water bodies it could inhabit (Arias & Torralba-Burrial 2014).

The main limiting factors for survival are thermal requirements. The species thrives in water temperatures ranging from 18 to 30 °C with an ideal range of 20-26 °C (Frisóczki *et al.* 2016). At temperatures below 18 °C the snail becomes inactive, and it cannot thrive for extended periods of time below 12 °C (Frisóczki *et al.* 2016). Temperatures of 8 °C have been proven to be lethal to *M. cornuarietis* after 8 hours of exposure. Another limiting factor impeding this alien species successful establishment is calcium concentration in the water body as this organism utilises this mineral for its shell (Arias & Torralba-Burrial 2014). These factors limit the species successful establishment in the environment to areas where calcium concentrations are sufficient and year-round temperatures meet their biological requirements. The species could not naturally spread to the risk assessment area due to the sea barriers between continents.

**A5. What is the global non-native distribution of the organism outside the risk assessment area?**

Response: *Marisa cornuarietis* has been introduced in North America, some Caribbean islands (Cuba, Guadeloupe, Martinique, Puerto Rico) and Africa (Egypt, Sudan, Tanzania) (Arias & Torralba-Burrial 2014).

**A6. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species been recorded and where is it established? The information needs be given separately for recorded (including casual or transient occurrences) and established occurrences. “Established” means the process of an alien species successfully producing viable offspring with the likelihood of continued survival<sup>2</sup>.**

<sup>2</sup> Convention on Biological Diversity, Decision VI/23

**A6a. Recorded: List regions**

**A6b. Established: List regions**

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

- Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea.

Comment on the sources of information on which the response is based and discuss any uncertainty in the response.

For delimitation of EU biogeographical regions please refer to <https://www.eea.europa.eu/data-and-maps/figures/biogeographical-regions-in-europe-2> (see also Annex VI).

For delimitation of EU marine regions and subregions consider the Marine Strategy Framework Directive areas; please refer to <https://www.eea.europa.eu/data-and-maps/data/msfd-regions-and-subregions/technical-document/pdf> (see also Annex VI).

Response (6a): The species was first recorded in the risk assessment area in 2014 in the Mediterranean biogeographic region (northern Spain, Arias & Torralba-Burrial 2014) and has subsequently been found in the Pannonian biogeographic region (Hungary) at the outflow of a thermal spa (Cowie *et al.* 2017).

Response (6b): Due to its viable reproduction in the risk assessment area since 2014, it is deemed to be established in both the Mediterranean and in the Pannonian biogeographical regions (Arias & Torralba-Burrial 2014, Cowie *et al.* 2017)

**A7. In which biogeographic region(s) or marine subregion (s) in the risk assessment area could the species establish in the future under current climate and under foreseeable climate change? The information needs to be given separately for current climate and under foreseeable climate change conditions.**

**A7a. Current climate: List regions**

**A7b. Future climate: List regions**

With regard to EU biogeographic and marine (sub) regions, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)

- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

Response (7a): Under current climate conditions, according to a Species Distribution model (Annex VIII), *M. cornuarietis* could potentially establish in several biogeographical regions of the risk assessment area including the Continental, Alpine, Atlantic and Black Sea regions. This is in addition to expansion in the Mediterranean and the Pannonian regions. Figure 5 illustrates the projected the current suitability of regions in the RA area. Note that the current model suggests that it should not be present in the Pannonian region, although present there in water associated with a thermal spring.

Response (7b): Predicted future climate conditions for the 2070s under both scenarios (RCP2.6, RCP4.5) indicate a low probability of *M. cornuarietis* establishing in the Alpine, Pannonian and Steppic regions, and also extending within the Atlantic, Black Sea, Continental and Mediterranean regions, compared to the present climatic conditions within the RA area. Increase in average winter temperature is the most likely factor to increase probability of projected suitability for this species. Figure 8 illustrates projected future suitability (2070s) of regions in the RA area under climate change scenario RCP4.5.

**A8. In which EU Member States has the species been recorded and in which EU Member States has it established? List them with an indication of the timeline of observations. The information needs be given separately for recorded and established occurrences.**

**A8a. Recorded: List Member States**

**A8b. Established: List Member States**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden.

The description of the invasion history of the species shall include information on countries invaded and an indication of the timeline of the first observations, establishment and spread.

Response (8a): The species was first recorded in the risk assessment area in 2014 in northern Spain (Arias & Torralba-Burrial 2014) and has been found in one area in Hungary close to the outflow of a thermal spa in 2015-2016 (Cowie *et al.* 2017). In Spain, Arias & Torralba-Burrial (2014) state that several specimens of *M. cornuarietis* were reported from multiple searches of the Nora River with adults and juveniles found indicating a thriving and reproducing population. In Hungary, the

population occurring downstream of a thermal spa in the Eger stream had a mixture of both adult and juvenile individuals indicating a reproducing population in the locality (Cowie *et al.* 2017).

Response (8b): The information from both the Spanish and Hungarian populations indicate that populations are established there within at least the last ten years (Arias & Torralba-Burrial 2014, Cowie *et al.* 2017).

**A9. In which EU Member States could the species establish in the future under current climate and under foreseeable climate change? The information needs be given separately for current climate and under foreseeable climate change conditions.**

**A9a. Current climate: List Member States**

**A9b. Future climate: List Member States**

With regard to EU Member States, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

Response (9a): Under current climate conditions, the SDM (Annex VIII) indicates that *M. cornuarietis* could establish in the UK, France, Spain, Italy, Slovenia, Greece, Portugal and Croatia. There is a degree of uncertainty, as noted in Figure 5b and Table 1.

Response (9b): In the 2070s, under climate change scenario RCP 4.5, *M. cornuarietis* could establish in many EU Member States. In particular, there seems to be a high establishment potential for the majority of Member States with increased potential (compared to current conditions) for Austria, Belgium, Bulgaria, Czech Republic, Denmark, Finland, Germany, Ireland, Luxembourg, the Netherlands and Sweden (Figure 7a) (Annex VIII). There is however considerable uncertainty associated with the model. Increase in average winter temperature is the most likely climate change factor to increase probability of establishment.

**A10. Is the organism known to be invasive (i.e. to threaten or adversely impact upon biodiversity and related ecosystem services) anywhere outside the risk assessment area?**

Response: The species is currently considered invasive in the USA and in Egypt, Tanzania and the Caribbean. *M. cornuarietis* impact on biodiversity and ecosystem services where introduced is directly related to density, with few impacts observed where densities remain low (Arias & Torralba-Burrial 2014). For example, in the USA alien populations of *M. cornuarietis* have shown to negatively impact macrophytes when the snail density becomes high with reduced macrophyte diversity and species elimination potentially occurring (Arias & Torralba-Burrial 2014). For this reason, in Puerto Rico and Florida, the species has been introduced for the purposes of aquatic weed control (Barker 2019).

This species is a voracious omnivore which can directly impact native snail populations through direct competition and predation (Arias & Torralba-Burrial 2014). The food habits of *M. cornuarietis* has previously led this species to be utilised as a biological control agent to control the snail vectors of *Schistosoma* spp., the cause of human schistosomiasis, through competition and predation, in Egypt, Tanzania and the Caribbean (Cowie *et al.* 2017). However, due to its invasive features, the introduction of the species for the purposes of controlling other organisms is no longer considered environmentally acceptable (Barker 2019).

**A11. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea

Response: The species has only been recorded in the wild in two biogeographical regions of the risk assessment area (Arias & Torralba-Burrial 2014, Cowie *et al.* 2017): Pannonian and Mediterranean. In these areas the species has become established, but no impact is currently known, although it is expected they will show signs of invasiveness in the future when they occur in high densities..

**A12. In which EU Member States has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden

Response: Reported occurrences of the species do not report signs of invasive characteristics in the risk assessment area. However, the species has been reported as alien and established in Spain and it is expected that indicators of invasiveness will increase in the future with increased population densities. Particularly in Spain where the climate facilitates the widespread occurrence of the species. In Hungary, the negative impacts of the species may be localised to hydrothermal waters.

**A13. Describe any known socio-economic benefits of the organism.**

including the following elements:

- Description of known uses for the species, including a list and description of known uses in the risk assessment area and third countries, if relevant.
- Description of social and economic benefits deriving from those uses, including a description of the environmental, social and economic relevance of each of those uses and an indication of associated beneficiaries, quantitatively and/or qualitatively depending on what information is available.

If the information available is not sufficient to provide a description of those benefits for the entire risk assessment area, qualitative data or different case studies from across the risk assessment area or third countries shall be used, if available.

Response: *M. cornuarietis* is a known biological control agent beneficial to humans under certain circumstances outside the RA area. It has been used to control snail vectors of *Schistosoma* spp., the cause of human schistosomiasis (Cowie *et al.* 2017). The control is through predation and competition with the potential to eradicate other snail species which are vectors of this parasitic disease (Pointier & David 2004). In addition, this species has previously been used to control aquatic weeds due to its voracious appetite in multiple weed control programs (Barker 2019). *M. cornuarietis* has been introduced to multiple territories outside of the risk assessment area for the control of both weeds and schistosomiasis (Arias & Torralba-Burrial 2014).

*M. cornuarietis* is also widely utilised as an aquatic pet and is traded worldwide in aquatic retail outlets but it is not possible to quantify the economic benefits of the trade of this species. Furthermore, the species is routinely used in laboratory and education settings due to its availability via aquatic retail (Barker 2019).

## SECTION B – Detailed assessment

### Important instructions:

- In the case of lack of information the assessors are requested to use a standardized answer: “No information has been found.” In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable).
- With regard to the scoring of the likelihood of events or the magnitude of impacts see Annexes I and II.
- With regard to the confidence levels, see Annex III.
- Highlight the selected response score and confidence level in **bold** but keep the other scores in normal text (so that the selected score is evident in the final document).

## 1 PROBABILITY OF INTRODUCTION AND ENTRY

### Important instructions:

- **Introduction** is the movement of the species into the risk assessment area (it may be either in captive conditions and/or in the environment, depending on the relevant pathways).
- **Entry** is the release/escape/arrival in the environment, i.e. occurrence in the wild
- Introduction and entry may coincide for species entering through pathways such as “corridor” or “unaided”, but it also may differ. If different, please consider all relevant pathways, both for the introduction into the risk assessment area and the entry in the environment.
- The classification of pathways developed by the Convention of Biological Diversity (CBD) should be used (see Annex IV). For detailed explanations of the CBD pathway classification scheme consult the IUCN/CEH guidance document<sup>3</sup> and the provided key to pathways<sup>4</sup>.
- For organisms which are already present (recorded or established) in the risk assessment area, the likelihood of introduction and entry should be scored as “very likely” by default.
- Repeated (independent) introductions and entries at separate locations in the risk assessment area should be considered here (see Qu. 1.7).

**Qu. 1.1. List relevant pathways through which the organism could be introduced into the risk assessment area and/or enter into the environment. Where possible give details about the specific origins and end points of the pathways as well as a description of any associated commodities.**

For each pathway answer questions 1.2 to 1.8 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 1.2a, 1.3a, etc. and then 1.2b, 1.3b etc. for the next pathway.

In this context a pathway is the route or mechanism of introduction and/or entry of the species.

<sup>3</sup> <https://circabc.europa.eu/sd/a/7e5f0bd4-34e8-4719-a2f7-c0cd7ec6a86e/2020-CBD-pathways-interpretation.pdf>

<sup>4</sup> <https://circabc.europa.eu/sd/a/0aeba7f1-c8c2-45a1-9ba3-bcb91a9f039d/TSSR-2016-010%20CBD%20pathways%20key%20full%20only.pdf>

The description of commodities with which the introduction of the species is generally associated shall include a list and description of commodities with an indication of associated risks (e.g. the volume of trade; the likelihood of a commodity being contaminated or acting as vector).

If there are no active pathways or potential future pathways this should be stated explicitly here, and there is no need to answer the questions 1.2-1.9.

Pathway name: Two main pathways of introduction for the species have been defined:

**Escape from confinement – Pet/Aquarium/Terrarium species (including live food for such species)**

*Marisa cornuarietis* is utilised for aquarium trade, laboratory studies (ecotoxicological studies) and educational purposes (primarily due to its availability via the aquatic retail).

It has previously been introduced to non-native regions through the aquarium trade (Pointier & David 2004). Establishment of the species in the wild has been attributed to the deliberate dumping of unwanted aquarium contents into natural water bodies (Barkler. 2019). The species have been utilised in the aquarium trade since the 1930s and contemporarily, the species is available to purchase both online and in aquatic retail outlets (Benson *et al.* 2021).

**Contaminant on plants (excluding parasites and species transported by host and vector)**

Another pathway for introduction is contamination on aquatic plants. *Marisa cornuarietis* has been noted to be introduced via attaching to floating macrophytes in the wild (Benson *et al.* 2021).

Individual specimens can be introduced on aquatic plants utilised for the aquatic plant trade and pond gardening and landscaping. This pathway is believed to have contributed to the introduction of this apple snail species to new regions (Barker 2019).

**Escape from confinement – Pet/Aquarium/Terrarium species (including live food for such species)**

**Qu. 1.2a. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	<b>intentional</b>	<b>CONFIDENCE</b>	low
	<b>unintentional</b>		medium
			<b>high</b>

Response: *M. cornuarietis* introduction to its non-native regions through this pathway can be both intentional and unintentional. The species has previously been introduced to the wild through the intentional disposal of aquarium contents in areas outside of the RA such as Florida and the Caribbean islands (Pointier & David 2004), which is considered being an active pathway of introduction and entry also for the risk assessment area. From August 2013, all species of Ampullariidae have been included in the Spanish legislation (Royal Decree 630/2013) as invasive species and listed in the Catálogo Español de Especies Exóticas Invasoras. Listing demands that procedures are in place to prevent introduction and establishment in Spain and its European territories (CABI.org). Since 2013 the

intentional release of *Marisa cornuarietis* to the wild is prohibited within the European Union (Frisóczki *et al.* 2016).

Unintentional escape from confinement, e.g. aquaria, can also occur (Arias & Torralba-Burrial 2014). It is believed that this is how the species first entered the wild in the RA area (Arias & Torralba-Burrial 2014, Frisóczki *et al.* 2016).

**Qu. 1.3a. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

Including the following elements:

- Discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- If relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: It is envisaged that the introduction of non- native species is likely to increase with increased global trade (Patoka *et al.* 2018). Contemporarily, it is likely a significant number of specimens of *Marisa cornuarietis* can potentially be introduced via this pathway as the species is commonly traded in aquatic retail outlets inside the RA region. Published literature only provides broad generalisations with regard to the number of individuals coming into the RA area for the pet trade, but the frequency is believed to be continuous as the target species is available for purchase online year round. The introductions and entry into the wild of *Marisa cornuarietis* in two separated biogeographical regions in the RA area are both suspected to be a result of the discarding of aquarium contents (Arias & Torralba-Burrial 2014, Frisóczki *et al.* 2016). Both introductions occurred within a short timeframe believed to be in the 2010s with both regions having regulations prohibiting the introduction of *Marisa cornuarietis* to the wild. Furthermore, both entries into the wild resulted in established populations. Due to the widespread availability of the species for the pet trade, reinvasion is likely to occur in the RA area if the species has been eradicated in the wild due to the possibility of further intentional or unintentional releases.

**Qu. 1.4a. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: *M.cornuarietis* is regularly imported into the RA area for the purposes of aquatic ornamental trade. The cited primary risk of spread for this species is aquatic trade (Barker. 2019) It is highly likely it will survive transport and subsequent storage in aquariums because the retailers create optimal conditions for transport. Furthermore, the species commonly reproduces in aquarium settings where its numbers are likely to increase.

**Qu. 1.5a. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The management practices currently in place to prevent the introduction of this organism via this pathway are limited to legislation prohibiting the introduction of the species to the wild (Arias & Torralba-Burrial . 2014). Since 2013 the intentional release of *Marisa cornuarietis* to the wild is prohibited within the European Union (Frisóczki *et al.* 2016). The species is sold via the aquarium trade throughout the RA area and they breed in captivity.

**Qu. 1.6a. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely	<b>CONFIDENCE</b>	low medium
-----------------	---------------------------	-------------------	---------------

	moderately likely likely <b>very likely</b>		<b>high</b>
--	---	--	-------------

Response: The organism is very likely to be introduced into the RA area via the aquarium trade and to enter the environment via this pathway as eggs of individual specimens. These could unintentionally be introduced to the environment through either discarding contents of an aquarium or during routine tank maintenance (Frisoczki *et al.* 2016). Furthermore, adult specimens could be introduced unintentionally via this pathway and go undetected in the natural environment for a significant period of time.

**Qu. 1.7a. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: The introduction and potential release of this non-native species through this pathway is widespread throughout the RA area due to its widespread trade for aquaria as an aquarium pet (CABI.org; www.aquariumnexus.com). and widespread proximity to both lotic and lentic freshwater environments.

**Qu. 1.8a. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: In general, the aquarium trade is one of the primary pathways of freshwater snails being translocated around the world (Appleton & Miranda 2015). *M. cornuarietis* is continually being utilised in the RA area for aquaria, making it currently a very likely pathway for introduction. Evidence based on the currently recorded occurrences of the species to the wild in the RA area were all associated with the aquarium pet trade making it highly plausible that the likelihood of further introductions of this species are inevitable under current management strategies.

**Pathway Name: Contaminant on plants (excluding parasites and species transported by host and vector)**

**Qu. 1.2b. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response: Introduction via this pathway is unintentional as *Marisa cornuarietis* is a contaminant on aquatic plants sold for trade purposes (Barker 2019).

**Qu. 1.3b. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

Including the following elements:

- Discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: The transport and sale of aquatic plants for trade purposes is a significant economic activity which occurs throughout the year in the RA area. Given that *M. cornuarietis* can be a contaminant on plants it is very likely that a large number of specimens enter the RA area. In terms of the number of specimens which reach the natural environment in the RA area via this pathway, no data are available. One fertilized female which spreads through this pathway has the potential to produce hundreds of eggs or more as they can store sperm needed in their genital tract. It is suspected that the species was

introduced to the environment via the disposal of aquarium contents in other regions (Barker 2019), suggesting it is highly plausible that the species is and will continue to be introduced unintentionally to the environment.

**Qu. 1.4b. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: Given that the species is transported and sold via aquatic trade (Barker 2019), it is highly likely that both its adults, eggs and juveniles will survive via this pathway as aquatic plants will come from regions inhabited by *M. cornuarietis* and have similar thermal requirements to the target species facilitating its survival and reproduction from the transport and storage of the plant matter.

**Qu. 1.5b. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Plants transported for aquarium trade that the species could potentially hitchhike on would more than likely have thermal requirements that would facilitate the survival of the species. Current management practices permit its safe passage in the RA area from this pathway as the species is not on the EPPO lists and no specific biosecurity measures are apparently currently in place during inspections at EU borders to prevent the species from using this pathway.

**Qu. 1.6b. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The species has previously been found in the wild in the RA area both in Hungary and Spain. On both occasions the origin for entry was suspected to have been via the disposal of aquarium contents and/or aquatic plant trade or direct trade of the species (Arias & Torralba-Burrial 2014, Frisóczki *et al.* 2016). There is a very low chance of noticing anyone disposing of aquatic plants that are contaminated with this species. Given the species large size, it may be found in the wild via searches by experienced personnel and citizen scientists trained to identify this species (Barker 2019). However, populations in the wild may not be identified until they are established in a region.

**Qu. 1.7b. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: Aquatic plant trade and aquarium pet trade are widespread occurring year round in the RA area. This indicates that *M. cornuarietis* can be introduced or enter the natural environment via this pathway in a significant proportion of the RA area.

**Qu. 1.8b. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Given that the two recorded establishments in the RA area were suspected of coming from this pathway, it is highly indicative that the introduction and entry of this species has previously occurred and will likely occur again under current management strategies as no biosecurity protocols are in place to prevent its transport via this pathway.

**Qu. 1.9. Estimate the overall likelihood of introduction into the risk assessment area or entry into the environment based on all pathways and specify if different in relevant biogeographical regions in current conditions.**

Provide a thorough assessment of the risk of introduction in relevant biogeographical regions in current conditions: providing insight into the risk of introduction into the risk assessment area.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The species is already present in the RA area. The Aquarium trade specifically aimed at the sale of this species, and the aquarium plant trade through which *M. cornuarietis* may be introduced into the risk assessment area as a contaminant, are the two most likely pathways. The two known introductions in the RA area are associated with these activities in both the Mediterranean and Pannonian biogeographic region (Arias & Torralba-Burrial 2014, Cowie *et al.* 2017).

**Qu. 1.10. Estimate the overall likelihood of introduction into the risk assessment area or entry into the environment based on all pathways in foreseeable climate change conditions?**

Thorough assessment of the risk of introduction in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of introduction (e.g. change in trade or user preferences)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely introduction within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely	<b>CONFIDENCE</b>	low <b>medium</b>
-----------------	---------------------------	-------------------	----------------------

	moderately likely likely <b>very likely</b>		high
--	---	--	------

Response: Although the number of introductions is unlikely to change under future climate conditions, this warm water species is likely to be introduced to more biogeographical regions where the potential for establishment is high under predicted climate models (Annex VIII) (Beckman *et al.* 2021). Predicted increases in annual precipitation and temperature will make these biogeographical regions susceptible to introductions and facilitate the establishment of the species in these biogeographical regions of the RA area.

## 2 PROBABILITY OF ESTABLISHMENT

### Important instructions:

- For organisms which are already established in parts of the risk assessment area or have previously been eradicated, the likelihood of establishment should be scored as “very likely” by default.
- Discuss the risk also for those parts of the risk assessment area, where the species is not yet established.

**Qu. 2.1. How likely is it that the organism will be able to establish in the risk assessment area based on similarity of climatic and abiotic conditions in its distribution elsewhere in the world?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The species is already established in both Hungary and Spain (Mediterranean and Pannonian biogeographic regions), although their occurrence in Hungary is limited to the outflow of a thermal spa as natural climatic conditions in Hungary do not support the species year round, which impedes their further spread in Hungary (see section A4 and Annex VIII). Other biogeographical regions which have a climate that can support the species requirements in which there are water bodies that have sufficient calcium concentrations (below 25 mg/l deemed suboptimal according to Arias & Torralba-Burrial 2014) are susceptible to introduced populations becoming established (Annex VIII). No information is available in regard to the extent of water bodies in which abiotic conditions are currently suitable for *M. cornuarietis* in the risk assessment area. However, information has been published on this species relating to the extent of areas where climatic conditions are currently suitable in the EU, a region encompassing the majority of the RA area (Patoka *et al.* 2017). Temperature suitability predictions based on all EU meteorological stations estimate 25.25% of the regions with currently climatic conditions suitable for the establishment of *M. cornuarietis*.

**Qu. 2.2. How widespread are habitats or species necessary for the survival, development and multiplication of the organism in the risk assessment area? Consider if the organism specifically requires another species to complete its life cycle.**

<b>RESPONSE</b>	very isolated isolated moderately widespread <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: *M. cornuarietis* can inhabit a multitude of lotic and lentic habitats such as lakes, river, ponds, irrigation channels, swamps and wetlands where it occurs at depths of less than 1 metre (Arias & Torralba-Burrial 2014). These habitats are widespread in the RA area suggesting that where climatic and abiotic factors are favourable these habitats are suitable for the establishment of populations of *M. cornuarietis*.

In terms of other organisms needed for its establishment, *Marisa cornuarietis* is an omnivore renowned for its voracious appetite feeding on live or decaying plants, fish, snail eggs, and juvenile snails (Benson *et al.* 2021). This generalist feeding behavior suggests that where the species is introduced to natural waters and where abiotic and climatic factors are favourable, it will thrive. Furthermore, as the species is already established in two, separate biogeographical regions of the RA area, habitats and the species required as food for its establishment are available in the RA region.

**Qu. 2.3. How likely is it that establishment will occur despite competition from existing species in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: There is limited information available in regard to species that will compete with *M. cornuarietis* in the RA area. Furthermore, there is limited information from other regions of the world indicating species that compete with *M. cornuarietis*. On the contrary, in many published works, the ability of *M. cornuarietis* to outcompete native snails and significantly alter macrophyte community structure (Arias & Torralba-Burrial 2014; Seaman & Porterfield 1964; Benson *et al.* 2021) in their newly established habitats indicates they are an ecosystem engineer. In any case, the establishment of this species in two separate biogeographical region of the RA signifies that it is able to establish despite the presence of other species with which it may compete.

**Qu. 2.4. How likely is it that establishment will occur despite predators, parasites or pathogens already present in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Similar to competition, there is limited information on predators, pathogens or parasites which will impede the establishment of the species in areas with suitable climatic conditions (Seaman and Porterfield 1964; Snyder and Kale 1983; Howells et al. 2006). However, the establishment of the species in two separate biogeographical regions of the RA indicate that establishment has occurred without the influence of avian or mammal predators, molluscan parasites or pathogens impeding the process.

**Qu. 2.5. How likely is the organism to establish despite existing management practices in the risk assessment area? Explain if existing management practices could facilitate establishment.**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: In certain regions, e.g. Belgium (Species Act 2009), and Spain the introduction of *Marisa cornuarietis* is prohibited. From August 2013, all species of Ampullariidae have been included in the Spanish legislation (Royal Decree 630/2013) as invasive species and listed in the Catálogo Español de Especies Exóticas Invasoras. However, the species has been introduced and entered into the wild and established populations in regions where such introductions are prohibited (Arias & Torralba-Burrial 2014, Frisóczki *et al.* 2016). As the species is commonly traded for aquatic retail, it is difficult to control incidences of entry into the wild and establishment in the RA either from intentional or unintentional introductions.

**Qu. 2.6. How likely is it that biological properties of the organism would allow it to survive eradication campaigns in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: No information was found in relation to eradication techniques of *Marissa cornuarietis*. However, information in relation to the control of apple snails, the family to which *Marisa cornuarietis* belongs, was available. Currently no management practices to control introduced populations in the RA area have been implemented.

Multiple control techniques for apple snails have been developed which include mechanical, chemical and biological control methods. Mechanical, control methods commonly used include snail traps, hand collection and mechanical collection (Gilioli *et al.* 2017). Biological controls methods include the use of molluscivorous fish and ducks (Teo 2001, Ip *et al.* 2014). Chemical control for apple snails routinely used molluscicides (Schnorbach *et al.* 2006). It is plausible that control methods listed above could be utilised for *M. cornuarietis* given the similarities between species upon which the control mechanisms were applied. However, *M. cornuarietis* may survive control techniques where the established population of the species in the RA is not isolated. In interconnected water courses where the species has spread sufficiently the species may avoid these control mechanisms.

**Qu. 2.7. How likely are the biological characteristics of the organism to facilitate its establishment in the risk assessment area?**

including the following elements:

- a list and description of the reproduction mechanisms of the species in relation to the environmental conditions in the risk assessment area
- an indication of the propagule pressure of the species (e.g. number of gametes, seeds, eggs or propagules, number of reproductive cycles per year) of each of those reproduction mechanisms in relation to the environmental conditions in the risk assessment area.
- If relevant, comment on the likelihood of establishment based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in establishment whereas for others high propagule pressure (many thousands of individuals) may not.
- If relevant, comment on the adaptability of the organism to facilitate its establishment and if low genetic diversity in the founder population would have an influence on establishment.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: 25.25% of the RA area is suitable in terms of temperature for this invasive species (Patoka *et al.* 2017). Furthermore, these areas support habitats with suitable water quality parameters for the species and it has already established reproductive populations in two biogeographical regions of the RA area indicating its biological characteristics are suitable for establishment in the RA area. *Marisa cornuarietis* reproduces sexually with breeding occurring in groups. Females are estimated to produce 1700 eggs per year and they have the ability to store sperm in their genital tract for months which facilitates spawning to coincide with favorable environmental conditions (Barker 2019). This indicates

that even very few introduced specimens could facilitate the establishment of new populations within the RA area.

**Qu. 2.8. If the organism does not establish, then how likely is it that casual populations will continue to occur?**

Consider, for example, a species which cannot reproduce in the risk assessment area, because of unsuitable climatic conditions or host plants, but is present because of recurring introduction, entry and release events. This may also apply for long-living organisms.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: This species has established two populations in the RA area in the last decade. Considering its availability in the ornamental trade, casual populations may occur in areas which are subject to continuing introductions even if their climatic conditions are not suitable to for the survival of the species throughout the year (for example, *Marisa cornuarietis* is not well adapted to surviving for extended periods of time below 12 °C, as reported by Frisóczki *et al.* 2016).

**Qu. 2.9. Estimate the overall likelihood of establishment in the risk assessment area under current climatic conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under current climatic conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in current conditions: providing insight in the risk of establishment in (new areas in) the risk assessment area.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The species is already established in two biogeographical regions of the RA area (Arias & Torralba-Burrial 2014, Frisóczki *et al.* 2016). A previous risk assessment for the EU that was completed in 2017 detailed 25.25% of the EU was suitable for the establishment of *M. cornuarietis* under current climatic conditions (Patoka *et al.* 2017). This information indicates that the species can establish in multiple biogeographical regions of the RA area (Annex VIII).

**Qu. 2.10. Estimate the overall likelihood of establishment in the risk assessment area under foreseeable climate change conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under foreseeable climate change conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of establishment (e.g. increase in average winter temperature, increase in drought periods)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely establishment within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

Under future predicted climate models for the 2070s (both RCP 2.6 and RCP 4.5) the species is likely to establish in more biogeographical regions (Annex VIII) in comparison to current conditions. Annual precipitation and annual minimum winter temperatures have been identified as drivers in predicting the suitability of an area to *M. cornuarietis* establishment in the future with increases in both cited as a driver of establishment in new areas. Individual biogeographical suitability under predicted climate conditions for *M. cornuarietis* are illustrated in Figures 7 and 8 in Annex VIII.

### 3 PROBABILITY OF SPREAD

**Important instructions:**

- Spread is defined as the expansion of the geographical distribution of an alien species within the risk assessment area.
- Repeated releases at separate locations do not represent continuous spread and should be considered in the probability of introduction and entry section (Qu. 1.7).

**Qu. 3.1. How important is the expected spread of this organism within the risk assessment area by natural means? (List and comment on each of the mechanisms for natural spread.)**

including the following elements:

- a list and description of the natural spread mechanisms of the species in relation to the environmental conditions in the risk assessment area.
- an indication of the rate of spread discussed in relation to the species biology and the environmental conditions in the risk assessment area.

The description of spread patterns here refers to the CBD pathway category “Unaided (Natural Spread)”. It should include elements of the species life history and behavioural traits able to explain its ability to spread, including: reproduction or growth strategy, dispersal capacity, longevity, dietary requirements, environmental and climatic requirements, specialist or generalist characteristics.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: In the two regions where *M. cornuarietis* has established, it is expected to spread in Spain only due to the availability of habitat and suitable climatic conditions. The population downstream of a thermal spa in Hungary is expected not to spread as the thermal requirements of the species will not be supported year-round in the region.

*M. cornuarietis* has been noted to be able to spread naturally in localised areas (Barker 2019) often thriving due to generalist feeding behavior. The species is largely immobile and its spread is limited by water parameters, hydrological characteristics of the catchment and the species thermal requirement (Barker 2019). Spread has also been noted following stream flooding during storms (Hunt 1958). Its life cycle is dependent on water temperature with specimens surviving for a maximum of two year (Benson *et al.* 2021). Furthermore, the species has been noted to spread downstream of localised sites on floating vegetation (Barker 2019) but no rate of spread has been found in the literature.. Females which spread to new areas may be able to spawn due to their ability to store sperm for months at a time which facilitates the establishment of new populations in new areas. Furthermore, it can produce up to 1700 eggs per year and spawn year-round under favourable conditions (Barker 2019, Benson *et al.* 2021).

**Qu. 3.2a. List and describe relevant pathways of spread other than "unaided". For each pathway answer questions 3.3 to 3.9 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 3.3a, 3.4a, etc. and then 3.3b, 3.4b etc. for the next pathway.**

including the following elements:

- a list and description of pathways of spread with an indication of their importance and associated risks (e.g. the likelihood of spread in the risk assessment area, based on these pathways; likelihood of survival, or reproduction, or increase during transport and storage; ability and likelihood of transfer from the pathway to a suitable habitat or host) in relation to the environmental conditions in the risk assessment area.
- an indication of the rate of spread for each pathway discussed in relation to the species biology and the environmental conditions in the risk assessment area.
- All relevant pathways of spread (except “Unaided (Natural Spread)”, which is assessed in Qu. 3.1) should be considered. The classification of pathways developed by the Convention of Biological Diversity shall be used (see Annex IV).

Pathway names: Three pathways of spread have been identified: **Corridor – Interconnected waterways / basins / seas (A)**, **Unintentional – Transport stowaway Angling equipment/ boat hull fouling (B)** and **Unintentional- Transport –Contamination on plants(C)**. These pathways importance for the spread of *M. cornuarietis* is currently undefined in the RA area.

**Qu. 3.3a. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response: In the RA area, the majority of water bodies are interconnected in some way which provides corridors of spread. allowing passive drift with water currents to facilitate settlement and establishment. For example, waterways and reservoirs connecting the Danube and Rhine basins have facilitated the establishment of the quagga mussel and later spread between previously isolated catchments (Bij de Vaate et al., 2013)

**Qu. 3.4a. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway

- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: It is very likely that a sufficient number of individuals may spread along this pathway to originate a viable population. One fertilized female which spreads through this pathway has the potential to produce hundreds of eggs or more as they can store sperm needed in their genital tract (Howells et al. 2006). Reinvasion is highly likely if the waterbody is interconnected to a waterbody with an established population of *M. cornuarietis*. No data is available on numbers spread along this pathway.

**Qu. 3.5a. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>		<b>CONFIDENCE</b>	
-----------------	--	-------------------	--

Response: The question does not apply for this pathway

**Qu. 3.6a. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Currently, there are no known legislated management practices for this species in place in the RA area to limit their spread once established. In regions outside the RA area there is no published literature on management techniques for stopping the spread of the species in waterways. The species is likely to survive any engineering of waterways, e.g. development of reservoirs or diversion of river sections.

**Qu. 3.7a. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: No information has been found in relation to monitoring of the species in the RA area. As this species is aquatic and its established populations are not routinely monitored under EU regulations e.g. Habitats and Water Framework Directive, there will probably be a lag between when a species invades a new area and when it is detected. However, monitoring for other snails or invertebrates may coincide with the early detection of this species if personnel are aware of the taxonomic characteristics of the species in order to identify their presence in non-native regions.

**Qu. 3.8a. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: 25.25% of the RA area is suitable for *M. cornuarietis* in terms of suitable water temperature (Patoka *et al.* 2017). Furthermore, these thermally suitable areas support habitats with suitable physiochemical parameters (calcium concentrations) for *M. cornuarietis*. The species is also a generalist omnivore (Arias & Torralba-Burrial 2014). These aquatic corridors which occur throughout the RA area facilitate the species spread to new habitats suitable for its establishment. Additionally, the climate modelling provided in the Annex indicated several regions are currently suitable for *M. cornuarietis* in the RA area.

**Qu. 3.9a. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area. (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly slowly	<b>CONFIDENCE</b>	<b>low</b> medium
-----------------	-----------------------	-------------------	----------------------

	<b>moderately</b> rapidly very rapidly		high
--	--	--	------

Response: No information is available in relation to the rate of spread using this pathway. Given that there are still relatively low numbers of established populations in the RA area (one of which is isolated and not spreading), the rate of spread is considered moderate. The environmental conditions facilitating spread through this pathway are restricted in terms of temperature and physiochemical parameters of interconnected water bodies.

**Qu. 3.3b. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	-------------------------------------	-------------------	------------------------------

Angling forms a significant proportion of recreational activities in freshwater sites in the RA area, However, spread via this pathway is generally unintentional as eggs, juveniles and adult specimens of *Marisa cornuarietis* can attach to nets, boats, waders etc and be transported to other water bodies. This is aided by the species capacity to aurally respire via a lung (Barker 2019),

**Qu. 3.4b. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Due to the species high fecundity rate in conjunction with the potential for eggs to be transported via this pathway, it is highly likely a sufficient number of individuals could be transported to originate a viable population over the course of one year. A single female is estimated to produce 1700 eggs per year and they have the ability to store sperm in their genital tract for months which facilitates spawning to coincide with favorable environmental conditions (Barker 2019).

**Qu. 3.5b. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Local spread due to anglers moving between water bodies, it is highly likely as the species will survive as in egg masses and in adults due to their capacity to breathe terrestrially via a lung. Reproduction is unlikely during transport. It must be noted that eggs could be attached to angling equipment and the number of specimens transported may be increased

**Qu. 3.6b. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Indirect biosecurity measures applied by recreational users of water bodies in the RA area may impede the spread of this invasive. Disinfectants commonly used for cleaning angling equipment for biosecurity purposes may potentially be useful against the spread of this invasive (De Stasio *et al.* 2019). However, it must be noted that these measures are usually the responsibility of individuals to disinfect their equipment before using water bodies and disinterest or lack of public awareness in recreational anglers may facilitate the spread of *Marisa cornuarietis*. Due to this it is likely a certain proportion of stowaways on angling equipment. In terms of boat hulls, eggs and snails can attach facilitating the spread of the species to new water bodies if biosecurity measures are not applied,

**Qu. 3.7b. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

As no information is available regarding the monitoring of this species in the RA area, it is plausible that the species may spread from angling activities from one water body to another. This is especially the case with the eggs which could easily go undetected in apparatus containing water or moist keep nets.

**Qu. 3.8b. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <i>medium</i> high
-----------------	--	-------------------	------------------------------

Stowaways on angling equipment generally facilitate local spread. Due to this, the climatic conditions of areas where established populations are being transported from are generally similar thus allowing organisms to establish in new waterways where suitable physico-chemical parameters facilitate.

**Qu. 3.9b. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area. (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Given that there are still relatively low numbers of established populations in the RA area (one of which is isolated and not spreading), the rate of spread is considered moderate. Environmental conditions facilitating spread through this pathway are restricted in terms of temperature and physiochemical parameters and spread is considered local/regional.

**Qu. 3.3c. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Spread along this pathway is unintentional as *Marisa cornuarietis* specimens and eggs can be unintentionally transported to new water bodies through commercial trade of plants for gardening and landscaping and aquatic plant trade (Barker. 2019).

**Qu. 3.4c. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Due to the reproductive capacity of the species and the capacity for eggs to be transported attached to plants (Barker 2019), it is very likely that this method of spread can facilitate populations spread to create independent new populations of the species over the course of one year.

**Qu. 3.5c. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

It is highly likely that species can survive and reproduce during transport and storage along this pathway as transported plants, especially those selected for the aquatic ornamental trade will likely have similar temperature and physicochemical requirement similar to the invasive (Barker 2019). Traders will create ideal conditions for transport of the plants and therefore conditions will also be ideal for *M. cornuarietis*.

**Qu. 3.6c. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
	unlikely		<b>medium</b>
	moderately likely		high
	likely		
	<b>very likely</b>		

No specific management practices exist and therefore the species is likely to survive.

**Qu. 3.7c. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
	unlikely		<b>medium</b>
	moderately likely		high
	<b>likely</b>		
	very likely		

The species is likely to spread undetected in the RA area. Response: No information has been found in relation to monitoring of the species in the RA area. As this species is aquatic and its established populations are not routinely monitored under EU regulations e.g. Habitats and Water Framework Directive, there will probably be a lag between when a species invades a new area and when it is detected. However, monitoring for other snails or invertebrates may coincide with the early detection of this species if personnel are aware of the taxonomic characteristics of the species in order to identify their presence in non-native regions.

**Qu. 3.8c. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
	unlikely		medium
	moderately likely		<b>high</b>
	likely		

	<b>very likely</b>		
--	--------------------	--	--

This is considered highly likely as plants from which *M.cornuarietis* are hitchhikers generally have similar environmental requirements as the invasive, furthermore, it has been highlighted that introductions of this invasive has occurred in other regions due to the hitchhiking on aquatic plants (Barker 2019).

**Qu. 3.9c. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area. (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	<b>low</b> <b>medium</b> high
-----------------	---	-------------------	-------------------------------------

25.25% of the RA area is deemed suitable for *Marisa cornuarietis* with regard to temperature (Patoka et al. 2017), these thermally suitable areas support habitats which are optimal in terms of their physicochemical attributes for this invasive. This in conjunction with the widespread transport of plant material, for horticulture, gardening and aquaria, further exacerbates the rate of spread through this pathway in the RA area.

**Qu. 3.10. Within the risk assessment area, how difficult would it be to contain the organism in relation to these pathways of spread?**

<b>RESPONSE</b>	very easy easy with some difficulty difficult <b>very difficult</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: In the RA area, containment of populations who utilise these pathways of spread is very difficult. In ponds, which are not interconnected with other water bodies, containment may be possible (Pointier & David 2004). However, in interconnected and large waterbodies containment will almost be impossible. The high potential of *M. cornuarietis* specimens and eggs to attach on floating vegetation and being carried with water currents to new areas and establish at considerable distances from its original sites is the main factor for the difficulty of containment. Additionally, specimens may also be swept away in strong currents. The species will also potentially spread to new areas unnoticed due to monitoring programs not being in place to identify this species. Round goby, zebra mussel and

quagga mussel are examples of aquatic invasive species that have spread throughout interconnected waterways in the RA area (Bij de Waate et al. 2002, 2013)

**Qu. 3.11. Estimate the overall potential rate of spread in relevant biogeographical regions under current conditions for this organism in the risk assessment area (indicate any key issues and provide quantitative data where possible).**

Thorough assessment of the risk of spread in relevant biogeographical regions in current conditions, providing insight in the risk of spread into (new areas in) the risk assessment area.

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: A previous risk assessment conducted by Patoka *et al* (2017) determined that climatic conditions were currently suitable for *Marisa cornuarietis* in 25.25% of the RA area. As the species thrive in water temperatures from 18 to 30 °C with an ideal range of 20- 26 °C (Frisóczyki *et al.* 2016) the areas to which it can spread to is limited but still significant in the RA area. Their spread is further restricted by their calcium requirements for shell building (Barker 2019).

**Qu. 3.12. Estimate the overall potential rate of spread in relevant biogeographical regions in foreseeable climate change conditions (provide quantitative data where possible).**

Thorough assessment of the risk of spread in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk, specifically if rates of spread are likely slowed down or accelerated.

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: The rate of spread is not expected to change, however both, the establishment rate and the biogeographical regions in which the species can potentially spread to are predicted to increase in the future (Annex VIII).

## 4 MAGNITUDE OF IMPACT

Important instructions:

- Questions 4.1-4.5 relate to biodiversity and ecosystem impacts, 4.6-4.8 to impacts on ecosystem services, 4.9-4.13 to economic impact, 4.14-4.15 to social and human health impact, and 4.16-4.18 to other impacts. These impacts can be interlinked, for example, a disease may cause impacts on biodiversity and/or ecosystem functioning that leads to impacts on ecosystem services and finally economic impacts. In such cases the assessor should try to note the different impacts where most appropriate, cross-referencing between questions when needed.
- Each set of questions starts with the impact elsewhere in the world, then considers impacts in the risk assessment area (=EU excluding outermost regions) separating known impacts to date (i.e. past and current impacts) from potential future impacts (including foreseeable climate change).
- Only negative impacts are considered in this section (socio-economic benefits are considered in Qu. A.7)
- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable).

### Biodiversity and ecosystem impacts

**Qu. 4.1. How important is the impact of the organism on biodiversity at all levels of organisation caused by the organism in its non-native range excluding the risk assessment area?**

including the following elements:

- Biodiversity means the variability among living organisms from all sources, including terrestrial, marine and other aquatic ecosystems and the ecological complexes of which they are part; this includes diversity within species, between species and of ecosystems
- impacted chemical, physical or structural characteristics and functioning of ecosystems

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: The impact of *M. cornuarietis* is believed to be density dependent with low densities coinciding with minimal impacts in the USA (Arias & Torralba-Burrial 2014). The densities of *M. cornuarietis* in its currently introduced range can reach 50-175 individuals per m<sup>2</sup>. Under these densities the most severe impacts of this species are observed.

The species is known as a voracious omnivore which can potentially significantly impact macrophyte flora (Pointier & David 2004). In the USA non-native populations of *Marissa cornuarietis* have shown

to negatively impact macrophytes when the snail density becomes high with reduced macrophyte diversity and species elimination potentially occurring (Arias & Torralba-Burrial 2014). Their ability to influence macrophyte composition and biomass in waterbodies is believed to be due to their dietary habits, high reproductive output and capacity to form dense populations (Barker 2019). This impact is linked to indirect impacts to the affected nutrient balance, turbidity and trophic structure in the ecosystem. Furthermore, their herbivory can have a significant effect on native aquatic flora (Barker 2019). This species is a voracious omnivore which can directly impact native snail populations through direct competition and predation (Arias & Torralba-Burrial .2014). It is a competitive feeder which actively feed on eggs and juveniles of certain snail species (Barker 2019, Benson *et al.* 2021). Furthermore, its appetite can potentially outcompete native snails (Pointier & David 2004).

**Qu. 4.2. How important is the current known impact of the organism on biodiversity at all levels of organisation (e.g. decline in native species, changes in native species communities, hybridisation) in the risk assessment area (include any past impact in your response)?**

Discuss impacts that are currently occurring or are likely occurring or have occurred in the past in the risk assessment area. Where there is no direct evidence of impact in the risk assessment area (for example no studies have been conducted), evidence from outside of the risk assessment area can be used to infer impacts within the risk assessment area.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: No published literature states the impacts of the established populations of *Marisa cornuarietis* in the RA area. It can be assumed that the same biodiversity impacts will occur in the RA which were discussed in Qu 4.1 where high densities occur. Arias & Torralba-Burrial (2014) reiterated these remarks highlighting the potential for Red List snails to be impacted by *M. cornuarietis*.

**Qu. 4.3. How important is the potential future impact of the organism on biodiversity at all levels of organisation likely to be in the risk assessment area?**

See comment above. The potential future impact shall be assessed only for the risk assessment area. A potential increase in the distribution range due to climate change does not *per se* justify a higher impact score.

<b>RESPONSE</b>	minimal minor <b>moderate</b>	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	-------------------------------------	-------------------	------------------------------

	major massive		
--	------------------	--	--

Response: There is limited published literature in relation to the expected impacts of established *Marisa cornuarietis* populations in the RA area. However, given that it can be assumed that similar impacts will be observed as to what has occurred in other regions, loss of macrophyte diversity and indigenous snail populations will occur where its population density reaches high levels in affected water bodies. This in turn will cause the biotope wide changes discussed in Qu 4.1 but not in the near future. The two established populations are not currently situated in ideal conditions, however it must be noted they are still established populations. The Hungarian population is isolated while the population inhabiting the Nora river in Spain is subject to less than ideal calcium concentrations in the water (Frisóczki *et al.* 2016, Arias & Torralba-Burrial 2014). Arias & Torralba-Burrial (2014) have noted the widespread use of the species in the aquarium trade and, given the environmental plasticity and natural spread of the established population in Spain, a further expansion is expected.

**Qu. 4.4. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism currently in the risk assessment area?**

including the following elements:

- native species impacted, including red list species, endemic species and species listed in the Birds and Habitats directives
- protected sites impacted, in particular Natura 2000
- habitats impacted, in particular habitats listed in the Habitats Directive, or red list habitats
- the ecological status of water bodies according to the Water Framework Directive and environmental status of the marine environment according to the Marine Strategy Framework Directive

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: No published information in relation to impacts on species or habitats protected under European or National conservation legislation in the RA area is available. Given that the species is expected to spread naturally and continued introductions will occur (Arias & Torralba-Burrial 2014), impacts to protected and/or endangered species or habitats, particularly aquatic snails, macrophytes, and their associated protected habitats could potentially occur where snail densities reach significant levels similar to what has occurred in regions outside of the RA area (50-175 individuals per m<sup>2</sup>) (Barker 2019). For example, Arias & Torralba-Burrial (2014) highlighted the potential for Red List organisms to be impacted by *M. cornuarietis*. In Europe, almost half of aquatic snails are threatened with extinction with 20% of species considered endemic (Cuttlod *et al.* 2011). Due to this, it is likely that *M. cornuarietis* may cause a severe impact to threatened European snails in the future. Aquatic freshwater habitats are also at risk due to the colonisation of the species and its ability to be an

ecosystem engineer. The Habitats Directive Annex 1 Lake Habitats Mixed *Najas flexilis* lake habitat (3130) and Hard-water lake habitat (3140) may be impacted by the invasion of this species.

**Qu. 4.5. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.3. and 4.4.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: In the near future, no major changes are expected to occur to the conservation value of protected habitats and species in the RA area. This is primarily due to the species occupation of less than ideal habitats in the RA area. The population in Hungary is expected not to spread via natural means due to their thermal requirements. The established population in Spain is currently spreading, but exists under less than ideal physicochemical parameters. However, given the potential for future introductions and the species ability to spread via natural and interconnected waterways it is plausible that the full impacts of this species will develop in water bodies in the RA in the future.

**Ecosystem Services impacts**

**Qu. 4.6. How important is the impact of the organism on provisioning, regulating, and cultural services in its non-native range excluding the risk assessment area?**

- For a list of services use the CICES classification V5.1 provided in Annex V.
- Impacts on ecosystem services build on the observed impacts on biodiversity (habitat, species, genetic, functional) but focus exclusively on reflecting these changes in relation to their links with socio-economic well-being.
- Quantitative data should be provided whenever available and references duly reported.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>Low</b> medium high
-----------------	---	-------------------	------------------------------

Response: Under the CICES classification V5.1 provided in Annex V for the provisioning, regulating, and cultural services *Marisa cornuarietis* can potentially have negative impacts in several services. It

must be noted however that no information directly addressing impacts on ecosystem services has been found.

The species can impact

(1) Provisioning/Genetic material from plant/animals. *M. cornuarietis* is known to cause species decline and loss of certain macrophytes species under certain circumstances resulting in the loss of genetic diversity (Arias & Torralba-Burrial 2014). Additionally, the species’ voracious appetite can cause the elimination of indigenous snails under certain circumstances (Pointier & David 2004) thus reducing genetic diversity.

(2) Provisioning/ Wild plants. This is due to the species generalist herbivory feeding habits (Barker 2019) which can potentially eliminate wild aquatic plants used for nutritional purposes.

(3) Regulation & Maintenance. *M. cornuarietis* can impact Transformation/mediation of wastes and water conditions services. This is due to the species feeding habits which can consume significant quantities of macrophyte biomass which in turn can potentially impact bioremediation services of aquatic macrophytes in controlled and natural environments. Due to changes in macrophyte community structure there can be changes in nutrient balance, turbidity, benthos and trophic structure of water bodies (Horgan et al. 2014).

(4) Cultural services, this species can potentially impact protected species and habitats which are classed as biotic characteristics of non-use value.

**Qu. 4.7. How important is the impact of the organism on provisioning, regulating, and cultural services currently in the different biogeographic regions or marine sub-regions where the species has established in the risk assessment area (include any past impact in your response)?**

- See guidance to Qu. 4.6.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: As the species is a relatively new arrival to the RA area, no information has been published in relation to its impact on provisioning, regulating and cultural services. However, multiple potential impacts have been stated by Arias & Torralba-Burrial (2014). It is expected that impacts observed in the species non-native range outside the RA area could potentially also occur in the RA, including high impact on other provisioning services (e.g. rice and other wetland crops).

**Qu. 4.8. How important is the impact of the organism on provisioning, regulating, and cultural services likely to be in the different biogeographic regions or marine sub-regions where the species can establish in the risk assessment area in the future?**

- See guidance to Qu. 4.6.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: No information has been found in relation to this issue but the impacts stated in 4.6 could potentially occur in suitable habitats located in the 25.25 % of the RA regions thermally suitable for the species to become established. In the predicted future models (Annex VIII) when the potential area for the species to become established in the RA increases, the impacts will entail other biogeographical areas not currently prone to the negative impacts of *Marisa cornuarietis*. At present these impacts and their extent is unknown.

### Economic impacts

**Qu. 4.9. How great is the overall economic cost caused by the organism within its current area of distribution (excluding the risk assessment area), including both costs of / loss due to damage and the cost of current management.**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the world these should be reported here. The assessment of the potential costs of / loss due to damage shall describe those costs quantitatively and/or qualitatively depending on what information is available. Cost of / loss due to damage within different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage. As far as possible, it would be useful to separate costs of / loss due to the organism from costs of current management.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: The economic impacts associated with *M. cornuarietis* are dependent on the density of infestation (Arias & Torralba-Burrial 2014). No information providing estimates of the economic cost associated with the species was found. Limited evidence of active control programs of the species is available. The economic implication of introductions of the species are currently unknown but they are known to incur costs in relation to multiple ecosystem services e.g. agriculture (Howells *et al.* 2006, Horgan *et al.* 2014).

**Qu. 4.10. How great is the economic cost of / loss due to damage (excluding costs of management) of the organism currently in the risk assessment area (include any past costs in your response)?**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the EU these should be reported here. Assessment of the potential costs of damage on human health, safety, and the economy, including the cost of non-action. A full economic assessment at EU scale might not be possible, but qualitative data or different case studies from across the EU (or third countries if relevant) may provide useful information to inform decision making. In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable). Cost of / loss due to damage within different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>	N/A	<b>CONFIDENCE</b>	
-----------------	-----	-------------------	--

Response: No information has been found on the issue.

**Qu. 4.11. How great is the economic cost of / loss due to damage (excluding costs of management) of the organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.10.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: No economic projections regarding this species are known for the current or future impacts in the RA area. Established populations are currently isolated to small regions but with the expected potential for continued introductions and natural spread, it is plausible that moderate costs may be incurred in the future from the impacts imparted in the RA region by this species.

A negative economic implication of this species is due to its voracious herbivorous dietary intake. The species is a known pest to crops in certain regions incurring costs in relation to lost production and control measures (Barker 2019). It is currently unknown if the species will negatively influence agriculture inside the RA area.

**Qu. 4.12. How great are the economic costs / losses associated with managing this organism currently in the risk assessment area (include any past costs in your response)?**

- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable).

<b>RESPONSE</b>	N/A	<b>CONFIDENCE</b>	
-----------------	-----	-------------------	--

Response No information has been found on the issue.

**Qu. 4.13. How great are the economic costs / losses associated with managing this organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.12.

<b>RESPONSE</b>	N/A	<b>CONFIDENCE</b>	
-----------------	-----	-------------------	--

Response: No information has been found on the issue.

## Social and human health impacts

**Qu. 4.14. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism for the risk assessment area and for third countries, if relevant (e.g. with similar eco-climatic conditions).**

The description of the known impact and the assessment of potential future impact on human health, safety and the economy, shall, if relevant, include information on

- illnesses, allergies or other affections to humans that may derive directly or indirectly from a species;
- damages provoked directly or indirectly by a species with consequences for the safety of people, property or infrastructure;
- direct or indirect disruption of, or other consequences for, an economic or social activity due to the presence of a species.

Social and human health impacts can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>	N/A	<b>CONFIDENCE</b>	
-----------------	-----	-------------------	--

Response: No information has been found on the issue.

**Qu. 4.15. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism in the future for the risk assessment area.**

- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable).

<b>RESPONSE</b>	N/A	<b>CONFIDENCE</b>	
-----------------	-----	-------------------	--

Response: No information has been found on the issue.

### **Other impacts**

**Qu. 4.16. How important is the organism in facilitating other damaging organisms (e.g. diseases) as food source, a host, a symbiont or a vector etc.?**

<b>RESPONSE</b>	N/A	<b>CONFIDENCE</b>	
-----------------	-----	-------------------	--

Response: No information has been found on the issue.

**Qu. 4.17. How important might other impacts not already covered by previous questions be resulting from introduction of the organism?**

<b>RESPONSE</b>	N/A	<b>CONFIDENCE</b>	
-----------------	-----	-------------------	--

Response: No information has been found on the issue.

**Qu. 4.18. How important are the expected impacts of the organism despite any natural control by other organisms, such as predators, parasites or pathogens that may already be present in the risk assessment area?**

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: *Marisa cornuarietis* has been noted to be predated on by fish and birds (Barker 2019). Hypothetically, this may provide some natural control in the RA area, however, at present natural control mechanisms in the RA area are unknown.

**Qu. 4.19. Estimate the overall impact in the risk assessment area under current climate conditions. In addition, details of overall impact in relevant biogeographical regions should be provided.**

Thorough assessment of the overall impact on biodiversity and ecosystem services, with impacts on economy as well as social and human health as aggravating factors, in current conditions.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: As the RA conducted by Patoka *et al.* (2017) concluded that 25.25% of the RA area is subject to the establishment of *Marisa cornuarietis* where suitable habitat is occurring, it is expected that under current climate conditions and the potential for further introductions throughout the RA, thermally suitable areas in relevant biogeographical regions will be prone to the aforementioned impacts of this species introduction and subsequent establishment.

**Qu. 4.20. Estimate the overall impact in the risk assessment area in foreseeable climate change conditions. In addition, details of overall impact in relevant biogeographical regions should be provided.**

Thorough assessment of the overall impact on biodiversity and ecosystem services, with impacts on economy as well as social and human health as aggravating factors, under future conditions.

- See also guidance to Qu. 4.3.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: The significance of the impacts is not expected to change under future climate conditions although some biogeographical regions (see Q. A7) (Annex VIII) may have a higher suitability of establishment in the future leading to a potential increase in the distribution of the impacts imparted by this species.

<b>RISK SUMMARIES</b>			
	<b>RESPONSE</b>	<b>CONFIDENCE</b>	<b>COMMENT</b>
<b>Summarise Introduction and Entry*</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	low medium <b>high</b>	Direct trade of <i>Marisa cornuarietis</i> through aquaria or the species being a contaminant on traded plants is the most likely cause of introduction. The species is already introduced and has entered into the wild in the Mediterranean and the Pannonian biogeographical regions in the RA area. It is very likely that the species will be repeatedly introduced and entered into the wild through these pathways
<b>Summarise Establishment*</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	low medium <b>high</b>	Currently, the species is established in two EU Member States (Spain and Hungary). Establishment is expected in 25% of the RA area (Patoka <i>et al.</i> 2017), depending on physico-chemical parameters such as calcium concentrations and suitable habitats such as lakes, rivers, ponds, streams. Further establishment of new populations is very likely. Under predicted future climate conditions, the species area within the RA where it could establish will increase
<b>Summarise Spread*</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>low</b> medium high	Spread is restricted by environmental conditions. Unaided spread and spread via interconnected corridors, as a transport stowaway on angling equipment and via –contamination on plants are deemed important for the species. Under predicted future climate conditions these pathways will still be the primary ways the species will spread.
<b>Summarise Impact*</b>	minimal minor <b>moderate</b> major massive	low <b>medium</b> high	The impacts of <i>M. cornuarietis</i> are currently unknown in the RA area due to its relatively recent arrival but impacts are expected to be similar to other regions of the world where the species has established in its non-native range. Impacts on indigenous flora and fauna and some ecosystem

			services (e.g. provisioning) have been identified in areas outside the RA and severity is dependent on population density. Economic costs (on agriculture) can also occur.
<b>Conclusion of the risk assessment (overall risk)</b>	low <b>moderate</b> high	low <b>medium</b> high	The species is established in two regions of the RA area and has the potential to spread. It is known to be invasive in regions outside the native range due to their ability to outcompete and displace native flora and fauna and impacts on the economy are possible.

\*in current climate conditions and in foreseeable future climate conditions

## **ANNEX I Scoring of Likelihoods of Events**

(taken from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

<b>Score</b>	<b>Description</b>	<b>Frequency</b>
Very unlikely	This sort of event is theoretically possible, but is never known to have occurred and is not expected to occur	1 in 10,000 years
Unlikely	This sort of event has occurred somewhere at least once in the last millenium	1 in 1,000 years
Moderately likely	This sort of event has occurred somewhere at least once in the last century	1 in 100 years
Likely	This sort of event has happened on several occasions elsewhere, or on at least once in the last decade	1 in 10 years
Very likely	This sort of event happens continually and would be expected to occur	Once a year

## ANNEX II Scoring of Magnitude of Impacts

(modified from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

Score	Biodiversity and ecosystem impact	Ecosystem Services impact	Economic impact (Monetary loss and response costs per year)	Social and human health impact, and other impacts
	<i>Question 5.1-5</i>	<i>Question 5.6-8</i>	<i>Question 5.9-13</i>	<i>Question 5.14-18</i>
Minimal	Local, short-term population loss, no significant ecosystem effect	No services affected <sup>5</sup>	Up to 10,000 Euro	No social disruption. Local, mild, short-term reversible effects to individuals.
Minor	Some ecosystem impact, reversible changes, localised	Local and temporary, reversible effects to one or few services	10,000-100,000 Euro	Significant concern expressed at local level. Mild short-term reversible effects to identifiable groups, localised.
Moderate	Measureable long-term damage to populations and ecosystem, but reversible; little spread, no extinction	Measureable, temporary, local and reversible effects on one or several services	100,000-1,000,000 Euro	Temporary changes to normal activities at local level. Minor irreversible effects and/or larger numbers covered by reversible effects, localised.
Major	Long-term irreversible ecosystem change, spreading beyond local area	Local and irreversible or widespread and reversible effects on one / several services	1,000,000-10,000,000 Euro	Some permanent change of activity locally, concern expressed over wider area. Significant irreversible effects locally or reversible effects over large area.
Massive	Widespread, long-term population loss or extinction, affecting several species with serious ecosystem effects	Widespread and irreversible effects on one / several services	Above 10,000,000 Euro	Long-term social change, significant loss of employment, migration from affected area. Widespread, severe, long-term, irreversible health effects.

<sup>5</sup> Not to be confused with “no impact”.

## ANNEX III Scoring of Confidence Levels

(modified from Bacher *et al.* 2017)

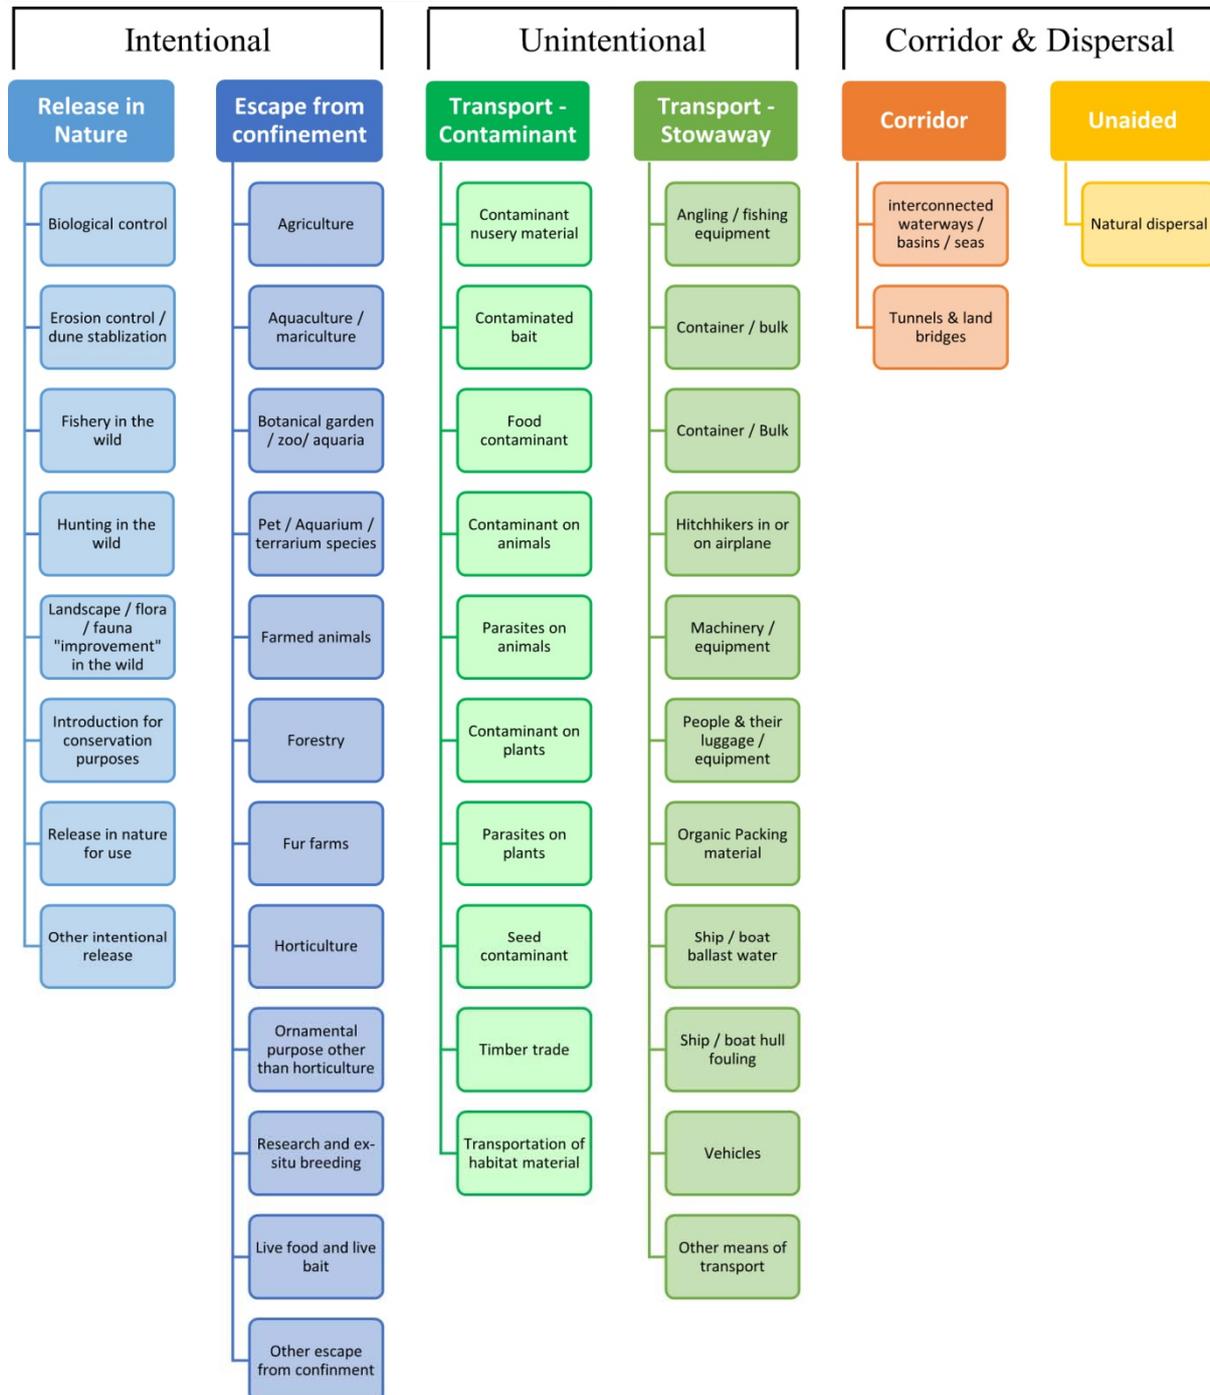

Each answer provided in the risk assessment must include an assessment of the level of confidence attached to that answer, reflecting the possibility that information needed for the answer is not available or is insufficient or available but conflicting.

The responses in the risk assessment should clearly support the choice of the confidence level.

Confidence level	Description
Low	There is no direct observational evidence to support the assessment, e.g. only inferred data have been used as supporting evidence <i>and/or</i> Impacts are recorded at a spatial scale which is unlikely to be relevant to the assessment area <i>and/or</i> Evidence is poor and difficult to interpret, e.g. because it is strongly ambiguous <i>and/or</i> The information sources are considered to be of low quality or contain information that is unreliable.
Medium	There is some direct observational evidence to support the assessment, but some information is inferred <i>and/or</i> Impacts are recorded at a small spatial scale, but rescaling of the data to relevant scales of the assessment area is considered reliable, or to embrace little uncertainty <i>and/or</i> The interpretation of the data is to some extent ambiguous or contradictory.
High	There is direct relevant observational evidence to support the assessment (including causality) <i>and</i> Impacts are recorded at a comparable scale <i>and/or</i> There are reliable/good quality data sources on impacts of the taxa <i>and</i> The interpretation of data/information is straightforward <i>and/or</i> Data/information are not controversial or contradictory.

## ANNEX IV CBD pathway categorisation scheme

Overview of CBD pathway categorisation scheme showing how the 44 pathways relate to the six main pathway categories. All of the pathways can be broadly classified into 1) those that involve intentional transport (blue), 2) those in which the taxa are unintentionally transported (green) and 3) those where taxa moved between regions without direct transportation by humans and/or via artificial corridors (orange and yellow). **Note that the pathways in the category “Escape from confinement” can be considered intentional for the introduction into the risk assessment area and unintentional for the entry into the environment.**

## ANNEX V Ecosystem services classification (CICES V5.1, simplified) and examples

For the purposes of this risk assessment, please feel free to use what seems as the most appropriate category / level / combination of impact (Section – Division – Group), reflecting information available.

Section	Division	Group	Examples (i.e. relevant CICES “classes”)
Provisioning	Biomass	<b>Cultivated <i>terrestrial</i> plants</b>	<p>Cultivated terrestrial plants (including fungi, algae) grown for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from cultivated plants, fungi, algae and bacteria for direct use or processing (excluding genetic materials);            Cultivated plants (including fungi, algae) grown as a <u>source of energy</u></p> <p><i>Example: negative impacts of non-native organisms to crops, orchards, timber etc.</i></p>
		<b>Cultivated <i>aquatic</i> plants</b>	<p>Plants cultivated by in- situ aquaculture grown for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from in-situ aquaculture for direct use or processing (excluding genetic materials);            Plants cultivated by in- situ aquaculture grown as an <u>energy source</u>.</p> <p><i>Example: negative impacts of non-native organisms to aquatic plants cultivated for nutrition, gardening etc. purposes.</i></p>
		<b>Reared animals</b>	<p>Animals reared for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from reared animals for direct use or processing (excluding genetic materials);            Animals reared to provide <u>energy</u> (including mechanical)</p> <p><i>Example: negative impacts of non-native organisms to livestock</i></p>
		<b>Reared <i>aquatic</i> animals</b>	<p>Animals reared by in-situ aquaculture for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from animals grown by in-situ aquaculture for direct use or processing (excluding genetic materials);            Animals reared by in-situ aquaculture as an <u>energy source</u></p> <p><i>Example: negative impacts of non-native organisms to fish farming</i></p>
		<b>Wild plants</b> (terrestrial and aquatic)	<p>Wild plants (terrestrial and aquatic, including fungi, algae) used for <u>nutrition</u>;  <u>Fibres and other materials</u> from wild plants for direct use or processing (excluding genetic materials);            Wild plants (terrestrial and aquatic, including fungi, algae) used as a <u>source of energy</u></p> <p><i>Example: reduction in the availability of wild plants (e.g. wild berries, ornamentals) due to non-native organisms (competition, spread of disease etc.)</i></p>
		<b>Wild animals</b> (terrestrial and aquatic)	<p>Wild animals (terrestrial and aquatic) used for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from wild animals for direct use or processing (excluding genetic materials);            Wild animals (terrestrial and aquatic) used as a <u>source of energy</u></p>

			<i>Example: reduction in the availability of wild animals (e.g. fish stocks, game) due to non-native organisms (competition, predations, spread of disease etc.)</i>
	<b>Genetic material</b> from all biota	<b>Genetic material</b> from plants, algae or fungi	<u>Seeds, spores and other plant materials</u> collected for maintaining or establishing a population; Higher and lower plants (whole organisms) used to <u>breed new strains or varieties</u> ; Individual genes extracted from higher and lower plants for the <u>design and construction of new biological entities</u>  <i>Example: negative impacts of non-native organisms due to interbreeding</i>
		<b>Genetic material</b> from animals	Animal material collected for the purposes of maintaining or establishing a population; Wild animals (whole organisms) used to breed new strains or varieties; Individual genes extracted from organisms for the design and construction of new biological entities  <i>Example: negative impacts of non-native organisms due to interbreeding</i>
	<b>Water</b> <sup>6</sup>	<b>Surface water</b> used for nutrition, materials or energy	Surface water for <u>drinking</u> ; Surface water used as a material ( <u>non-drinking purposes</u> ); Freshwater surface water, coastal and marine water used as an <u>energy source</u>  <i>Example: loss of access to surface water due to spread of non-native organisms</i>
		<b>Ground water</b> for used for nutrition, materials or energy	Ground (and subsurface) water for <u>drinking</u> ; Ground water (and subsurface) used as a material ( <u>non-drinking purposes</u> ); Ground water (and subsurface) used as an <u>energy source</u>  <i>Example: reduced availability of ground water due to spread of non-native organisms and associated increase of ground water consumption by vegetation.</i>
<b>Regulation &amp; Maintenance</b>	<b>Transformation</b> of biochemical or physical inputs to ecosystems	<b>Mediation of wastes or toxic substances</b> of anthropogenic origin by living processes	<u>Bio-remediation</u> by micro-organisms, algae, plants, and animals; <u>Filtration/sequestration/storage/accumulation</u> by micro-organisms, algae, plants, and animals  <i>Example: changes caused by non-native organisms to ecosystem functioning and ability to filtrate etc. waste or toxics</i>
		<b>Mediation of nuisances</b> of anthropogenic origin	<u>Smell reduction</u> ; <u>noise attenuation</u> ; <u>visual screening</u> (e.g. by means of green infrastructure)  <i>Example: changes caused by non-native organisms to ecosystem structure, leading to reduced ability to mediate nuisances.</i>
	<b>Regulation</b> of physical, chemical, biological conditions	<b>Baseline flows and extreme event</b> regulation	Control of <u>erosion</u> rates; Buffering and attenuation of <u>mass movement</u> ; <u>Hydrological cycle and water flow regulation</u> (Including flood control, and coastal protection); <u>Wind</u> protection; <u>Fire</u> protection

<sup>6</sup> Note: in the CICES classification provisioning of water is considered as an abiotic service whereas the rest of ecosystem services listed here are considered biotic.

			<p><i>Example: changes caused by non-native organisms to ecosystem functioning or structure leading to, for example, destabilisation of soil, increased risk or intensity of wild fires etc.</i></p>
		<p><b>Lifecycle maintenance, habitat and gene pool protection</b></p>	<p>Pollination (or 'gamete' dispersal in a marine context); <u>Seed dispersal</u>; Maintaining <u>nursery populations and habitats</u> (Including gene pool protection)</p> <p><i>Example: changes caused by non-native organisms to the abundance and/or distribution of wild pollinators; changes to the availability / quality of nursery habitats for fisheries</i></p>
		<p><b>Pest and disease control</b></p>	<p>Pest control; Disease control</p> <p><i>Example: changes caused by non-native organisms to the abundance and/or distribution of pests</i></p>
		<p><b>Soil quality regulation</b></p>	<p><u>Weathering processes</u> and their effect on soil quality; <u>Decomposition and fixing processes</u> and their effect on soil quality</p> <p><i>Example: changes caused by non-native organisms to vegetation structure and/or soil fauna leading to reduced soil quality</i></p>
		<p><b>Water conditions</b></p>	<p>Regulation of the <u>chemical condition</u> of freshwaters by living processes; Regulation of the chemical condition of salt waters by living processes</p> <p><i>Example: changes caused by non-native organisms to buffer strips along water courses that remove nutrients in runoff and/or fish communities that regulate the resilience and resistance of water bodies to eutrophication</i></p>
		<p><b>Atmospheric composition and conditions</b></p>	<p>Regulation of <u>chemical composition</u> of atmosphere and oceans; Regulation of <u>temperature and humidity</u>, including ventilation and transpiration</p> <p><i>Example: changes caused by non-native organisms to ecosystems' ability to sequester carbon and/or evaporative cooling (e.g. by urban trees)</i></p>
<b>Cultural</b>	<b>Direct, in-situ and outdoor interactions</b> with living systems that depend on presence in the environmental setting	<p><b>Physical and experiential</b> interactions with natural environment</p>	<p>Characteristics of living systems that that enable activities promoting health, recuperation or enjoyment through <u>active or immersive interactions</u>;</p> <p>Characteristics of living systems that enable activities promoting health, recuperation or enjoyment through <u>passive or observational interactions</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that make it attractive for recreation, wild life watching etc.</i></p>
		<p><b>Intellectual and representative</b> interactions with natural environment</p>	<p>Characteristics of living systems that enable <u>scientific investigation</u> or the creation of traditional ecological knowledge;</p> <p>Characteristics of living systems that enable <u>education and training</u>;</p> <p>Characteristics of living systems that are resonant in terms of <u>culture or heritage</u>;</p> <p>Characteristics of living systems that enable <u>aesthetic experiences</u></p>

			<i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have cultural importance</i>
	<b>Indirect, remote, often indoor interactions</b> with living systems that do not require presence in the environmental setting	<b>Spiritual, symbolic</b> and other interactions with natural environment	<p>Elements of living systems that have <u>symbolic meaning</u>;</p> <p>Elements of living systems that have <u>sacred or religious meaning</u>;</p> <p>Elements of living systems used for <u>entertainment or representation</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have sacred or religious meaning</i></p>
		Other biotic characteristics that have a <b>non-use value</b>	<p>Characteristics or features of living systems that have an <u>existence value</u>;</p> <p>Characteristics or features of living systems that have an <u>option or bequest value</u></p> <p><i>Example: changes caused by non-native organisms to ecosystems designated as wilderness areas, habitats of endangered species etc.</i></p>

# ANNEX VIII Projection of environmental suitability for *Marisa cornuarietis* establishment in Europe

Björn Beckmann, Frances Lucy, Darren Garland and Dan Chapman

27 September 2021

## *Aim*

To project the suitability for potential establishment of *Marisa cornuarietis* in Europe, under current and predicted future climatic conditions.

## *Data for modelling*

Species occurrence data were obtained from the Global Biodiversity Information Facility (GBIF) (228 records), iNaturalist (111 records), the Integrated Digitized Biocollections (iDigBio) (70 records), the Biodiversity Information Serving Our Nation database (BISON) (38 records), and additional records from the risk assessment team. We scrutinised occurrence records from regions where the species is not known to be established and removed any dubious records or where the georeferencing was too imprecise (e.g. records referenced to a country or island centroid) or outside of the coverage of the predictor layers (e.g. small island or coastal occurrences). We excluded a record from Hungary at the outflow of a thermal spa (Frisoczki et al. 2016), because even though this is an established outdoor population, the artificially warm and constant conditions here would not be reflected in the predictor layers. The remaining records were gridded at a 0.25 x 0.25 degree resolution for modelling, yielding 118 grid cells with occurrences (Figure 1a). As a proxy for recording effort, the density of Ampullariidae records held by GBIF was also compiled on the same grid (Figure 1b).

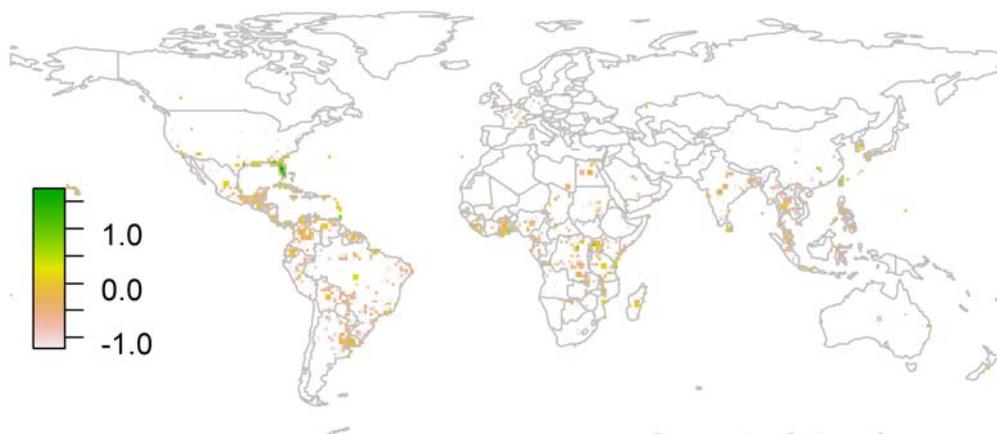

## Page Break

**Figure 1.** (a) Occurrence records obtained for *Marisa cornuarietis* and used in the modelling, showing native and invaded distributions. (b) The recording density of Ampullariidae on GBIF, which was used as a proxy for recording effort.

(a) Species distribution used in modelling

(b) Estimated recording effort (log10-scaled)

Climate data were selected from the 'Biodlim' variables contained within the WorldClim database (Hijmans et al., 2005), originally at 5 arcminute resolution (0.083 x 0.083 degrees of longitude/latitude) and aggregated to a 0.25 x 0.25 degree grid for use in the model.

Based on the biology of *Marisa cornuarietis*, the following climate variables were used in the modelling:

- Mean temperature of the warmest quarter (Bio10)
- Mean temperature of the coldest quarter (Bio11)
- Annual precipitation (Bio12)
- Precipitation seasonality (Bio15)

To estimate the effect of climate change on the potential distribution, equivalent modelled future climate conditions for the 2070s under the Representative Concentration Pathways (RCP) 2.6 and 4.5 were also obtained. These represent low and medium emissions scenarios, respectively. The above variables were obtained as averages of outputs of eight Global Climate Models (BCC-CSM1-1, CCSM4, GISS-E2-R, HadGEM2-AO, IPSL-CM5A-LR, MIROC-ESM, MRI-CGCM3, NorESM1-M), downscaled and calibrated against the WorldClim baseline (see [http://www.worldclim.org/cmip5\\_5m](http://www.worldclim.org/cmip5_5m)).

## *Species distribution model*

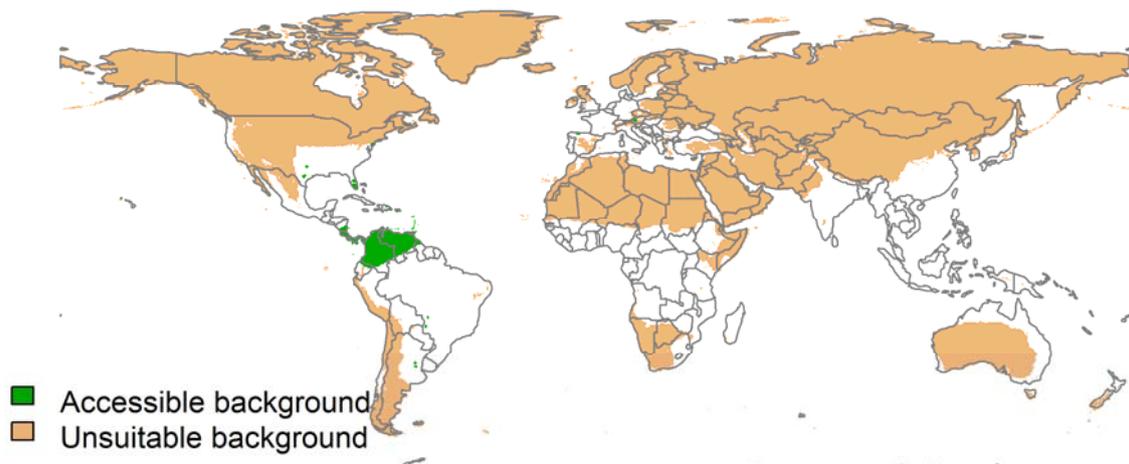

A presence-background (presence-only) ensemble modelling strategy was employed using the BIOMOD2 R package version 3.4.6 (Thuiller et al., 2020, Thuiller et al., 2009). These models contrast the environment at the species' occurrence locations against a random sample of the global background environmental conditions (often termed 'pseudo-absences') in order to characterise and project suitability for occurrence. This approach has been developed for distributions that are in equilibrium with the environment. Because invasive species' distributions are not at equilibrium and subject to dispersal constraints at a global scale, we took care to minimise the inclusion of locations suitable for the species but where it has not been able to disperse to (Chapman et al. 2019). Therefore the background sampling region included:

- The area accessible by native *Marisa cornuarietis* populations, in which the species is likely to have had sufficient time to disperse to all locations. Based on presumed maximum dispersal distances, the accessible region was defined as a 400km buffer around the native range occurrences; AND
- A 50km buffer around the non-native occurrences, encompassing regions likely to have had high propagule pressure for introduction by humans and/or dispersal of the species; AND
- Regions where we have an *a priori* expectation of high unsuitability for the species so that absence is assumed irrespective of dispersal constraints (see Figure 2). The following rules were applied to define a region expected to be highly unsuitable for *Marisa cornuarietis* at the spatial scale of the model:
  - Mean temperature of the warmest quarter (Bio10) < 14°C
  - Mean temperature of the coldest quarter (Bio11) < -1.3°C
  - Annual precipitation (Bio12) < 500mm

Altogether, 2.5% of occurrence grid cells were located in the unsuitable background region.

Within the unsuitable background region, 10 samples of 5000 randomly sampled grid cells were obtained. In the accessible background (comprising the accessible areas around native and non-native occurrences as detailed above), the same number of pseudo-absence samples were drawn as there were presence records (118), weighting the sampling by a proxy for recording effort (Figure 1(b)).

**Figure 2.** The background from which pseudo-absence samples were taken in the modelling of *Marisa cornuarietis*. Samples were taken from a 400km buffer around the native range and a 50km buffer around non-native occurrences (together forming the accessible background), and from areas expected to be highly unsuitable for the species (the unsuitable background region). Samples from the accessible background were weighted by a proxy for recording effort (Figure 1(b)).

Each dataset (i.e. combination of the presences and the individual background samples) was randomly split into 80% for model training and 20% for model evaluation. With each training dataset, seven statistical algorithms were fitted with the default BIOMOD2 settings and rescaled using logistic regression, except where specified below:

- Generalised linear model (GLM)
- Generalised boosting model (GBM)
- Generalised additive model (GAM) with a maximum of four degrees of freedom per smoothing spline
- Artificial neural network (ANN)
- Multivariate adaptive regression splines (MARS)
- Random forest (RF)
- Maxent

Since the total background sample was larger than the number of occurrences, prevalence fitting weights were applied to give equal overall importance to the occurrences and the background. Normalised variable importance was assessed and variable response functions were produced using BIOMOD2's default procedure.

Model predictive performance was assessed by the following three measures:

- AUC, the area under the receiver operating characteristic curve (Fielding & Bell 1997). Predictions of presence-absence models can be compared with a subset of records set aside for model evaluation (here 20%) by constructing a confusion matrix with the number of true positive, false positive, false negative and true negative cases. For models generating non-dichotomous scores (as here) a threshold can be applied to transform the scores into a dichotomous set of presence-absence predictions. Two measures that can be derived from the confusion matrix are sensitivity (the proportion of observed presences that are predicted as such, quantifying omission errors), and specificity (the proportion of observed absences that are predicted as such, quantifying commission errors). A receiver operating characteristic (ROC)

curve can be constructed by using all possible thresholds to classify the scores into confusion matrices, obtaining sensitivity and specificity for each matrix, and plotting sensitivity against the corresponding proportion of false positives (equal to  $1 - \text{specificity}$ ). The use of all possible thresholds avoids the need for a selection of a single threshold, which is often arbitrary, and allows appreciation of the trade-off between sensitivity and specificity. The area under the ROC curve (AUC) is often used as a single threshold-independent measure for model performance (Manel et al. 2001). AUC is the probability that a randomly selected presence has a higher model-predicted suitability than a randomly selected absence (Allouche et al. 2006).

- Cohen's Kappa (Cohen 1960). This measure corrects the overall accuracy of model predictions (ratio of the sum of true presences plus true absences to the total number of records) by the accuracy expected to occur by chance. The Kappa statistic ranges from -1 to +1, where +1 indicates perfect agreement and values of zero or less indicate a performance no better than random. Advantages of Kappa are its simplicity, the fact that both commission and omission errors are accounted for in one parameter, and its relative tolerance to zero values in the confusion matrix (Manel et al. 2001). However, Kappa has been criticised for being sensitive to prevalence (the proportion of sites in which the species was recorded as present) and may therefore be inappropriate for comparisons of model accuracy between species or regions (McPherson et al. 2004, Allouche et al. 2006).
- TSS, the true skill statistic (Allouche et al. 2006). TSS is defined as sensitivity + specificity - 1, and corrects for Kappa's dependency on prevalence. TSS compares the number of correct forecasts, minus those attributable to random guessing, to that of a hypothetical set of perfect forecasts. Like Kappa, TSS takes into account both omission and commission errors, and success as a result of random guessing, and ranges from -1 to +1, where +1 indicates perfect agreement and values of zero or less indicate a performance no better than random (Allouche et al. 2006).

An ensemble model was created by first rejecting poorly performing algorithms with relatively extreme low AUC values and then averaging the predictions of the remaining algorithms, weighted by their AUC. To identify poorly performing algorithms, AUC values were converted into modified z-scores based on their difference to the median and the median absolute deviation across all algorithms (Iglewicz & Hoaglin 1993). Algorithms with  $z < -2$  were rejected. In this way, ensemble projections were made for each dataset and then averaged to give an overall suitability, as well as its standard deviation.

Projections were classified into suitable and unsuitable regions using a "lowest presence threshold" (Pearson et al. 2007), setting the cut-off as the lowest value at which 98% of all presence records are classified correctly under the current climate (here 0.69). In order to express the sensitivity of classifications to the choice of this threshold, thresholds at which 95% and 99% of records are classified correctly (here 0.86 and 0.65 respectively) were used in the calculation of error bars in Figures 9 and 10 below in addition to taking account of uncertainty in the projections themselves.

We also produced a limiting factor map for Europe following Elith et al. (2010). For this, projections were made separately with each individual variable fixed at a near-optimal value. These were chosen as the median values at the occurrence grid cells. Then, the most strongly limiting factors were identified as the ones resulting in the highest increase in suitability in each grid cell.

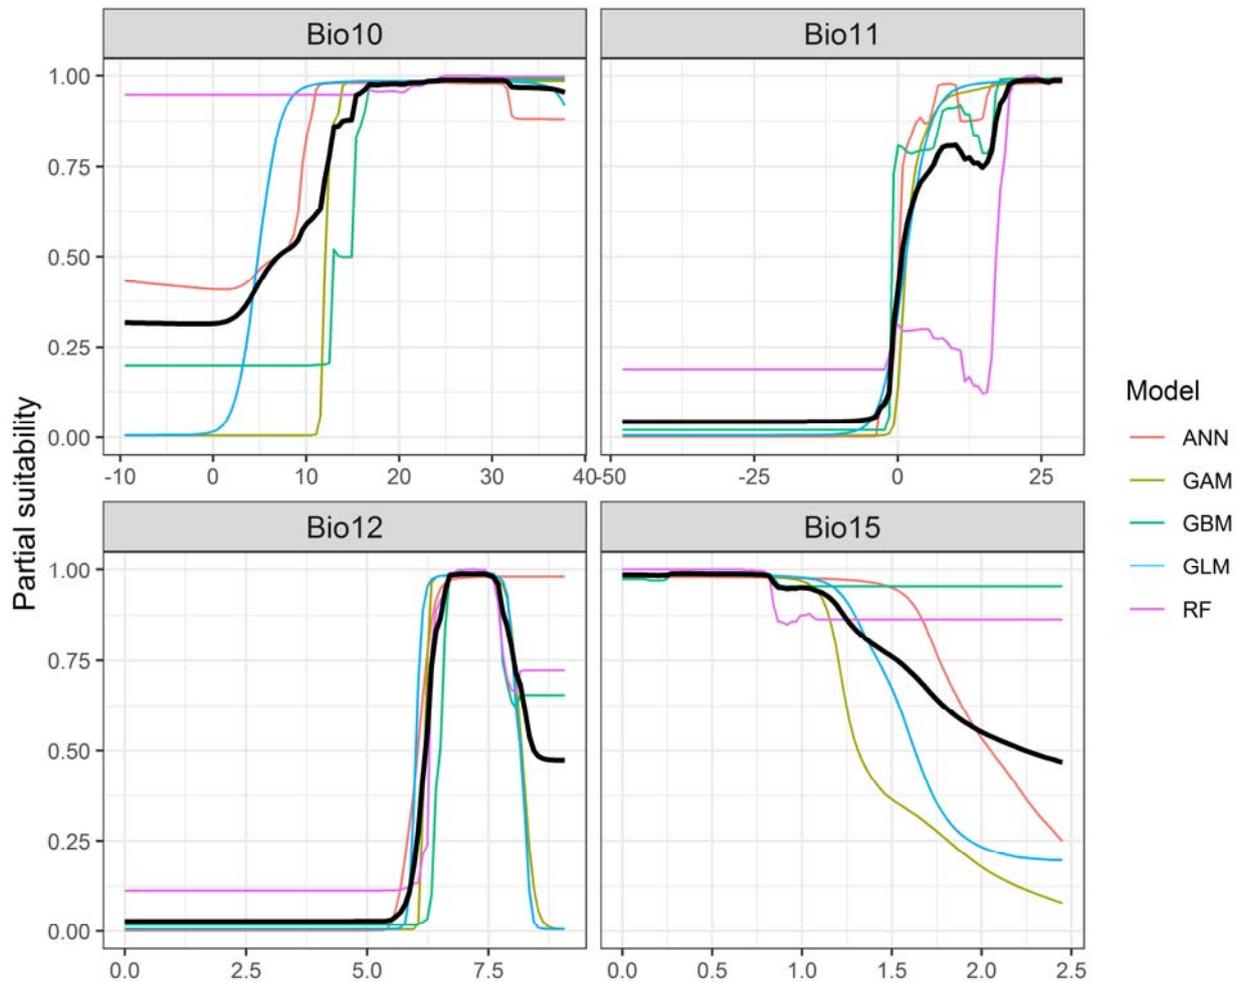

## Results

The ensemble model suggested that suitability for *Marisa cornuarietis* was most strongly determined by Annual precipitation (Bio12), accounting for 42.3% of variation explained, followed by Mean temperature of the coldest quarter (Bio11) (41.2%), Mean temperature of the warmest quarter (Bio10) (13.5%) and Precipitation seasonality (Bio15) (2.9%) (Table 1, Figure 3).

**Table 1.** Summary of the cross-validation predictive performance (AUC, Kappa, TSS) and variable importance of the fitted model algorithms and the ensemble (AUC-weighted average of the best performing algorithms). Results are the average from models fitted to 10 different background samples of the data.

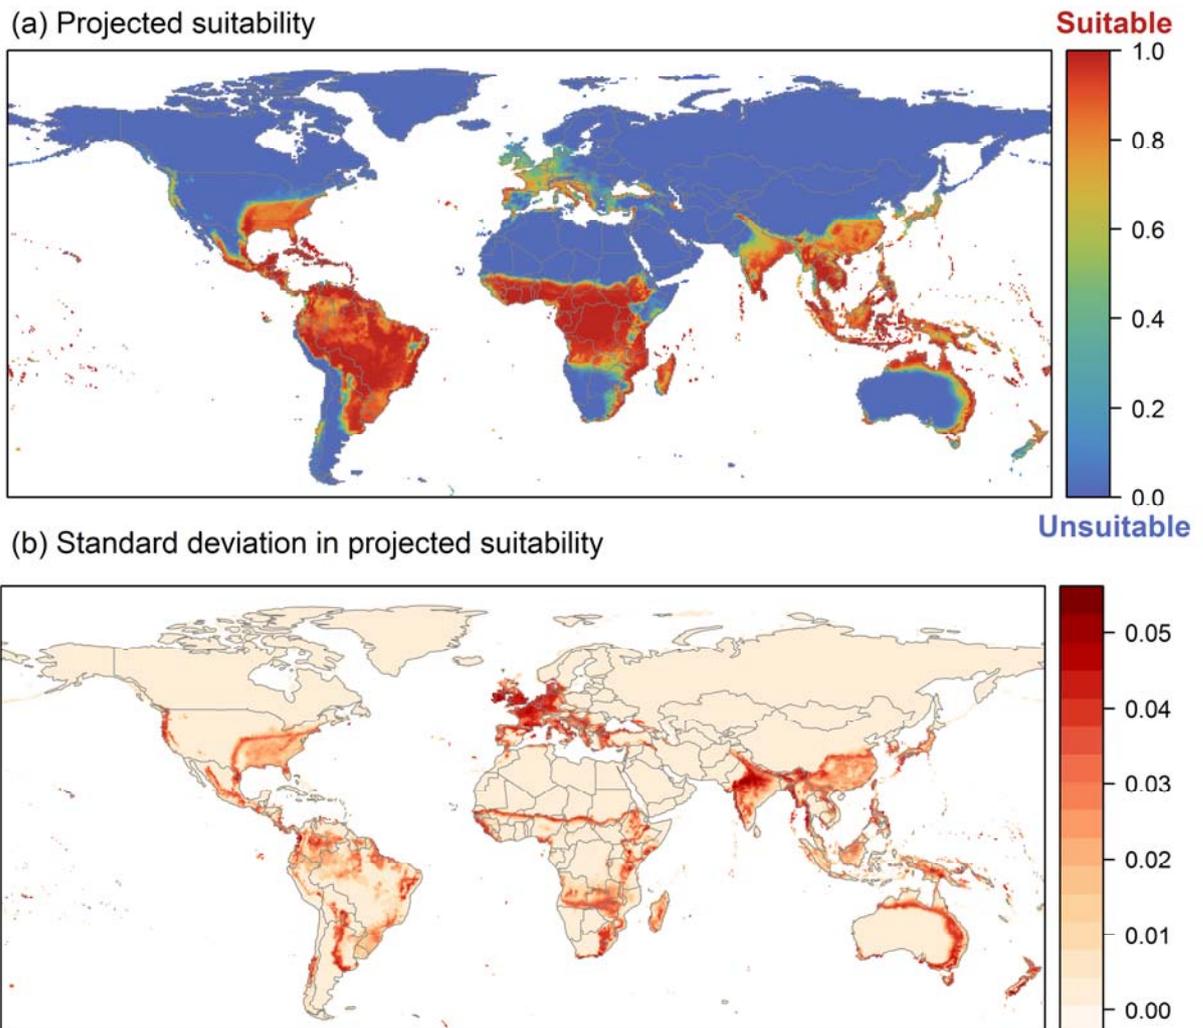

Algorithm	AUC	Kappa	TSS	Used in the ensemble	Variable importance (%)			
					Annual precipitation (Bio12)	Mean temperature of the coldest quarter (Bio11)	Mean temperature of the warmest quarter (Bio10)	Precipitation seasonality (Bio15)
GLM	0.989	0.643	0.955	yes	40	47	8	5
GAM	0.988	0.650	0.959	yes	40	41	16	3
GBM	0.986	0.652	0.934	yes	47	38	15	0
ANN	0.987	0.634	0.973	yes	37	47	11	4
MARS	0.985	0.643	0.957	no	38	47	8	7
RF	0.986	0.640	0.940	yes	47	33	18	2
Maxent	0.969	0.648	0.911	no	39	38	16	6
<b>Ensemble</b>	<b>0.988</b>	<b>0.647</b>	<b>0.975</b>		<b>42</b>	<b>41</b>	<b>13</b>	<b>3</b>

**Figure 3.** Partial response plots from the fitted models. Thin coloured lines show responses from the algorithms in the ensemble, while the thick black line is their ensemble. In each plot, other model variables are held at their median value in the training data. Some of the divergence among algorithms is because of their different treatment of interactions among variables.

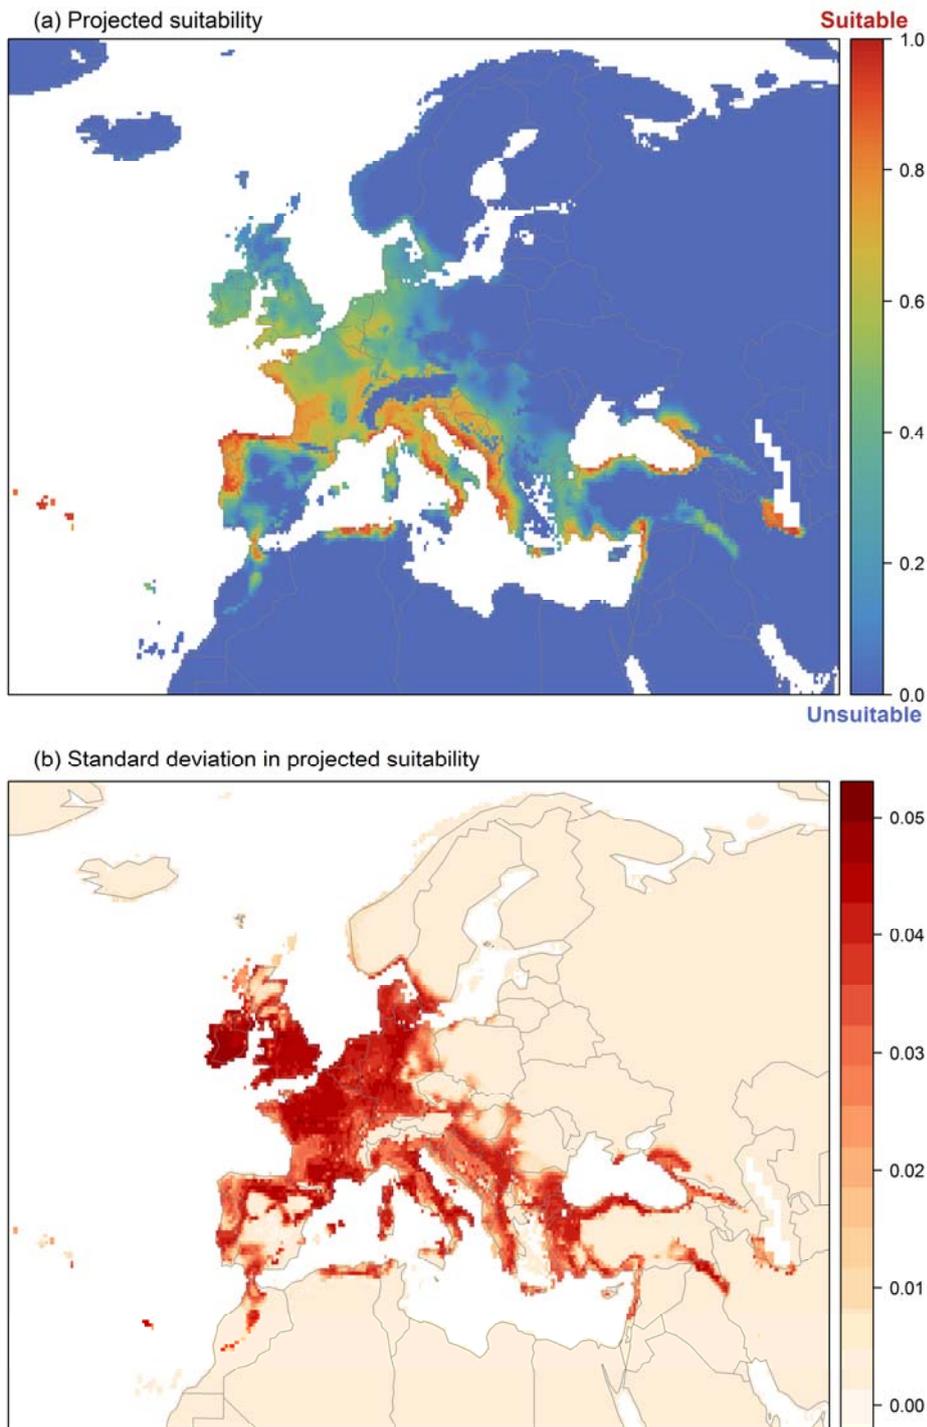

Page Break

**Figure 4.** (a) Projected global suitability for *Marisa cornuarietis* establishment in the current climate. For visualisation, the projection has been aggregated to a 0.5 x 0.5 degree resolution, by taking the maximum suitability of constituent higher resolution grid cells. Values > 0.69 are suitable for the species, with 98% of global presence records above this threshold. Values below 0.69 indicate lower relative suitability. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

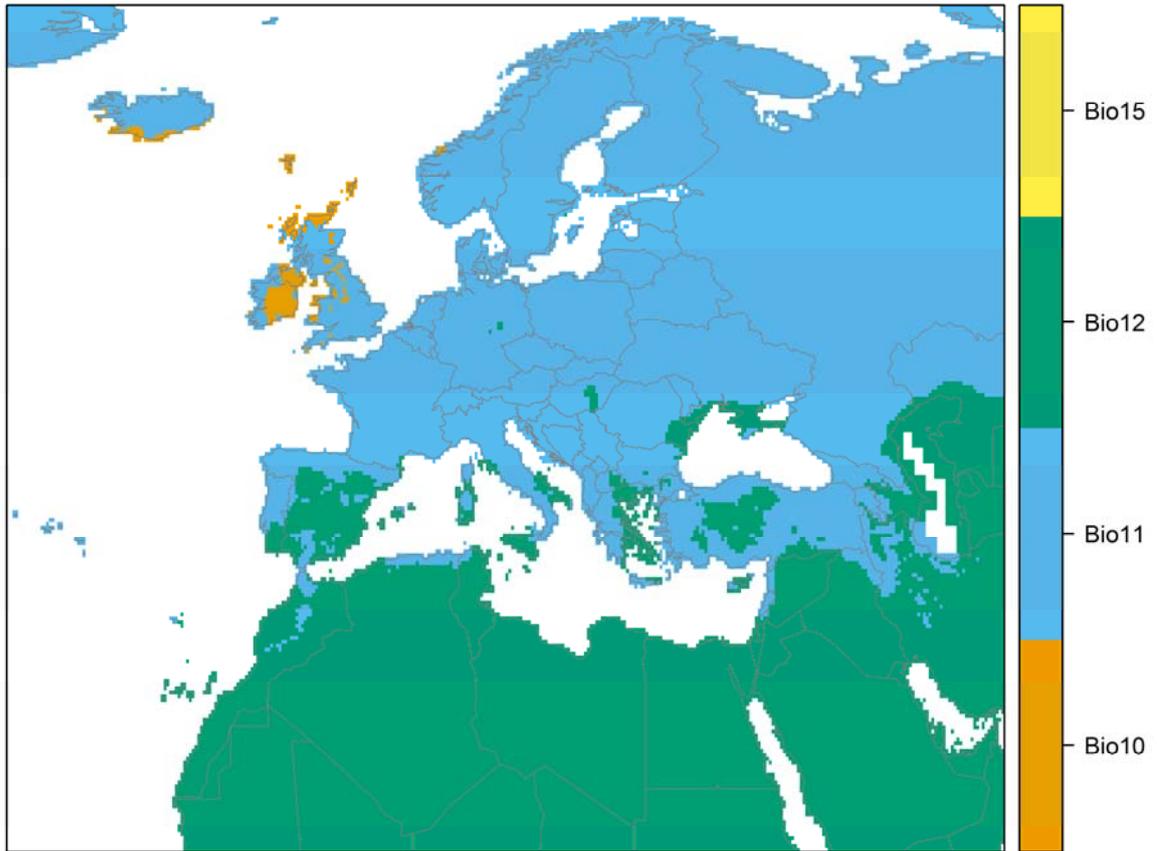

Page Break

**Figure 5.** (a) Projected current suitability for *Marisa cornuarietis* establishment in Europe and the Mediterranean region. Values  $> 0.69$  are suitable for the species, with 98% of global presence records above this threshold. Values below 0.69 indicate lower relative suitability. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

**Figure 6.** The most strongly limiting factors for *Marisa cornuarietis* establishment estimated by the model in Europe and the Mediterranean region in current climatic conditions.

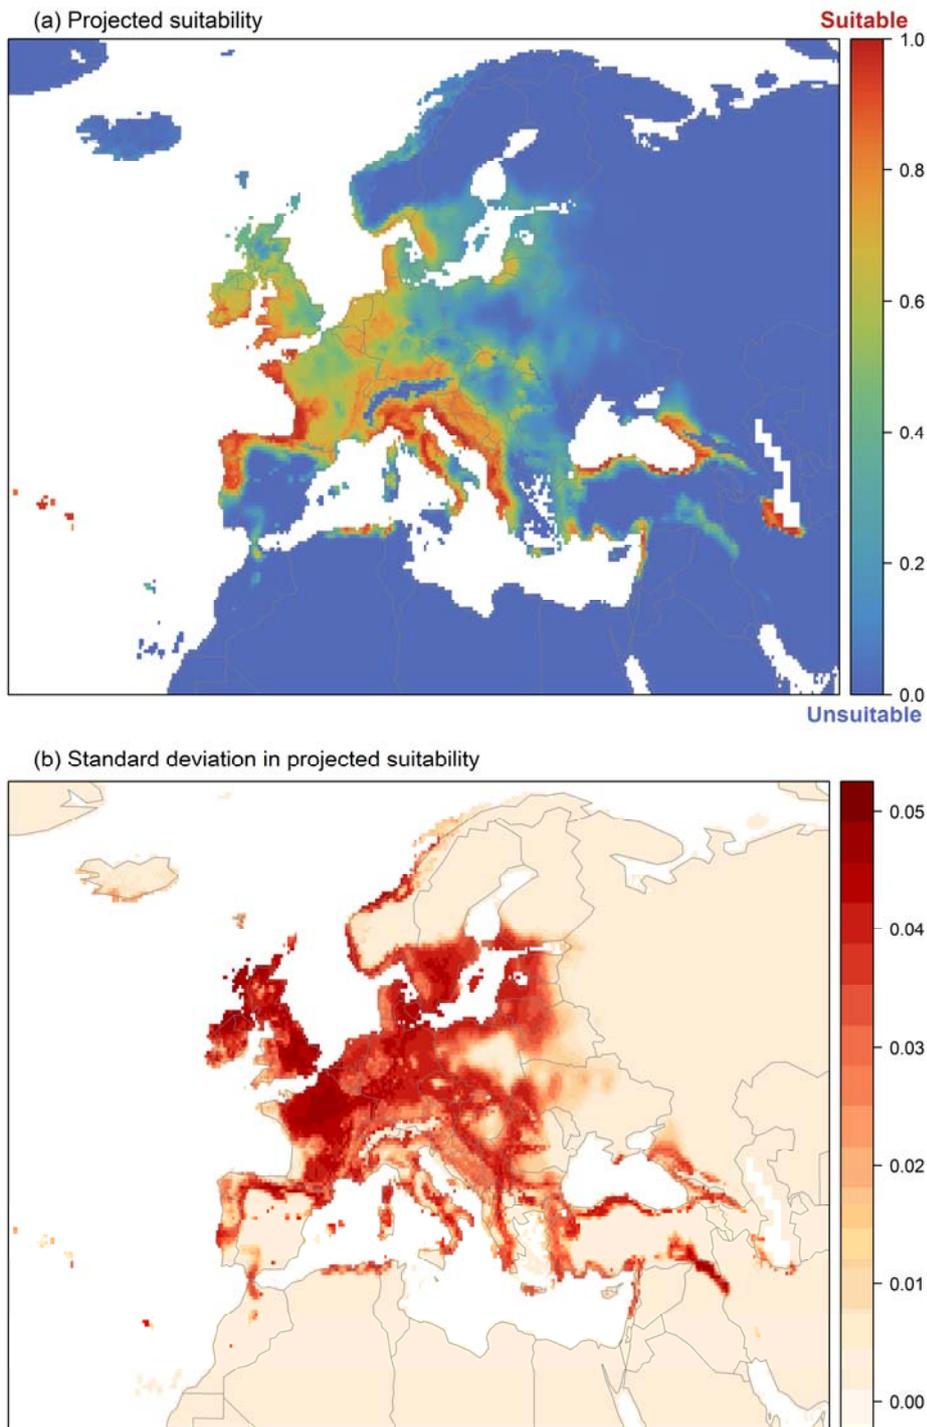

Page Break

**Figure 7.** (a) Projected suitability for *Marisa cornuarietis* establishment in Europe and the Mediterranean region in the 2070s under climate change scenario RCP2.6. Values > 0.69 are suitable for the species, with 98% of global presence records above this threshold under current climate. Values below 0.69 indicate lower relative suitability. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

Page Break

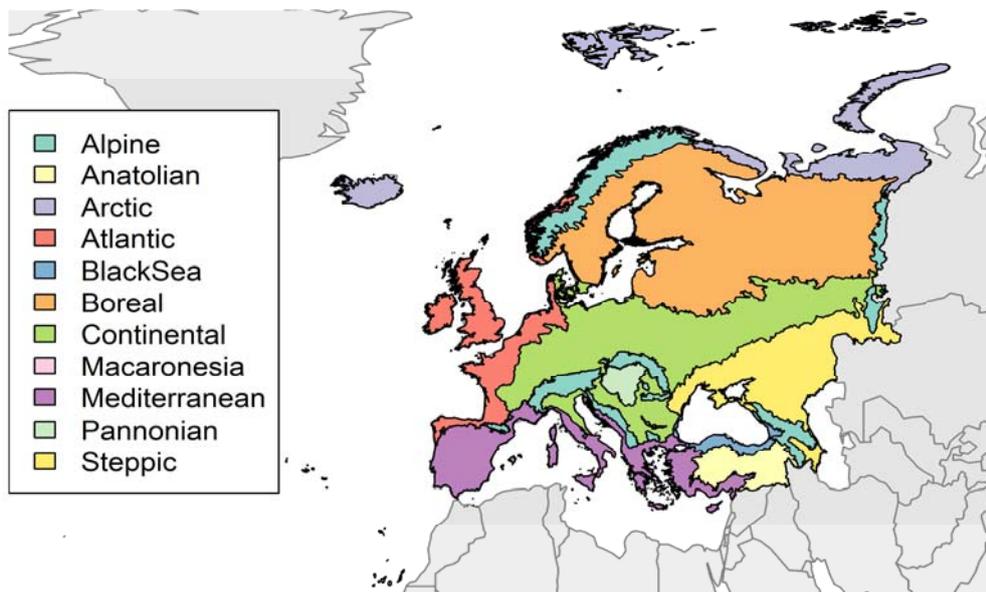

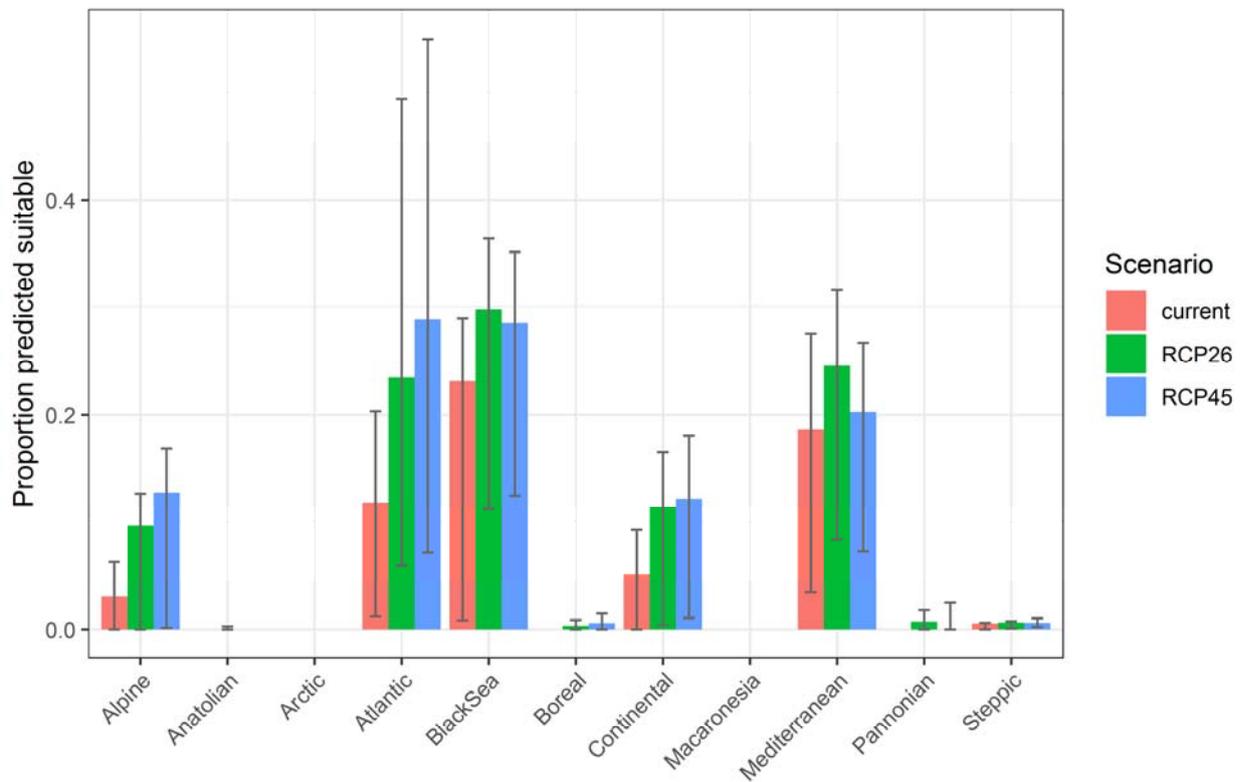

**Figure 8.** (a) Projected suitability for *Marisa cornuarietis* establishment in Europe and the Mediterranean region in the 2070s under climate change scenario RCP4.5. Values > 0.69 are suitable for the species, with 98% of global presence records above this threshold under current climate. Values below 0.69 indicate lower relative suitability. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

Page Break

**Figure 9.** Variation in projected suitability for *Marisa cornuarietis* establishment among Biogeographical Regions of Europe (<https://www.eea.europa.eu/data-and-maps/data/biogeographical-regions-europe-3>). The bar plots show the proportion of grid cells in each region classified as suitable (with values > 0.69) in the current climate and projected climate for the 2070s under two RCP emissions scenarios. Error bars indicate uncertainty due to both the choice of classification threshold (cf. p.5/6) and uncertainty in the projections themselves (cf. part (b) of

Figures 5, 7 and 8). The location of each region is also shown. The Arctic and Macaronesian regions are not part of the study area, but are included for completeness.

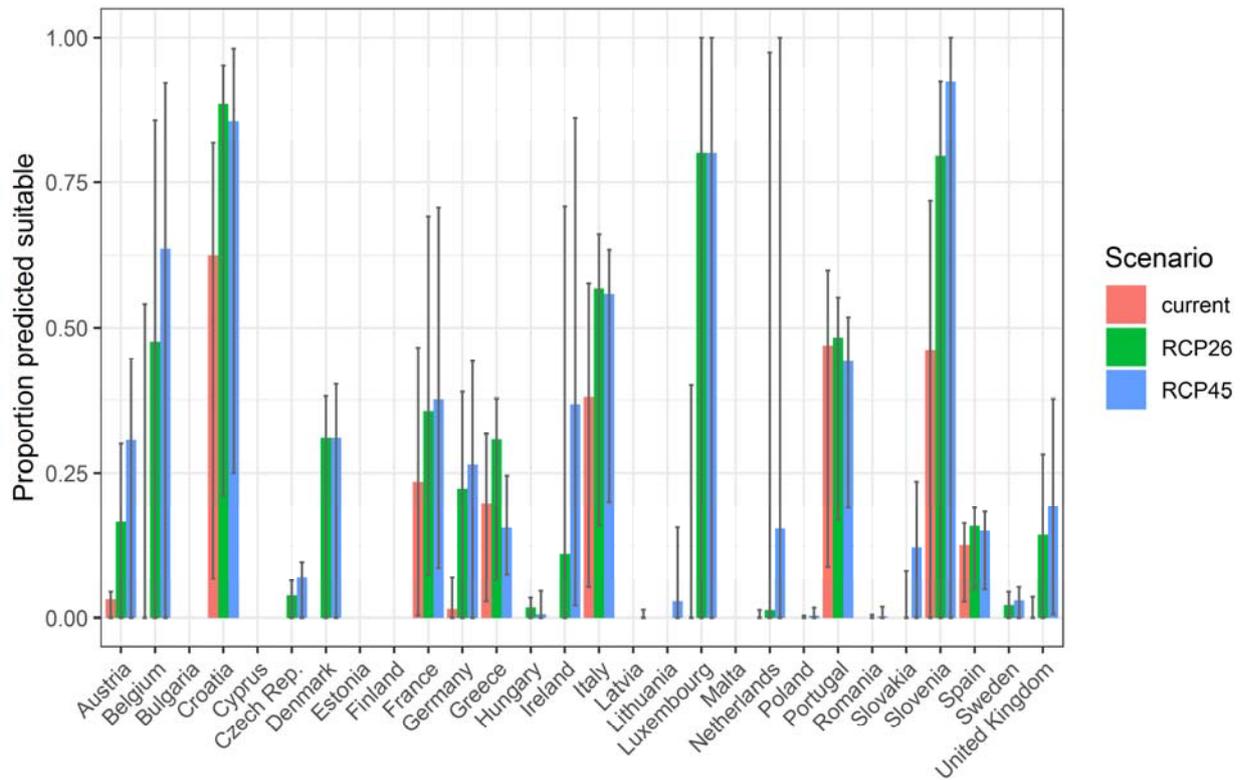

Page Break

**Table 2.** Variation in projected suitability for *Marisa cornuarietis* establishment among Biogeographical regions of Europe (numerical values of Figure 9 above). The numbers are the proportion of grid cells in each region classified as suitable in the current climate and projected climate for the 2070s under two RCP emissions scenarios. The Arctic and Macaronesian biogeographical regions are not part of the study area, but are included for completeness.

### *Caveats to the modelling*

The number of presence records available for modelling (118 at the model resolution) was low, and therefore the indication they provide of the species' environmental preferences may not be very comprehensive.

To remove spatial recording biases, the selection of the background sample from the accessible background was weighted by the density of Ampullariidae records on the Global Biodiversity Information Facility (GBIF). While this is preferable to not accounting for recording bias at all, it may not provide the perfect measure of recording bias.

There was substantial variation among modelling algorithms in the partial response plots (Figure 3). In part this will reflect their different treatment of interactions among variables. Since partial plots are made with other variables held at their median, there may be values of a particular variable at which this does not provide a realistic combination of variables to predict from.

Other variables potentially affecting the distribution of the species, such as types of land cover were not included in the model.

## Annex with evidence on measures and their implementation cost and cost-effectiveness

<b>Species (scientific name)</b>	<b><i>Marisa cornuarietis</i></b>
<b>Species (common name)</b>	<b>Giant Ramshorn Snail</b>
<b>Author(s)</b>	<b>Frances Lucy and Darren Garland</b>
<b>Reviewer</b>	<b>Elena Tricarico, Hugo Verreycken</b>
<b>Date Completed</b>	<b>15/10/2021</b>

### Summary<sup>1</sup>

Highlight of measures that provide the most cost-effective options to prevent the introduction, achieve early detection, rapidly eradicate and manage the species, including significant gaps in information or knowledge to identify cost-effective measures.

*Marisa cornuarietis* is a freshwater snail native to South America, inhabiting both open and closed water systems, is quite large in size with shell size in adults typically reaching 18-22 mm in height and 48-56 mm in diameter (Barkley 2019). In the RA area, *M. cornuarietis* has established in both Spain and Hungary (Frisóczki *et al.* 2016) with the Hungarian population isolated to an outflow downstream of a thermal spa. A significant proportion of the RA area is prone to the introduction of *M. cornuarietis* due to its ongoing use in the ornamental aquatic trade where introductions to both open and closed water bodies are likely from people discarding contents of aquaria (Arias & Torralba-Burrial 2014, Frisóczki *et al.* 2016, Pointier & David 2004). Legislation which aims to ban or restrict the importation and trade of this species and associated ornamental aquatic flora is one proposed measure to prevent the introduction of this invasive to natural water bodies (open and closed systems) in the RA. However, control of the internet trade for this aquarium pet indicates a low confidence in terms of managing the pathway.

Provision of information in a range of member state languages on *M. cornuarietis* could be provided for a range of stakeholders, initially targeting those involved in the aquatic ornamental trade and customer base. This is given a medium level of confidence.

Due to the widespread occurrence of the species in the pet trade, early detection of populations entered into the wild is important and can be achieved through regular monitoring and surveillance of watercourses where climatic and physiochemical parameters are suitable for its establishment. This early detection can be achieved in a cost-effective way, through incorporating surveillance of the species into already developed monitoring programmes such as the Water Framework Directive (2000/60/EC) and by other surveys carried out by academic researchers, MS agencies, NGOs and citizen scientists. This would provide a method of routinely monitoring open and closed water bodies to potentially detect recently introduced populations of *Marisa cornuarietis* and is considered medium in terms of effectiveness.

Like many freshwater species, eradication is only potentially feasible if the species is confined to a small, closed system such as a small lake or pond. If the species is widely established or present in an open water system then eradication is very unlikely to be achieved. There are no studies that describe the successful eradication of this species, or the similar *Pomacea canaliculata*. In terms of potential methods, larger specimens can be physically

removed. It is plausible that chemical control methods listed for *Pomacea canaliculata* could be utilised for *M. cornuarietis* given the similarities between species upon which the control mechanisms were applied. However, it is not known whether these would be effective, they would require permits/derogations and could only be utilized for small closed systems. Biological control measures to suppress numbers have been successful for the similar apple snail *Pomacea canaliculata*, using different ducks, both wild and domestic breeds, in rice fields (Vega et al. 1992; Teo. 2001) and this could be successful in controlling *M. cornuarietis* in closed and open water systems. Control in open water systems is considered unmanageable unless populations were restricted to a very small area. Confidence in all control methods is low as no research has been found on specific control and management of *M. cornuarietis*. No costings were available for treatment methods on *P. canaliculata*. Further research trialling control options on this species, either where it occurs in the RA area or in other invaded regions would be beneficial in developing tools which could then be utilised where established populations are occurring.

Detailed assessment			
	Description of measures <sup>2</sup>	Assessment of implementation cost and cost-effectiveness (per measure) <sup>3</sup>	Level of confidence <sup>4</sup>
<b>Methods to achieve prevention of intentional and unintentional introduction<sup>5</sup></b>	<p><b>Managing the pathways</b></p> <p><i>M. cornuarietis</i> is already present in the RA area, but we cannot discount the risk of further intentional and unintentional release of this species to the wild. This could be achieved through a ban of importation and trade of <i>M. cornuarietis</i> for the aquatic ornamental trade. Further action could involve banning the import and trade of aquatic plants, coming from areas where <i>M. cornuarietis</i> is established, as the species is known to hitchhike on aquatic plants, which can potentially result in their unintentional release to natural watercourses. Although the EU legislation for apple snails (2012/697/EU) provides legal</p>	<p>This species is popular as a pet snail for the aquatic ornamental trade, so a ban on importation could create some opposition from the public. Importation can still continue illegally via the internet trade even if a legal ban was imposed and therefore the supply to customers could continue.</p> <p>However, as there are other snail species that pose no or little risk available to the aquarium and live food trades, the ban of live sale of <i>M. cornuarietis</i> would have little or no economic impact. Costs of implementation could be kept to a minimum by utilising existing enforcement processes for other IAS species particularly for aquatic plants on which they hitchhike. Specific training in snail recognition should be provided for the aquatic ornamental trade so they can recognise this species. Implementation of legislation should be coupled with public awareness campaigns and spread of codes of conduct to be more effective. No literature was found regarding effectiveness of implementing the 2012 ban on <i>Pomacea</i> apple snail species in the RA area and in fact it is still for sale on some websites.</p>	<b>Low.</b>

	<p>measures to prevent the introduction into and the spread within the Union of the genus <i>Pomacea</i> (Perry) it does not include this apple snail (<i>M. cornuarietis</i>). Release of all apple snails to the wild has been prohibited in some member states in the RA area such as Spain (Arrias and Toralba-Burrial 2014)</p>		
	<p><b>Increasing public awareness</b>  Provision of information in a range of member state languages on <i>M. cornuarietis</i> could be provided for a range of stakeholders, initially targeting those involved in the aquatic ornamental trade and customer base.</p>	<p>Implementation of legislation should be coupled with targeted public awareness campaigns, e.g. codes of conduct for aquatic ornamental retailers and for purchasers. Effective communication of clear messages is essential to raise awareness of the real threat posed by IAS. Such communication should be centred on species, habitats and invasion biology (Caffrey et al. 2015) Campaigns to educate and increase awareness on IAS are an effective way to curb illegal introductions, especially those targeted at specific sectors. Public awareness campaigns, however, do need to be maintained so they do not drop out of the collective consciousness, but are also renewed periodically to avoid fatigue. Engagement with stakeholders involved in waterbody management and citizens to promote awareness of the potential impacts posed by the establishment of this species would potentially limit the extent of introductions. Cost for outreach such as seminars, codes of practice, and other awareness campaigns can be expensive particularly when translations into different Member State languages are considered. Design, translation and provision of leaflets and pdfs is estimated at 1,000 euro per language and can be produced approximately within three months.</p>	<p><b>Medium</b></p>

		There is no information available on the impact this measure would have in reducing introductions of <i>M. cornuarietis</i> .	
<b>Methods to achieve early detection<sup>6</sup></b>	<p><b>Effective surveillance and regulations</b></p> <p>In the RA area, molluscs are indirectly routinely monitored in some open and closed waters as part of the requirement of the Water Framework Directive. They may also be found during field studies by academics, NGOs or by citizen scientists. The species can be detected via direct searches (Barkley 2019) or through indirect sampling via kick sampling. Environmental DNA approaches could be also considered.</p>	<p>Routine monitoring personnel should be trained in identification, to increase potential for early detection and rapid response</p> <p>Identification training in freshwater IAS for citizen scientists and stakeholders involved in waterbody management that includes this species will also aid the early detection. Currently, there is no information available for costs of detecting <i>M. cornuarietis</i> in the RA area but if incorporated into existing water monitoring programmes or included with other IAS training for citizens and other stakeholders then costs would be significantly reduced in comparison to setting up individual monitoring programs.</p> <p>Monitoring is a low risk activity. Public opinion is likely to be supportive of early detection measures particularly if there is involvement via citizen science initiatives, for example bioblitzes.</p> <p>The traditional sampling methods may not be effective where low densities of the species are present, while environmental DNA approaches may be a suitable alternative for detecting if the species is present in a waterbody when low densities occur (Darling and Mahon 2011). Costings for eDNA approaches are approximately between 30 and 50 euro per sample, including eDNA extraction, inhibition test, and qPCR of one target species. The above includes laboratory labour (but not field work) and it assumes that a species specific eDNA (qPCR) assay has already been developed for the target organism/environment/geographic area. There is no information in relation to specific monitoring programs for the detection of this invasive in the RA area but this could relate to limited spread and in fact successful detection has been undertaken for this species in the USA where spread has been across a number of states (Howells et al. 2006) Citizen science campaigns have been found effective in detecting new</p>	<b>Medium.</b>

		<p>aquatic IAS in the RA area. Those involved in detection should ensure boots and equipment are disinfected to assure biosecurity and prevent spread of any aquatic IAS between waterbodies. Once this is in place, there is no perceived environmental harm or environmental cost involved in these methods.</p>	
<p><b>Methods to achieve eradication<sup>7</sup></b></p>	<p><b>Chemical removal</b></p>	<p>Like many freshwater species, eradication is only potentially feasible if the species is confined to a small, closed system such as a small lake or pond. If the species is widely established or present in an open water system then eradication is very unlikely to be achieved. There are no studies that describe the successful eradication of this species, or of the similar <i>Pomacea canaliculata</i>.</p> <p>Chemical controls utilising molluscicides over several years can potentially eradicate the species, but 100% mortality has been noted to be difficult due to differential susceptibility of individuals in populations (Barkley 2019).</p> <p>One old study suggests that a concentration of 0-03 Frescon (N-tritylmorpholine) is applied for at least four days to a closed water body to control this species (Meier-Brook and Tjhen 1977) however this product appears to be no longer on the market.</p> <p>Tributyltin (TBT) has previously been shown to be effective as a control agent (Lyssimachou et al 2009) but this is now a banned substance in the RA and more widely.</p> <p>In South East Asia, chemical control for <i>Pomacea canaliculata</i> has been achieved with the use of two approved synthetic molluscicides, niclosamide and metaldehyde (Schnorbach et al. 2006). These compounds are likely to have negative impacts on the environment. It is not known if these compounds could be used for management of <i>M. cornuarietis</i> in the RA area and their use would likely be restricted to closed systems only and require permits from relevant agencies in MS. Public acceptance of chemical methods could be low. Health and Safety measures are required for safe usage of chemicals.</p>	<p><b>Low</b></p>

		<p>significant reduction in pest density from 5 snails m<sup>-1</sup> to less than 1 snail m<sup>-1</sup> consuming equally well under low and high pest population densities. Therefore, potential exists to use ducks to control <i>M. cornuarietis</i> in closed and possibly open waters. Implementation cost would be low as existing duck populations could be utilised. Acceptance by stakeholders is perceived to be high, and environmental harm low as ducks are a normal feature of wetland systems. Risk of harm to humans would be extremely low.</p>

## Guidelines for Completing the Annex

1 Provide a brief summary description of the most cost-effective methods drawing on the reviews in the detailed assessments

2 Provide a description of the potential method. This should be based on the available key scientific evidence which should be gathered from sources including articles and reviews in technical and scientific journals, internet searches, online databases, grey literature and relevant books and personal communications from scientists, stakeholders, conservation practitioners and governmental bodies. This information should include a full bibliographic list detailing the literature and sources considered.

3 Provide an assessment of the likely cost and effectiveness of the method. Where information is available, consider the following range of questions, accepting that not all questions will be appropriate in all circumstances.

- How effective has this approach proven to be in the past or in an analogous situation?
- How publically acceptable is the approach likely to be?
- Over what period of time would this approach need to be applied to be effective?
- What is the direct cost of implementing this approach?
- How likely are the methods used in the approach to be available?
- How likely is it that relevant licences or other approvals to undertake the approach would be difficult to obtain?
- How likely is it that health and safety issues would prevent the use of this approach?
- How significant is the environmental harm caused by this approach?
- How significant is the economic harm caused by this approach?
- How significant is the social harm caused by this approach?
- How likely is it that the approach will be criticised on welfare grounds?
- How likely is it that the approach will be acceptable to other stakeholders?

Where available, factual information on the costs of specialist equipment, or case studies of management costs from across the Union or third countries should be provided. When describing case studies, if the information is available then provide both total cost and the area over which control was undertaken so that a cost per unit area might be derived. Where such quantitative information is not available, then any qualitative information from the literature is acceptable to help guide decision making. It is accepted that in the majority of cases the information required to assess the potential total cost of management at a member state level is unlikely to be available. This would normally require information on the extent and abundance of the species which is beyond the scope of this assessment. Assessors are not expected to extrapolate the potential total costs of management at a member state level, only to report on the information provided within the literature.

4 Provide an overall assessment of the confidence that can be applied to the information provided for this method. This confidence should relate to the quality of the available information using the guidance below. It should NOT relate to the confidence in the effectiveness of the method

The confidence scores are:

- **High:** Information comes from published material, or current practices based on expert experience applied in one of the EU countries or third country with similar environmental, economic and social conditions.
- **Medium:** Information comes from published data or expert opinion, but it is not commonly applied, or it is applied in regions that may be too different from Europe (e.g. tropical regions) to guarantee that the results will be transposable.
- **Low:** data are not published in reliable information sources and methods are not commonly practiced or are based solely on opinion; This is for example the case of a novel situation where there is little evidence on which to base an assessment.

If there are further factors beyond these that have determined the chosen level of confidence, then provide a brief written description to support the choice of the level of confidence.

5 Measures for preventing the species being introduced intentionally or unintentionally into the territory of a Member State (cf. Articles 7(1)(a), 7(2), 13, 15), i.e. preventing a species entering by blocking its pathways, including pre-border prevention and prevention of escape or release into the environment and secondary spread whenever relevant. Measures for preventing the species reproducing while in containment should be included, if appropriate. Consider all methods that might be applied, including any that have not proven useful. Provide a description of each method in turn, using separate rows to consider each method.

6 Measures to run an effective surveillance system for achieving an early detection of a new occurrence (cf. Article 16). This section assumes that the species is not currently present in a Member State, or part of a Member State's territory.

7 Measures to achieve eradication. Preferably, but not exclusively, used at an early stage of invasion, after an early detection of a new occurrence (cf. Article 17). Consider all methods that might be applied, including any that have not proven useful. Provide a description of each method in turn, using separate rows to consider each method.

8 Measures to achieve management of the species once it has become widely spread within a Member State territory (cf. Article 19). These measures can be aimed at eradication, population control or containment of a population of the species. Consider all methods that might be applied, including any that have not proven useful. Provide a description of each method in turn, using separate rows to consider each method.

The development and completion of this template forms part of the EU project **No 07.0202/2020/834529/ETU/ENV.D.2** Study on Invasive Alien Species – Development of risk assessments to tackle priority species and enhance prevention.

**Risk assessment template developed under the "Study on Invasive Alien Species – Development of risk assessments to tackle priority species and enhance prevention"  
Contract No 07.0202/2020/834529/ETU/ENV.D.2<sup>1</sup>**

**Name of organism:** *Mulinia lateralis* (Say, 1822)

**Author(s) of the assessment:**

Christine A. Wood, The Marine Biological Association, Plymouth, UK

Marika Galanidi, Dr, Ustun Energy Engineering Ltd, Izmir, Turkey

Björn Beckmann, Dr, Centre for Ecology & Hydrology, Edinburgh, UK

**Risk Assessment Area:** The risk assessment area is the territory of the European Union 27 and the United Kingdom, excluding the EU-outermost regions.

**Peer review 1:** Argyro Zenetos, Hellenic Centre for Marine Reseach, Anavyssos, Greece

**Peer review 2:** Francis Kerckhof, Royal Belgian Institute of Natural Sciences (RBINS), Oostende, Belgium

**Date of completion:** 15/10/2021

---

<sup>1</sup> This template is based on the Great Britain non-native species risk assessment scheme (GBNNRA). A number of amendments have been introduced to ensure compliance with Regulation (EU) 1143/2014 on IAS and relevant legislation, including the Delegated Regulation (EU) 2018/968 of 30 April 2018, supplementing Regulation (EU) No 1143/2014 of the European Parliament and of the Council with regard to risk assessments in relation to invasive alien species (see <https://eur-lex.europa.eu/legal-content/en/TXT/?uri=CELEX%3A32018R0968>).

## SECTION A – Organism Information and Screening

**A1. Identify the organism. Is it clearly a single taxonomic entity and can it be adequately distinguished from other entities of the same rank?**

including the following elements:

- the taxonomic family, order and class to which the species belongs;
- the scientific name and author of the species, as well as a list of the most common synonym names;
- names used in commerce (if any)
- a list of the most common subspecies, lower taxa, varieties, breeds or hybrids

As a general rule, one risk assessment should be developed for a single species. However, there may be cases where it may be justified to develop one risk assessment covering more than one species (e.g. species belonging to the same genus with comparable or identical features and impact). It shall be clearly stated if the risk assessment covers more than one species, or if it excludes or only includes certain subspecies, lower taxa, hybrids, varieties or breeds (and if so, which subspecies, lower taxa, hybrids, varieties or breeds). Any such choice must be properly justified.

Response: This risk assessment covers one species: *Mulinia lateralis* (Say, 1822)

**Phylum:** Mollusca, **Class:** Bivalvia, **Order:** Venerida, **Family:** Mactridae

**Synonyms:** *Mactra lateralis* Say, 1822  
*Mactra rostrata* Philippi, 1849

**Common names:** Dwarf surf clam (EN), Mactre naine (FR), Amerikaanse strandschelp (NE), Amerikanische Trogmuschel, Zwergbrandungsmuschel (DE), Coot clam (US), Little surf clam (US).

Figure 1: Key morphological identification characteristics of *Mulinia lateralis*: (A) the outside of the valves with the radial ridge and (B) the anterior cardinal tooth, which is parallel to the edge of the shell, and the non-serrated lateral teeth. Photos by Koen Lock, and published on Waarnemingen.be

Figure 2: Photo by Vlaams Instituut voor de Zee (VLIZ).

**A2. Provide information on the existence of other species that look very similar [that may be detected in the risk assessment area, either in the environment, in confinement or associated with a pathway of introduction]**

Include both native and non-native species that could be confused with the species being assessed, including the following elements:

- other alien species with similar invasive characteristics, to be avoided as substitute species (in this case preparing a risk assessment for more than one species together may be considered);
- other alien species without similar invasive characteristics, potential substitute species;
- native species, potential misidentification and mis-targeting

Response: *Mulinia lateralis* is a small bivalve in the family Mactridae. The shells are triangular, distinctly convex, thin, and smooth with very fine concentric lines. The exterior of the shell is white to cream with a thin yellowish-orange periostracum, while the interior is bright white. It has a radial ridge along the posterior end of the valves, and a distinctly broad cardinal area between the beaks in larger specimens. It does not have an externally visible ligament. Adults are approximately 15 to 20 mm in length (but note – in The Netherlands shell lengths ranged from less than 7 mm to 21.2 mm), while newly metamorphosed juvenile shell lengths are 200 to 700 µm.

Similar species: *Mulinia lateralis* is most likely to be confused with native juvenile *Spisula subtruncata*, juvenile *Macra stultorum* or non-native juvenile *Rangia cuneata* (Vermeen et al., 2006; Kerckhof, 2019; Craeymeersch et al., 2019). *Macra stultorum* has an oval shell, no radial ridge, a thin visible external ligament, and no fine concentric growth lines. *Spisula subtruncata* has no radial ridge, a thin visible external ligament, and a brown periostracum. *Rangia cuneata* has distinctly inequilateral shells, an umbo that curves markedly towards the anterior, and a pale brown periostracum, in adults the shell is thick and heavy. Craeymeersch et al. (2019) provides more detail of the main morphological differences between these species, and a key to all species of the subfamily Mactrinae of the NE Atlantic, including the non-native *Rangia cuneata*.

Other possible native confusion species could be *Spisula solida* (F. Kerckhof, pers. comm., 17<sup>th</sup> August 2021), *S. elliptica* (M. Willing, Conchological Society of Great Britain and Ireland, pers. comm. 25<sup>th</sup> February 2021), although this species lives further offshore, and juvenile *Mercenaria mercenaria* (Lippson & Lippson, 2006).

DNA based identification is also possible (Craeymeersch et al., 2019; Klunder et al., 2019), and the complete mitochondrial genome is available (Liu et al., 2020).

**A3. Does a relevant earlier risk assessment exist? Give details of any previous risk assessment, including the final scores and its validity in relation to the risk assessment area.**

Response: No formal risk assessment has been carried out.

In the UK, *Mulinia lateralis* was included in the latest Horizon Scanning exercise for invasive alien species carried out in 2019 (Roy et al., 2019). It was rated in the top four marine species when combining likelihood of arrival, establishment, and impact on biodiversity. It is included in the MSFD UK priority surveillance list (MSFD UK, 2021). A risk assessment for Great Britain is in development (C. A. Wood, in prep.).

#### A4. Where is the organism native?

including the following elements:

- an indication of the continent or part of a continent, climatic zone and habitat where the species is naturally occurring
- if applicable, indicate whether the species could naturally spread into the risk assessment area

Response: *Mulinia lateralis* is native to the Western Atlantic, encompassing the Temperate North West Atlantic to the Tropical Western Atlantic (Spalding et al., 2007). Its range extends continuously from the Gulf of St Lawrence, Canada; along the eastern coast of the United States (US); and Mexico as far as the Yucatan peninsula, at the southeastern edge of the Gulf of Mexico (Verrill, 1879; Calabrese et al., 1970; Turgeon et al., 2009; GBIF, 2021; OBIS, 2021).

It is widely reported from bays along the Atlantic coast of the US, in a wide range of salinities, from 5 to 80 psu; where it appears to be a mainly estuarine species (Craeymeersch et al., 2019 and references therein). In the Gulf of Mexico, *M. lateralis* is reported from coastal lagoons, which can experience hypersaline conditions during droughts (González-Solis et al., 2018) and offshore banks (Turgeon et al., 2009).

This species prefers soft sediments, such as mud and sand, within the low intertidal and shallow subtidal zones (Snelgrove et al., 1993; Klunder et al., 2019). Although it is also found on offshore banks and shoals (Aller, 1912; Turgeon et al., 2009); Turgeon et al. (2009) report it occurring at depths of up to 134 m in the Gulf of Mexico.

Figure 3: Occurrence records of *M. lateralis* in the native (red) and invaded (blue) range. Data points retrieved from the literature, biodiversity databases and screened as explained in Qu. A4-A6 and the modelling Annex (Annex IX). Map created by Bjorn Beckmann for the purposes of this RA.

**A5. What is the global non-native distribution of the organism outside the risk assessment area?**

Response: None. *Mulinia lateralis* has only been reported as non-native from within the risk assessment area. GBIF (2021) shows a record from the west coast of the US, but the geographical coordinates do not match with the location described as being in Campeche, in the Gulf of Mexico.

**A6. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species been recorded and where is it established? The information needs to be given separately for recorded (including casual or transient occurrences) and established occurrences. “Established” means the process of an alien species successfully producing viable offspring with the likelihood of continued survival<sup>2</sup>.**

**A6a. Recorded: List regions**

**A6b. Established: List regions**

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

- Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea.

Comment on the sources of information on which the response is based and discuss any uncertainty in the response.

For delimitation of EU biogeographical regions please refer to <https://www.eea.europa.eu/data-and-maps/figures/biogeographical-regions-in-europe-2> (see also Annex VI).

For delimitation of EU marine regions and subregions consider the Marine Strategy Framework Directive areas; please refer to <https://www.eea.europa.eu/data-and-maps/data/msfd-regions-and-subregions/technical-document/pdf> (see also Annex VI).

Response (6a): Greater North Sea, incl. the Kattegat and the English Channel.

*Mulinia lateralis* was first discovered in this subregion in 2017 (Craeymeersch et al., 2019). It has been recorded from the southeastern part of the subregion, from The Netherlands, Germany and Belgium (Craeymeersch et al., 2019; Klunder et al., 2019; Kerckhof, 2019). The identity of specimens from The

<sup>2</sup> Convention on Biological Diversity, Decision VI/23

Netherlands and Germany have been confirmed by DNA analysis (Craeymeersch et al., 2019; Klunder et al., 2019). For more details on the locations within each country, see response to Qu. A8a.

Response (6b): Greater North Sea, incl. the Kattegat and the English Channel.

*Mulinia lateralis* is considered established in The Netherlands (Craeymeersch et al., 2019; Klunder et al., 2019), Germany and Belgium, see response to Qu. A8b for more details. It has been found at multiple locations within The Netherlands, sometimes at high densities, and it has been recorded every year from 2017 to 2021. As *M. lateralis* has a maximum life-span of only two years this indicates that reproduction is occurring (Calabrese, 1969b). In 2017, dense populations of up to almost 6000 ind. m<sup>2</sup> were recorded from the Voordelta (southwestern Dutch coastal waters) and again in 2018 at densities of 1000 ind. m<sup>2</sup> (Craeymeersch et al., 2019). In 2017, *M. lateralis* was reported from sites in the Eems-Dollard estuary spanning the Dutch and German parts of the Wadden Sea (Klunder et al., 2019). It was recorded there again in 2018 (Craeymeersch et al., 2019; Klunder et al., 2019), and 2019 (GBIF, 2021). In 2018, it was found in the western part of the Dutch Wadden Sea (Craeymeersch et al., 2019; GBIF, 2021). In 2018, *M. lateralis* was recorded at high density (820 ind. m<sup>2</sup>) in the Westerschelde (Craeymeersch et al., 2019). Subsequently, in 2019, it was recorded there at 18/44 sites sampled, at an average of five ind. m<sup>2</sup> (Walles et al., 2020). *M. lateralis* has been reported from multiple sites, all along the Belgian coast.

**A7. In which biogeographic region(s) or marine subregion(s) in the risk assessment area could the species establish in the future under current climate and under foreseeable climate change? The information needs to be given separately for current climate and under foreseeable climate change conditions.**

**A7a. Current climate: List regions**

**A7b. Future climate: List regions**

With regard to EU biogeographic and marine (sub)regions, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

Response (7a): The response is based on combining physiological tolerances and the results from the distribution modeling (see Qu. 2.1, Qu. 2.9 and Annexes VIII & IX for details). For purposes of mapping and assessing the risk of establishment, the following tolerance limits were defined:

- Average surface temperature of the warmest month > 15 °C
- Average surface temperature of the warmest month < 32.5 °C
- Minimum surface salinity > 12.5 psu

Baltic Sea: moderately likely, low confidence (western part)

Greater North Sea: very likely, high confidence

Celtic Seas: moderately likely, medium confidence

Bay of Biscay and the Iberian coast: likely, medium confidence

Mediterranean Sea: likely, medium confidence

Black Sea: moderately likely, medium confidence

*Mulinia lateralis* is expected to exhibit boom and bust dynamics in Atlantic Europe, where conditions will limit spawning and recruitment to the summer months. An abundance of suitable habitats (estuaries, extensive intertidal and subtidal seabed areas) will make widespread establishment likely. In the Mediterranean Sea, should the species be introduced there, wide establishment is more likely to take place in the western part of the basin which receives higher freshwater discharges, while the more arid eastern Mediterranean contains a lower number of highly suitable habitats, which are mostly concentrated in the northern Aegean. Nevertheless, because climatic conditions there are favourable for larval development throughout most of the year, it is more likely that populations will become more stable and dominant members of the macrobenthos. The Baltic Sea only offers salinity conditions suitable for establishment in its westernmost part. Establishment is also considered possible in the Black Sea, although low winter temperatures are likely to limit reproduction to the warmer months of the year.

Response (7b): The response is based on combining physiological tolerances and the results from the distribution modeling (see Qu. 2.1, Qu. 2.9 and Annexes VIII & IX for details). Aspects of climate change most likely to affect future distribution were considered as an increase in minimum and maximum Sea Surface Temperatures (SST). The methodology for the developed models is described in Annex IX and considers scenarios RCP 2.6 and RCP 4.5 by 2070. See also Qu. 2.10.

Baltic Sea: moderately likely, low confidence (western part)

Greater North Sea: very likely, high confidence

Celtic Seas: likely, medium confidence

Bay of Biscay and the Iberian coast: likely, medium confidence

Mediterranean Sea: likely, medium confidence

Black Sea: moderately likely, medium confidence

The species distribution model (SDM) predicted a small reduction in projected suitability for *M. lateralis* for the Mediterranean Sea and a corresponding increase for the North-East Atlantic marine subregions under future climate change and, consequently, a small northward shift of the overall suitable area for the species. An increase in sea surface temperature will offer suitable conditions for spawning and larval development for prolonged periods throughout the whole of Atlantic Europe and is predicted to extend its potential range further north along the coast of northern England, Scotland and Ireland. Suitable conditions in the Mediterranean are likely to become even more restricted spatially and temporally, rendering establishment in this marine subregion more localized, especially in the east and south.

Note: Even though the SDM takes into account salinity variability in the form of distance from river mouths, a future scenario for river discharge was not taken into account and would take very elaborate

data processing to bring into the model. It is anticipated that extreme weather phenomena, like droughts and storms/flooding, will be more frequent and intense under future climate conditions and this will increase the uncertainty of predictions as well as the population fluctuations of *M. lateralis*.

**A8. In which EU Member States has the species been recorded and in which EU Member States has it established? List them with an indication of the timeline of observations. The information needs to be given separately for recorded and established occurrences.**

**A8a. Recorded: List Member States**

**A8b. Established: List Member States**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden.

The description of the invasion history of the species shall include information on countries invaded and an indication of the timeline of the first observations, establishment and spread.

Response (8a):

**Belgium:** *Mulinia lateralis* was first identified in January 2019 from washed up shells from a beach between Oostende and De Haan (Kerckhof, 2019). In February 2019, sixty-four live specimens were found offshore of De Haan (Waarnemingen, 2021), with subsequent reports of live clams from Heist, De Haan and Zeebrugge. There is a large population present in the port of Zeebrugge (F. Kerckhof, pers. comm. 17<sup>th</sup> August 2021).

**Germany:** This species was first reported from the German area of the Eems-Dollard estuary within the Wadden sea in 2017 and again in 2018 (Klunder et al., 2019). It has not been recorded from elsewhere in Germany.

**The Netherlands:** In 2017, *M. lateralis* was first discovered in the Voordelta (Dutch coastal waters) (Craeymeersch et al., 2019). Also in 2017, it was reported from sites in the Eems-Dollard estuary within the Dutch Wadden Sea (Craeymeersch et al., 2019; Klunder et al., 2019). Additionally in 2018, it was found in the western part of the Dutch Wadden Sea (Craeymeersch et al., 2019; GBIF, 2021) and in the Westerschelde (Craeymeersch et al., 2019).

Response (8b):

**Belgium:** All the records of live *Mulinia lateralis* from Belgium are from citizen science records, however many have been verified and are accompanied by high quality images. Although only recorded from Belgium over the last two years, it has been reported from multiple sites, all along the Belgian coast. It was first identified in Belgium in January 2019 from washed up shells from a beach between Oostende and De Haan (Kerckhof, 2019). In February 2019, sixty-four live specimens were found offshore of De Haan (Waarnemingen, 2021), with subsequent reports of live clams from Heist, De Haan and Zeebrugge. In 2020, there are records from multiple sites along the whole of the Belgian coast from Knokke to De Panne (on the border with France) (Waarnemingen, 2021).

**Germany:** *M. lateralis* was first reported from two sites, referred to as Ems-Krummhörn, in the German part of the Eems-Dollard estuary within the Wadden sea in 2017, and from one of the same sites again in 2018 (Klunder et al., 2019). It has not been recorded from elsewhere in Germany. However, its continued presence throughout the Dutch part of the Eems-Dollard estuary has been recorded from 2017 to 2019 (Craeymeersch et al., 2019; Klunder et al., 2019; GBIF, 2021), longer than the species' maximum life-span of two years (Calabrese, 1969b), so it can be presumed that it is also established in the German part.

**The Netherlands:** *M. lateralis* is considered established in The Netherlands (Craeymeersch et al., 2019; Klunder et al., 2019). It has been found at multiple locations, in high densities at some localities, and recorded every year from 2017 to 2021. As *M. lateralis* has a maximum life-span of only two years this indicates that reproduction is occurring (Calabrese, 1969b). In 2017, dense populations of up to almost 6000 ind. m<sup>2</sup> were recorded from the Voordelta (Dutch coastal waters) (Craeymeersch et al., 2019). It was found there again in 2018 at densities of 1000 ind. m<sup>2</sup> (Craeymeersch et al., 2019). In 2017, it was reported from sites in the Eems-Dollard estuary in the Dutch part of the Wadden Sea (Klunder et al., 2019). It was recorded from multiple sites again in 2018 (Craeymeersch et al., 2019; Klunder et al., 2019), and 2019 (GBIF, 2021). In 2018, it was found in the western part of the Dutch Wadden Sea (Craeymeersch et al., 2019, GBIF, 2021). In 2018 it was recorded at high density (820 ind. m<sup>2</sup>) in the Westerschelde (Craeymeersch et al., 2019). Subsequently, in 2019, it was recorded at 18/44 sites sampled in the estuary, at an average density of five ind. m<sup>2</sup> (Wallis et al., 2020). In 2020 it was recorded at multiple sites along the Dutch coastal zone and estuaries as well as the Dutch part of the Wadden Sea (Troost et al., 2021).

**A9. In which EU Member States could the species establish in the future under current climate and under foreseeable climate change? The information needs be given separately for current climate and under foreseeable climate change conditions.**

**A9a. Current climate: List Member States**

**A9b. Future climate: List Member States**

With regard to EU Member States, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

Response (9a): The Species Distribution Model outlined in Annex IX provides a projection of environmental suitability for *Mulinia lateralis* establishment in Europe. According to the model the species could establish in Belgium, Bulgaria, Croatia, Denmark, France, Germany, Greece, Italy, Netherlands, Slovenia, and Spain, and also in the non-member state the United Kingdom.

Along the Portuguese coast seasonal upwellings result in relatively low summer temperatures (Vidal et al., 2007) and cause a reduction in the overall GDD (Growing Degree Days, see Annex IX for details), which emerges as the limiting factor for establishment in the model. This effect however is less pronounced towards the south of the country, where late summer temperatures are well above the minimum needed for establishment (Silva et al., 2009). Furthermore, we expect that at a finer scale the lagoons and estuaries will be warmer and shallower than indicated by the model, and thus Portugal would also be suitable for establishment.

Response (9b): Belgium, Bulgaria, Croatia, Denmark, France, Germany, Greece, Italy, Netherlands, Portugal, Romania, Slovenia, Spain, and Sweden, and also in the non-member state the United Kingdom.

The response to 9b is based on the RCP 4.5 scenario for the period 2050/2070. The aspect of climate change most likely to affect the organism's ability to establish is an increase in winter sea surface temperatures. Higher winter temperatures in Atlantic Europe will favour larvae for longer periods and at higher latitudes (see Annexes VIII & IX for details on modelling and future climate conditions in the RA area).

**A10. Is the organism known to be invasive (i.e. to threaten or adversely impact upon biodiversity and related ecosystem services) anywhere outside the risk assessment area?**

Response: No. *Mulinia lateralis* has not been reported as present anywhere other than within its native range, or the risk assessment area.

**A11. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea

Response: Greater North Sea, incl. the Kattegat and the English Channel.

*Mulinia lateralis* was only first recorded as an introduced species in The Netherlands and Germany in 2017 (Craeymeersch et al., 2019; Klunder et al., 2019), although Klunder et al. (2019) suggest that it probably arrived in 2016. With such a recent arrival, it is not yet possible to determine if it will be invasive in the long term. However, Craeymeersch et al. (2019) considered it potentially invasive due to its ability to rapidly colonize defaunated areas, its high fecundity, short generation time, planktonic larvae, and its tolerance for anoxia and temperature extremes. In the Voordelta, dense settlements of up to 6000 ind. m<sup>2</sup> have been recorded. In its native range it can become dominant when conditions are optimal, achieving average densities as high as 21,000 ind. m<sup>2</sup> (Santos & Simon, 1980; Chalermwat et al., 1991). Klunder et al. (2019) state that *M. lateralis* seems to have become a successful invader in the Dutch Wadden Sea, with fast spread to all suitable areas there to be expected, given the current rate of spread since its first detection. This species has now, within just four years of its arrival, spread to over 450 km of coast from the Eems-Dollard estuary on the German/Dutch border, to De Panne on the Belgian/French border. In the Westerschelde, in 2019, it was recorded at 18/44 sites sampled (Wallis et al., 2020). Potential environmental impacts of this species are discussed by Craeymeersch et al. (2019), including competition for space with native benthic species, and food with other filter-feeding organisms. Other potential impacts include the introduction and/or spread of parasites e.g. *Perkinsus* spp.

In its native range, *M. lateralis* frequently undergoes population crashes due to a variety of causes including starvation, predation, hypoxia, very low salinities events, or physical displacement from trawls or storm disturbance (Santos & Simon, 1980; Shumway & Newell, 1984; Powell et al., 1986; Cleveland, et al., 2002; de Buron et al., 2013). Such mass die-offs of bivalves are known to influence abiotic factors that negatively affect other organisms in the ecosystem (Cherry et al., 2005; Cooper et al., 2005), however no such phenomena have been observed or studied in the RA area to date.

**A12. In which EU Member States has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden.

Response: The Netherlands.

*Mulinia lateralis* was only first recorded as an introduced species in The Netherlands in 2017 (Craeymeersch et al., 2019; Klunder et al., 2019), although Klunder et al. (2019) suggest that it probably arrived in 2016. With such a recent arrival, it is not yet possible to determine if it will be invasive in the long term. However, Craeymeersch et al. (2019) considered it potentially invasive due to its ability to rapidly colonize defaunated areas, its high fecundity, short generation time, planktonic larvae, and its tolerance for anoxia and temperature extremes. In the Voordelta, dense settlements of up to 6000 ind. m<sup>2</sup> have been recorded. In its native range it can become dominant when conditions are optimal, achieving average densities as high as 21,000 ind. m<sup>2</sup> (Santos & Simon, 1980; Chalermwat et al., 1991). This species has now, within just four years of its arrival, spread to many areas of the Netherlands including the Voordelta, the Eems-Dollard estuary, the western part of the Dutch Wadden Sea, and the Westerschelde. Klunder et al. (2019) states that *M. lateralis* seems to have become a successful invader

in the Dutch Wadden Sea, with fast spread to all suitable areas there to be expected, given the current rate of spread since its first detection. In the Westerschelde, in 2019, it was recorded at 18/44 sites sampled (Wallès et al., 2020). See Qu. A11 and Magnitude of Impact section for potential impacts.

**A13. Describe any known socio-economic benefits of the organism.**

including the following elements:

- Description of known uses for the species, including a list and description of known uses in the risk assessment area and third countries, if relevant.
- Description of social and economic benefits deriving from those uses, including a description of the environmental, social and economic relevance of each of those uses and an indication of associated beneficiaries, quantitatively and/or qualitatively depending on what information is available.

If the information available is not sufficient to provide a description of those benefits for the entire risk assessment area, qualitative data or different case studies from across the risk assessment area or third countries shall be used, if available.

Response: Due to its small size, short generation time, and ease of culture and maintenance, *Mulinia lateralis* is considered potentially important as a model species for bivalve development, genetic and transgenic studies (Calabrese, 1969b; Liu et al., 2020; Yang et al., 2021). It has been used extensively in marine pollution bioassays (His et al., 1999; Cripe, 2006). Within its native range, *M. lateralis* is considered important for recreational hunting and fishing as it provides a food source for birds and fish (Kennedy & Mihursky, 1971; Mendenhall, 2015).

## SECTION B – Detailed assessment

### Important instructions:

- In the case of lack of information the assessors are requested to use a standardized answer: “No information has been found.” In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable).
- With regard to the scoring of the likelihood of events or the magnitude of impacts see Annexes I and II.
- With regard to the confidence levels, see Annex III.
- Highlight the selected response score and confidence level in **bold** but keep the other scores in normal text (so that the selected score is evident in the final document).

## 1 PROBABILITY OF INTRODUCTION AND ENTRY

### Important instructions:

- **Introduction** is the movement of the species into the risk assessment area (it may be either in captive conditions and/or in the environment, depending on the relevant pathways).
- **Entry** is the release/escape/arrival in the environment, i.e. occurrence in the wild
- Introduction and entry may coincide for species entering through pathways such as “corridor” or “unaided”, but it also may differ. If different, please consider all relevant pathways, both for the introduction into the risk assessment area and the entry in the environment.
- The classification of pathways developed by the Convention of Biological Diversity (CBD) should be used (see Annex IV). For detailed explanations of the CBD pathway classification scheme consult the IUCN/CEH guidance document<sup>3</sup> and the provided key to pathways<sup>4</sup>.
- For organisms which are already present (recorded or established) in the risk assessment area, the likelihood of introduction and entry should be scored as “very likely” by default.
- Repeated (independent) introductions and entries at separate locations in the risk assessment area should be considered here (see Qu. 1.7).

**Qu. 1.1. List relevant pathways through which the organism could be introduced into the risk assessment area and/or enter into the environment. Where possible give details about the specific origins and end points of the pathways as well as a description of any associated commodities.**

For each pathway answer questions 1.2 to 1.8 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 1.2a, 1.3a, etc. and then 1.2b, 1.3b etc. for the next pathway.

In this context a pathway is the route or mechanism of introduction and/or entry of the species.

<sup>3</sup> <https://circabc.europa.eu/sd/a/7e5f0bd4-34e8-4719-a2f7-c0cd7ec6a86e/2020-CBD-pathways-interpretation.pdf>

<sup>4</sup> <https://circabc.europa.eu/sd/a/0aeba7f1-c8c2-45a1-9ba3-bcb91a9f039d/TSSR-2016-010%20CBD%20pathways%20key%20full%20only.pdf>

The description of commodities with which the introduction of the species is generally associated shall include a list and description of commodities with an indication of associated risks (e.g. the volume of trade; the likelihood of a commodity being contaminated or acting as vector).

If there are no active pathways or potential future pathways this should be stated explicitly here, and there is no need to answer the questions 1.2-1.9.

Pathway names: No pathway(s) have been proven for *Mulinia lateralis*. This species has not previously been introduced anywhere outside the RA area, and has only recently arrived in NW Europe, possibly as the result of a single introduction (Klunder et al., 2019). *M. lateralis* is free-living and does not attach to substrates; therefore hull fouling, floating debris and shellfish imports are unlikely pathways of introduction, particularly as this species is not part of the fouling community as it lives shallowly buried in soft sediments, so would not adhere to or crawl or burrow into other attached fouling organisms. Unaided natural dispersal is not feasible, as the larvae do not remain in the plankton for sufficient time to drift across the Atlantic. *M. lateralis* is used as a model organism for various experimental studies (see Qu. A13). Thus, escape from confinement (research and ex-situ breeding) is a potential pathway of introduction. However, it was considered an unlikely pathway for entry to the RA area, as the relevant studies are carried out either in the US (where the species is native) or in China, where it was recently (2017) introduced for this purpose (Yang et al., 2021). Similar studies in European laboratories mostly use suitable native species e.g. *Mytilus* spp. or native oyster species (His et al., 1999).

**TRANSPORT-STOWAWAY (ship/boat ballast water and sediments)**

Kerckhof (2019) suggests that *M. lateralis* was introduced into NW Europe with ballast water, like the bivalve *Ensis leei*, also a species originally from the N. American east coast. In addition, ballast water has been suggested as the pathway for two other recently introduced bivalves, the closely related *Rangia cuneata* and the tellinid *Theora lubrica* (Verween et al., 2006; Faasse et al, 2019).

**TRANSPORT-STOWAWAY (other means of transport: marine aggregates & dredging)**

The global dredging sector is very important in Europe, particularly in Belgium and The Netherlands. M. Faasse proposed the accidental transfer of dredged materials as a possible pathway (pers. comm., 25<sup>th</sup> February 2021). This could occur from Canada or Mexico within the native range (but not the US, see Qu. 1.3b.).

Pathway name:

**a) TRANSPORT-STOWAWAY (ship/boat ballast water and sediments)**

**Qu. 1.2a. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response: There is no doubt the uptake of larvae or adults in ballast water is accidental. See categorization of pathways in Annex IV.

**Qu. 1.3a. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: The planktotrophic (free swimming) larvae of *Mulinia lateralis* larvae can be taken in with ballast water. In addition, small juveniles and adults that live only slightly below the surface could also be taken up with any sediments disturbed and accidentally loaded with the water (Gollasch & David, 2019). Entry into the environment will occur during the de-ballasting process.

The propagule pressure will depend on the larval densities in the donor location, the time of the year (i.e. if uptake of ballast water coincides with the peak spawning period), as well as the densities of the adult population. There are large populations of *M. lateralis* in many estuaries along the east coast of N. America, where it can reach average densities of up to 21,000 ind. m<sup>2</sup> (Santos & Simon, 1980; Walker & Tenore, 1984). The reproductive period of *M. lateralis* varies from just a few months in the Gulf of St. Lawrence to all year round in the Gulf of Mexico (Montagna et al., 1993). Each female produces 3-4 million eggs (for details on reproductive traits please see Qu. 2.7). Calabrese (1970) recorded peak larval densities of 2,500-3,500 ind. m<sup>3</sup> from Long Island Sound.

Although no information could be found of *M. lateralis* being detected in ballast water, Gollasch et al. (2002) reported 42 bivalve taxa in ballast water in Europe, including the closely related *Macra corallina*. Ballast water has been specifically implicated in the introduction of several bivalve species e.g. *Ensis leei*, *Rangia cuneata* and *Theora lubrica* (Von Cosel et al., 1982; Verween et al., 2006; Faasse et al., 2019). The lowest estimates of the volumes of ballast water taken up, transferred and discharged into world oceans each year are around 10 billion tonnes (Interwies & Khuchua, 2017), whereas just one cubic metre of ballast water may contain from 21 up to 50,000 zooplankton specimens (Locke et al.,

1991, 1993; Gollasch, 1997) and a heavy bulk carrier can carry more than 130,000 tonnes of ballast water (GloBallast, 2021). In addition, it is estimated that over 100 million tons of ballast tank sediments are being transported annually by ships (Endresen et al., 2003). It is thus evident from the above information that the potential for sufficiently high numbers of *M. lateralis* larvae or adults to travel along this pathway is high.

The transatlantic shipping routes from the east coast of N. America to Northern Europe and the Mediterranean represent a major east-west trade lane, being particularly important for containerized trade, with annual US exports to Europe of 3M TEU (twenty-foot equivalent units). New York, Houston, Savannah, Virginia and Charleston are the main exporting ports (Kaluza et al., 2010; UNCTAD, 2019; JOC, 2020).

**Qu. 1.4a. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: The organism has already entered Europe, putatively via ballast water. Larvae of *Mulinia lateralis* can survive salinities of 7-38 psu and temperatures of 7-33 °C (Calabrese, 1969a). They can remain in the free-swimming planktotrophic phase for up to 22 days (Mann et al., 1991). They are filter-feeders and can feed on a wide variety of phytoplankton and natural seston (particularly bacteria) (Shumway & Newell, 1984; Chalermwat et al., 1991). Thus, there is considerable probability of survival in ballast waters.

Shipping time from the east coast of N. America to the RA area can take 6-30 days (Ports.com, 2021), so the larvae could still be free-swimming when the water is discharged. It is also possible larvae could metamorphose within the ballast water tanks, settle in the ballast sediments, and develop into adults, alongside any adults that had been taken in during the uptake of ballast water.

Adult clams can survive temperatures of -2 °C to 35 °C (Calabrese, 1969a; Kennedy & Mihursky, 1971), anoxic conditions, and salinities of 5-80 psu (Parker, 1975), so should be perfectly able to survive and grow in the ballast tank sediments. *M. lateralis* has a very short generation time (reaching sexual maturity in 1-2 months (Guo & Allen, 1994)) therefore it is likely that, particularly on slower voyages, a significant proportion of any adult clams will be sexually mature.

*M. lateralis* spawns when water temperatures reach above 16 °C (Calabrese, 1969a). The ballast water temperature is likely to be above this for most of the year for journeys from ports south of Washington DC, to the Mediterranean and Atlantic coasts. Thus, any adults present could release large numbers of larvae into the ballast water.

**Qu. 1.5a. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: The International Maritime Organization (IMO) Ballast Water Management Convention (BWMC) entered into force in September 2017. It requires ships in international traffic to apply ballast water management measures, in particular:

- ballast water exchange in open seas, away from coastal areas (D-1 standard for an interim period)
- fulfil a certain discharge standard (D-2 standard according to the ship specific application schedule phased in up to 8 September 2024). D-2 standard requires the installation of a certified ballast water treatment device, which enables sterilization to avoid transfers of ballast water mediated species.

Ballast Water Exchange (BWE) is currently practiced and requires ships to exchange a minimum of 95% ballast water volume whenever possible at least 200 nautical miles (nm) from the nearest land and in water depths of at least 200 metres. When this is not possible, the BWE shall be conducted at least 50 nm from the nearest land and in waters at least 200 metres in depth (David et al., 2007; and BWMC Guideline 6). Even though BWE can reduce the concentration of live organisms in ballast by 80–95% (Ruiz & Reid 2007; Darling et al., 2018), its application has severe limitations, primarily dependant on shipping patterns of a port (e.g., shipping routes, length of voyages) and local specifics i.e., distance from nearest shore, water depth (David et al., 2007). This is particularly the case for EU Seas where it is often not possible to meet these conditions. In addition, organisms may still remain in the volume of ballast not exchanged and in ballast sediment, or BWE may not be possible due to weather conditions or other safety restrictions. The survival of zooplanktonic organisms (including *M. lateralis* larvae) is thus not unlikely when only BWE measures are implemented.

As a result, ballast water treatment has been deemed necessary, such that ships shall discharge (in relation to the organism size range of interest for *M. lateralis*): less than 10 viable organisms per cubic metre greater than or equal to 50 micrometres in minimum dimension (IMO D-2 standard). Ballast water treatment options include mechanical (filtration, separation), physical (heat treatment, ozone, UV light) and chemical methods (biocides). Efficiencies of various technologies utilised for ballast water treatment are reviewed in Tsolaki & Diamadopoulos (2009), and can vary with treatment method but the application of many combined methods (e.g., Filtration+UV or Hydroclone+chemical disinfectant) can decrease live zooplankton to undetectable levels, practically diminishing propagule pressure. Under the D-2 standard, all ships shall be required to regularly remove and dispose of sediments from spaces designed to carry ballast water in accordance with the ship’s Ballast Water Management Plan. Sediments will be disposed of at designated sediment reception facilities in ports (GloBallast, 2017).

As such, the survival of *M. lateralis* larvae in ballast water, and adults in sediments, with full implementation of the D-2 standard (i.e. after 2024) is considered unlikely. Until then (i.e. currently), planktonic propagules of the species are likely to survive in ballast water and adults in the sediments.

**Qu. 1.6a. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: *Mulinia lateralis* has already entered Europe undetected, putatively via ballast water (Kerckhof, 2019). The introduction into The Netherlands probably occurred in 2016 or earlier (Klunder et al., 2019) but was not detected until September 2017, during monitoring surveys associated with the Rotterdam harbour extension (Craeymeersch et al., 2019). The probability of observing the initial introduction event, particularly at the larval stage is minimal without targeted monitoring surveys at introduction hotspots (Andersen et al., 2014). The gross morphology of adult *M. lateralis* is similar to some common native species, as described in A.2. The adults are small (10-20 mm in length), while newly metamorphosed juvenile shell lengths range from 200 to 700 µm (Wang & Guo, 2008). Thus, *M. lateralis* could easily be overlooked during casual surveys, or if it settles in inaccessible port areas.

After September 2017, with the BWMC coming into effect and gradually being implemented, detection of larval stages in ballast water during Port State Control inspections may be possible. According to Resolution MEPC.252(67), if initial inspections of ballast water samples indicate non-compliance with the D-2 standard, detailed inspections will be carried out. eDNA methodologies are rapidly becoming one of the fastest and most cost-efficient tools for the detection of NIS<sup>5</sup> in introduction water samples (Darling et al., 2017; Borrell et al., 2017; Koziol et al., 2019). However, full implementation of the BWMC is not anticipated until 2024. Until then, the risk that *M. lateralis* will enter the RA area undetected in ballast waters and sediments remains likely.

**Qu. 1.7a. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated widespread ubiquitous	<b>CONFIDENCE</b>	low medium high
-----------------	--------------------------------------	-------------------	-----------------------

<sup>5</sup> NIS: non-indigenous species, term used in the Marine Strategy Framework Directive, synonym of “alien species” as used in the framework of Regulation (EU) 1143/2014

Response: *Mulinia lateralis* favours low-energy sheltered coastal waters, estuaries and lagoons. It prefers soft sediments, such as mud and sand, within the low intertidal and shallow subtidal zones (Snelgrove et al., 1993; Klunder et al., 2019). It is quick to colonise disturbed areas, such as sites recently dredged or defaunated for other reasons (Santos & Simon, 1980; Pollack et al., 2018).

In Atlantic Europe, the main ports of entry are located within a relatively confined region, i.e. both coasts of the English Channel, but principally the Le Havre-Hamburg range along the north coast of continental Europe. Ports in northern and western Europe are often situated in or near estuaries that exhibit major fluctuations in salinity that *M. lateralis* can take full advantage of, see Qu. 1.4a for more details.

Conversely in the Mediterranean Sea, potential recipient ports are relatively evenly spaced but slightly more concentrated along the central and western Mediterranean, with a small number in Malta, southern Italy and Spain acting as the main transshipment hubs (Rodrigue, 2020). However most Mediterranean ports are located in coastal areas, not lagoons, thus the main risk areas are more isolated. However, this species can survive on the open coast in Belgium, and in its native range, thus it is feasible that possible points of introduction could be widespread; hence we have proposed a conservatively moderate score of isolated, with low confidence.

Repeated introductions from the native range may continue to occur until full implementation of the D-2 standard has taken place.

**Qu. 1.8a. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Regarding existing populations of the organism in the RA area, although not proven, ballast water and sediment transport is considered the most likely pathway of introduction (Kerckhof, 2019). Management measures implemented so far (i.e. BWE) have not proven adequate to prevent the introduction of this and other marine invasive species in EU marine waters. With the recent ratification of the BWMC (September 2017), compliance with the D-2 standard is expected to greatly reduce the likelihood of new introductions of *Mulinia lateralis* into Europe with ballast water and sediments. However, this is not expected before 2024 and there may be difficulties in fully implementing it. For example, there are already some early reports of operational problems with the currently installed Ballast Water Management Systems, presumably due to poor installation and inadequate testing in the field (source: <https://www.seatrade-maritime.com/news/asia/operating-problems-with-60-80-of-ballast-water-treatment-systems-intertanko/>).

A concrete protocol for the verification of ballast water compliance monitoring devices has been proposed by IOC-UNESCO, ICES and ISO to IMO (IOC-UNESCO, ICES, ISO, 2019). This protocol builds on the method presented in documents PPR 6/4 and MEPC 74/4/11 (Denmark) (First et al., 2018)

and suggests a practices for verifying ballast water compliance monitoring devices using laboratory and shipboard tests. The intention is that the protocol can be the basis for the development of a standard for such devices, which may be used during commissioning testing, data gathering during the experience-building phase, compliance testing by Port State Control, or self-monitoring.

Pathway name:

**b) TRANSPORT-STOWAWAY (other means of transport: marine aggregates & dredging)**

**Qu. 1.2b. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	intentional	<b>CONFIDENCE</b>	low
	<b>unintentional</b>		medium
			<b>high</b>

Response: *Mulinia lateralis* has no commercial value; the international dredging activities referred to in this pathway do not include dredging of commercial shellfish beds, and do not intentionally collect this species (but see Qu. 3.3c). See categorization of pathways in Annex IV and guidance notes in the beginning of this section.

**Qu. 1.3b. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
	unlikely		<b>medium</b>
	<b>moderately likely</b>		high
	likely		
	very likely		

Response: The global dredging sector is very important in Europe, particularly in Belgium and The Netherlands. European dredging companies have a 90% market share of dredging in worldwide open markets (EuDA, 2013; Van Oord, 2020), and four of the largest dredging companies in the world are Belgian (Jan De Nul, DEME) or Dutch (Boskalis, Van Oord) (Rabobank, 2013). Dutch and Belgian companies have been involved in dredging in Mexico and Canada, at the southern and northern extremes of the native range of *Mulinia lateralis* (Maritime Journal, 2010; Van Oord, 2019; Wikipedia, 2021). However, dredging in the US, which extends over a large part of the native range, is restricted to vessels built, owned and flagged in America (as a result of the ‘Jones Act’) (Frittelli, 2019), and there was no evidence found of US dredging companies operating in Europe. Thus, dredging as a pathway from the native range is possible but somewhat restricted.

Dredging is a major activity in the current invaded range, within the RA area. There is significant dredging and disposal activity all along the Dutch, German and Belgian coasts. For example, the Port of Rotterdam requires intensive maintenance dredging that yields 12-15 million m<sup>3</sup> of dredged material annually (Kirichek et al., 2018). Intensive dredging is also taking place in the port of Zeebrugge and the dredgers often move from one operation zone to another, e.g. from Belgium to the Baltic Sea (F. Kerckhof, pers. comm., 17th August 2021). Dredged materials are distributed along the Dutch and Belgian coasts to help prevent coastal erosion and aid land reclamation (ICES, 2018). There are large populations of *M. lateralis* in the sheltered waters such as estuaries, lagoons, harbours and coastal areas in the Gulf of Mexico and, to a lesser extent, in the Gulf of St Lawrence, Canada (see Qu. 1.3a for more detail regarding propagule pressure). Any dredging of these sediments will inevitably collect a high percentage of any *M. lateralis* adults present. The adults are small (10-20 mm in length), while newly metamorphosed juvenile shell lengths range from just 200 to 700 µm (Wang & Guo, 2008), thus can easily be taken up by all forms of dredging. The bulk of the dredged material will be disposed of in the country of origin at designated sites. However, some residual sediment will inevitably be retained in the vessel and on any equipment used. Additionally, larvae of the species may be contained in hopper water. This is water used to fill the hopper (i.e. the storage compartment) of the dredger to increase vessel stability when it is not loaded with sediment. The frequency of events in which European vessels operate in the native range, and then return to Europe without prior extensive cleaning, is unknown, but likely to be very low. Any residual sediment may be washed out in the home port, or may become mixed with waste from the next project (see Qu. 3.6b for more detail). Hopper water with entrained larvae may also be released at the home port or subsequent destinations.

**Qu. 1.4b. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: During the period of retention on the vessel, the adults will remain in the sediments they were collected with, so should be able to survive, and possibly even reproduce. While in transit, adults can

survive anoxic conditions, salinities of 5-80 psu (Parker, 1975), and temperatures from -2 °C to 35 °C (Calabrese, 1969a; Kennedy & Mihursky, 1971). Larvae in hopper water can also survive in a wide range of temperatures and salinities, even though growth may not be optimal (see Qu 2.1, 2.7). *Mulinia lateralis* can also burrow up to the surface if buried (Maurer et al., 1981), and actively thrives in dredged areas (Flint & Younk, 1983). Shipping time from the east coast of N. America to Europe is estimated to take 6-30 days (Freightos, 2021). If food resources fall below the energy requirements of *M. lateralis*, its inability to catabolize protein reserves can cause mass mortalities (Shumway & Newell, 1984).

**Qu. 1.5b. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: No EC regulations regarding the cleaning of vessels and equipment or the exchange of hopper water before returning from overseas could be found. It does not appear to be common practice to clean equipment and exchange hopper water between dredging localities, as contractors considered this to be additional work when new requirements were introduced in Wales, UK (ABPmer, 2019; G. Wynne, B. Wray & S. Vye (Natural Resources Wales), pers. comm. 21<sup>st</sup> April 2021).

**Qu. 1.6b. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: If the vessel and equipment are cleaned on arrival in Europe, *Mulinia lateralis* will be deposited in the port of entry. If the vessel is not cleaned the residual sediments will be mixed with the next dredge load, and would be dumped with a significant amount of sediment, in the designated disposal site. Similarly, larvae in hopper water can also be released at these locations. See Qu. 1.6a for more detail on difficulty of detection.

**Qu. 1.7b. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated widespread ubiquitous	<b>CONFIDENCE</b>	low medium high
-----------------	--------------------------------------	-------------------	-----------------------

Response: See Qu. 1.7a. Companies based in The Netherlands and Belgium carry out the majority of overseas dredging, so there is a higher risk of these countries being sites of introduction. However, although it is probable that dredging vessels working overseas would return to their homeport on project completion, it is possible that sometimes they will travel directly to the site of their next contract, which could be anywhere in Europe.

**Qu. 1.8b. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low medium high
-----------------	--	-------------------	-----------------------

Response: Accidental transport with dredge spoils has been proposed as a possible means of introduction, as dredging companies based in the countries within the RA area where *Mulinia lateralis* was first observed are known to carry out major dredging operations in the species' native range. *M. lateralis* larvae and adults/juveniles could potentially survive in hopper water and residual sediments respectively, and be released in home ports or at subsequent dredging destinations. The major unknown factor in this pathway is the frequency with which dredging vessels move between sites in the native range and the RA area.

**Qu. 1.9. Estimate the overall likelihood of introduction into the risk assessment area or entry into the environment based on all pathways and specify if different in relevant biogeographical regions in current conditions.**

Provide a thorough assessment of the risk of introduction in relevant biogeographical regions in current conditions: providing insight in to the risk of introduction into the risk assessment area.

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
-----------------	---------------	-------------------	-----

	unlikely moderately likely likely <b>very likely</b>		medium <b>high</b>
--	---	--	-----------------------

Response: *Mulinia lateralis* has already been introduced into the RA area, but possibly only once. Ballast water and sediments is considered the most plausible pathway for this introduction, due to the volume of traffic, and its importance as a vector in the transfer of bivalve molluscs with similar life histories. This theory is supported by its presence in the region of a major shipping hub. However, there is no direct evidence to support ballast water and sediments as the original pathway, and it is possible that this single introduction resulted from a much rarer event such as the accidental transfer of residual dredging waste. The transatlantic shipping routes from the east coast of N. America to Northern Europe and the Mediterranean represent a major east-west trade lane. Despite its current non-native range being limited to the Greater North Sea, further introductions are also likely in the Mediterranean parts of the RA area, where prevailing temperatures favour the survival of planktotrophic larvae likely to be carried by ballast waters (see Risk of Establishment section).

Baltic Sea: moderately likely, low confidence (western part)

Greater North Sea: very likely, high confidence

Celtic Seas: moderately likely, medium confidence

Bay of Biscay and the Iberian coast: moderately likely, medium confidence

Mediterranean Sea: likely, medium confidence

Black Sea: moderately likely, medium confidence

**Qu. 1.10. Estimate the overall likelihood of introduction into the risk assessment area or entry into the environment based on all pathways in foreseeable climate change conditions?**

Thorough assessment of the risk of introduction in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of introduction (e.g. change in trade or user preferences)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely introduction within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
-----------------	---------------	-------------------	-----

	unlikely moderately likely likely <b>very likely</b>		medium <b>high</b>
--	---	--	-----------------------

Response: Climate change is most likely to affect future introductions as a result of an increase in minimum and maximum Sea Surface Temperatures (SST). The methodology for the developed models is described in Annex IX and considers scenarios RCP 2.6 and RCP 4.5 by 2070.

Ballast water: The rise in maximum SST will increase the likelihood of further introductions into the RA area. In the northern part of the native range there would likely be an extension to the reproductive period, and possibly larger populations on average, providing greater opportunities for larval uptake with ballast water, e.g. in Long Island Sound, an important shipping hub for exports to Europe.

It is anticipated that extreme weather phenomena, such as droughts and storms/flooding, will be more frequent and intense under future climate conditions. Within the native range, this will likely lead to greater fluctuations in salinity, and more frequent defaunation events, facilitating the establishment of opportunistic high-density populations of *Mulinia lateralis*, and leading to a corresponding rise in larval density. More frequent storms leading to greater disturbance of inshore waters, may also increase the likelihood of juvenile and small adults being present in the water-column and thus available for uptake in ballast water. Higher frequency and severity of storms can also increase the amount of time vessels have to spend in port, increasing the likelihood of entrainment (Galil et al., 2019).

The likelihood of introductions into the Greater North Sea and Celtic Seas subregions, will increase as conditions will be favourable over a longer period of the year for survival of larvae discharged with ballast water. It is not anticipated that there will any change in the volume of transatlantic shipping as a result of climate change.

International Dredging: The more intense proliferation of native *M. lateralis* populations, discussed above for ballast water, could also result in a higher risk of *M. lateralis* adults and larvae being present in any residual sediments and water, remaining in European dredging vessels and on equipment, when they return from dredging works in N. America. Dredging activity in the native range may increase in response to rising sea levels, leading to an increase in demand for coastal protection. In addition, an increase in extreme weather events (e.g. flooding with associated terrigenous inputs), may increase the need for dredging to maintain water channels and protect property. As the European dredging sector have a 90% market share of dredging worldwide, it is likely that there will be an increase in the frequency of European dredging vessels operating in the native range.

Baltic Sea: moderately likely, low confidence (western part)

Greater North Sea: very likely, high confidence

Celtic Seas: likely, medium confidence

Bay of Biscay and the Iberian coast: likely, medium confidence

Mediterranean Sea: likely, medium confidence

Black Sea: moderately likely, medium confidence

## 2 PROBABILITY OF ESTABLISHMENT

### Important instructions:

- For organisms which are already established in parts of the risk assessment area or have previously been eradicated, the likelihood of establishment should be scored as “very likely” by default.
- Discuss the risk also for those parts of the risk assessment area, where the species is not yet established.

**Qu. 2.1. How likely is it that the organism will be able to establish in the risk assessment area based on similarity of climatic and abiotic conditions in its distribution elsewhere in the world?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The species is already established in the RA area, specifically in the Wadden Sea, coastal waters and estuaries in Belgium, the Netherlands and Germany (see Qu. A6).

*Mulinia lateralis* is a eurythermal and euryhaline species with a latitudinal distribution extending from the Bay of St. Lawrence, Canada to the Gulf of Mexico, Yucatan, Mexico (Turgeon et al., 2009; see also Qu. A3 for details). This distribution corresponds to low winter temperatures of approximately -1 °C to 24 °C (average temperature of the coldest month, retrieved from BIO-ORACLE 2 (Assis et al., 2018)) and high summer temperatures ranging from 17 °C to 30.5 °C (average temperature of the warmest month, retrieved from BIO-ORACLE 2), conditions which are met throughout most of the RA area (see Annex VIII). Under experimental conditions, this temperature range is further extended to -2 °C for adult survival and to 33 °C for larval survival (Calabrese, 1969a). Spawning occurs at different times of the year at different latitudes, e.g. in Canada from mid-July to early September (Sullivan, 1948), in Maryland from May to November with a peak in September (Hanks, 1968), in Texas from January to April, while year-round spawning has also been reported (Montagna et al., 1993). In the Long Island Sound, larvae appear in the water in early July at temperatures ranging between 16 °C and 20 °C but are more abundant at 19-21 °C (Calabrese, 1970). Field observations agree rather well with laboratory results, which indicate that the temperature threshold for larval growth that ensures metamorphosis before the larvae die in the water column lies somewhere between 15 °C and 17.5 °C (Calabrese, 1969a). Thus, temperature does not seem to be a major limiting factor for establishment at a large scale, except perhaps around northern UK waters, where maximum summer temperatures drop below 15 °C. Nevertheless, because *M. lateralis* is primarily an inshore, estuarine species (Walker & Tenore, 1984), coarse grain temperature maps may not accurately reflect local conditions. For example, temperature measurements in marinas and harbours along the UK coast demonstrate water temperatures typically between 16 °C and 22 °C in July – October, all the way up to northern England (Bishop et al., 2015; C. Wood, unpublished data).

The species can also withstand a wide range of salinities, reportedly between 5-80 psu (Parker, 1975 in Montagna et al., 1993). *M. lateralis* can persist equally in low salinity estuarine environments as in hypersaline conditions in lagoons, associated with prolonged drought periods (e.g. in Baffin Bay, Texas, where the species is dominating the infaunal community at salinities up to 60 psu). It is generally observed though that major recruitment events are triggered by big salinity changes caused by freshwater inflow, rather than absolute salinity levels (Montagna & Kalke, 1995; Van Diggelen & Montagna, 2016). On the other hand, its presence along the Dutch and Belgian coasts, as well as the shallow sublittoral in its native range (Cleveland et al., 2002) indicates it can also establish in fully marine areas. Regarding larval development, in laboratory experiments it was shown to be normal between 12.5 to 35 psu, although survival was observed within a much larger range of 7-38 psu (Calabrese 1969a).

**Qu. 2.2. How widespread are habitats or species necessary for the survival, development and multiplication of the organism in the risk assessment area? Consider if the organism specifically requires another species to complete its life cycle.**

<b>RESPONSE</b>	very isolated isolated moderately widespread <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: *Mulinia lateralis* is an infaunal (i.e. living in soft sediments), opportunistic species that proliferates in shallow, sheltered areas with mixed fine sediments (Walker & Tenore, 1984). It is widespread in coastal bays and often dominates the infaunal assemblages in estuaries and lagoons (Montagna et al., 1993; Reguero & Raz-Guzman, 2018). Even though in its native range it is considered primarily a near-shore, subtidal species, in the RA area it has been repeatedly observed in the intertidal zone and appears capable of establishing there too (Craeymeersch et al., 2019; Klunder et al., 2019). Such habitats are relatively widespread in the RA area; in particular, estuaries and intertidal areas are especially widespread in the North-East Atlantic region while lagoons are more common in the Mediterranean region (Figure 4). Klunder et al. (2019) constructed a habitat suitability map for *M. lateralis* in the Wadden Sea, based on sediment characteristics at a fine scale. This predicted that a considerable part of the Dutch Wadden Sea could provide suitable habitat.

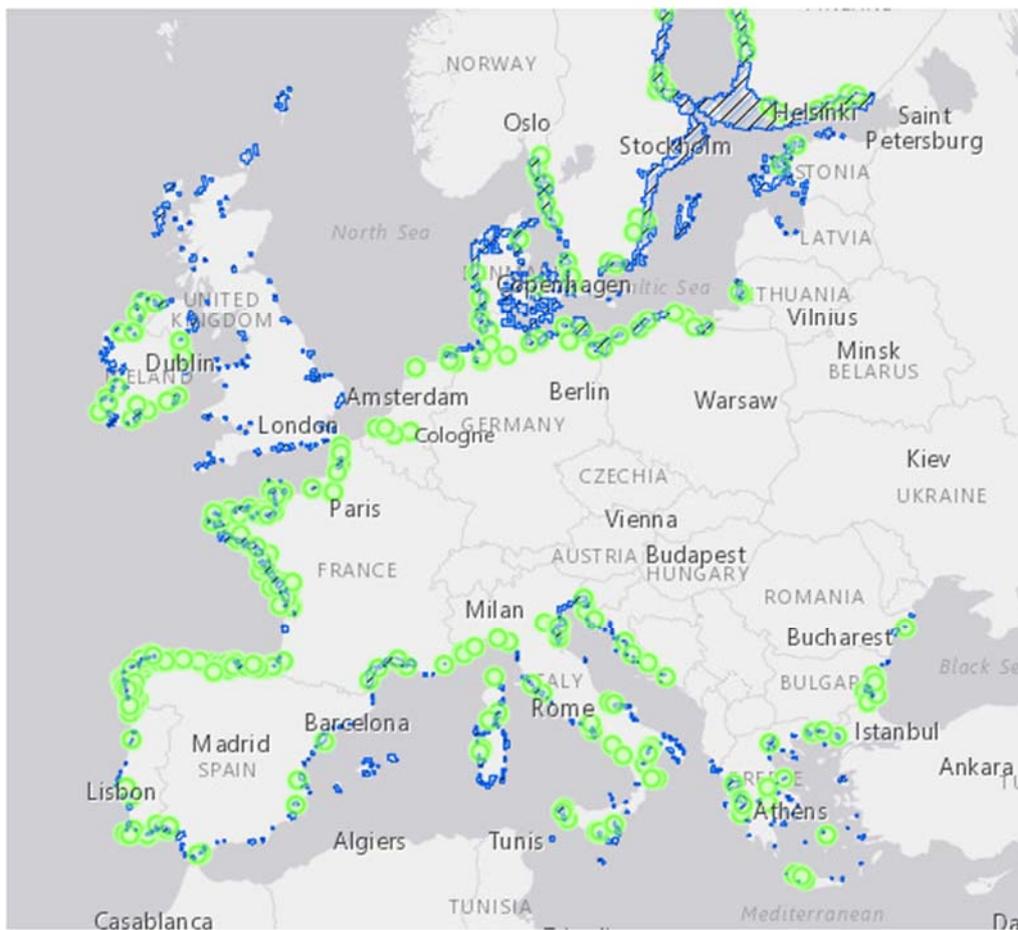

Figure 4: Coastal lagoons (blue polygons) and Estuaries (green circles) in the Natura 2000 network of Europe (source: Natura 2000 Network Viewer).

**Qu. 2.3. How likely is it that establishment will occur despite competition from existing species in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: *Mulinia lateralis* is a typical r-selected species with high fecundity, short generation times and fast maturation (Williams et al., 1986; see also Qu. 2.7). As such, it is a characteristic early colonizer in macrobenthic community succession after periodic or stochastic catastrophic events (e.g., Santos & Simon, 1980; Flint & Younk, 1983) and, according to ecological theory, is not meant to be a good competitor (Rosenberg 1972; 1973; Grassle & Grassle, 1974; McCall, 1977; Rhoads et al., 1978). This is also demonstrated in field studies, where its numerical presence is much reduced in locations with

high bivalve diversity (McKeon et al., 2015) or with the strong presence of bioturbating deposit feeders (Levinton & Bambach, 1970). However, because it can withstand a large range of salinities, it recovers very fast from physical disturbance events and rapidly colonises defaunated habitats, it can persist and dominate in frequently “disturbed” environments, such as estuaries and other transitional systems. Moreover, because it can attain significant densities, has a high filtration rate and is adapted to quickly exploit high concentrations of food resources (Shumway et al., 1983; Craeymeersch et al., 2019), it has the capacity to become an effective competitor for space and food, especially if settlement occurs earlier than for native bivalves with a similar trophic ecology and habitat preference. In the Wadden Sea, with extensive tidal flats and a salinity range of approximately 12-31 psu (Duran-Matute et al., 2014), the species is already established, having been recorded for the first time in 2017 (Klunder et al., 2019). In the Voordelta, in The Netherlands, *M. lateralis* was found together with *Spisula subtruncata* both at high densities at the same site, and likewise in the Westerschelde, it was found with *Cerastoderma edule* both at high densities (Craeymeersch et al., 2019). Thus, competition with functionally similar species (i.e. infaunal suspension feeders) has not prevented establishment.

**Qu. 2.4. How likely is it that establishment will occur despite predators, parasites or pathogens already present in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: In its native range, *Mulinia lateralis* constitutes an important food source for a variety of organisms both in estuaries and in coastal waters. Predation by various finfish species (drums, croakers, spots) (Blundon & Kennedy, 1982; Pollack et al., 2018), blue crab *Callinectes sapidus* (Williams et al., 1986), rays (Ajemian & Powers, 2012), starfish *Asterias forbesi* (MacKenzie, 1981) and *Luidia clathrata* (McClintock & Lawrence, 1985), diving ducks, e.g., scaup and ruddy ducks (Perry & Uhler, 1982; Stroud et al., 2019), is well documented along the coasts of North America and the Gulf of Mexico. In Chesapeake Bay, it has been suggested that the seasonal fluctuations of the dwarf clams, with very low abundances in the summer, are due to increased predation by crabs and fish but the clams persist in the face of predation by continuous recruitment (Blundon & Kennedy, 1982). Something similar is likely to happen in the RA area, where the species is already established, with predation by native species of crabs, fish, starfish, shore birds and diving ducks.

*M. lateralis* is reported as the intermediate host for larvae of two parasitic cestode species, *Duplicibothrium minutum* and *Rhodobothrium paucitesticulare*, however no associated pathology to the examined specimens was observed (de Buron et al., 2013). The species is also a host for the protozoan parasite *Perkinsus chesapeaki* (Reece et al., 2008), which infects a wide variety of clam species (Bureson et al., 2005) and is pathogenic to its clam host *Mya arenaria* (Dungan et al., 2002; McLaughlin & Faisal, 1998). No pathogeny has been described though for *M. lateralis* specifically, such that the potential effect of *Perkinsus* infections on the risk of establishment cannot be reliably assessed. The

other two *Perkinsus* species that have been reported in European waters, *P. olseni* and *P. mediterraneus* (Carrasco et al., 2014), can indeed infect clam species but have not been observed in *M. lateralis*.

Brown tide event: In a Texas estuary, a prolonged brown tide event caused the demise of the *M. lateralis* population for two years, although it was not established whether this was due to reproductive failure or direct toxic effects (Montagna et al., 1993). The population rebounded after 2 years in the native range, however recovery may not be possible after such an event in the invaded range with a newly established or isolated population.

**Qu. 2.5. How likely is the organism to establish despite existing management practices in the risk assessment area? Explain if existing management practices could facilitate establishment.**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: While Ballast Water Exchange (BWE) and Ballast Water Treatment (BWT) can reduce propagule pressure and, consequently, the rate of establishment (see Qu. 1.5a for details), these management practices are not always possible or yet in effect. On the other hand, bivalve transportations for aquaculture purposes (which constitute a pathway of spread) offer suitable habitats to *Mulinia lateralis* in the form of the aquaculture plots themselves and, thus, facilitate establishment. Moreover, seed relaying offers favourable substrates and conditions for settlement and growth, enhancing establishment potential. Dredging activities also enhance the potential for establishment, both at the dredged sites, which are known to be rapidly colonised by the species (Flint & Younk, 1983; Clarke & Miller-Way, 1992) but also at disposal sites with dredge spoils containing *M. lateralis*, or at new dredging locations with contaminated equipment (see Probability of Spread section for details). In a similar way, dredging to remove nuisance species close to shellfish culture plots, sometimes practiced for predatory starfish or the invasive mollusc *Crepidula fornicata*, which heavily infests oyster and mussel beds (Bohn, 2014), may also provide cleared space and promote settlement and establishment of *M. lateralis*.

**Qu. 2.6. How likely is it that biological properties of the organism would allow it to survive eradication campaigns in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: No attempts to eradicate this organism are known. Due to its small size a considerable proportion of the population would be expected to pass through typical commercial towed gear used for removal. Moreover, its burrowing lifestyle, high fecundity, prolonged/continuous recruitment and resistance to disturbance make it a very unlikely candidate for successful eradication as the above characteristics allow the species to maintain low-density “reservoir” populations even under adverse environmental conditions and/or heavy predation (Williams et al., 1986) and recover fast after mass mortality events.

**Qu. 2.7. How likely are the biological characteristics of the organism to facilitate its establishment in the risk assessment area?**

including the following elements:

- a list and description of the reproduction mechanisms of the species in relation to the environmental conditions in the risk assessment area
- an indication of the propagule pressure of the species (e.g. number of gametes, seeds, eggs or propagules, number of reproductive cycles per year) of each of those reproduction mechanisms in relation to the environmental conditions in the risk assessment area.
- If relevant, comment on the likelihood of establishment based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in establishment whereas for others high propagule pressure (many thousands of individuals) may not.
- If relevant, comment on the adaptability of the organism to facilitate its establishment and if low genetic diversity in the founder population would have an influence on establishment.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: *Mulinia lateralis* is a gonochoric (i.e. with separate sexes), broadcast spawner with external fertilisation. It has a short life span, up to 2 years, and reaches sexual maturity at a length of 3 mm and at an age of 60 days (Calabrese, 1969b). The species has free-swimming planktotrophic larvae with pelagic larval duration (PLD) of 7 to 22 days (Mann et al., 1991). It thus has a short generation time of about 3 months (Guo & Allen, 1994) and can spawn more than once a year, depending on ambient temperatures, with a mean fecundity of 3-4 million eggs per female per spawning event (Calabrese, 1969b). Spawning occurs at different times of the year at different latitudes, e.g. in Canada from mid-July to early September (Sullivan, 1948), in Maryland from May to November with a peak in September (Hanks, 1968), in Texas from January to April, while year-round spawning has also been reported (Montagna et al., 1993).

Abiotic parameter thresholds for larval development are outlined in Qu. 2.1. In brief, normal larval development and larval growth in the laboratory are achieved at temperatures not lower than 15 °C and

as high as 32.5 °C, which was the highest temperature tested (Calabrese, 1969a), and at salinities between 12.5 and 37.5 psu. However, satisfactory embryonic development occurred at a more restricted salinity range of 20-32.5 psu (Calabrese, 1969a). Nevertheless, it is generally accepted that it is salinity fluctuations and not absolute salinity values per se that trigger recruitment (Van Diggelen & Montagna, 2016), such that exact salinity thresholds for reproduction are not easy to set. Such conditions are met throughout most of the RA area, at least for the short duration needed for larval development. The only exception is the Baltic Sea, where salinity drops to <10 psu beyond the western Baltic, and northern UK waters, where maximum summer temperatures are close to or below the lower limit for larval development and growth. Abiotic conditions in the Mediterranean Sea are particularly favourable for prolonged or even continuous spawning, with minimum water temperatures >16 °C in the eastern and southern parts of the basin, whereas in Atlantic Europe spawning and recruitment are likely to be more discreet events, limited to the warmer summer months.

**Qu. 2.8. If the organism does not establish, then how likely is it that casual populations will continue to occur?**

Consider, for example, a species which cannot reproduce in the risk assessment area, because of unsuitable climatic conditions or host plants, but is present because of recurring introduction, entry and release events. This may also apply for long-living organisms.

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: Conditions for successful reproduction are encountered throughout most of the RA area. However, long-term establishment most likely requires specific water body types, such as estuaries, lagoons and sheltered inshore waters. Accordingly, the occurrence of casual populations would depend on repeated introductions of either larvae in ballast water or benthic stages in dredged material (and to a lesser extent in ballast sediments), being released at suitable locations. Concerning ballast water, for transatlantic voyages, ballast water exchange is expected to have occurred at sufficient distances away from European coasts such that the risk of introduction is not very high and will be even lower after full implementation of the BWMC. With regards to the transport of aggregates from native donor areas however, the risk of additional introductions remains, as long as operations of European companies continue along areas where *Mulinia lateralis* is native (see relevant pathway in the Probability of Introduction section – Qu. 1.3b, 1.8b). It is worth noting here that an area particularly vulnerable to the occurrence of casual populations is the Baltic Sea, which encompasses a salinity gradient ranging from highly suitable to unsuitable for larval development. Thus, competent larvae entering the Baltic through the high salinity Kattegat can still survive in the western Baltic and eventually settle, even as far as the Baltic proper. Adult clams can survive the salinity in this region but the next generation of larvae would not develop properly. Another area where ephemeral/casual populations may appear is the coast around Ireland, which presents a marginal environment for the species’ larval survival in terms of maximum

summer temperature (15-16 °C). Adult clams entering via anthropogenic pathways can survive and may even reproduce locally in a warmer than average year, but long-term establishment doesn't appear likely.

**Qu. 2.9. Estimate the overall likelihood of establishment in the risk assessment area under current climatic conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under current climatic conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in current conditions: providing insight in the risk of establishment in (new areas in) the risk assessment area.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The species is already established in the southwestern North Sea and further establishment throughout most of the RA area is considered very likely. The population dynamics and persistence of *Mulinia lateralis* populations in its native range are governed by different combinations of reproductive seasonality, abiotic mortality, and predation at different latitudes, as well as local disturbance regimes (Williams et al., 1986). Thus, at lower latitudes, where temperature conditions for spawning and larval development are favourable throughout most of the year, continuous recruitment offsets population losses due to predation and stochastic mass mortality events. On the other hand, at higher latitudes (from Long Island Sound to Canada), where recruitment events are discreet and confined to only a few months per year, populations of the species are described as ephemeral and sporadic, maintained at low density reservoir levels for most of the year.

Similarly, *M. lateralis* is expected to exhibit boom and bust dynamics in Atlantic Europe, where conditions will limit spawning and recruitment to the summer months. Competition and predation by native species have not hindered establishment thus far and are expected to regulate populations of the species in ways similar to what is observed in the native range. In the Mediterranean Sea, should the species be introduced there, it is more likely that populations will become more stable and dominant members of the macrobenthos, especially in the highly variable lagoonal and estuarine systems of the region. The Baltic Sea only offers salinity conditions suitable for establishment in its western part. Establishment is also considered possible in the Black Sea, although areas of freshwater input are fewer in the RA part of this subregion, and low winter temperatures are likely to limit reproduction to the warmer months of the year.

Baltic Sea: moderately likely, low confidence (western part)

Greater North Sea: very likely, high confidence

Celtic Seas: moderately likely, medium confidence

Bay of Biscay and the Iberian coast: likely, medium confidence

Mediterranean Sea: likely, medium confidence

Black Sea: likely, medium confidence

**Qu. 2.10. Estimate the overall likelihood of establishment in the risk assessment area under foreseeable climate change conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under foreseeable climate change conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of establishment (e.g. increase in average winter temperature, increase in drought periods)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely establishment within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The response is based on combining physiological tolerances and the results from the distribution modeling (see Qu. 2.1, Qu. 2.9 and Annexes VIII & IX for details). Aspects of climate change most likely to affect future distribution were considered as an increase in minimum and maximum Sea Surface Temperatures (SST). The methodology for the developed models is described in Annex IX and considers scenarios RCP 2.6 and RCP 4.5 by 2070.

Baltic Sea: moderately likely, low confidence (western part)

Greater North Sea: very likely, high confidence

Celtic Seas: likely, medium confidence

Bay of Biscay and the Iberian coast: likely, medium confidence

Mediterranean Sea: likely, medium confidence

Black Sea: moderately likely, medium confidence

The SDM predicted a small reduction in projected suitability for *Mulinia lateralis* for the Mediterranean Sea and a corresponding increase for North-East Atlantic marine subregions under future climate change and, consequently, a small northward shift of the overall suitable area for the species. An increase in sea surface temperature will offer suitable conditions for spawning and larval development for prolonged periods throughout the whole Atlantic Europe and is predicted to extend its potential range further north along the coast of northern England, Scotland and Ireland. Suitable conditions in the Mediterranean are

likely to become even more restricted spatially and temporally, rendering establishment in this marine subregion more localized, especially in the east and south.

Note: Even though the SDM takes into account salinity variability in the form of distance from river mouths, a future scenario for river discharge was not taken into account and would take very elaborate data processing to bring into the model. It is anticipated that extreme weather phenomena, like droughts and storms/flooding, will be more frequent and intense under future climate conditions and this will increase the uncertainty of predictions as well as the population fluctuations of *M. lateralis*.

### 3 PROBABILITY OF SPREAD

**Important instructions:**

- Spread is defined as the expansion of the geographical distribution of an alien species within the risk assessment area.
- Repeated releases at separate locations do not represent continuous spread and should be considered in the probability of introduction and entry section (Qu. 1.7).

**Qu. 3.1. How important is the expected spread of this organism within the risk assessment area by natural means? (List and comment on each of the mechanisms for natural spread.)**

including the following elements:

- a list and description of the natural spread mechanisms of the species in relation to the environmental conditions in the risk assessment area.
- an indication of the rate of spread discussed in relation to the species biology and the environmental conditions in the risk assessment area.

The description of spread patterns here refers to the CBD pathway category “Unaided (Natural Spread)”. It should include elements of the species life history and behavioural traits able to explain its ability to spread, including: reproduction or growth strategy, dispersal capacity, longevity, dietary requirements, environmental and climatic requirements, specialist or generalist characteristics.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response:

Natural larval dispersal: *Mulinia lateralis* can generate a high propagule pressure as it can form dense populations, has a high fecundity, and in some regions of the RA area could reproduce all year round. In its native range in estuaries along the east coast of N. America, it can reach average densities of up to 21,000 ind. m<sup>2</sup> (Santos & Simon 1980; Walker & Tenore, 1984), and in The Netherlands, up to almost 6000 ind. m<sup>2</sup> were recorded from the Voordelta (Craeymeersch et al., 2019). Each female produces 3-4 million eggs per spawning event (for more details on reproductive traits please see Qu. 2.7). In Long Island Sound, Calabrese (1970) recorded peak larval densities of 2,500-3,500 ind. m<sup>3</sup>.

In its native range, the reproductive period of *M. lateralis* varies from just a few months in the Gulf of St. Lawrence to all year round in the Gulf of Mexico (Montagna et al., 1993), depending on the length of time when seawater temperature is above 16 °C (Calabrese et al., 1969a). If this species becomes established in the Mediterranean Sea, the thermal requirements for successful larval development are met throughout most of the year, this would lead to significant potential for natural dispersal. In Atlantic Europe, lower seawater temperatures will limit the period with conditions suitable for reproduction (see Annex VIII), as well as extending the duration of larval development.

*M. lateralis* larvae remain in the free-swimming planktotrophic phase for 7-22 days (Mann et al., 1991), during which time they could travel hundreds of kilometres. However, Shanks & Brink (2005) reported that in N. Carolina, during a period of upwelling and downwelling, *M. lateralis* larvae actively remained within 5 km of shore despite cross-shelf currents and the exchange of nearshore waters with offshore waters, i.e. they did not behave as passive particles. This phenomenon has been demonstrated for other species with a similar native distribution (e.g. Feng et al., 2017). For *M. lateralis* in particular, a rather limited (spatially) molecular study with populations from Long Island, Virginia and S. Carolina has found that all three populations are rather homogeneous for 19 genetic loci, supporting larval dispersal along the Atlantic coast (Wenne, 1992). However Mann et al. (1991) observed that larvae of this species use their preference for salinity discontinuities or higher salinity water to assist retention in partially mixed estuaries (Mann et al., 1991). Thus, larvae may generally remain entrained in estuaries where they have established. This species is currently limited to the southern part of the North Sea, its invaded range encompassing the full lengths of the Dutch and Belgian coasts, and the German part of the Wadden Sea.

The prevailing currents would tend to carry the larvae from the Wadden Sea eastwards towards Denmark, Norway and the Baltic Sea (De Hauwere, 2016). However, the populations along the Belgian coast appear to be spreading westward. Anthropogenic factors are likely implicated in this spread pattern; this westward spreading of introduced species along the North Sea coasts being rather common e.g. *Petricolaria pholadiformis* and *Ensis leei* (F. Kerckhof, pers. comm., 17<sup>th</sup> August 2021). However local circulation patterns aided by seasonal wind forcing can vary considerably and can also carry larvae westwards, depending on the timing of spawning (Barney et al., 2003; Lefebvre et al., 2003; Dauvin et al., 2007). If *M. lateralis* continues to spread westward into the English Channel, this may well provide a source of larvae that could be carried to the south coast of the UK, as demonstrated by Lefebvre et al. (2003) for the brittle star *Ophiothrix fragilis*, which has a similar larval duration of 26 days.

*M. lateralis* is not currently present in the Mediterranean Sea, and it is very unlikely it could disperse there naturally from its current invaded range in the North Sea. However, if it arrived by a human-assisted pathway, it could potentially spread by natural dispersal throughout the Mediterranean. Surface circulation of the Mediterranean consists basically of a separate counter-clockwise movement of the water in each of the two basins. Because of the complexity of the northern coastline and of the numerous islands, many small eddies and other local currents form essential parts of the general circulation (Millot & Taupier-Letage, 2005). Natural dispersal of planktonic larvae can vary at the subregional level as well as seasonally but has been estimated with modelling simulations in the range of  $10^2$ - $10^3$  km for organisms with PLDs similar to *M. lateralis* (Bray et al., 2017; Andrello et al., 2013). Larvae of *M. lateralis* can easily survive the current environmental conditions throughout most of the RA area, see Qu. 2.1 for details. Its preferred salinity range is 18-30 psu (Lippson & Lippson, 1984), and it is especially adapted to mixohaline sites where salinity levels fluctuate. Although, its presence along the Dutch and Belgian coasts indicates it can also establish in fully marine areas. Suitable habitats for *M. lateralis* larvae to settle, consisting of soft sediments on intertidal shores or in the shallow sublittoral, can be found throughout much of the RA area, where there are many estuaries, lagoons and sheltered coastal waters (Craeymeersch et al., 2019; Klunder et al., 2019; Yang et al., 2021).

Natural dispersal of adults: *Mulinia lateralis* juveniles and adults are small, light due to their thin shells, and they live very close to the surface (Chalermwat et al., 1991). Disturbances to the sediment through strong wave action, or bottom trawling, may lead to excavation of large numbers of clams. These can then be transported by bedload transport, tidal currents, or longshore currents, before deposition elsewhere (Cleveland et al., 2002; Prezant et al., 2010). On St Catherine's Island, Georgia, US,

Cleveland et al. (2002) reported a mass exhumation of *M. lateralis*, from a subtidal population, possibly caused by strong wave action or shrimp trawling. The clams were likely transported by the strong tidal currents before deposition in an area covering over 7000 m<sup>2</sup> of intertidal shore. Rees et al. (1977) also noted storm-induced strandings of several bivalve species along the coast of North Wales. They stated that wave activity could be a factor in the maintenance of soft bottom benthic associations in near-shore waters. This method of transport has also been described for: *Cerastoderma edule* (Richardson et al., 1993); *Mya arenaria* (Emerson & Grant, 1991); *Mercenaria mercenaria*, and several other bivalve species (Prezant et al., 2010). Dispersal is probably over relatively short distances of a few kilometres (Prezant et al., 2010).

A rapid rate of natural spread is predicted, resulting from longer distance larval dispersal along the coast, with some restriction due to larval retention in estuaries, and the short distances involved in adult clam dispersal.

**Qu. 3.2a. List and describe relevant pathways of spread other than "unaided". For each pathway answer questions 3.3 to 3.9 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 3.3a, 3.4a, etc. and then 3.3b, 3.4b etc. for the next pathway.**

including the following elements:

- a list and description of pathways of spread with an indication of their importance and associated risks (e.g. the likelihood of spread in the risk assessment area, based on these pathways; likelihood of survival, or reproduction, or increase during transport and storage; ability and likelihood of transfer from the pathway to a suitable habitat or host) in relation to the environmental conditions in the risk assessment area.
- an indication of the rate of spread for each pathway discussed in relation to the species biology and the environmental conditions in the risk assessment area.
- All relevant pathways of spread (except "Unaided (Natural Spread)", which is assessed in Qu. 3.1) should be considered. The classification of pathways developed by the Convention of Biological Diversity shall be used (see Annex IV).

Pathway name: Four potential pathways/ vectors were identified and are listed in order of importance:

**a) TRANSPORT-STOWAWAY (ship/boat ballast water and sediments)**

Kerekhof (2019) suggests that *Mulinia lateralis* was introduced into NW Europe with ballast water, like the bivalve *Ensis leei*, also a species originally from the N. American east coast. In addition, ballast water has been suggested as the pathway for two other recently introduced bivalves, *Rangia cuneata* and *Theora lubrica* (Verween et al., 2006; Faasse et al., 2019).

With respect to the RA area, movement of vessels between ports within its boundaries is less restricted and ballast water regulations do not apply to short journeys within states. This means that the potential of ballast waters and sediments transport to act as a vector of spread of *M. lateralis* within the risk assessment area is significant.

**b) TRANSPORT-STOWAWAY (other means of transport: marine aggregates & dredging)**

Dredging is carried out throughout the EU for a number of reasons including: keeping waterways and ports navigable; creation of new ports; coastal protection; land reclamation; and the extraction of sediments as sand and gravel for use by the construction industry (EuDA, 2013; Rabobank, 2013). The dredged sediments from ports and channels may be re-used “beneficially“ for coastal protection, land reclamation or offshore construction, or are disposed of in designated disposal sites in the open sea.

The introduction of a closely related bivalve, *Rangia cuneata*, into the Vistula Lagoon in the Baltic Sea, and its spread in the UK and the US have been attributed to dredging activities. (Gallagher & Wells, 1969; Rudinskaya & Gusev, 2012; Willing, 2017).

**c) TRANSPORT-CONTAMINANT (contaminant of animals: mariculture)**

In shellfish farming, dredging is used extensively in the relaying of shellfish for on-growing or purification (Capelle et al., 2017; DG SANTE, 2018). *M. lateralis* has similar habitat requirements to many cultivated bivalves, so is likely to settle and grow in areas where shellfish are being farmed (McKeon et al., 2015; Craeymeersch et al., 2019). Thus, relaying of shellfish from areas where *M. lateralis* is present is likely to result in transfer of *M. lateralis* larvae or adults, as contaminants of the water or sediment associated with the shellfish.

**d) TRANSPORT-STOWAWAY (other means of transport: boat bilge water)**

The bilge water of small vessels, such as fishing boats, yachts and motor boats, not subject to the BWMC, can contain bivalve larvae and juveniles (Darbyson et al., 2009; Fletcher et al., 2017). These vessels typically move between marinas and harbours, or sheltered inland waters such as estuaries, that are likely to provide a habitat suited to the establishment of *M. lateralis*. The European Boating Industry (2020) estimates that over 6 million boats are kept in European waters, while 10,000 marinas provide one million berths both inland and in coastal areas.

**a) TRANSPORT-STOWAWAY (ship/boat ballast water)**

**Qu. 3.3a. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional	<b>CONFIDENCE</b>	low
	<b>unintentional</b>		medium
			<b>high</b>

Response: It can be stated with high certainty that this pathway is unintentional. There is no doubt that uptake of larvae in ballast water is accidental. See categorization of pathways in Annex IV and guidance notes in the beginning of this section.

**Qu. 3.4a. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: For reproductive output, ship ballast water and sediment volumes, and potential larval concentrations, see Qu. 1.3a. With respect to spread of the organism within the RA area, transshipment operations constitute the main maritime traffic that will act as the vector for spread. Important transshipment hubs are situated along the southern Mediterranean (serving the rest of the Mediterranean and the Black Sea) and the Le Havre-Hamburg range, serving the UK, the Baltic and Scandinavia (Notteboom & de Langen, 2015). Regional vessel movements are more likely, than those from outside the RA area, to pass over suitable habitat where any larvae or adults released in transit may be able to survive. In particular, small vessels may take routes close to the coast and shelter in estuaries or bays overnight or in bad weather, habitats favoured by *Mulinia lateralis*, see Qu. 1.7a for more details.

Noteworthy, are also larger passenger/ car ferries which operate in most regions, and which have a high traffic volume. Due to the routes taken, measures described in the ballast water convention cannot easily be followed (exchange at depth and distance from shore) so the risk of depositing propagules at suitable locations is higher. These vessels are currently often unchecked, untreated and unregulated, with member states permitted under the BWMC to allow exemptions to apparently low risk inter-regional shipping routes (Olenin et al., 2016). Considering that *M. lateralis* is favoured by water temperatures encountered in many parts of the RA area but has a moderate pelagic larval duration and most likely discreet recruitment periods in Atlantic Europe, it is considered moderately likely that sufficient numbers can be transferred with ballast water along this pathway.

**Qu. 3.5a. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: As in Qu.1.4.a. Additionally, the shorter duration of sea shipping routes between EU ports, and the ferry routes between many European locations, further increases the likelihood of survival within ballast waters, compared with the transatlantic routes from N. America.

**Qu. 3.6a. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: See Q1.5a. BWE for EU short sea-shipping routes is usually restricted to the second criterion of at least 50 nm from the nearest land, and in waters at least 200 metres in depth in the Mediterranean Sea, and even this is often not feasible in northern European Seas (David et al., 2007). Thus, ballast water exchange is not likely to be effective in preventing the spread of *Mulinia lateralis* (and other organisms potentially transferred in ballast water) within European Seas. Regarding the IMO D2 standard, compliance can practically diminish propagule pressure of zooplankton, but full implementation of the BWMC is not expected to happen before 2024. However, even then some of the regulations and requirements under the BWMC may be relaxed for shorter, low-risk shipping routes under regional exemption options.

**Qu. 3.7a. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: As in Qu. 1.6a.

**Qu. 3.8a. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: *Mulinia lateralis* is typically found in the sheltered, soft sediment habitats common around ports and harbours, which are widely distributed in the RA area. If ballast water exchange occurs in open seas rather than in coastal areas, transfer of planktonic larvae and adults to suitable substrate will be hampered. If, however, untreated ballast water is released in ports, estuaries or other coastal areas, then establishment will be dependent on availability of suitable habitat. Considering: a) the breadth of habitat that characterizes the species; b) the wide distribution of such habitats in the RA area; and c) the initial invasion of the species in The Netherlands, close to Rotterdam (Craeymeersch et al., 2019; Klunder et al., 2019), the third busiest port in the world; there is a high likelihood that *M. lateralis* can transfer to a suitable habitat after release with ballast water.

**Qu. 3.9a. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area. (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: Given: a) the amount of maritime traffic between ports and harbours within the RA area (thousands of journeys per year); b) the ballast volume of commercial vessels ( $10^4$ - $10^5$  tonnes) (GloBallast, 2021); c) the potentially high densities of both adult *Mulinia lateralis* on the seabed as well as larvae in surface waters; and d) its wide environmental tolerances (see Qu. 1.4a for details); the potential rate of spread of the species via ballast water is high. Ballast water is considered to be one of the main vectors for spread of the closely related mactrid bivalve *Rangia cuneata* that has recently invaded and rapidly spread throughout northern European waters (Faillettaz et al., 2020). In addition, ballast water is the most likely vector for long dispersal jumps to other subregions. However, there is currently no evidence of spread within the RA area from ballast water discharge (i.e. no long dispersal jumps combined with sudden appearance in/close to port areas), and potential recipient sites in the Mediterranean are possibly isolated (see Qu. 1.7a), although regional vessel movements are more likely, than those from outside the RA area, to pass over suitable habitat where any larvae or adults released in

transit may be able to survive. For these reasons we have proposed a conservatively moderate rate of spread, with low confidence, acknowledging the novelty of the invasion and the possibility that the rate of spread may increase in the future. Due to the limited duration of favourable environmental conditions (seawater temperature) for reproduction in the more northerly parts of the NE Atlantic Ocean, the likelihood that dense populations will develop there is lower.

**b) TRANSPORT-STOWAWAY (other means of transport: marine aggregates & dredging)**

**Qu. 3.3b. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional	<b>CONFIDENCE</b>	low
	<b>unintentional</b>		medium
			<b>high</b>

Response: *Mulinia lateralis* has no commercial value. The dredging activities referred to in this pathway do not include dredging of commercial shellfish beds, and do not intentionally collect this species (but see Qu. 3.3c). See categorization of pathways in Annex IV and guidance notes in the beginning of this section.

**Qu. 3.4b. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
	unlikely		<b>medium</b>
	moderately likely		high
	<b>likely</b>		
	very likely		

Response: Dredging is carried out for a number of reasons, including: maintenance to keep waterways and ports navigable, creation of new ports, coastal protection, land reclamation, and the extraction of

sediments as sand and gravel, which are used by the construction industry (EuDA, 2013; Rabobank, 2013). The dredged material from ports and channels is usually disposed of in designated areas in the open sea. However, there is a move towards ‘beneficial dredging’ where, whenever possible, dredging waste is re-used for land reclamation, coastal protection, or offshore construction, reducing the need for newly excavated aggregates (ICES, 2016). Thus, dredged materials can be dispersed widely.

Dredging is a major activity in Europe, particularly within The Netherlands, the UK, Denmark and Belgium. For example, over 51 million m<sup>3</sup> of marine aggregate was extracted in 2017, approximately 40% as aggregate for construction, 40% for beach replenishment and 19% for land reclamation (ICES, 2018). Maintenance dredging takes place at virtually all harbours, and many marinas throughout the EU. Within the current invaded range of the RA area, there is significant dredging and disposal activity all along the Dutch, German and Belgian coasts. For example, the Port of Rotterdam requires intensive maintenance dredging that yields 12-15 million m<sup>3</sup> of dredged material annually (Kirichek et al., 2018). Intensive dredging is also taking place in the port of Zeebrugge and the dredgers often move from one operation zone to another, e.g. from Belgium to the Baltic Sea (F. Kerckhof, pers. comm., 17th August 2021). Large quantities of dredged materials are distributed along the Dutch and Belgian coasts to help prevent coastal erosion and aid land reclamation. *Mulinia lateralis* lives, shallowly buried, in the surface soft sediments of sheltered waters such as estuaries, lagoons, harbours and coastal areas. Dredging activity is high in such areas as they are prone to silt accumulation. Any dredging of these sediments will inevitably collect a high percentage of any *M. lateralis* adults present, but also larvae in ballasting hopper water. The adults are small (10-20 mm in length), while newly metamorphosed juvenile shell lengths range from 200 to 700 µm (Wang & Guo, 2008), thus can easily be taken up by all forms of dredging. For details of the *M. lateralis* propagule pressure generated, see Qu. 1.3a.

M. Faasse proposed the accidental transfer of dredged materials as a possible pathway of spread (pers. comm., 25<sup>th</sup> February 2021). The introduction of a closely related bivalve, *Rangia cuneata*, into the Vistula Lagoon in the Baltic Sea, and its spread in the UK and the US have been attributed to dredging activities. (Gallagher & Wells, 1969; Rudinskaya & Gusev, 2012; Willing, 2017).

**Qu. 3.5b. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: During the period of retention on the vessel, the adults will remain in the sediments they were collected with, so should be able to survive, and possibly even reproduce. While in transit, adults can survive anoxic conditions, salinities of 5-80 psu (Parker, 1975), and temperatures from -2 to 35 °C (Calabrese, 1969a; Kennedy & Mihursky, 1971). *Mulinia lateralis* can also burrow up to the surface if

buried (Maurer et al., 1981) and actively thrives in dredged areas (Flint & Younk, 1983). Larvae in hopper water are also likely to survive (Qu 1.4b).

**Qu. 3.6b. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: The disposal of dredged materials is regulated throughout the EU (summarised by Mink et al., 2006). OSPAR guidelines specify best environmental practice for managing dredged material (OSPAR, 2014). Member states use these guidelines to manage dredging and dumping and to minimise effects on the marine environment. The main management tools are marine licence and control systems. These require assessments of the environmental impact of planned disposal activities in relation to a specific dumpsite, sediment characteristics and contamination load. Dredging activities are also regulated under the Marine Strategy Framework Directive (MSFD) 2008/56/EC, the Water Framework Directive (WFD) 2000/60/EC and the EC Habitats Directive (92/43/EC). However, the licencing procedures in member states tend to focus mainly on the sediment characteristics and the prevention of the disposal of waste containing contaminants such as heavy metals and pathogens, not non-native species. In addition, many maintenance-dredging activities are exempt or have a reduced licencing requirement (Gov.UK, 2021). No EC regulations on the cleaning of dredging vessels and equipment between projects were found. Thus, residual waste intended for disposal at one site could become mixed with a subsequent load and be disposed of accidentally at another location. As the major dredging corporations are based in the North Sea, see Qu. 1.3b, where this species is now established, there is a risk of spread to other areas within the EU where these corporations operate. For example, there are currently major dredging projects throughout the Mediterranean and Black Sea (Dredging Today, 2021, Van Oord, 2020).

Regulations may vary from country to country. For example in Wales, UK, the completion of a Biosecurity Risk Assessment when applying for a marine licence for dredging and/or disposal, is now required for all activities. Marine licencing conditions imposed include the washing of seabed equipment and filter screens at the end of a campaign, the requirement for the circulation and exchange of hopper water away from shore, and the removal of hopper sediment prior to entering a different region of the UK (ABPmer, 2019; G. Wynne, B. Wray & S. Vye (Natural Resources Wales,) pers. comm. 21<sup>st</sup> April 2021). However, these management practices are not yet statutory, and do not apply to the rest of the UK. In general, restrictions on disposal based on the risk associated with the source areas would be an effective management method, as long as extensive and up-to-date data on the distribution of the high-risk non-native species are available.

**Qu. 3.7b. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: Any *Mulinia lateralis* accidentally collected would be dumped with a significant amount of sediment, in the designated disposal site. It is unlikely any regular checks will be made at the disposal sites, particularly where the dredge waste is being re-used for land reclamation, offshore construction, or coastal protection. The transportation and release of larvae in hopper water is even less likely to be monitored or detected.

Adult *M. lateralis* are small (10-20 mm in length), and the gross morphology is similar to some common native species, as described in A.2, so may easily be overlooked. Newly metamorphosed juvenile shell lengths range from 200 to 700  $\mu\text{m}$  (Wang & Guo, 2008), so transfers at the larval or juvenile stage, within the associated sediment or water, are very likely to go undetected.

**Qu. 3.8b. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: *Mulinia lateralis* will be deposited along with the sediment or hopper water it was collected with, so the immediate habitat will be very suitable. If the waste is being used for coastal protection or land reclamation, the deposition will probably be made close to shore in a sheltered area. Licensed dredged waste disposal sites may be further offshore, but again the seabed is likely to consist of soft sediments from previous disposals. *M. lateralis* can also burrow up to the surface if buried during the deposition (Maurer et al., 1981).

**Qu. 3.9b. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area. (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly	<b>CONFIDENCE</b>	low
-----------------	-------------	-------------------	-----

	slowly <b>moderately</b> rapidly very rapidly		<b>medium</b> high
--	--	--	-----------------------

Response: Given the high frequency and volumes involved in maintenance and capital dredging activities, the likely high survival rate during transit, and deposition commonly being into suitable habitat, there is a high risk of spread. This is especially the case in the Greater North Sea area where the waste is normally re-used ‘beneficially’ for coastal protection or land reclamation, e.g. in The Netherlands, Denmark and Belgium (ICES, 2016). Under these circumstances, disposal sites may be greater distances away from the initial collection site, than would be the case for designated waste disposal sites. Although the disposal site is likely to be within the same member state, or a close neighbouring member state. Long dispersal events with dredge spoils are probably likely to be more sporadic compared with spread via ballast water/sediment due to the higher volume and frequency of commercial ship journeys.

**c) TRANSPORT-CONTAMINANT (contaminant of animals: mariculture)**

**Qu. 3.3c. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response: *Mulinia lateralis* is not grown commercially for food, thus its introduction into commercial shellfish beds is unintentional. In addition, as it will compete with the cultivated shellfish for space and food, so would be considered a nuisance species.

**Qu. 3.4c. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Cultivated shellfish are frequently moved between sites locally, regionally and internationally, for the purposes of: restocking; to enhance production; relaying for fattening purposes; relaying for cleansing; or to keep fresh and alive before consumption (McKindsey et al., 2007; Brenner et al., 2014; Muehlbauer et al., 2014). It is known that many non-native species can hitchhike with these movements, including the Manila clam, *Ruditapes philippinarum* (McKindsey et al., 2007, and references therein).

Production of bivalve molluscs in the EU averages 500,000 tonnes annually (350,000 tonnes of mussels, 100,000 tonnes of oysters and 50,000 tonnes of clams), France and Spain are the most important countries in terms of production volume and value (DG SANTE, 2018). Spain, Ireland, France, Italy and the UK are the most important regarding trade of live bivalve molluscs for farming and relaying. France is particularly important in terms of the number of movements of live bivalve molluscs for relaying before putting on the market, and the natural production of seed spat of Pacific oysters and mussels that is subject to movements either within France or to other member states. There are also a large number of movements from Spain, particularly from Galicia to Italy, for relaying and purification (Robert et al., 2013; DG SANTE, 2018). Mussel bottom culture is typically practiced on shallow mudflats in areas where there are extensive naturally occurring mussel seed beds. In the Netherlands, Germany, UK, and Ireland, seed fished from natural beds is the main source for bottom culture (Kamermans & Smaal, 2002).

*Mulinia lateralis* is likely to establish and thrive in habitats typically used for benthic shellfish cultivation, e.g. in Chesapeake Bay in its native range, it is found in association with several commercial species (Reece et al., 2008), and in the Wadden Sea, it was found to be abundant amongst the edible clam, *Spisula subtruncata* (Craeymeersch et al., 2019). *Mytilus edulis*, the Blue mussel, is produced in the Western part of the Dutch Wadden Sea and in the Oosterschelde estuary, both areas where *Mulinia* has already invaded (Robert et al., 2013; Craeymeersch et al., 2019; Faasse et al., 2019). For details of the *M. lateralis* propagule pressure generated, see Qu. 1.3a.

The relaying of spat for on-growing, or adult bivalves for fattening or cleansing, is carried out by dredging the donor site (using a variety of methods), then relaying the bivalves at the new location (Diaz et al., 2012; Gaspar et al., 2013; Robert et al., 2013; Capelle et al., 2014). Although *M. lateralis* does not attach to other shellfish, juveniles and adults present as contaminants in the sediment would be collecting as by-catch during the dredging process, also larvae may be captured in water taken up during the dredging.

<b>Qu. 3.5c. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?</b>
--

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: In order to successfully transfer the target commercial bivalve species, the dredging, on-board conditions, and transit time will all be optimized to ensure the target species survives and remains healthy. This process will also enable the survival of *Mulinia lateralis*, a species with wide environmental tolerances, see Qu. 1.4a for more details. Reproduction during transit is unlikely as the period between dredging and relaying of the target species is short, particularly for spat, as the shellfish need to be kept alive and healthy; although some larvae may metamorphose.

**Qu. 3.6c. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: At the EU level, COUNCIL REGULATION (EC) No 708/2007 concerning use of alien and locally absent species in aquaculture defines the procedures to be followed that minimize the risk of introducing non-target alien species accompanying commercial shellfish spat and stocks. It requires a permit procedure, involving risk assessment for the non-target species and a quarantine period for the translocated stock. Importantly, in relation to spread within the RA area, the regulation does not apply to movements of locally absent species within the member states (i.e. in this case cultivated native species of bivalves) “except for cases where, on the basis of scientific advice, there are grounds for foreseeing environmental threats due to the translocation, Art. 2 para. 2.” Additionally, movements of the bivalves *Magallana gigas* and *Ruditapes philippinarum*, listed in Annex IV of the Council Regulation, which could be contaminated with *M. lateralis*, are permitted without any risk assessment or quarantine. However, local/national legislation exists that can limit the translocation possibilities of species like *M. gigas*, e.g. see WG-AS & Gittenberger (2018) for the trilateral Wadden Sea area. With regard to mussel relaying in Wales, UK a walkover survey of the source site is required checking for before a licence is granted (G. Wynne, B. Wray & S. Vye (Natural Resources Wales,) pers. comm. 21<sup>st</sup> April 2021). Moreover, if the import region is a Natura 2000 area, regulations can be much stricter as they aim to protect the conservation objectives of the protected area first.

Where the commercial shellfish are cleaned before transfer, removing any sediment, this will significantly reduce the level of contamination by *Mulinia lateralis* larvae and juveniles, as these would not be attached to the shellfish. Sorting by size may also limit contamination of adult commercial stocks as *M. lateralis* only grows to 10-20 mm.

In general, restrictions on transfers based on the risk associated with the source areas is an effective management method, as long as extensive and up-to-date data on the distribution of the high-risk non-native species are available. However, delays in identifying new non-native species, and their distribution in the RA area, can mean that spread, particularly within member states, is not prevented. For example, in The Netherlands, mussel seed is fished from seed beds which generally occur in the Wadden Sea, it is then transported to culture plots in the Wadden Sea and the Oosterschelde (Robert et al., 2013), although movement is not permitted in the other direction. This offers a possible explanation of the finding of *M. lateralis* in the Oosterschelde. Visual inspections of the dredged shellfish are unlikely to detect *M. lateralis*, unless it is present in large numbers, due to its small size, and larvae would not be visible. Moves within the commercial shellfish sector towards hatchery culture of spat, and rope culture for mussels, will reduce the need for dredging (Robert et al., 2013; Smaal et al., 2019).

**Qu. 3.7c. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: Perfunctory visual inspections during bivalve aquaculture operations are likely to miss adult *Mulinia lateralis* as they are small (10-20 mm in length), and the gross morphology is similar to some common native species, as described in A.2. Newly metamorphosed juvenile shell lengths range from 200 to 700 µm (Wang & Guo, 2008), so transfers at the larval or juvenile stage, within the associated sediment or water, are very likely to go undetected.

**Qu. 3.8c. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: If bivalve seed/stock contaminated with *Mulinia lateralis* is relayed on cultivation plots without any prior management measures, the likelihood of transfer to other suitable habitats is very high (the cultivation plots themselves are suitable habitats, see Qu. 3.4c). These plots are often situated in coastal areas in close proximity to additional suitable natural habitat to which individuals may spread.

**Qu. 3.9c. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area. (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: Shellfish movements are a likely mechanism of spread in the RA area, particularly at the local level, where spat is dredged and then relayed at nearby sites for on-growing. However, considering the degree of regulation of the industry and the fact that in many cases transfers are predominantly conducted within member states, spread to distant locations through this pathway may be less important than spread through other pathways such as ballast water and sediments.

**d) TRANSPORT-STOWAWAY (other means of transport: boat bilge water)**

**Qu. 3.3d. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response: Bilge water is not taken up intentionally; it results from rough seas, leaks in the hull, rain, washing of equipment on deck, or other interior spillage. Thus, there is no doubt the presence of any *Mulinia lateralis* in bilge water is accidental. See categorization of pathways in Annex IV.

**Qu. 3.4d. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway

- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: It depends on:

- The number of yachts and vessels arriving in a hub;
- Volume of bilge water;
- Theoretical distance, time to first discharge (assuming constant and linear travel);
- Propagule pressure; and
- Survival of the species.

An indication of the number of recreational vessels in the RA area is given by the European Boating Industry (2020), which estimates that over 6 million boats are kept in European waters while 10,000 marinas provide one million berths, both inland and in coastal areas. Fletcher et al. (2017) recorded bilge water volumes of between 0.9 and 29 l from 15 motorboats sampled, and 0.2-200 l from 15 yachts, including a large catamaran, in New Zealand. Fletcher et al. (2020) noted that yachts in particular, have a high likelihood of bilge water being on board when leaving port (i.e. high-risk source regions for *Mulinia lateralis* larvae). Extrapolating from CPS Authority et al. (2017), approximately 30% of these vessels travel distances >100 km from their home port. Assuming travel speeds of 5 knots (Fletcher et al., 2017) considerable distances can be travelled within the RA area within a matter of days, which significantly increases the likelihood that sufficient viable propagules of *M. lateralis* can spread along this pathway from already established populations in the RA area. For propagule pressure, see Qu. 1.3a.

**Qu. 3.5d. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Analysis of samples collected from yachts and motorboats in Canada and New Zealand, found bivalve larvae and juveniles in the bilge water (Darbyson et al., 2009; Fletcher et al., 2017). Considering: the pelagic larval duration of *Mulinia lateralis* (7 to 22 days); the relatively short travel times of small vessels within the RA area; the tolerance of the organism to salinities down to 5 psu; and its tolerance of oil pollution (a common contaminant of bilge water (Grassle & Grassle, 1974); the

likelihood of survival along this pathway is assessed as high. As adults are unlikely to be taken in with the small water incursions that accumulate as bilge water, it is unlikely that *M. lateralis* will reproduce during transport.

**Qu. 3.6d. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: Legislation regarding discharge of bilge water only relates to large commercial vessels and is included under the BWMC, see Qu. 3.6a. For smaller vessels, there is currently no EC legislation in place specifically covering bilge water. However, since 2008 some member states are requiring the installation of holding tanks in recreational vessels for waste water, although this is mainly to control ‘black water’ or ‘grey water’ from the toilets or washing facilities, and does not generally cover bilge water (Noonsite, 2019). Most recreational vessels now have bilge water pumps that operate automatically so the boat owner cannot control the location of discharge (Fletcher et al., 2017).

**Qu. 3.7d. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: See response Qu. 1.6a. In order to reach Good Environmental Status (GES) targets with reference to Descriptor D2, most EU states are already designing or implementing national/regional NIS-targeted monitoring programmes. Monitoring should focus on introduction hotspots (e.g. ports, marinas, aquaculture plots) and this will increase the detectability of *Mulinia lateralis* entering the RA area through bilge water, particularly if molecular methods are employed (Hayes et al., 2004).

**Qu. 3.8d. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Recreational vessels spend substantial periods of time stationary; berthed in marinas and ports, or on moorings in estuaries (Ashton et al., 2006). At other times, they generally remain in sheltered inland waters. Thus, if viable propagules are discharged with untreated bilge water they are likely to transfer to a suitable habitat consisting of soft sediments on intertidal shores or in the shallow sublittoral, see Qu. 1.7a for more detail on habitat.

**Qu. 3.9d. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area. (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: Small vessels travelling within the RA area can easily spread this organism while in transit, through automatic bilge water discharge, or at the next destination. However, compared to the transport of ballast water by larger vessels, the volumes of water transported are much smaller, the distances covered are generally much shorter, and the voyages less frequent. So the contribution of this pathway to the overall potential rate of spread is assessed as relatively lower than ballast water (see Qu. 3.9a).

**Qu. 3.10. Within the risk assessment area, how difficult would it be to contain the organism in relation to these pathways of spread?**

<b>RESPONSE</b>	very easy easy with some difficulty difficult <b>very difficult</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: Naturally dispersing organisms are very difficult to contain, especially species such as *Mulinia lateralis* with high fecundity, relatively long pelagic larval duration, and the capability to

develop extremely dense populations in a very short time (See Qu. 2.7 for the biological characteristics of the species). Currently this species is restricted to the Greater North Sea region, and there is no evidence of repeated introductions into the RA area. Thus, it may be feasible to delay the rapid spread of the species, especially long dispersal jumps, if restrictions based on the risk associated with the source areas are rapidly adopted by the industry. The current legal instruments and levels of implementation of voluntary measures are not sufficient to ensure containment of the organism, when transferred by ballast water (but this can change with full implementation of the D-2 Standard), dredging, bivalve movements, or bilge water.

**Qu. 3.11. Estimate the overall potential rate of spread in relevant biogeographical regions under current conditions for this organism in the risk assessment area (indicate any key issues and provide quantitative data where possible).**

Thorough assessment of the risk of spread in relevant biogeographical regions in current conditions, providing insight in the risk of spread into (new areas in) the risk assessment area.

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: Unaided dispersal and multiple pathways of human-aided spread create a considerable potential for spread. This is illustrated by the known spread of the species along approximately 450 km of coastline during the 4 years since its arrival.

Ballast water and sediment transport is the most likely vector to facilitate rapid spread via long distance transport of the species within European waters, until the BWMC is fully implemented. However, there is a lack of evidence of *Mulinia lateralis* being transported in ballast water and of the likelihood of it being transported to suitable habitats in other subregions, see Qu 1.7a and Qu 3.9a.

The movements of dredging waste may already have contributed to the current spread of *Mulinia lateralis* in the Greater North Sea region. Bivalve transfers are another likely mechanism of spread in the RA area, especially within member states but potentially also between marine regions/subregions. Particular attention is needed when transferring oyster consignments between Atlantic Europe and the Mediterranean. Finally, bilge waters, a vector that has been overlooked until recently, appears to be able to transport viable propagules of the species in the relatively short duration of intra-European journeys.

Due to the difficulty of predicting the potential for long dispersal jumps via ballast water or the other pathways, we have proposed a conservative rate of spread of moderately, with low confidence.

**Qu. 3.12. Estimate the overall potential rate of spread in relevant biogeographical regions in foreseeable climate change conditions (provide quantitative data where possible).**

Thorough assessment of the risk of spread in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk, specifically if rates of spread are likely slowed down or accelerated.

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: The rate of spread is not expected to change significantly under foreseeable climate change conditions. An overall rise in sea surface temperatures will increase the potential for adult populations and larval production in the Greater North Sea and Celtic Seas subregions, with a corresponding increase in the likelihood of spread via all pathways. Whereas in the Mediterranean Sea, an increase in SST may result in fewer source populations (see Qu. 2.10 for more detail), and thus reduce the likelihood of spread. Higher frequency and severity of storms can increase the amount of time vessels have to spend in port, increasing the likelihood of entrainment in ballast water (Galil et al., 2019).

Dredging activity may increase in response to rising sea levels, leading to an increase in demand for coastal protection. In addition, an increase in extreme weather events (e.g. flooding with associated terrigenous inputs), may increase the need for dredging to maintain water channels and protect property. Heat waves can cause mass mortality of aquaculture bivalves, leading to increased shellfish transfers to replenish the stocks (Rodrigues et al., 2015). More shellfish movements may be associated with a higher risk of introduction if the stocks/seed originate from areas with a high risk of contamination with *Mulinia lateralis* and the necessary precautions are not taken.

## 4 MAGNITUDE OF IMPACT

Important instructions:

- Questions 4.1-4.5 relate to biodiversity and ecosystem impacts, 4.6-4.8 to impacts on ecosystem services, 4.9-4.13 to economic impact, 4.14-4.15 to social and human health impact, and 4.16-4.18 to other impacts. These impacts can be interlinked, for example, a disease may cause impacts on biodiversity and/or ecosystem functioning that leads to impacts on ecosystem services and finally economic impacts. In such cases the assessor should try to note the different impacts where most appropriate, cross-referencing between questions when needed.
- Each set of questions starts with the impact elsewhere in the world, then considers impacts in the risk assessment area (=EU excluding outermost regions) separating known impacts to date (i.e. past and current impacts) from potential future impacts (including foreseeable climate change).
- Only negative impacts are considered in this section (socio-economic benefits are considered in Qu. A.7)
- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable).

### Biodiversity and ecosystem impacts

**Qu. 4.1. How important is the impact of the organism on biodiversity at all levels of organisation caused by the organism in its non-native range excluding the risk assessment area?**

including the following elements:

- Biodiversity means the variability among living organisms from all sources, including terrestrial, marine and other aquatic ecosystems and the ecological complexes of which they are part; this includes diversity within species, between species and of ecosystems
- impacted chemical, physical or structural characteristics and functioning of ecosystems

RESPONSE	NA	CONFIDENCE	
----------	----	------------	--

Response: There is no evidence to suggest that this species is non-native anywhere else in the world outside the RA area.

**Qu. 4.2. How important is the current known impact of the organism on biodiversity at all levels of organisation (e.g. decline in native species, changes in native species communities, hybridisation) in the risk assessment area (include any past impact in your response)?**

Discuss impacts that are currently occurring or are likely occurring or have occurred in the past in the risk assessment area. Where there is no direct evidence of impact in the risk assessment area (for

example no studies have been conducted), evidence from outside of the risk assessment area can be used to infer impacts within the risk assessment area.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: *Mulinia lateralis* has only been present within the RA area since 2016, and its current distribution is limited to the southern North Sea (see Qu. A6). No studies of impact have been reported from the RA area, so it is not yet possible to reliably assess its current impact on biodiversity. However, this species' rapid population growth within the RA, its population dynamics within the native range, and the known impacts on biodiversity from other invasive bivalve species, indicate that *M. lateralis* is likely already having some impact.

**Competition:** In 2017, dense populations of up to almost 6000 ind. m<sup>2</sup> were recorded from the Voordelta (southwestern Dutch coastal waters), and again in 2018 at densities of 1000 ind. m<sup>2</sup> (Craeymeersch et al., 2019). In 2018, *M. lateralis* was recorded at high density (820 ind. m<sup>2</sup>) in the Westerschelde (Craeymeersch et al., 2019). Subsequently, in 2019, it was recorded there at 18/44 sites sampled, at an average of five ind. m<sup>2</sup> (Wallis et al., 2020). In its native range in estuaries along the east coast of N. America, it can reach average densities of up to 21,000 ind. m<sup>2</sup> (Santos and Simon 1980; Walker & Tenore, 1984). It is possible that such dense settlements are competing with native bivalves for space and food, but see Qu. 4.3.

**Impacts of similar species (i.e. shallowly buried, infaunal suspension feeders with an r-strategy) in the Greater North Sea region:**

*Ensis leei*: In Belgium, declines in abundance of other bivalves such as *Macra stultorum*, *Cerastoderma edule*, *Spisula subtruncata*, *Ensis magnus* and tellinids have been observed since the introduction of *E. leei* (Gollasch et al., 2015).

*Rangia cuneata*: sympatric with *M. lateralis* in their native range (temperate west Atlantic, Gulf of Mexico), this mactrid bivalve has recently invaded and rapidly spread throughout northern European waters (Faillettaz et al., 2020). It has managed to establish numerical dominance in many of the invaded locations (estuaries, tidal reaches, brackish waters) with its numbers exceeding those of native species such as *Macoma balthica* and *Cerastoderma glaucum* in the Gulf of Gdansk (Janas et al., 2014).

**Qu. 4.3. How important is the potential future impact of the organism on biodiversity at all levels of organisation likely to be in the risk assessment area?**

See comment above. The potential future impact shall be assessed only for the risk assessment area. A potential increase in the distribution range due to climate change does not *per se* justify a higher impact score.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response:

**Competition:** Most bivalve species largely utilize the same food source and are therefore competitors for food. Whether food competition leads to an introduced species out-competing indigenous species is dependent on many factors such as filtration capacity, selection and absorption efficiency, and energy demand (Shumway & Newell 1984). *Mulinia lateralis* is adapted to quickly exploit high concentrations of phytoplankton and natural seston (particularly bacteria) but has a relatively high-energy demand and an apparent inability to catabolize protein during prolonged periods of starvation, which may be the cause of observed mass mortalities in its native range (Shumway and Newell, 1984; Chalermwat et al., 1991).

Within its native range, *M. lateralis* is considered an opportunistic species that tends to rapidly colonise disturbed areas at high population densities, but can just as quickly disappear (see Qu. A.11 and Qu. 2.3). According to McKeon et al. (2015), from studies in its native range, *M. lateralis* reaches its greatest densities when released from competition with other bivalves. However, in the Voordelta, in The Netherlands, *M. lateralis* was found together with *Spisula subtruncata* (a native species considered to be threatened (Cardoso et al., 2007)), both at high densities at the same site, and likewise in the Westerschelde, where *M. lateralis* was found with *Cerastoderma edule* both at high densities (Craeymeersch et al., 2019). Both native species are summer spawners, with the main spatfall occurring from June to September (Smaal et al., 1997; Cardoso et al., 2007). Thus, there is considerable overlap likely with *M. lateralis* during spat settlement (presuming its reproductive period in the North Sea is similar to that in the northern part of its native range (Calabrese, 1970)). Therefore, *M. lateralis* may well compete successfully both for space and food with native bivalves. Whether this will lead to native species' declines cannot be predicted with any certainty due to the novelty of the invasion, however increased settlement seems likely as the species establishes dense populations and expands its range. In addition, its colonisation of recently defaunated areas may prevent native opportunistic species from establishing at those sites.

**Shellfish disease:** In its native range, *M. lateralis* is a host for the protozoan parasite *Perkinsus chesapeaki*, recently recorded from the Mediterranean and Atlantic coasts of France and Spain, which can infect clams and cockles. According to Carrasco et al. (2014), no clear evidence of relevant host reaction was observed in *Cerastoderma edule* tissues, although *P. chesapeaki* seemed to cause damage to the structure of gill lamellae, see Qu. 2.4. If *P. chesapeaki* is present in the *M. lateralis* populations in the RA area, this disease could infect and lead to a decline in native clam or cockle populations.

**Hybridisation:** *M. lateralis* can hybridise with other clams e.g. *Spisula solidissima* (Lindell et al., 2006), whether it will hybridise naturally with clams native to the RA area, such as other *Spisula* species, is not known.

**Trophic interactions:** Many native species could potentially utilise *M. lateralis* as a food resource. *M. lateralis* lives very close to the sediment surface and has a thin shell, so is easily available to a wide variety of predators (see Qu. 2.4). Craeymeersch et al. (2019) anticipate many native species in the North

Sea will be able to feed on *Mulinia*. Whether *M. lateralis* would provide equivalent energy and nutrient levels as current native prey species would require detailed investigation. In its native range, *M. lateralis* is an important food source for wildfowl during the winter (Calabrese, 1970) and it was found to be an adequate replacement nutritionally for *Ischadium recurvum*, the Hooked Mussel (Wells-Berlin et al., 2015). Baffin Bay, a hypersaline estuary in the Gulf of Mexico, supports an important recreational and commercial fishery for black drum *Pogonias cromis*, this benthic predator is highly reliant on *M. lateralis* as a food source, the biomass of which varies with the rapid changes in salinity that occur there (Pollack et al., 2018; Rubio et al., 2018). The sudden crashes in *M. lateralis* populations could lead to starvation of predators such as crabs and fish that have come to rely on it (Walker & Tenore, 1984). For example, wintering scaup (*Aythya affinis*) populations in Lake Pontchartrain, Louisiana, declined precipitously a year after a hurricane caused mass mortalities of their preferred bivalve prey, i.e. the clams *Rangia cuneata* and *M. lateralis* (Stroud et al., 2019).

Mass mortality events: Mass die-offs of bivalves can affect the ecosystem in 3 ways:

a) Food web structure, nutrient cycling and transfer of energy to higher trophic levels - The interaction between infaunal filter feeders, such as *M. lateralis*, and resuspended microphytobenthos and detritus can be particularly important in estuaries (e.g. Jones et al., 2016). The sudden loss of large amounts of bivalve biomass can disrupt the transfer of carbon and energy in the system.

b) Water quality - Mass die-offs of bivalves are known to influence abiotic factors that negatively affect other organisms in the ecosystem through organic matter decomposition with associated reduced dissolved oxygen and elevated ammonia concentrations, sometimes to toxic levels (e.g. Cherry et al., 2005; Cooper et al., 2005), although such impacts are less likely to be severe or long-lived in well-flushed environments.

c) Habitat alteration - In its native range, very dense settlements of *M. lateralis* that then die off can leave large amounts of dead shells in areas of predominantly soft sediments; these can also be transported to local shores (Levinton, 1970; Powell et al., 1986). Changes in habitat complexity and seabed structural properties can in turn greatly affect the communities living within soft sedimentary environments (Bodis et al., 2014). Although this may be considered a positive impact as shell deposits can increase species' richness through provision of shelter and substrate for other species (Gutiérrez et al., 2003). However, Nicastro et al. (2009) found that even large depositions of shells of the non-native gastropod, *Maoricolpus roseus*, into a soft-sediment habitat within a dynamic coastal lagoon, did not affect the community structure.

Regional differences: In the Mediterranean Sea, should the species be introduced there, the impacts will probably be greater as it is likely that *M. lateralis* populations will become more dominant members of the macrobenthos throughout the year, especially in the highly variable lagoonal and estuarine systems (with low diversity) of the region, see Qu. 2.9. Interaction with the dominant bivalve *Abra ovata* is possible. As a result, strong trophic interactions are more likely to develop but also population crashes of dense settlements are more likely to produce negative effects.

**Qu. 4.4. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism currently in the risk assessment area?**

including the following elements:

- native species impacted, including red list species, endemic species and species listed in the Birds and Habitats directives
- protected sites impacted, in particular Natura 2000

- habitats impacted, in particular habitats listed in the Habitats Directive, or red list habitats
- the ecological status of water bodies according to the Water Framework Directive and environmental status of the marine environment according to the Marine Strategy Framework Directive

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response:

**The Netherlands:** The Wadden Sea is the largest unbroken system of intertidal sand and mud flats in the world; it stretches from The Netherlands to Denmark, and is recognised as a UNESCO World Heritage Site. It is known for its habitat variability and unique (benthic) biodiversity. The invasion of non-native species can alter the synergetic community currently present in this ecosystem, which provides vital support to migratory birds as a staging, moulting and wintering area. The availability of food and a low level of disturbance are essential factors that contribute to the key role of the property in supporting the survival of migratory species (UNESCO, 2021). The Voordelta, Oosterschelde, Westerschelde and North Sea coastal zone are all designated as Natura 2000 sites under the Habitat Directive and the European Birds Directive. *Mulinia lateralis* is present in all of these areas (see Qu. A8).

**Belgium:** Most of the Belgian coast is designated either under the European Birds Directive and/or the Habitat Directive, the largest area is the Vlaamse Banken between Ostend and the French border. *M. lateralis* has been found scattered along the whole Belgian coast.

**Germany:** The Wadden Sea – see The Netherlands above.

The habitat types where *M. lateralis* has established in these member states are Estuaries (X01), Marine littoral sediment (A2), and Marine sublittoral sediment (A5). The broadscale habitat features suitable for establishment of *M. lateralis* are littoral sand and muddy sand, mud, and mixed sediments; and sublittoral, sand, mud, and mixed sediments; corresponding to the EUNIS level 3 codes: A2.2, A2.3, A2.4, A5.2, A5.3, A5.4.

Changes through competition to infaunal bivalve populations, such as *Cerastoderma edule*, *Macra stultorum* or *Spisula subtruncata*, have the potential to affect the overwintering success of protected diving seabirds such as the common eider (*Somateria mollissima*) and common scoter (*Melanitta nigra*), which depend upon these prey resources for their survival (Bräger et al., 1995). With respect to the environmental status of the sites it has invaded, its impact could be related to the MSFD descriptors D1 (biodiversity), D2 (NIS), D3 (fishing), and D4 (food webs). Yet, the degree impact on GES, based on the MSFD descriptors by *M. lateralis* has not been quantitatively assessed. The only evident measured impact is presently the indicator D2 (criterion D2C1: number of new NIS per 6 years).

**Qu. 4.5. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.3. and 4.4.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: The conservation status of many estuarine and lagoonal Natura 2000 sites, MPAs and SSSIs could be degraded. Any decline in conservation value is likely to be greater in the Mediterranean Sea, should the species be introduced there, as it is more likely that, due to the potential for prolonged recruitment, year-round reproductive populations will develop, especially in the highly variable lagoonal and estuarine systems of the region, see Qu. 2.9. In addition to the habitats noted in Qu. 4.4, the biodiversity of saline (X02) and brackish lagoon habitats (X03) within the Mediterranean, along the Atlantic coast, and in the Black Sea could be impacted. Considering that lagoonal habitats are important as nursery areas for many fish populations (Pérez-Ruzafa et al., 2011; Newton et al., 2018), as well as feeding grounds for waterfowl, changes in trophic interactions and the overall food web could have short to medium term effects on their conservation value, which is already degraded/unfavourable in large parts of the RA area (EEA – Habitats Directive reporting under Article 17).

Figure 5: Conservation status of coastal lagoons (Habitat 1150) for the period 2013-2018 for EU28. (Source: European Environment Agency, available at <https://nature-art17.eionet.europa.eu/article17/>)

With respect to the environmental status of any conservation sites if invaded, the impact of *M. lateralis* could be related to the MSFD descriptors D1 (biodiversity), D2 (NIS), D3 (fishing), and D4 (food webs).

## Ecosystem Services impacts

**Qu. 4.6. How important is the impact of the organism on provisioning, regulating, and cultural services in its non-native range excluding the risk assessment area?**

- For a list of services use the CICES classification V5.1 provided in Annex V.
- Impacts on ecosystem services build on the observed impacts on biodiversity (habitat, species, genetic, functional) but focus exclusively on reflecting these changes in relation to their links with socio-economic well-being.
- Quantitative data should be provided whenever available and references duly reported.

<b>RESPONSE</b>	NA	<b>CONFIDENCE</b>	
-----------------	----	-------------------	--

Response: There is no evidence to suggest that the species is non-native anywhere else in the world outside the RA area.

**Qu. 4.7. How important is the impact of the organism on provisioning, regulating, and cultural services currently in the different biogeographic regions or marine subregions where the species has established in the risk assessment area (include any past impact in your response)?**

- See guidance to Qu. 4.6.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: *Mulinia lateralis* has only been present within the RA area since 2016, and its current distribution is limited to the southern North Sea (see Qu. A6). No studies of impact have been reported from the RA area, so it is not yet possible to reliably assess its current impact on ecosystem services. However, this species' rapid population growth within the RA, its population dynamics within the native range, and the known impacts on ecosystem services from other invasive bivalve species, indicate that *M. lateralis* is likely already having some impact.

Potential causes of as yet unidentified impacts:

**Provisioning:** Biomass - Although competition for food and space with cultivated bivalves is a potential source of loss, it is unclear if *M. lateralis* is a strong competitor to commercial species (see Qu. 2.3). The Wadden Sea and Oosterschelde are important areas for shellfish culture.

**Regulation and Maintenance:** In the North Sea, where this species is established, it is vulnerable to mass die-offs resulting from storms, low salinity events, or seawater temperatures being too low to sustain annual reproduction. Such events could affect water quality (see Qu. A11, Qu. 2.9 and Qu. 4.3.)

**Qu. 4.8. How important is the impact of the organism on provisioning, regulating, and cultural services likely to be in the different biogeographic regions or marine subregions where the species can establish in the risk assessment area in the future?**

- See guidance to Qu. 4.6.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: Potential causes of impacts:

**Provisioning:** Biomass - Although competition for food and space with cultivated bivalves is a potential source of loss, it is unclear if *Mulinia lateralis* is a strong competitor to commercial species (see Qu. 2.3). These effects are likely to be greater in subregions where abiotic conditions are most suitable for year-round reproductive populations to establish, i.e. the Mediterranean, and the Bay of Biscay and the Iberian coast subregions (see Qu. 2.9).

**Regulation and maintenance:**

**Water** - In the North Sea, where this species is established, it is vulnerable to mass die-offs resulting from storms, low salinity events, or seawater temperatures being too low to sustain annual reproduction. Such events could affect water quality (see Qu. A11, Qu. 2.9 and Qu. 4.3). These impacts are likely to be greater in subregions where abiotic conditions are not optimal, i.e. the Greater North Sea, Celtic Seas, Baltic Sea and Black Sea (see Qu. 2.9).

**Lifecycle maintenance** - Maintaining nursery populations and habitats. By altering trophic interactions in lagoons, it has the potential to affect the nursery function of these habitats, especially if it undergoes population fluctuations tied to seasonal and/or stochastic events.

**Pest and disease control** - *M. lateralis* may facilitate the spread of the pathogenic parasite *P. chesapeaki* to commercial clam species (see Qu. 4.11), or cestode parasites to elasmobranchs (see Qu. 4.16). This will have most effect in the Mediterranean and the Bay of Biscay and Iberian coast subregions where commercial clam growing is greatest (see Qu. 4.11).

**Cultural:**

**Physical and experiential** - It may affect the amenity and recreational value of infested areas by reducing recreational harvests of other shellfish such as clams and cockles, if *M. lateralis* replaces these species on intertidal shores.

## Economic impacts

**Qu. 4.9. How great is the overall economic cost caused by the organism within its current area of distribution (excluding the risk assessment area), including both costs of / loss due to damage and the cost of current management.**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the world these should be reported here. The assessment of the potential costs of / loss due to damage shall describe those costs quantitatively and/or qualitatively depending on what information is available. Cost of / loss due to damage within different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage. As far as possible, it would be useful to separate costs of / loss due to the organism from costs of current management.

RESPONSE		CONFIDENCE	
	minimal		low
	minor		<b>medium</b>
	<b>moderate</b>		high
	major		
	massive		

Outside of its native range, *Mulinia lateralis* is not known to be present, other than within the RA area.

Impacts as a result of trophic interactions in the native range: The Baffin Bay complex (Texas) supports a large commercial Black Drum fishery (Grubbs et al., 2013; Olsen, 2016) which was compromised in a 2012 emaciation event due to reduced *M. lateralis* availability (its preferred prey), linked to extreme salinity conditions in the bay in 2012 (Pollack et al., 2018). (See also Qu. 4.3). Baffin Bay saw roughly a 33% drop in production by weight in 2012. Considering that the coastwide fishery of Black Drum was estimated as worth approximately \$1.5 million per year at the time and the Baffin Bay fishery contributes roughly 50% to the overall landings (Grubbs et al., 2013), the economic impact is estimated as moderate.

Other potential causes of unidentified losses in the native range: Although competition for food and space with cultivated bivalves is a potential source of loss, it is unclear if *M. lateralis* is a strong competitor to commercial species, see Qu. 2.3. *M. lateralis* is a host to the parasitic pathogen *Perkinsus chesapeakei*, which also infects the commercial clam *Mya arenaria* and is likely to affect its growth, reproduction and possibly mortality (Dungan et al., 2002).

**Qu. 4.10. How great is the economic cost of / loss due to damage (excluding costs of management) of the organism currently in the risk assessment area (include any past costs in your response)?**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the EU these should be reported here. Assessment of the potential costs of damage on human health, safety, and the economy, including the cost of non-action. A full economic assessment at EU scale might not be possible, but qualitative data or different case studies from across the EU (or third countries if relevant) may provide useful information to inform decision making. In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. In this case, no score and

confidence should be given and the standardized “score” is N/A (not applicable). Cost of / loss due to damage within different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>	N/A	<b>CONFIDENCE</b>	
-----------------	-----	-------------------	--

Response: No information has been found on the issue. *Mulinia lateralis* has only been present within the RA area since 2016, and its current distribution is limited to the southern North Sea (see Qu. A6). No studies of impact have yet been reported from the RA area, and no economic costs have yet been identified or estimated, so it is not possible to reliably assess its current economic impact.

**Qu. 4.11. How great is the economic cost of / loss due to damage (excluding costs of management) of the organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.10.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response:

Competition: This species is not itself of direct commercial importance (Calabrese, 1970). It may compete with commercially grown bivalves for food and space in natural habitats, potentially reducing the crop harvest, but it is unclear if it is a strong competitor (see Qu. 2.3).

Shellfish disease: Perkinsosis is a disease affecting numerous mollusc species worldwide, causing significant mortalities and economic losses. The main causative species of disease in oysters is *Perkinsus marinus*, and in clams is *P. olseni*, currently these are the only species classed as notifiable in Europe. However, *Mulinia lateralis* is a host for *P. chesapeaki*, recently recorded from the Mediterranean and Atlantic coasts of France and Spain, that can infect commercial clams and cockles including *Ruditapes decussatus*, *R. philippinarum* and *Cerastoderma edule*, and possibly affect production (Dungan et al., 2002; Reece et al., 2008; Arzul et al., 2012; Carrasco et al., 2014; Ruano et al., 2015).

According to Carrasco et al. (2014), no clear evidence of relevant host reaction was observed in *C. edule* tissues, although *P. chesapeaki* seemed to cause damage to the structure of gill lamellae. Carrasco et al. (2014) conclude that the impact of *P. chesapeaki* in *C. edule*, as well as in other cohabiting bivalves such as clams, with high commercial value in the region, needs to be urgently addressed. Park et al. (2010) found that the fecal discharge (faeces and pseudofaeces) and decomposition of infected clam tissue could be the two major routes of transmission for *Perkinsus* parasites. Thus, dense populations of *M. lateralis*, either alive or after a mass die-off, could significantly mediate the spread of these parasites.

Despite a relatively low production in Europe, clams are a high value seafood product, economically important in many European countries, particularly in Spain, Italy and Portugal. Annual production of clams averages 50,000 tonnes (DG SANTE, 2018), with the main producer of clams being Italy. Clams in aquaculture alone (36,000 tonnes in 2019) are worth 240 million Euros (FAO, Fisheries Statistics, 2021). Any potential impacts of *M. lateralis* would be indirect, to the extent that transport of adult, parasite-infested individuals would facilitate the spread of *Perkinsus* species to commercial clams. Considering the high value of the clam industry in Europe, moderate economic losses are a plausible scenario, although this estimate comes with high uncertainty.

**Qu. 4.12. How great are the economic costs / losses associated with managing this organism currently in the risk assessment area (include any past costs in your response)?**

- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable).

<b>RESPONSE</b>	minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	--	-------------------	-----------------------

Response: No specific management plans are in place for this particular organism in Europe. For marine invasive species introduced by ballast water there are considerable management measures at various stages of implementation (see also Management Annex). These costs are not specific for *Mulinia lateralis* and therefore not included in the score. Within the Wadden Sea, management measures are in place regarding shellfish transportation (WG-AS & Gittenberger, 2019) again these are not specific to this species.

**Qu. 4.13. How great are the economic costs / losses associated with managing this organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.12.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: *Mulinia lateralis* is already established in the Greater North Sea, and eradication would likely not be an economically viable option due to the open nature of the marine environment and life history traits of the species. However, measures to prevent its spread to other regions of the RA area, particularly the Mediterranean may be considered, given the likelihood of greater impact on biodiversity and clam fisheries in that region. Costs related to shipping (ballasts/fouling) will be borne by the shipping companies. Significant costs can be associated with the ratification of relevant legislation, e.g. the Ballast Water Management Convention, in ensuring its compliance, related to planning, monitoring, enforcement and capacity building. However, these costs are not specific to *M. lateralis* and will prevent/reduce the introduction of a wide range of species carried by ballast water.

If management is taken forward then likely costs would include:

Dredging: Introduction of regulations regarding the cleaning of dredging vessels and equipment, such as water exchange and sediment removal from hoppers, between projects; and regulations regarding the 'beneficial' use of dredging spoil. There would be significant costs associated with the ratification of any such legislation, and in ensuring compliance, related to planning, monitoring and enforcement. Operational costs would be borne by the dredging companies. However, these costs are not specific to *M. lateralis* and will prevent/reduce the introduction and spread of a wide range of species. To prevent spread to new sites within the RA area, dredging sites would need to be tested for *M. lateralis* (and other NIS). Currently, under Marine Licensing regulations these sites are initially checked for chemical contaminants and pathogens, but not NIS.

Shellfish movements and disease: Introduction of further controls over shellfish relaying and movements of other commercial shellfish between natural habitats to include testing for a range of NIS. Current regulations relate to pathogens and diseases. These costs would not be specific to *M. lateralis* and will prevent/reduce the spread of a wide range of species. A ban on imports or restrictions in the movement of shellfish seed/stock from areas where *M. lateralis* is present could have potentially significant economic implications for shellfish producers. Monitoring of clam and cockle populations for *P. chesapeaki* infections - This is not currently a notifiable species, although other Perkinsus species are. Detection of infested *M. lateralis* specimens among commercial clam beds may warrant the early harvesting of clams, with associated costs and economic losses (Andrews & Ray, 1988).

Conservation status: As this species would be very difficult to eradicate or contain once it is present in a designated conservation area, and direct impact on biodiversity is considered to be 'minor' (see Qu. 4.3) any monitoring carried out would not result in management costs directly attributable to this species. However, *M. lateralis* should be included in MSFD D2 monitoring programmes within the RA area, with particular awareness of its trophic interactions with species of conservation importance.

With regards to the cost of monitoring, an indicative estimate comes from Denmark, where the cost of a proposed hotspot monitoring programme for all marine NIS (covering 13 ports and three areas with discharges of cooling water) was estimated at approximately €125,000 for the period 2015-2017 (Andersen et al., 2014). In the UK, a broad initial estimate of monitoring costs for MSFD D2 alone (considering that existing or new surveys for other descriptors will also contribute to the monitoring of NIS) suggests that they would be less than €974,000 over 10 years (DEFRA, 2012) with an additional €103,000 euros for drafting legislation and guidance.

## Social and human health impacts

**Qu. 4.14. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism for the risk assessment area and for third countries, if relevant (e.g. with similar eco-climatic conditions).**

The description of the known impact and the assessment of potential future impact on human health, safety and the economy, shall, if relevant, include information on

- illnesses, allergies or other affections to humans that may derive directly or indirectly from a species;
- damages provoked directly or indirectly by a species with consequences for the safety of people, property or infrastructure;
- direct or indirect disruption of, or other consequences for, an economic or social activity due to the presence of a species.

Social and human health impacts can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>	N/A	<b>CONFIDENCE</b>	
-----------------	-----	-------------------	--

Response: No information has been found on the issue.

**Qu. 4.15. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism in the future for the risk assessment area.**

- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable).

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: There may be an impact on the recreational harvesting of bivalves such as clams and cockles, if *Mulinia lateralis* replaces these species on intertidal shores. Other recreational activities, such as fishing and bird-watching may be affected if *M. lateralis* becomes a dominant prey resource and predator populations follow its fluctuations.

## Other impacts

**Qu. 4.16. How important is the organism in facilitating other damaging organisms (e.g. diseases) as food source, a host, a symbiont or a vector etc.?**

RESPONSE		CONFIDENCE	
	minimal		low
	<b>minor</b>		medium
	moderate		high
	major		
	massive		

Response: *Mulinia lateralis* is a host for the parasitic pathogen *Perkinsus chesapeaki* that can infect other clam and cockle species See Qu. 4.11. *M. lateralis* is also reported as the intermediate host for larvae of two elasmobranch parasitic cestode species, *Duplicibothrium minutum* and *Rhodobothrium paucitesticularae*, see Qu. 2.4. In the native range of *M. lateralis*, the Cownose ray, is the host for both species. No information could be found as to whether either species could potentially infect any elasmobranchs within the RA area.

**Qu. 4.17. How important might other impacts not already covered by previous questions be resulting from introduction of the organism?**

RESPONSE	NA	CONFIDENCE	

Response: No additional impacts could be identified.

**Qu. 4.18. How important are the expected impacts of the organism despite any natural control by other organisms, such as predators, parasites or pathogens that may already be present in the risk assessment area?**

RESPONSE		CONFIDENCE	
	minimal		low
	minor		medium
	<b>moderate</b>		high
	major		
	massive		

Response:

Predation: Within its native range, a wide variety of species prey on *Mulinia lateralis*. Something similar is likely to happen in the RA area, with predation by native species of crabs, fish, starfish, shore birds

and diving ducks. In the port of Zeebrugge many Oystercatchers have been observed preying on the abundant *M. lateralis* living on an intertidal mudflat (F. Kerckhof, pers. comm., 17th August 2021). In the colder parts of its native range predation by crabs and fish is probably the major factor controlling adult population size, at least during warmer months, and numbers increase drastically in the absence of predators (Virnstein, 1977). Wildfowl feeding may become an important regulator (Wells-Berlin et al., 2015), see Qu. 2.4 for more detail. Such trophic interactions however are likely to mediate impacts, rather than temper them, if specific predator-prey relationships develop (as in Qu. 4.3).

Parasites/pathogens: The parasitic pathogen *Perkinsus chesapeaki* or tapeworm infections may effect some control over abundance, although no pathology has been reported from the native range, see Qu 2.4 for more detail.

**Qu. 4.19. Estimate the overall impact in the risk assessment area under current climate conditions. In addition, details of overall impact in relevant biogeographical regions should be provided.**

Thorough assessment of the overall impact on biodiversity and ecosystem services, with impacts on economy as well as social and human health as aggravating factors, in current conditions.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: As *Mulinia lateralis* has not previously invaded anywhere else in the world outside the RA area, and as it has only been recorded in the RA area since 2017, there is very little evidence available regarding its likely overall impact. The bulk of the information regarding the likely behavior and potential impacts of *M. lateralis* in the RA area, presented in this assessment, have been inferred from its life-history traits and population dynamics throughout its native range along the east coast of N. America. What little early indicators of impact there are regarding its recent invasion of the RA area, come from the Greater North Sea subregion, an area corresponding climatically to the northern limit of this species' native range, and thus may not be indicative of impacts in other subregions.

No impacts have yet been reported from the RA area. However, *M. lateralis* appears to have the potential to cause minor to moderate environmental impacts within the RA area, with the greatest impacts being predicted for the Mediterranean, if invaded, as populations are more likely to become dominant members of the macrobenthos throughout the year. The habitats primarily affected are estuaries and lagoons, which are both of high conservation value.

Biodiversity: Initial indications are that population densities could be sufficient to impact on native bivalve biodiversity, through competition for space and food; and affect trophic interactions by potentially altering predator/prey relationships e.g. with crabs, fish and shorebirds (Craeymeersch et al., 2019; Klunder et al., 2019). It is likely that mass die-offs, typical of this species, will occur which could have multiple effects on: food web structure; nutrient cycling; the transfer of energy to higher trophic levels; water quality; and habitat structure through the deposition of dead shells. These impacts are likely

to be greater in subregions where abiotic conditions are not optimal, i.e. the Greater North Sea, Celtic Seas, Baltic Sea and Black Sea. Other potential impacts on biodiversity include facilitating the spread of the protozoan parasite *Perkinsus chesapeaki* to clams and cockles or cestode parasites to elasmobranchs.

Ecosystem services: Competition for food and space with, and the possible spread of *P. chesapeaki* to, cultivated bivalves are potential sources of economic loss. By altering trophic interactions in lagoons, *M. lateralis* has the potential to affect the nursery function of these habitats, especially if it undergoes population fluctuations tied to seasonal and/or stochastic events.

Economy: Competition for food and space with, and the possible spread of *P. chesapeaki* to cultivated bivalves are potential sources of economic loss.

Social and human health: Recreational harvests of other shellfish such as clams and cockles could also be reduced, if *M. lateralis* replaces these species on intertidal shores.

Baltic Sea: minor, low confidence (western part)

Greater North Sea: minor, low confidence

Celtic Seas: minor, low confidence

Bay of Biscay and the Iberian coast: moderate, low confidence

Mediterranean Sea: moderate, low confidence

Black Sea: minor, low confidence

**Qu. 4.20. Estimate the overall impact in the risk assessment area in foreseeable climate change conditions. In addition, details of overall impact in relevant biogeographical regions should be provided.**

Thorough assessment of the overall impact on biodiversity and ecosystem services, with impacts on economy as well as social and human health as aggravating factors, under future conditions.

- See also guidance to Qu. 4.3.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: See Qu. 4.19.

An increase in sea surface temperature will offer suitable conditions for spawning and larval development for longer periods throughout the Greater North Sea and Celtic Seas; this could reduce the likelihood of mass die-offs in those subregions, but increase the effects of competition on native bivalve biodiversity. In addition, it is anticipated that extreme weather phenomena, like droughts and storms/flooding, will be more frequent and intense under future climate conditions, this may lead to higher salinity variations and mechanical substrate disturbance, factors that facilitate colonisation by *Mulinia lateralis*.

Baltic Sea: minor, low confidence (western part)

Greater North Sea: moderate, low confidence

Celtic Seas: moderate, low confidence

Bay of Biscay and the Iberian coast: moderate, low confidence

Mediterranean Sea: moderate, low confidence

Black Sea: minor, low confidence

<b>RISK SUMMARIES</b>			
	<b>RESPONSE</b>	<b>CONFIDENCE</b>	<b>COMMENT</b>
<b>Summarise Introduction and Entry*</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	low medium <b>high</b>	<i>Mulinia lateralis</i> has already been introduced into the RA area, but possibly only once. Ballast water and sediments is considered the most plausible pathway due to the volume of traffic, its importance as a vector in the transfer of bivalve molluscs with similar life histories, and its presence in the region of a major shipping hub. However, it is possible that this single introduction resulted from a much rarer event such as the accidental transfer of residual dredging waste or hopper water.
<b>Summarise Establishment*</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	low medium <b>high</b>	The species is already established in the southeastern North Sea and further establishment throughout most of the RA area is considered very likely. <i>M. lateralis</i> is expected to exhibit boom and bust dynamics in Atlantic Europe, where conditions will limit spawning and recruitment to the summer months. Establishment is considered likely up as far as northern England and Ireland. In the Mediterranean Sea, should the species be introduced there, it is more likely that due to the potential for prolonged recruitment, year-round, dense populations will develop, especially in the highly variable lagoonal and estuarine systems of the region. The Baltic Sea only offers salinity conditions suitable for establishment in its western part. Localised establishment is also considered possible in the Black Sea, although conditions there are sub-optimal. Under future climate change a small northward shift and slight increase of the overall suitable area for the species is expected.
<b>Summarise Spread*</b>	very slowly slowly <b>moderately</b> rapidly	<b>low</b> medium high	There is considerable potential for spread through unaided larval dispersal on ocean currents, and multiple pathways of human-aided

	very rapidly		<p>spread (ballast water and sediments, dredging activities, shellfish transfers, and boat bilge water).</p> <p>Ballast water and sediment transport may facilitate long distance transport of larvae and adults within European waters, until the BWMC is fully implemented.</p> <p>Dredging activities, bivalve transfers, and movements of small boats containing bilge waters, usually involve shorter distances, generally remaining within member states.</p> <p>However, international dredging contracts and bivalve transfers do also take place between marine regions/subregions, e.g. with the transfer of oyster consignments between Atlantic Europe and the Mediterranean.</p> <p>Under future climate conditions, an overall rise in SST will increase the potential for adult populations and larval production in the Greater North Sea and Celtic Seas, with a corresponding increase in the likelihood of spread via all pathways. Whereas in the Mediterranean Sea, an increase in SST may result in fewer source populations in the south and east of the region, and thus reduce the likelihood of spread. There may also be an increased demand for dredging and shellfish movements.</p>
<b>Summarise Impact*</b>	minimal minor <b>moderate</b> major massive	<b>low</b> medium high	<p><i>Mulinia lateralis</i> appears to have the potential to cause minor to moderate environmental impacts within the RA area, with the greatest impacts being predicted for the Mediterranean. The habitats primarily affected are estuaries and lagoons, which are both of high conservation value.</p> <p><i>M. lateralis</i> may impact native bivalve biodiversity, through competition for space and food, and affect trophic interactions by potentially altering predator/prey relationships. Mass die-offs, typical of this species, could affect</p>

			<p>food web structure, nutrient cycling, the transfer of energy to higher trophic levels, water quality, and habitat structure. It may also facilitate spread of the protozoan parasite <i>Perkinsus chesapeaki</i> to clams and cockles or cestode parasites to elasmobranch species. <i>M. lateralis</i> also has the potential to affect the nursery function of lagoonal habitats. There may be economic losses in the cultivation of bivalves through competition for space and food, and the possible spread of <i>P. chesapeaki</i>. Recreational harvests of other shellfish such as clams and cockles could also be reduced.</p>
<b>Conclusion of the risk assessment (overall risk)</b>	low <b>moderate</b> high	low <b>medium</b> high	<p><i>Mulinia lateralis</i> is an opportunistic, infaunal bivalve already introduced in the North Sea, either by ballast water/sediments or by dredger vessels operating in its native range. Further spread via natural dispersal is expected to proceed relatively quickly, and the human-mediated pathways are likely to cause secondary introductions into the other RA subregions. While dense populations may be ephemeral in Atlantic Europe, the species is expected to persist more in lagoons and estuaries of the northern and western Mediterranean. Minor to moderate impacts may be anticipated, through competition and altered trophic interactions with native species, primarily in estuaries and lagoons. The ecosystem services and conservation value of these habitats are likely to be moderately affected, especially after mass die-offs of <i>M. lateralis</i>, while the bivalve aquaculture sector may be at risk by increased spread of <i>Perkinsus</i> parasites.</p>

## Distribution Summary

Please answer as follows:

- Yes if recorded, established or invasive
- if not recorded, established or invasive
- ? Unknown; data deficient

The columns refer to the answers to Questions A5 to A12 under Section A.

For data on marine species at the Member State level, delete Member States that have no marine borders.

In all other cases, provide answers for all columns.

EU-Member States, and United Kingdom

	Recorded	Established (currently)	Possible establishment (under current climate)	Possible establishment (under foreseeable climate)	Invasive (currently)
Belgium	Yes	Yes	Yes	Yes	
Bulgaria	-	-	Yes	Yes	
Croatia	-	-	Yes	Yes	
Cyprus	-	-	-	-	
Denmark	-	-	Yes	Yes	
Estonia	-	-	-	-	
Finland	-	-	-	-	
France	-	-	Yes	Yes	
Germany	Yes	Yes	Yes	Yes	
Greece	-	-	Yes	Yes	
Ireland	-	-	No (casual)	No (casual)	
Italy	-	-	Yes	Yes	
Latvia	-	-	-	-	
Lithuania	-	-	-	-	
Malta	-	-	-	-	
Netherlands	Yes	Yes	Yes	Yes	
Poland	-	-	-	-	
Portugal	-	-	Yes	Yes	
Romania	-	-	-	Yes	
Slovenia	-	-	Yes	Yes	
Spain	-	-	Yes	Yes	
Sweden	-	-	-	Yes	
United Kingdom	-	-	Yes	Yes	

Marine regions and subregions of the risk assessment area

	Recorded	Established (currently)	Possible establishment (under current climate)	Possible establishment (under foreseeable climate)	Invasive (currently)
Baltic Sea			Yes (limited)	Yes (limited)	
Black Sea			Yes	Yes	
North-east Atlantic Ocean	Yes	Yes	Yes	Yes	
Bay of Biscay and the Iberian Coast			Yes	Yes	
Celtic Sea			Yes	Yes	
Greater North Sea	Yes	Yes	Yes	Yes	
Mediterranean Sea			Yes	Yes	
Adriatic Sea			Yes	Yes	
Aegean-Levantine Sea			Yes	Yes	
Ionian Sea and the Central Mediterranean Sea			Yes (limited)	Yes (limited)	
Western Mediterranean Sea			Yes	Yes	

## ANNEX I Scoring of Likelihoods of Events

(taken from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

<b>Score</b>	<b>Description</b>	<b>Frequency</b>
Very unlikely	This sort of event is theoretically possible, but is never known to have occurred and is not expected to occur	1 in 10,000 years
Unlikely	This sort of event has occurred somewhere at least once in the last millennium	1 in 1,000 years
Moderately likely	This sort of event has occurred somewhere at least once in the last century	1 in 100 years
Likely	This sort of event has happened on several occasions elsewhere, or on at least once in the last decade	1 in 10 years
Very likely	This sort of event happens continually and would be expected to occur	Once a year

## ANNEX II Scoring of Magnitude of Impacts

(modified from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

Score	Biodiversity and ecosystem impact	Ecosystem Services impact	Economic impact (Monetary loss and response costs per year)	Social and human health impact, and other impacts
	<i>Question 5.1-5</i>	<i>Question 5.6-8</i>	<i>Question 5.9-13</i>	<i>Question 5.14-18</i>
Minimal	Local, short-term population loss, no significant ecosystem effect	No services affected <sup>6</sup>	Up to 10,000 Euro	No social disruption. Local, mild, short-term reversible effects to individuals.
Minor	Some ecosystem impact, reversible changes, localised	Local and temporary, reversible effects to one or few services	10,000-100,000 Euro	Significant concern expressed at local level. Mild short-term reversible effects to identifiable groups, localised.
Moderate	Measurable long-term damage to populations and ecosystem, but reversible; little spread, no extinction	Measurable, temporary, local and reversible effects on one or several services	100,000-1,000,000 Euro	Temporary changes to normal activities at local level. Minor irreversible effects and/or larger numbers covered by reversible effects, localised.
Major	Long-term irreversible ecosystem change, spreading beyond local area	Local and irreversible or widespread and reversible effects on one / several services	1,000,000-10,000,000 Euro	Some permanent change of activity locally, concern expressed over wider area. Significant irreversible effects locally or reversible effects over large area.
Massive	Widespread, long-term population loss or extinction, affecting several species with serious ecosystem effects	Widespread and irreversible effects on one / several services	Above 10,000,000 Euro	Long-term social change, significant loss of employment, migration from affected area. Widespread, severe, long-term, irreversible health effects.

<sup>6</sup> Not to be confused with “no impact”.

## ANNEX III Scoring of Confidence Levels

(modified from Bacher et al., 2017)

Each answer provided in the risk assessment must include an assessment of the level of confidence attached to that answer, reflecting the possibility that information needed for the answer is not available or is insufficient or available but conflicting.

The responses in the risk assessment should clearly support the choice of the confidence level.

<b>Confidence level</b>	<b>Description</b>
Low	There is no direct observational evidence to support the assessment, e.g. only inferred data have been used as supporting evidence <i>and/or</i> Impacts are recorded at a spatial scale which is unlikely to be relevant to the assessment area <i>and/or</i> Evidence is poor and difficult to interpret, e.g. because it is strongly ambiguous <i>and/or</i> The information sources are considered to be of low quality or contain information that is unreliable.
Medium	There is some direct observational evidence to support the assessment, but some information is inferred <i>and/or</i> Impacts are recorded at a small spatial scale, but rescaling of the data to relevant scales of the assessment area is considered reliable, or to embrace little uncertainty <i>and/or</i> The interpretation of the data is to some extent ambiguous or contradictory.
High	There is direct relevant observational evidence to support the assessment (including causality) <i>and</i> Impacts are recorded at a comparable scale <i>and/or</i> There are reliable/good quality data sources on impacts of the taxa <i>and</i> The interpretation of data/information is straightforward <i>and/or</i> Data/information are not controversial or contradictory.

## ANNEX IV CBD pathway categorisation scheme

Overview of CBD pathway categorisation scheme showing how the 44 pathways relate to the six main pathway categories. All of the pathways can be broadly classified into 1) those that involve intentional transport (blue), 2) those in which the taxa are unintentionally transported (green) and 3) those where taxa moved between regions without direct transportation by humans and/or via artificial corridors (orange and yellow). **Note that the pathways in the category “Escape from confinement” can be considered intentional for the introduction into the risk assessment area and unintentional for the entry into the environment.**

## ANNEX V Ecosystem services classification (CICES V5.1, simplified) and examples

For the purposes of this risk assessment, please feel free to use what seems as the most appropriate category / level / combination of impact (Section – Division – Group), reflecting information available.

Section	Division	Group	Examples (i.e. relevant CICES “classes”)
Provisioning	Biomass	<b>Cultivated <i>terrestrial</i> plants</b>	<p>Cultivated terrestrial plants (including fungi, algae) grown for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from cultivated plants, fungi, algae and bacteria for direct use or processing (excluding genetic materials);            Cultivated plants (including fungi, algae) grown as a <u>source of energy</u></p> <p><i>Example: negative impacts of non-native organisms to crops, orchards, timber etc.</i></p>
		<b>Cultivated <i>aquatic</i> plants</b>	<p>Plants cultivated by in- situ aquaculture grown for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from in-situ aquaculture for direct use or processing (excluding genetic materials);            Plants cultivated by in- situ aquaculture grown as an <u>energy source</u>.</p> <p><i>Example: negative impacts of non-native organisms to aquatic plants cultivated for nutrition, gardening etc. purposes.</i></p>
		<b>Reared animals</b>	<p>Animals reared for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from reared animals for direct use or processing (excluding genetic materials);            Animals reared to provide <u>energy</u> (including mechanical)</p> <p><i>Example: negative impacts of non-native organisms to livestock</i></p>
		<b>Reared <i>aquatic</i> animals</b>	<p>Animals reared by in-situ aquaculture for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from animals grown by in-situ aquaculture for direct use or processing (excluding genetic materials);            Animals reared by in-situ aquaculture as an <u>energy source</u></p> <p><i>Example: negative impacts of non-native organisms to fish farming</i></p>
		<b>Wild plants</b> (terrestrial and aquatic)	<p>Wild plants (terrestrial and aquatic, including fungi, algae) used for <u>nutrition</u>;  <u>Fibres and other materials</u> from wild plants for direct use or processing (excluding genetic materials);            Wild plants (terrestrial and aquatic, including fungi, algae) used as a <u>source of energy</u></p> <p><i>Example: reduction in the availability of wild plants (e.g. wild berries, ornamentals) due to non-native organisms (competition, spread of disease etc.)</i></p>
		<b>Wild animals</b> (terrestrial and aquatic)	<p>Wild animals (terrestrial and aquatic) used for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from wild animals for direct use or processing (excluding genetic materials);            Wild animals (terrestrial and aquatic) used as a <u>source of energy</u></p>

			<i>Example: reduction in the availability of wild animals (e.g. fish stocks, game) due to non-native organisms (competition, predations, spread of disease etc.)</i>
	<b>Genetic material</b> from all biota	<b>Genetic material</b> from plants, algae or fungi	<u>Seeds, spores and other plant materials</u> collected for maintaining or establishing a population; Higher and lower plants (whole organisms) used to <u>breed new strains or varieties</u> ; Individual genes extracted from higher and lower plants for the <u>design and construction of new biological entities</u>  <i>Example: negative impacts of non-native organisms due to interbreeding</i>
		<b>Genetic material</b> from animals	Animal material collected for the purposes of maintaining or establishing a population; Wild animals (whole organisms) used to breed new strains or varieties; Individual genes extracted from organisms for the design and construction of new biological entities  <i>Example: negative impacts of non-native organisms due to interbreeding</i>
	<b>Water</b> <sup>7</sup>	<b>Surface water</b> used for nutrition, materials or energy	Surface water for <u>drinking</u> ; Surface water used as a material ( <u>non-drinking purposes</u> ); Freshwater surface water, coastal and marine water used as an <u>energy source</u>  <i>Example: loss of access to surface water due to spread of non-native organisms</i>
		<b>Ground water</b> for used for nutrition, materials or energy	Ground (and subsurface) water for <u>drinking</u> ; Ground water (and subsurface) used as a material ( <u>non-drinking purposes</u> ); Ground water (and subsurface) used as an <u>energy source</u>  <i>Example: reduced availability of ground water due to spread of non-native organisms and associated increase of ground water consumption by vegetation.</i>
<b>Regulation &amp; Maintenance</b>	<b>Transformation</b> of biochemical or physical inputs to ecosystems	<b>Mediation of wastes or toxic substances</b> of anthropogenic origin by living processes	<u>Bio-remediation</u> by micro-organisms, algae, plants, and animals; <u>Filtration/sequestration/storage/accumulation</u> by micro-organisms, algae, plants, and animals  <i>Example: changes caused by non-native organisms to ecosystem functioning and ability to filtrate etc. waste or toxics</i>
		<b>Mediation of nuisances</b> of anthropogenic origin	<u>Smell reduction</u> ; <u>noise attenuation</u> ; <u>visual screening</u> (e.g. by means of green infrastructure)  <i>Example: changes caused by non-native organisms to ecosystem structure, leading to reduced ability to mediate nuisances.</i>
	<b>Regulation</b> of physical, chemical, biological conditions	<b>Baseline flows and extreme event</b> regulation	Control of <u>erosion</u> rates; Buffering and attenuation of <u>mass movement</u> ; <u>Hydrological cycle and water flow regulation</u> (Including flood control, and coastal protection); <u>Wind</u> protection; <u>Fire</u> protection

<sup>7</sup> Note: in the CICES classification provisioning of water is considered as an abiotic service whereas the rest of ecosystem services listed here are considered biotic.

			<p><i>Example: changes caused by non-native organisms to ecosystem functioning or structure leading to, for example, destabilisation of soil, increased risk or intensity of wild fires etc.</i></p>
		<p><b>Lifecycle maintenance, habitat and gene pool protection</b></p>	<p>Pollination (or 'gamete' dispersal in a marine context); <u>Seed dispersal</u>; Maintaining <u>nursery populations and habitats</u> (Including gene pool protection)</p> <p><i>Example: changes caused by non-native organisms to the abundance and/or distribution of wild pollinators; changes to the availability / quality of nursery habitats for fisheries</i></p>

see <https://eur-lex.europa.eu/legal-content/en/TXT/?uri=CELEX%3A32018R0968>

## **ANNEX VIII *Mulinia lateralis* physiological requirements and thresholds**

(text and analysis specifically developed for the purposes of this risk assessment)

*Mulinia lateralis* is a eurythermal and euryhaline species with a latitudinal distribution extending from the Bay of St. Lawrence, Canada, to the Gulf of Mexico, Yucatan, Mexico (Turgeon et al., 2009; see also Qu. A3 for details). This distribution corresponds to low winter temperatures of approximately -1 °C to 24 °C (mean temperature of the coldest month, retrieved from BIO-ORACLE 2 (Assis et al., 2018)) and high summer temperatures ranging from 17 °C to 30.5 °C (mean temperature of the warmest month, retrieved from BIO-ORACLE 2), conditions which are met throughout most of the RA area. Spawning occurs at different times of the year at different latitudes, e.g. in Canada from mid-July to early September (Sullivan, 1948), in Maryland from May to November with a peak in September (Hanks, 1968), in Texas from January to April, while year-round spawning has also been reported (Montagna et al., 1993). In the Long Island Sound, larvae appear in the water in early July at temperatures ranging between 16 °C and 20 °C but are more abundant at 19-21 °C (Calabrese, 1970). Field observations agree rather well with laboratory results, which indicate that the temperature threshold for larval growth that ensures metamorphosis before the larvae die in the water column lies somewhere between 15 °C and 17.5 °C (Calabrese, 1969a). Thus, temperature doesn't seem to be a major limiting factor for establishment at a large scale, except perhaps around northern UK waters, where maximum summer temperatures drop below 15°C. Nevertheless, because *M. lateralis* is primarily an inshore, estuarine species (Walker & Tenore, 1984), coarse grain temperature maps may not accurately reflect local conditions. For example, temperature measurements in marinas and harbours along the UK coast demonstrate water temperatures from 16-22°C in July – October, every year, all the way up to northern England (Bishop et al., 2015; C. Wood, unpublished data).

Regarding upper temperature limits for larval development, in the laboratory normal development and growth were achieved at temperatures as high as 32.5 °C (Calabrese, 1969b). Considering potential discrepancies between large-scale modelled data and local measurements, especially in shallow waters, this generally agrees well with the condition the species is faced with in the wild.

For modeling purposes, conditions unsuitable for establishment were defined as:

**Mean temperature of the warmest month (LtMax) <15 °C**

**Mean temperature of the warmest month >32.5 °C**

The same temperature limits were used for the calculation of growing degree days (GDD) in the Modeling Annex.

The species can also withstand a wide range of salinities, reportedly between 5-80 psu (Parker, 1975 in Montagna et al., 1993). This extremely wide range does not necessarily mean that *M. lateralis* from all geographical areas are able to withstand such extreme salinities, nor does it mean that all stages of reproduction are accomplished at the extremes of the salinity range.

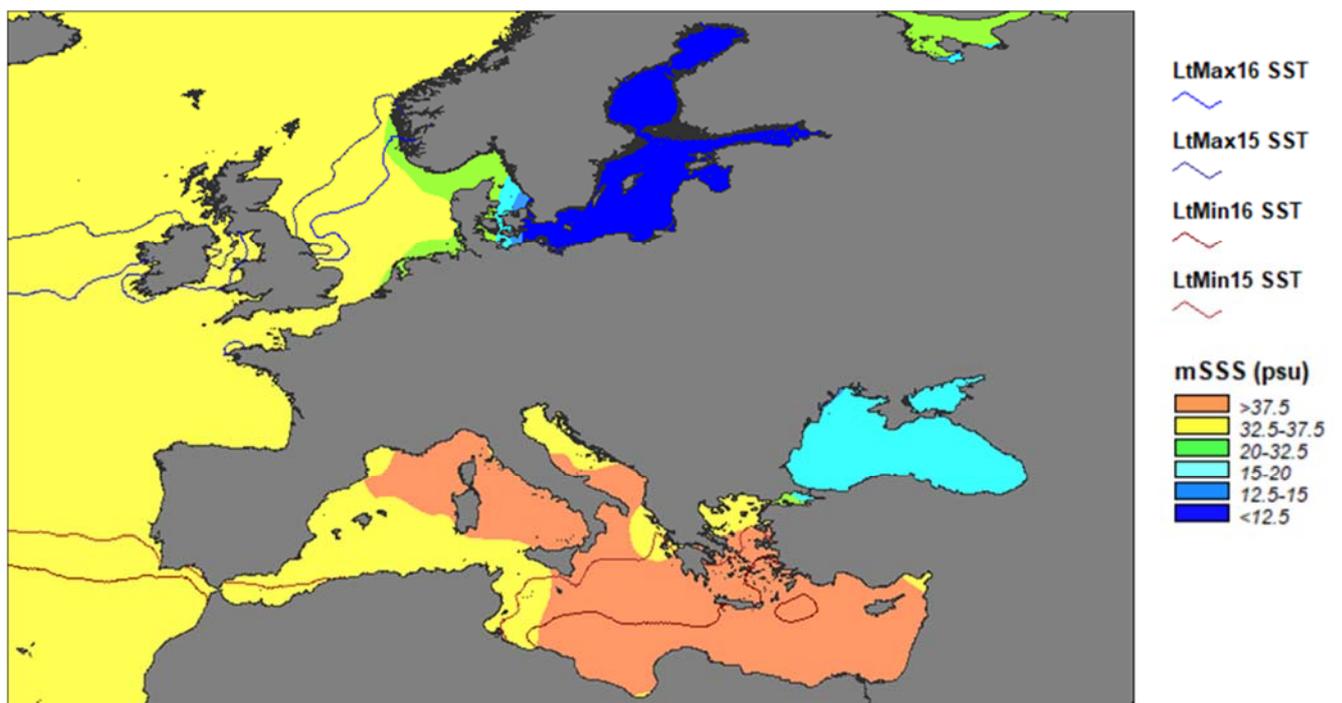

*M. lateralis* can persist equally in low salinity estuarine environments as in hypersaline conditions in lagoons, associated with prolonged drought periods (e.g. in Baffin Bay, Texas, where the species is dominating the infaunal community at salinities between 40-60 psu). It is generally observed though that major recruitment events are triggered by big salinity changes caused by freshwater inflow, rather than absolute salinity levels (Montagna & Kalke, 1995; Van Diggelen & Montagna, 2016). On the other

hand, its presence along the Dutch and Belgian coasts, as well as in the shallow sublittoral in its native range (Cleveland et al., 2002) indicates it can also establish in fully marine areas. Regarding larval development, in laboratory experiments it was shown to be normal between 12.5 and 37.5 psu. Larval survival was observed within a larger range of 7-38 psu (Calabrese, 1969), however satisfactory embryonic development occurred at a more restricted salinity range of 20-32.5 psu (Calabrese, 1969a). Thus, as long as spawning and embryonic development take place at appropriate salinities, larvae can disperse and will survive and grow in different water bodies.

It is apparent from the above that, when it comes to salinity, it is difficult to set a hard limit for larval development, especially considering that large scale salinity maps are modeling products themselves and do not capture small scale salinity variations near the coast. **For the purpose of defining the unsuitable background for modeling, a limit of 12.5 psu was tentatively set** for mean surface salinity. However, in an effort to capture the influence of salinity variability we employ an additional parameter, namely distance to the nearest river mouth (see Annex IX, the Species Distribution Model).

The above-mentioned potential limitations to establishment are displayed in Figure 1. This map intends to serve as a first indication of rough geographical limits set by low summer temperatures (blue contour lines of 15°C and 16°C temperature of the warmest month LtMax), and broad salinity ranges (mSSS), as well as indicating areas where continuous recruitment is likely (red contour line of 15°C and 16°C temperature of the coldest month LtMin).

**Figure 1.**

## **ANNEX IX Species Distribution Model**

Projection of environmental suitability for *Mulinia lateralis* establishment in Europe

Björn Beckmann, Marika Galanidi, Christine Wood and Dan Chapman

22 June 2021

### **Aim**

To project the suitability for potential establishment of *Mulinia lateralis* in Europe, under current and predicted future climatic conditions.

### **Data for modelling**

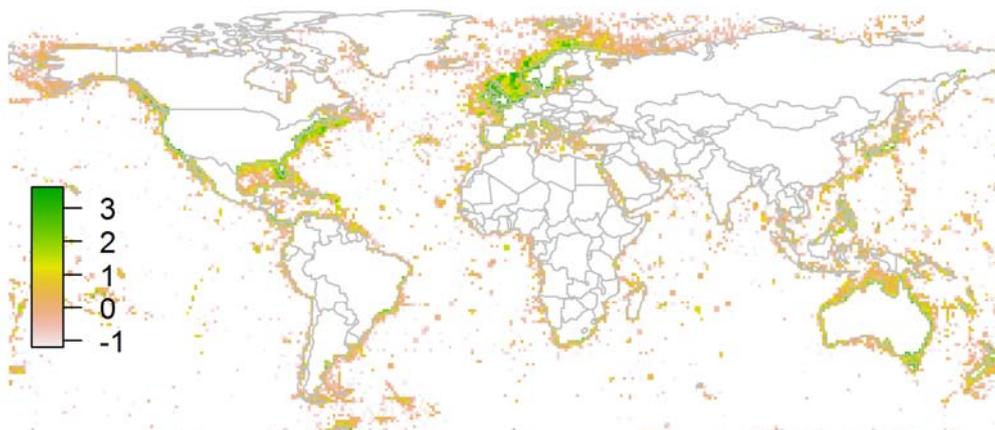

Species occurrence data were obtained from the Global Biodiversity Information Facility (GBIF) (195 records), iNaturalist (161 records), the Biodiversity Information Serving Our Nation database (BISON) (121 records), and additional records from the risk assessment team. We scrutinised occurrence records and removed any dubious ones and records where the georeferencing was too imprecise or outside of the coverage of the predictor layers. The records were gridded at a 0.25 x 0.25 degree resolution for modelling, yielding 77 grid cells with occurrences (Figure 1a). As a proxy for recording effort, the density of *Bivalvia* records held by GBIF was also compiled on the same grid (Figure 1b).

**Figure 1.** (a) Occurrence records obtained for *Mulinia lateralis* and used in the modelling, showing native and invaded distributions. (b) The recording density of *Bivalvia* on GBIF, which was used as a proxy for recording effort.

(a) Species distribution used in modelling

(b) Estimated recording effort (log10-scaled)

Predictors describing the marine environment were selected from the ‘Bio-ORACLE2’ set of GIS rasters providing geophysical, biotic and environmental data for surface and benthic marine realms (Tyberghein et al., 2012; Assis et al., 2018), supplemented by variables calculated from MARSPEC monthly sea surface temperature data (Sbrocco & Barber, 2013). Both were originally at 5 arcminute resolution (0.083 x 0.083 degrees of longitude/latitude) and aggregated to a 0.25 x 0.25 degree grid for use in the model.

Based on the biology of *Mulinia lateralis*, the following variables were used in the modelling:

- Maximum long-term temperature (templtmax\_ss)
- Minimum long-term temperature (templtmin\_ss)
- Mean salinity (salinitymean\_ss)
- Mean bathymetry (bathymean)

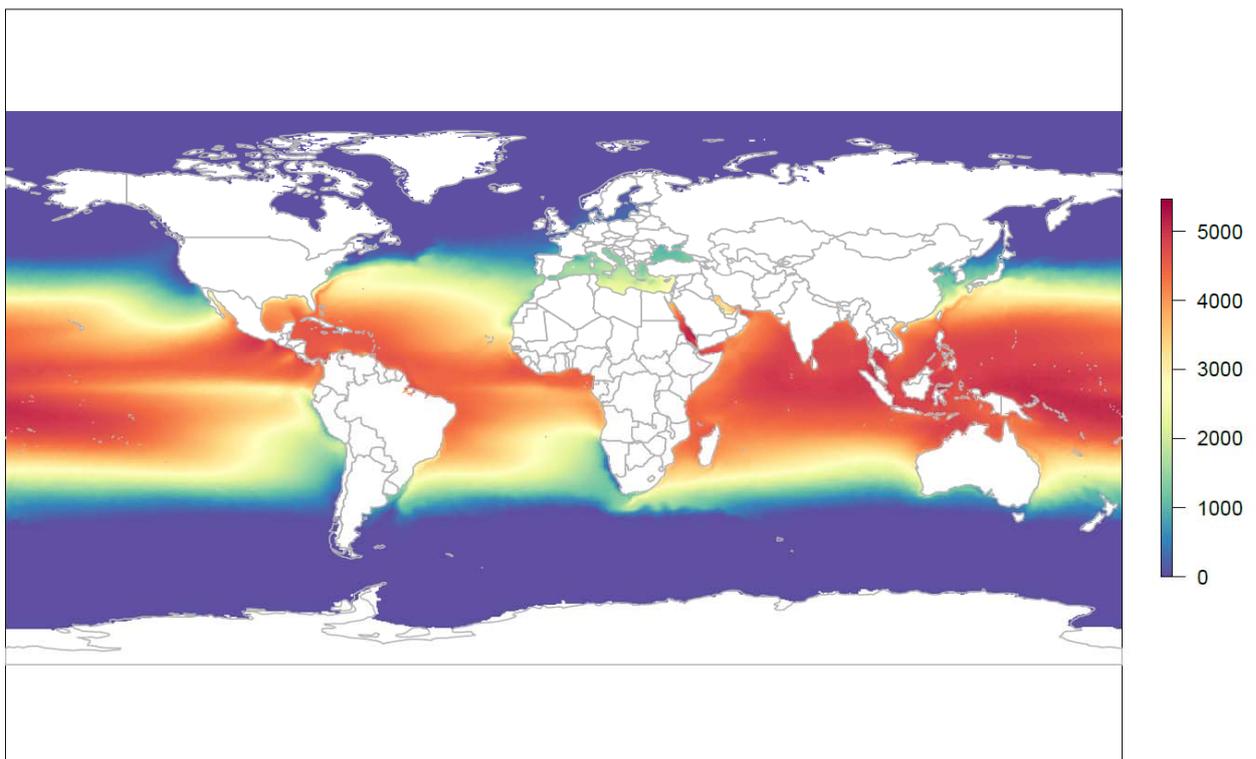

- Growing Degree Days between 15 and 32.5°C (gdd\_15\_32.5)
- Sea distance to nearest river mouth with average discharge >10 m<sup>3</sup>/s (sea\_dist\_10cms), log+1 transformed to increase normality.

All parameters (except depth) are measured at the sea surface.

Growing Degree Days (GDD) have been widely used as a measure of the “biologically useful” sum of warmth between threshold temperatures where processes of interest occur (McMaster & Wilhelm, 1997). For *Mulinia lateralis*, larval development occurs between approximately 15 and 32.5°C (see Risk Assessment for details). GDD are usually calculated from daily temperature data, but since these are not available for the marine environment at a global scale, GDD were calculated from MARSPEC monthly mean temperature data. First, all grid cells with temperatures less than 15°C or more than 32.5°C were excluded for each month. Then, any positive difference from the lower temperature threshold was multiplied by the number of days in the month. For example, a grid cell with a temperature of 17°C in January had a value of 17°C - 15°C = 2°C x 31 days = 62 GDD for January. Finally, GDD values for all months were summed to produce an annual total for each grid cell (Figure 2).

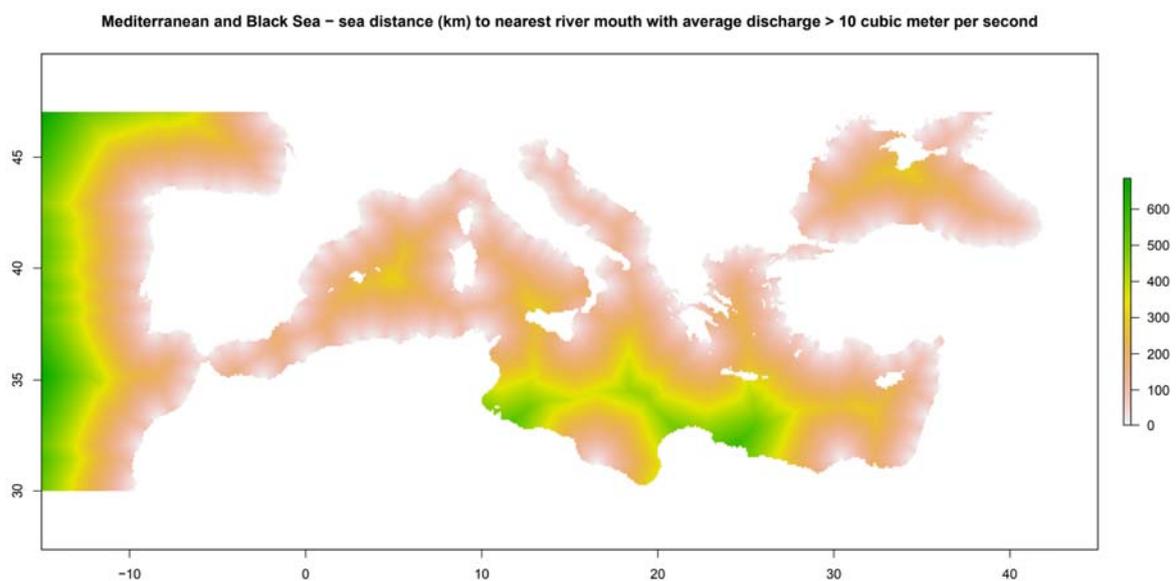

**Figure 2.** Annual Growing Degree Days (GDD) between 15°C and 32.5°C for the current climate, calculated from MARSPEC monthly mean sea surface temperatures.

**Growing Degree Days between 15 and 32.5°C  
for current climate**

The distance to the nearest large river mouth (with average discharge  $>10 \text{ m}^3/\text{s}$ ) was used as a proxy for presence of brackish water (in addition to the Bio-ORACLE2 salinity layer mentioned above). The location of rivers and their average discharge was taken from the “HydroRIVERS” dataset, version 1.0 (Lehner et al., 2008). Point locations of river mouths were “rasterized” to the model grid, summing discharge per  $0.25 \times 0.25$  degree grid cell in case there were several river mouths per cell. Endorheic rivers (not flowing into the oceans) were excluded. For each model grid cell, distance-by-sea (in meters) to the nearest cell with average discharge  $> 10 \text{ m}^3/\text{sec}$  was then calculated using “gridDistance” in the R package “raster”, version 3.4.5 (Hijmans, 2020). Figure 3 shows the Mediterranean and Black Sea areas of the final layer (with distances in km).

**Figure 3.** Proximity to the nearest river mouth with average discharge  $> 10 \text{ m}^3/\text{sec}$ . Layer created as a proxy for salinity variation.

To estimate the effect of climate change on the potential distribution of *Mulinia lateralis*, equivalent modelled future conditions for the 2070s under the Representative Concentration Pathways (RCP) 2.6 and 4.5 were also obtained. These represent low and medium emissions scenarios, respectively. Projections for the 2070s were calculated as averages of projections for the 2040s and 2090s (which are the time periods available on Bio-ORACLE).

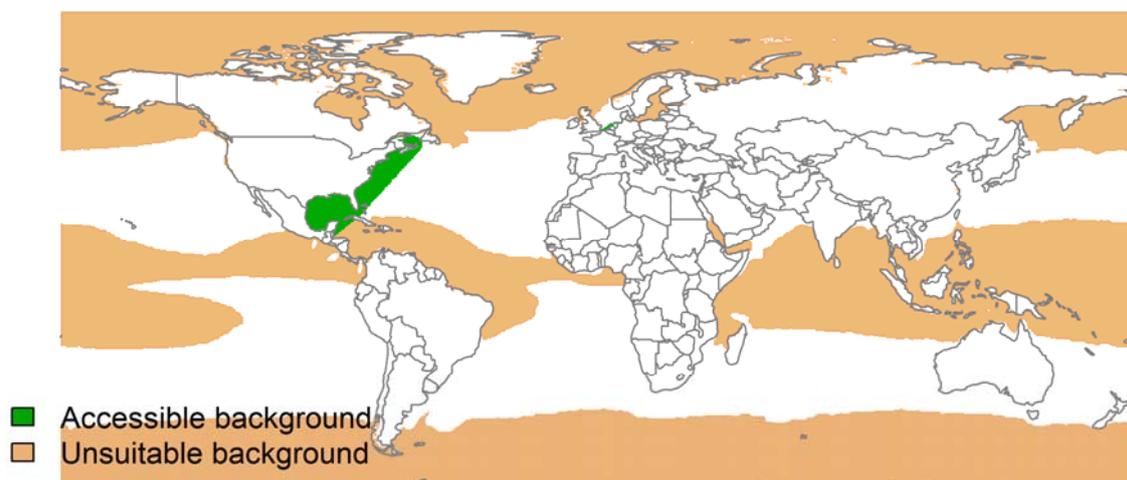

### Species distribution model

A presence-background (presence-only) ensemble modelling strategy was employed using the BIOMOD2 R package version 3.4.6 (Thuiller et al., 2009; Thuiller et al., 2020). These models contrast the environment at the species' occurrence locations against a random sample of the global background environmental conditions (often termed 'pseudo-absences') in order to characterise and project suitability for occurrence. This approach has been developed for distributions that are in equilibrium with the environment. Because invasive species' distributions are not at equilibrium and subject to dispersal constraints at a global scale, we took care to minimise the inclusion of locations suitable for the species but where it has not been able to disperse to (Chapman et al., 2019). Therefore the background sampling region included:

- The area accessible by native *Mulinia lateralis* populations, in which the species is likely to have had sufficient time to disperse to all locations. Based on presumed maximum dispersal distances, the accessible region was defined as a 400 km buffer around the native range occurrences (the Pacific Ocean was excluded from this area because *Mulinia lateralis* occurs only on the Atlantic coasts of North America and historically could not readily disperse to the Pacific side); AND
- A 100 km buffer around the non-native occurrences, encompassing regions likely to have had high propagule pressure for introduction by humans and/or dispersal of the species; AND
- Regions where we have an *a priori* expectation of high unsuitability for the species so that absence is assumed irrespective of dispersal constraints (see Figure 4). The following rules were applied to define a region expected to be highly unsuitable for *Mulinia lateralis* at the spatial scale of the model:
  - Minimum long-term temperature (templtmin\_ss) > 25 °C
  - Maximum long-term temperature (templtmax\_ss) < 15 °C
  - Mean salinity (salinitymean\_ss) < 12.5 psu

Altogether, 2.6% of occurrence grid cells were located in the unsuitable background region.

Within the unsuitable background region, 10 samples of 5000 randomly sampled grid cells were obtained. In the accessible background (comprising the accessible areas around native and non-native occurrences as detailed above), the same number of pseudo-absence samples were drawn as there were presence records (77), weighting the sampling by a proxy for recording effort (Figure 1(b)). **Figure 4.** The background from which pseudo-absence samples were taken in the modelling of *Mulinia lateralis*. Samples were taken from a 400 km buffer around the native range and a 100 km buffer around non-native occurrences (together forming the accessible background), and from areas expected to be highly unsuitable for the species (the unsuitable background region). Samples from the accessible background were weighted by a proxy for recording effort (Figure 1(b)).

Each dataset (i.e. combination of the presences and the individual background samples) was randomly split into 80% for model training and 20% for model evaluation. With each training dataset, five

statistical algorithms were fitted with the default BIOMOD2 settings and rescaled using logistic regression, except where specified below:

- Generalised linear model (GLM)
- Generalised boosting model (GBM)
- Generalised additive model (GAM) with a maximum of four degrees of freedom per smoothing spline
- Artificial neural network (ANN)
- Multivariate adaptive regression splines (MARS)
- Random forest (RF)
- Maxent

Since the total background sample was larger than the number of occurrences, prevalence fitting weights were applied to give equal overall importance to the occurrences and the background. Normalised variable importance was assessed and variable response functions were produced using BIOMOD2's default procedure.

Model predictive performance was assessed by the following three measures:

- AUC, the area under the receiver operating characteristic curve (Fielding & Bell, 1997). Predictions of presence-absence models can be compared with a subset of records set aside for model evaluation (here 20%) by constructing a confusion matrix with the number of true positive, false positive, false negative and true negative cases. For models generating non-dichotomous scores (as here) a threshold can be applied to transform the scores into a dichotomous set of presence-absence predictions. Two measures that can be derived from the confusion matrix are sensitivity (the proportion of observed presences that are predicted as such, quantifying omission errors), and specificity (the proportion of observed absences that are predicted as such, quantifying commission errors). A receiver operating characteristic (ROC) curve can be constructed by using all possible thresholds to classify the scores into confusion matrices, obtaining sensitivity and specificity for each matrix, and plotting sensitivity against the corresponding proportion of false positives (equal to  $1 - \text{specificity}$ ). The use of all possible thresholds avoids the need for a selection of a single threshold, which is often arbitrary, and allows appreciation of the trade-off between sensitivity and specificity. The area under the ROC curve (AUC) is often used as a single threshold-independent measure for model performance (Manel et al., 2001). AUC is the probability that a randomly selected presence has a higher model-predicted suitability than a randomly selected absence (Allouche et al., 2006).
- Cohen's Kappa (Cohen, 1960). This measure corrects the overall accuracy of model predictions (ratio of the sum of true presences plus true absences to the total number of records) by the accuracy expected to occur by chance. The Kappa statistic ranges from -1 to +1, where +1 indicates perfect agreement and values of zero or less indicate a performance no better than random. Advantages of Kappa are its simplicity, the fact that both commission and omission errors are accounted for in one parameter, and its relative tolerance to zero values in the confusion matrix (Manel et al., 2001). However, Kappa has been criticised for being sensitive to prevalence (the proportion of sites in which the species was recorded as present) and may therefore be inappropriate for comparisons of model accuracy between species or regions (McPherson et al., 2004; Allouche et al., 2006).

- TSS, the true skill statistic (Allouche et al., 2006). TSS is defined as sensitivity + specificity - 1, and corrects for Kappa's dependency on prevalence. TSS compares the number of correct forecasts, minus those attributable to random guessing, to that of a hypothetical set of perfect forecasts. Like Kappa, TSS takes into account both omission and commission errors, and success as a result of random guessing, and ranges from -1 to +1, where +1 indicates perfect agreement and values of zero or less indicate a performance no better than random (Allouche et al., 2006).

An ensemble model was created by first rejecting poorly performing algorithms with relatively extreme low AUC values and then averaging the predictions of the remaining algorithms, weighted by their AUC. To identify poorly performing algorithms, AUC values were converted into modified z-scores based on their difference to the median and the median absolute deviation across all algorithms (Iglewicz & Hoaglin, 1993). Algorithms with  $z < -2$  were rejected. In this way, ensemble projections were made for each dataset and then averaged to give an overall suitability, as well as its standard deviation.

Projections were classified into suitable and unsuitable regions using a "lowest presence threshold" (Pearson et al., 2007), setting the cut-off as the lowest value at which 98% of all presence records are classified correctly under the current climate (here 0.77). In order to express the sensitivity of classifications to the choice of this threshold, thresholds at which 95% and 99% of records are classified correctly (here 0.89 and 0.72 respectively) were used in the calculation of error bars in Figures 11 and 12 below in addition to taking account of uncertainty in the projections themselves.

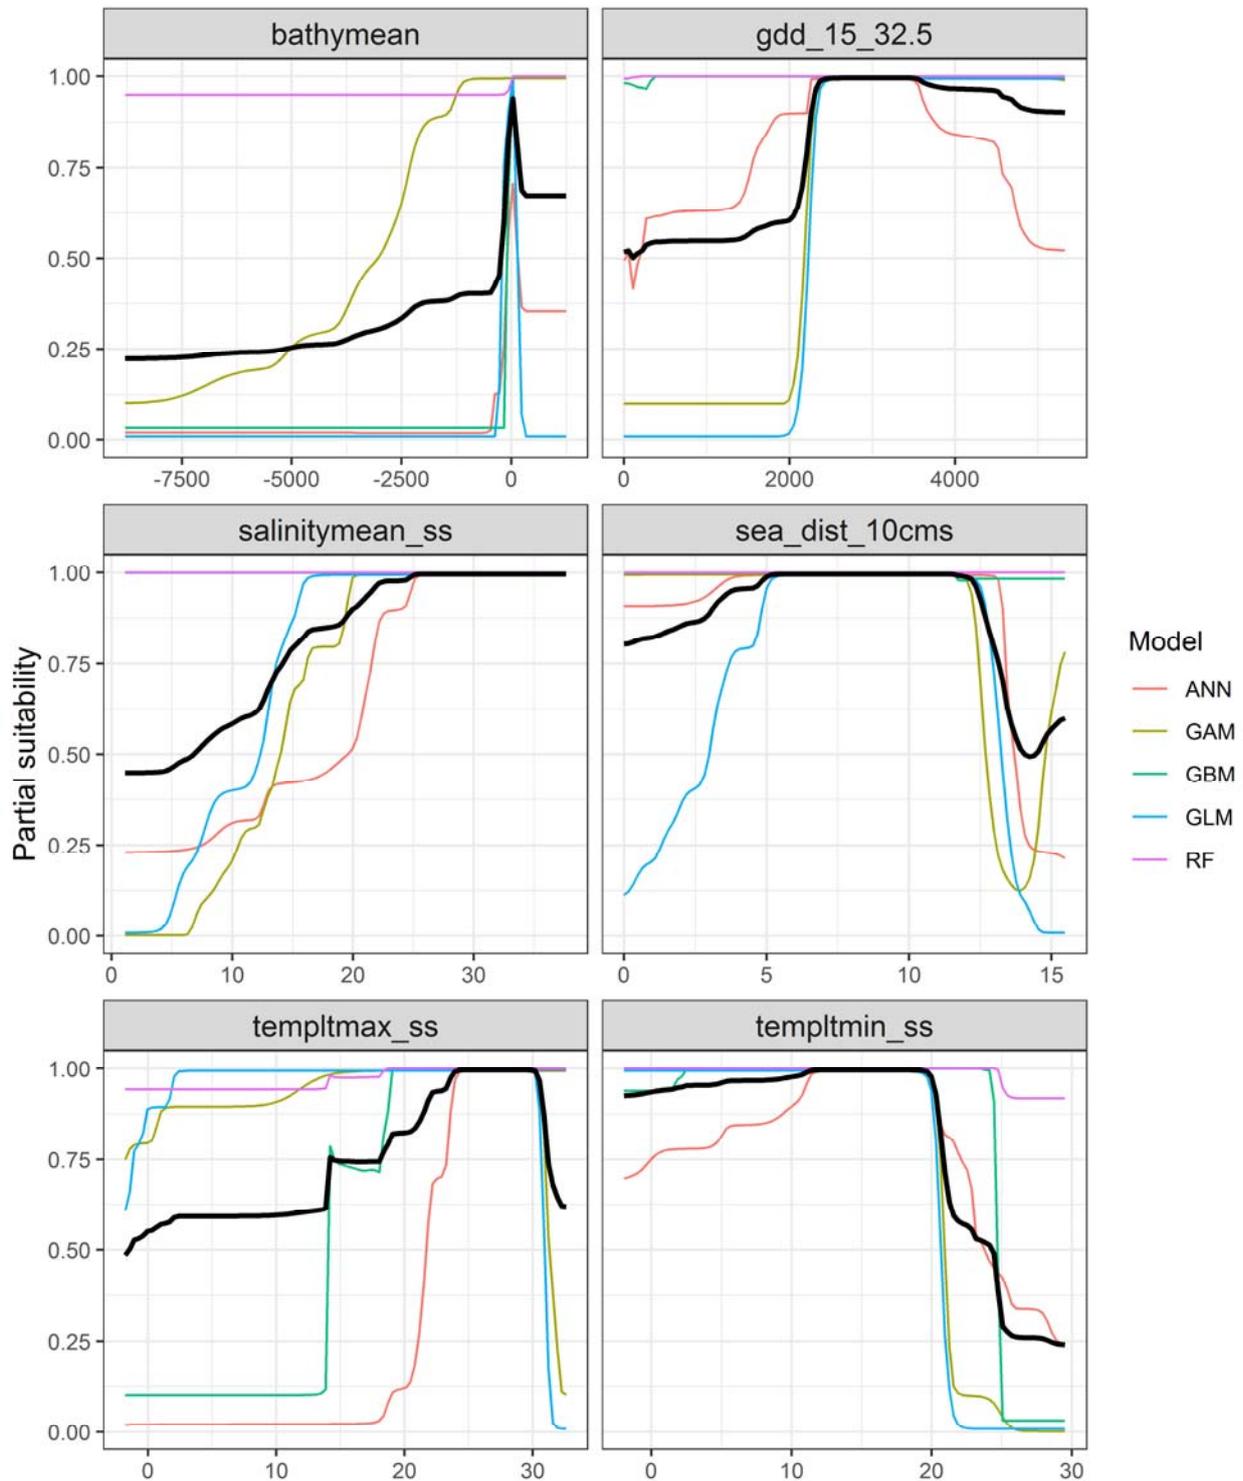

We also produced limiting factor maps for Europe following Elith et al. (2010). For this, projections were made separately with each individual variable fixed at a near-optimal value. These were chosen as the median values at the occurrence grid cells. Then, the most strongly limiting factors were identified as the one resulting in the highest increase in suitability in each grid cell.

## Results

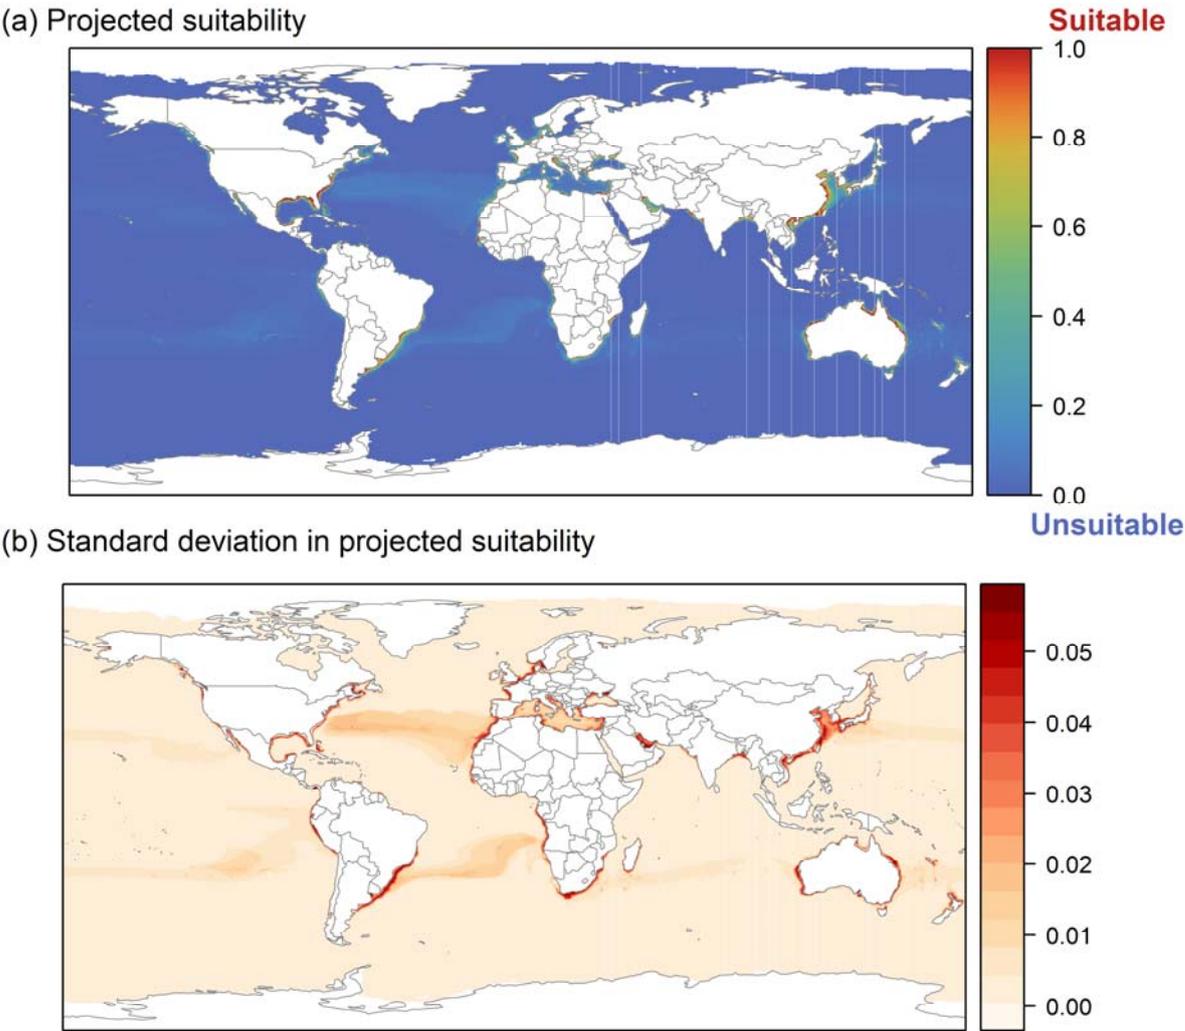

The ensemble model suggested that suitability for *Mulinia lateralis* was most strongly determined by Mean bathymetry (bathymean), accounting for 23.9% of variation explained, followed by Maximum long-term temperature (temptlmax\_ss) (23.7%), Minimum long-term temperature (temptlmin\_ss) (22.4%), Growing Degree Days between 15 and 32.5°C (gdd\_15\_32.5) (17.1%), Sea distance to nearest river mouth with average discharge >10 m<sup>3</sup>/s (sea\_dist\_10cms) (10.8%) and Mean salinity (salinitymean\_ss) (2%) (Table 1, Figure 5). **Table 1.** Summary of the cross-validation predictive performance (ROC, Kappa, TSS) and variable importance of the fitted model algorithms and the ensemble (AUC-weighted average of the best performing algorithms). Results are the average from models fitted to 10 different background samples of the data.

Algorithm	AUC	Kappa	TSS	Used in the ensemble	Variable importance (%)					
					Mean bathymetry (bathymean)	Maximum long-term temperature (temptlmax_ss)	Minimum long-term temperature (temptlmin_ss)	Growing Degree Days between 15 and 32.5°C (gdd_15_32.5)	Sea distance to nearest river mouth with average discharge >10 m <sup>3</sup> /s (sea_dist_10cms)	Mean salinity (salinitymean_ss)
GLM	0.986	0.749	0.960	yes	23	14	17	27	18	2

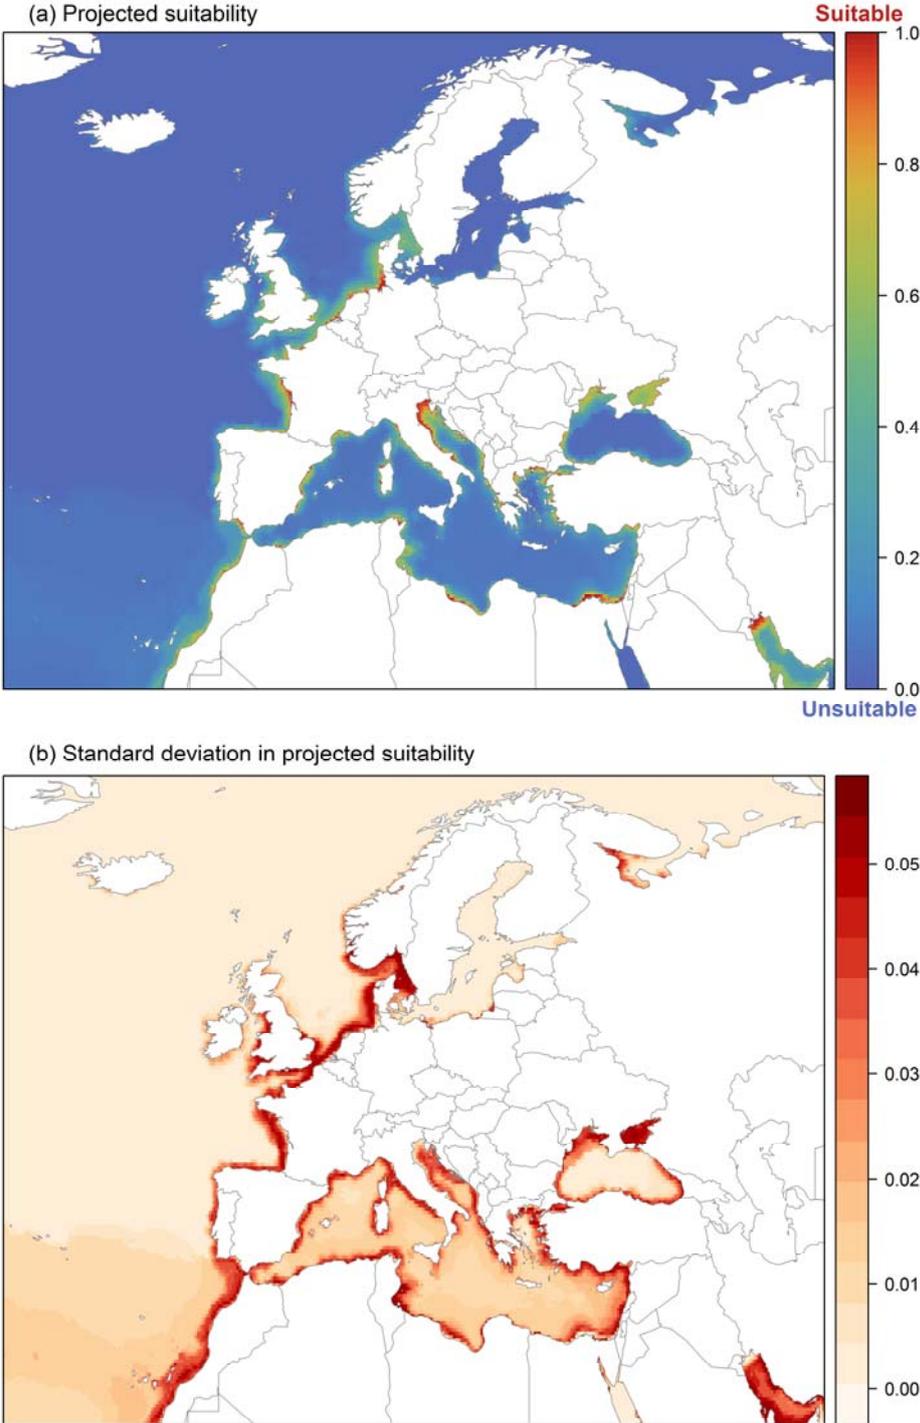

**Figure 5.** Partial response plots from the fitted models. Thin coloured lines show responses from the algorithms in the ensemble, while the thick black line is their ensemble. In each plot, other model variables are held at their median value in the training data. Some of the divergence among algorithms is because of their different treatment of interactions among variables.

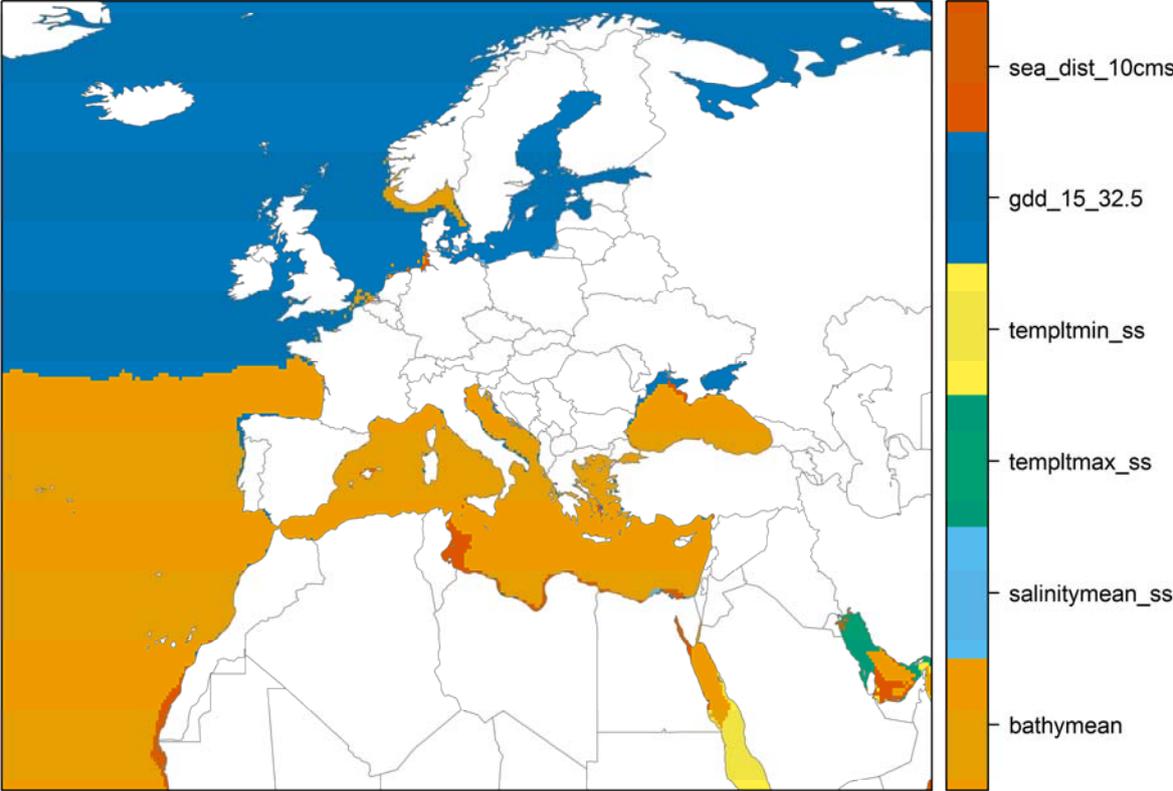

**Figure 6.** (a) Projected global suitability for *Mulinia lateralis* establishment in the current climate. For visualisation, the projection has been aggregated to a 0.5 x 0.5 degree resolution, by taking the maximum suitability of constituent higher resolution grid cells. Values > 0.77 are suitable for the species, with 98% of global presence records above this threshold. Values below 0.77 indicate lower relative suitability. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

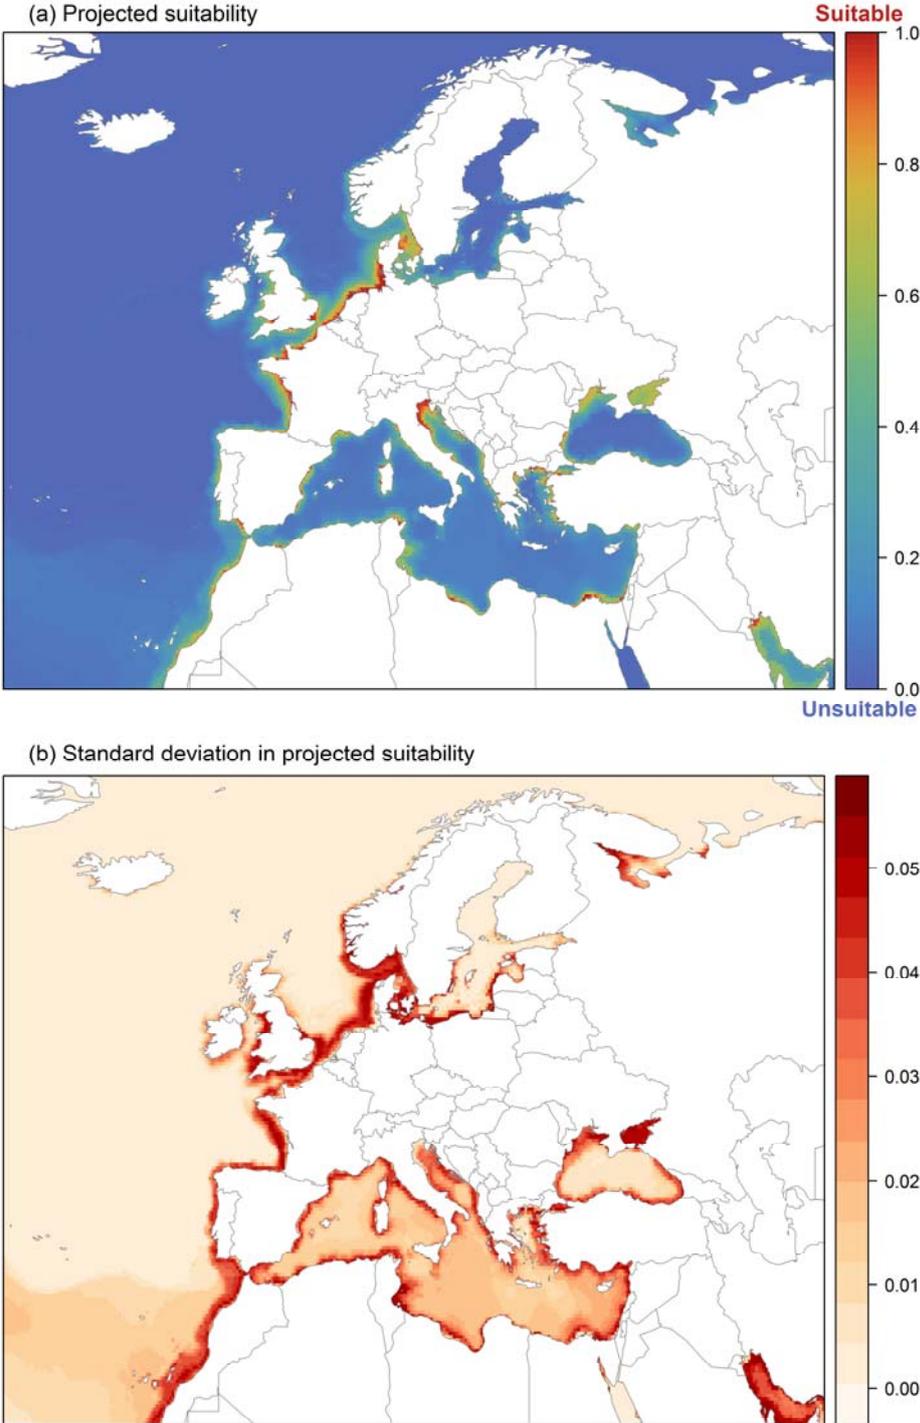

**Figure 7.** (a) Projected current suitability for *Mulinia lateralis* establishment in Europe and the Mediterranean region. Values > 0.77 are suitable for the species, with 98% of global presence records above this threshold. Values below 0.77 indicate lower relative suitability. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

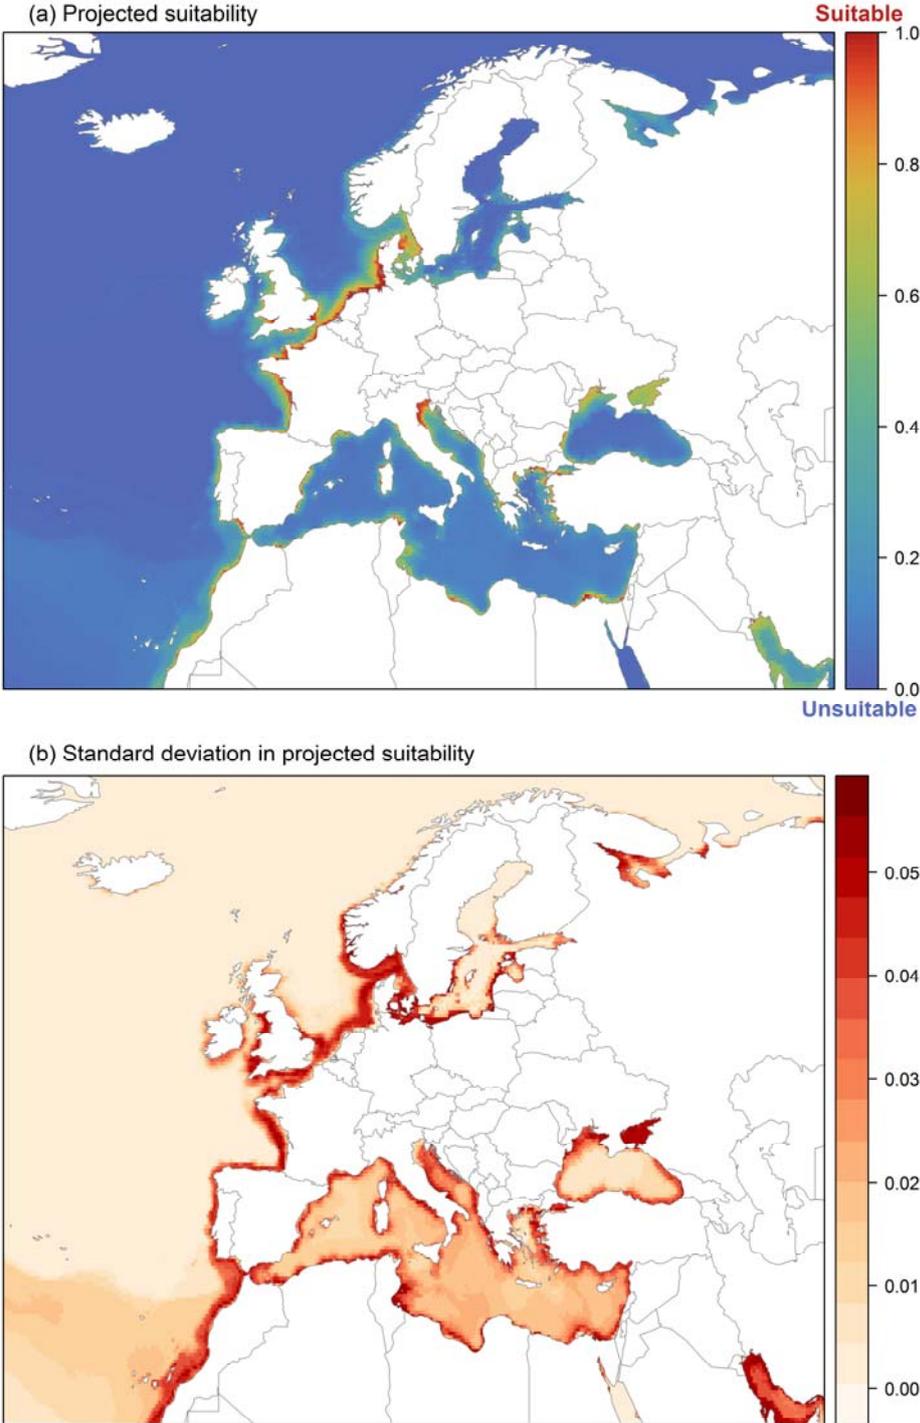

**Figure 8.** The most strongly limiting factors for *Mulinia lateralis* establishment estimated by the model in Europe and the Mediterranean region in current climatic conditions.

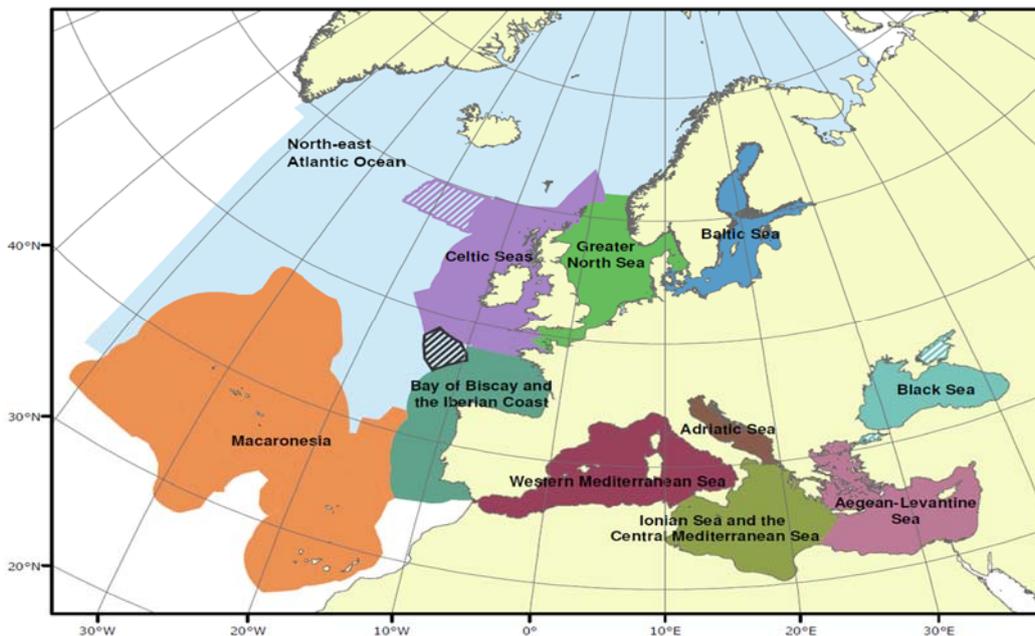

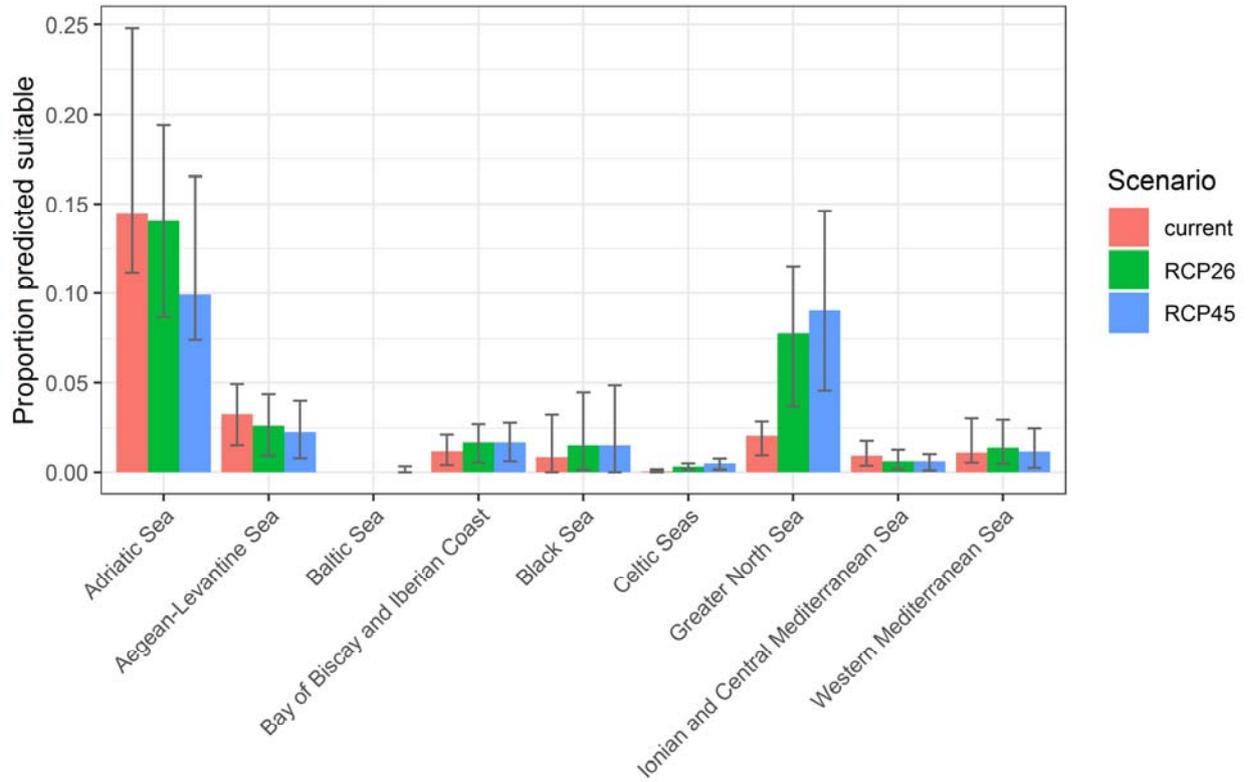

**Figure 9.** (a) Projected suitability for *Mulinia lateralis* establishment in Europe and the Mediterranean region in the 2070s under climate change scenario RCP 2.6. Values > 0.77 are suitable for the species, with 98% of global presence records above this threshold under current climate. Values below 0.77 indicate lower relative suitability. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

**Figure 10.** (a) Projected suitability for *Mulinia lateralis* establishment in Europe and the Mediterranean region in the 2070s under climate change scenario RCP 4.5. Values > 0.77 are suitable for the species, with 98% of global presence records above this threshold under current climate. Values below 0.77 indicate lower relative suitability. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

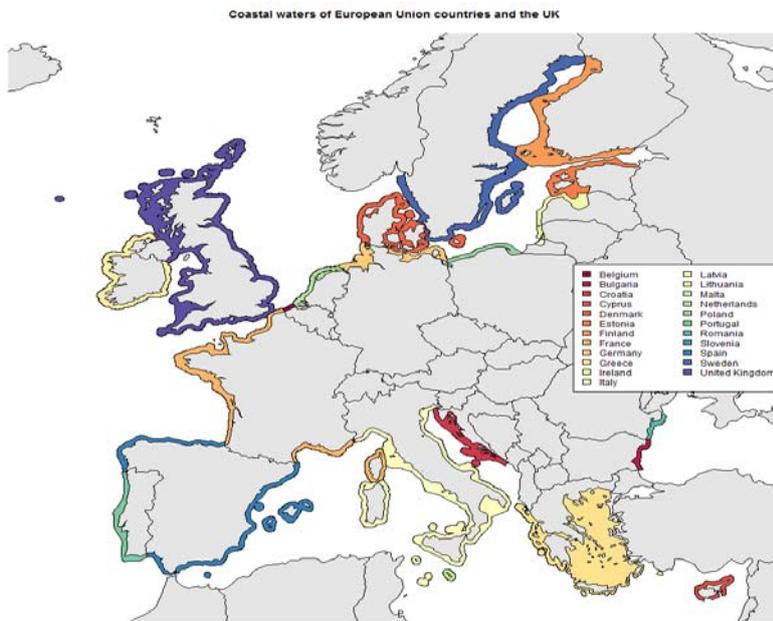

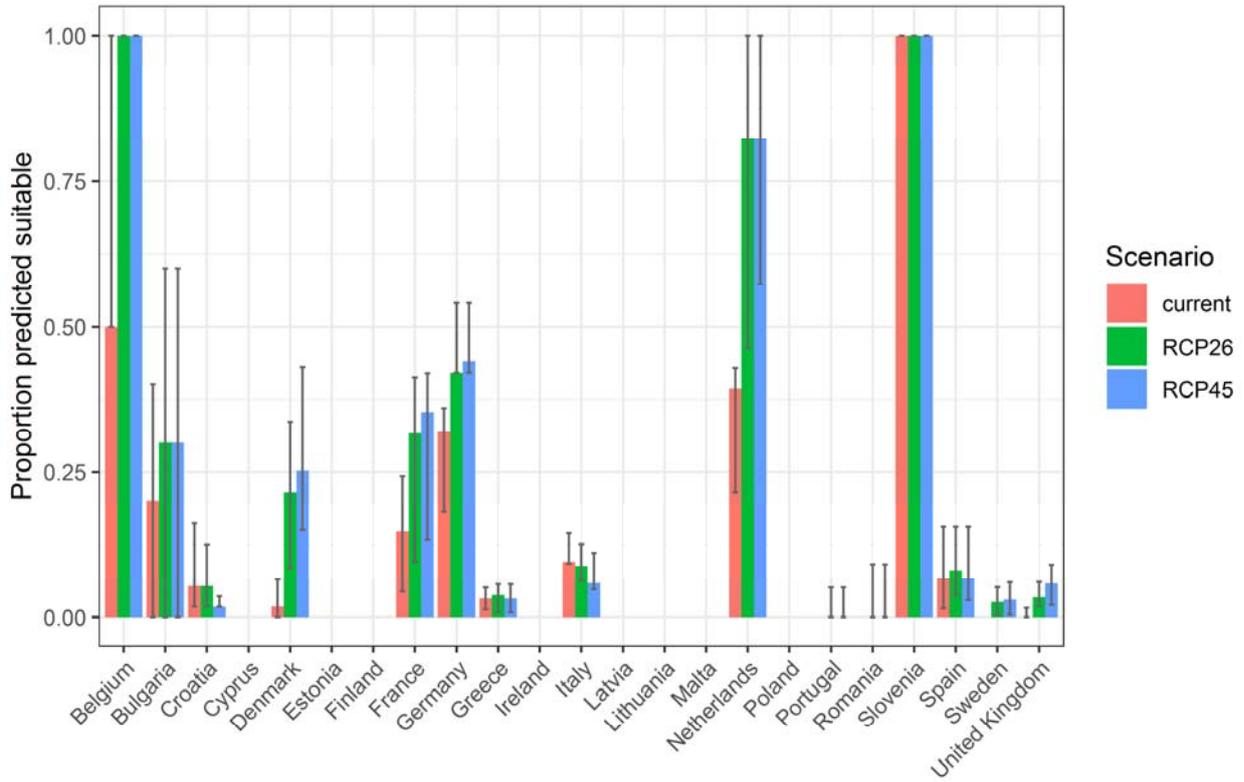

**Figure 11.** Variation in projected suitability for *Mulinia lateralis* establishment among marine subregions of Europe. The bar plots show the proportion of grid cells in each region classified as suitable (with values > 0.77) in the current climate and projected climate for the 2070s under two RCP emissions scenarios. Error bars indicate uncertainty due to both the choice of classification threshold and uncertainty in the projections themselves (cf. part (b) of Figures 7, 9 and 10). The location of each region is also shown. Macaronesia is excluded as it is not part of the study area.

**Table 2.** Variation in projected suitability for *Mulinia lateralis* establishment among marine subregions of Europe (numerical values of Figure 11 above). The numbers are the proportion of grid cells in each region classified as suitable in the current climate and projected climate for the 2070s under two RCP emissions scenarios.

**Figure 12.** Variation in projected suitability for *Mulinia lateralis* establishment among the territorial coastal waters of European Union countries and the UK (from osm-boundaries.com). The bar plots show the proportion of grid cells in each country classified as suitable (with values > 0.77) in the current climate and projected climate for the 2070s under two RCP emissions scenarios. Error bars indicate uncertainty due to both the choice of classification threshold and uncertainty in the projections themselves (cf. part (b) of Figures 7, 9 and 10). The location of each region is also shown.

**Table 3.** Variation in projected suitability for *Mulinia lateralis* establishment among territorial waters of European Union countries and the UK (numerical values of Figure 12 above). The numbers are the proportion of grid cells in each country classified as suitable in the current climate and projected climate for the 2070s under two RCP emissions scenarios.

### **Caveats to the modelling**

To remove spatial recording biases, the selection of the background sample from the accessible background was weighted by the density of *Bivalvia* records on the Global Biodiversity Information Facility (GBIF). While this is preferable to not accounting for recording bias at all, it may not provide the perfect measure of recording bias.

There was substantial variation among modelling algorithms in the partial response plots (Figure 5). In part this will reflect their different treatment of interactions among variables. Since partial plots are made with other variables held at their median, there may be values of a particular variable at which this does not provide a realistic combination of variables to predict from.

Other variables potentially affecting the distribution of the species, such as sediment composition, were not included in the model, due to the lack of suitable global layers.

*M. lateralis* is primarily an inshore, estuarine species and coarse grain temperature maps may not accurately reflect local conditions, e.g. water temperature in shallow, sheltered areas or in harbours and marinas. Finally, even though the model takes into account salinity variability in the form of distance from river mouths, a future scenario for river discharge was not taken into account and would take very elaborate data processing to bring into the model. We used the same predictor layer for both current and future climate conditions.

### Summary<sup>1</sup>

Highlight of measures that provide the most cost-effective options to prevent the introduction, achieve early detection, rapidly eradicate and manage the species, including significant gaps in information or knowledge to identify cost-effective measures.

*Mulinia lateralis* is a small infaunal bivalve, native to the west Atlantic, which recently entered the RA area and has a limited distribution along the southern North Sea region, from Germany to Belgium. It is an opportunistic species that can attain significant densities in lagoons and estuaries and is prone to mass mortality events. Prevention of new introductions and limiting subsequent spread are the best opportunities for management. Once established in the wild there are no effective methods to eradicate or control this species.

Prevention: The main pathways of introduction and spread of *M. lateralis* are ship-related (i.e. ballast water, dredging/aggregate extraction operations, and bilge water of recreational vessels), and bivalve transfers. The risk of further introductions and spread through ballast waters will be greatly reduced once the Ballast Water Management Convention is fully implemented (presumably by 2024), as compliance with the IMO D2 standard can decrease larval concentrations to undetectable levels. Current EU-wide regulations in place concerning the dredging and aggregate extraction sector are not adequate to prevent new introductions and the spread of *M. lateralis* and marine alien species in general. Local regulations recently adopted in Wales, UK, regarding marine licencing conditions require thorough cleaning of vessels and dredging equipment in between projects or when moving to different regions, and are expected to prove much more effective. Shellfish transfers between and within EU countries is mainly relevant as a pathway for spread within the RA area, unless national/regional regulations provide a stricter regulatory framework than the EC regulations, especially with respect to clam and mussel transfers, which may be a main pathway for the target species. Restrictions on transfers based on the risk associated with the source areas are generally practiced by the industry and provide an effective management method, as long as extensive and up-to-date data on the distribution of the high-risk non-indigenous species (NIS) are available and risks are communicated to shellfish growers. Bilge waters of recreational and other small vessels are not managed for invasive alien species (IAS) but this pathway of spread could be addressed with awareness raising campaigns to boat owners and the promotion/adoption of relatively simple measures, such as discharge of bilge water in the source region or retention

and subsequent treatment. Current levels of compliance with other, voluntary biosecurity measures by leisure craft owners however, indicate that voluntary guidelines are not sufficiently adopted to eliminate the risk of IAS spread.

Early detection: Surveillance for early detection will rely on formal monitoring campaigns, targeting marine alien species in general, or *M. lateralis* specifically, in introduction hotspots (i.e., ports, marinas, aquaculture areas, dredging locations), and on the vectors themselves, within the context of preventative measures. Existing monitoring schemes for the implementation of the Marine Strategy Framework Directive (MSFD) are likely to be a useful source of sightings, detection however may be delayed by the long processing times required to analyse large amounts of sediment samples. Environmental DNA (eDNA) methodologies offer the fastest, as well as most cost-efficient option for the early detection of both pelagic (larvae) and benthic life stages, both in water and in sediment samples. Citizen scientist observations have already contributed to our knowledge of the current spread of the species but refer to washed up specimens of already established populations.

Rapid eradication: Due to the infaunal existence of the species in open water habitats and unaided larval dispersal, eradication is not considered feasible. If population removals were to be attempted, towed fishing gear like trawls and dredges would be employed. Due to the small adult size, and the ability of the species to rapidly colonise defaunated habitats, eradication is very unlikely to be achieved. Moreover, dredging outside commercial operations and cultured bivalve beds is likely to have serious negative impacts on local species and habitats. If *M. lateralis* is detected during a shellfish transfer (e.g. to an on-growing site), the transfer must stop and bivalves should not be relayed. They may be placed in quarantine to ensure removal of the invader or be destroyed.

Management: As above, population control efforts in the wild are regarded as very unlikely to be effective. The best way to manage the species, once established, is to prevent long dispersal jumps by managing the pathways of secondary introduction and spread. Where *M. lateralis* infected with the parasite *Perkinsus* is detected among cultivated or commercially harvested bivalve beds, the recommended action would be for close monitoring of all clam species for infection and early harvesting of clams, alongside the invader.

Detailed assessment			
	Description of measures <sup>2</sup>	Assessment of implementation cost and cost-effectiveness (per measure) <sup>3</sup>	Level of confidence <sup>4</sup>
Methods to achieve prevention of intentional and unintentional introduction <sup>5</sup>	<p><b>Managing the pathway “TRANSPORT-STOWAWAY (ship/boat ballast water and sediment)”</b></p> <p>Regulation (EU) No 1143/2014 (EU, 2014) on the prevention and management of the introduction and spread of invasive alien species recognises the IMO Ballast Water Management Convention (BWMC) (IMO, 2004) as one of the possible management measures for invasive species of concern. The BWMC entered into force in September 2017 and requires ships in international traffic to apply ballast water management measures, such as ballast water exchange (D-1 standard for an interim period) and fulfil certain discharge standards (D-2 standard according to the ship specific application schedule). D-2 states that ships shall discharge less than 10 viable organisms per cubic metre greater than or equal to 50 micrometres in minimum dimension. This can be achieved through mechanical (filtration,</p>	<p>Ballast Water Exchange (BWE) can reduce the concentration of live organisms in ballast by 80–95% (Ruiz &amp; Reid, 2007). Its application, however, has severe limitations, primarily dependant on geography (David et al., 2007), weather conditions, and other safety restrictions (ship instability). In addition, BWE effectiveness is influenced by tank structure and the skill and experience of the ship crew, while it cannot be used to manage ballast water of vessels on shorter coastal (non-transoceanic) voyages (Bailey, 2015). Costs related to Ballast Water Management (BWM) and the implementation of the IMO’s D2 Standard are not specific to <i>M. lateralis</i> but refer to all marine NIS. The cost of installing Ballast Water Management Systems will be borne by shipping companies. Installation costs can vary from €140K-€1.675m per ship (figure reported in DEFRA (2012), after consultation with the UK Marine Coastguard Agency). Efficiencies of various technologies utilised for ballast water treatment are reviewed in Tsolaki &amp; Diamadopoulos (2009) and can vary with treatment method, but the application of many combined methods (e.g., Filtration+UV or Hydroclone+chemical disinfectant) can decrease live zooplankton to undetectable levels, practically diminishing propagule pressure.</p>	High

	<p>separation), physical (heat treatment, ozone, UV light) and chemical methods (biocides).</p> <p>Full implementation of the BWMC is expected to take some years (as late as 2024 – see <a href="http://maritime-executive.com/article/imo-pushes-back-ballast-water-compliance-dates">http://maritime-executive.com/article/imo-pushes-back-ballast-water-compliance-dates</a>).</p> <p>Eventually, most ships will need to install an on-board ballast water treatment system, and all ships will be required to carry a ballast water record book and an international ballast water management certificate.</p> <p>Under the D-2 standard, all ships will also be required to regularly remove and dispose of sediments from spaces designed to carry ballast water at designated sediment reception facilities in ports.</p>	<p>Significant costs can be associated with the ratification of the BWMC in ensuring its compliance, related to, for example, planning, monitoring, enforcement and capacity-building. As an example, in Croatia, approximately €1.26 million will be incurred by the state for institutional capacity building and in fulfilment of its flag State and port State obligations (Interwies &amp; Khuchua, 2017). This is broken down into €470k from flag state obligations (with 150 registered ships in 2015) and €482k from port state obligations (with 6 major ports). The remaining €308k are preparatory phase costs. Compliance costs will need to be incurred anyway to enable trade with other countries. Additionally, Regulations A4 and A3 of the BMWC enable the granting of exemptions from the requirement for BWM (provisions made in the BWMC for regular routes and other cases – Olenin et al., 2016). Such requests must fulfil certain criteria and require a risk assessment according to BWMC guidelines (Stuer-Lauridsen et al., 2018).</p>	
	<p><b>Managing the pathway “TRANSPORT-STOWAWAY (other means of transport: marine aggregates &amp; dredging)</b></p> <p>The disposal of dredged materials is regulated throughout the EU (summarised by Mink et al., 2006). OSPAR guidelines specify best environmental practice for managing dredged material (OSPAR, 2014). The main management tools are marine</p>	<p>Licensing procedures in member states tend to focus mainly on the sediment characteristics and the prevention of the disposal of waste containing contaminants such as heavy metals and pathogens, not non-native species. Thus, they would be ineffective in preventing the spread of <i>M. lateralis</i> in the RA area. Moreover, no EC regulations on the cleaning of dredging vessels and equipment <u>between</u> projects were found. Additional local or national regulations may apply that introduce further biosecurity measures for the effective</p>	<p>Medium</p>

	<p>licence and control systems. These require assessments of the environmental impact of planned disposal activities in relation to a specific dumpsite, sediment characteristics and contamination load. Dredging activities are also regulated under the Marine Strategy Framework Directive (MSFD) 2008/56/EC, the Water Framework Directive (WFD) 2000/60/EC and the EC Habitats Directive (92/43/EC). The ballast water and sediments carried in ballast tanks of dredger vessels is regulated under the Ballast Water Management Convention (see above).</p>	<p>prevention of NIS spread via dredging operations. For example, in Wales, UK, marine licencing conditions recently imposed include the washing of seabed equipment and filter screens at the end of a campaign, the requirement for the circulation and exchange of hopper water (i.e. water used to fill the storage compartment) away from shore, and the removal of hopper sediment prior to entering a different region of the UK (ABPmer, 2019; G. Wynne, B. Wray &amp; S. Vye (Natural Resources Wales) pers. comm. 21 April 2021). Such measures can prove effective, particularly to reduce spread between the existing North Sea populations and other RA subregions (e.g. Baltic Sea, Celtic Seas) but are expected to increase the cost of operations.</p> <p>No quantitative information on relevant costs was found but any management costs would not be specific to <i>M. lateralis</i> and would cover other organisms potentially transferred through this pathway.</p>	
<p><b>Reducing spread</b></p>	<p><b>Managing the pathway “CONTAMINANT ON ANIMALS - Mariculture”</b></p> <p>1. COUNCIL REGULATION (EC) No 708/2007 concerning use of alien and locally absent species in aquaculture defines the procedures to be followed. According to the regulation, all aquaculture operators who intend to introduce an alien species or translocate a locally absent species must first apply</p>	<p>The measures are cost-effective as the regulations and industry practices are already in effect. However, the bivalves <i>M. gigas</i> and <i>R. philippinarum</i>, listed in Annex IV of Council Regulation 708/2007, constitute an exception and can be moved without any risk assessment or quarantine; also, the regulation does not apply to movements of locally absent species within the Member States “except for cases where, on the basis of scientific advice, there are grounds for foreseeing environmental threats due to the translocation, Art. 2 para. 2.”</p>	<p>High</p> <p>These are well established and widely approved practices, some of them already translated into legislation with demonstrated effectiveness. Some</p>

	<p>for a permit from the competent authority of the Member State where the transfer will take place. The Regulation specifies the information to be provided by the applicant and the type of assessment that the competent authority must perform before granting the permit.</p> <p>2. The ICES Code of Practice on the Introductions and Transfers of Marine Organisms (ICES, 2005) recommends the procedure for introduced or transferred species which are part of current commercial practice. The procedure states clearly that:</p> <p>a) All products should originate from sources in areas that meet current codes, such as the OIE International Aquatic Animal Health Code or equivalent EU directives.</p> <p>b) If required, there should be inspection, disinfection, quarantine or destruction of the introduced organisms and transfer material (e.g., transport water, packing material, and containers) based on OIE or EU directives.</p> <p>3. Use locally harvested or hatchery produced seed for non-native cultivated bivalves such as <i>Magallana gigas</i> and</p>	<p>Additional local, national or European regulations may apply that limit the translocation possibilities of species like <i>M. gigas</i> and <i>R. philippinarum</i> in certain areas (e.g., for the Wadden Sea see Gittenberger et al., 2017; WG-AS &amp; Gittenberger, 2018). More stringent controls for these species could take the form of the prohibition of imports from areas where <i>M. lateralis</i> is known to be present. Alternatively, such imports could be subjected to quarantine measures. In many cases voluntary or mandatory measures to protect against non-native species are already implemented (see below), such that stakeholder acceptance and compliance are expected to be high. This would be the case in particular, where a pathogen posing a risk to the commercial operation might be suspected or identified (e.g. <i>Perkinsus</i> parasites).</p> <p>Regarding the relaying of mussels and clams within Member States for on-growing or purification, restrictions based on risks associated with source areas are in place in certain areas (e.g. in Wales and The Netherlands) and are an effective management method, as long as extensive and up-to-date data on the distribution of the high-risk non-native species are available.</p> <p>As a matter of standard industry practices, there are sampling and monitoring protocols for the inspection of shellfish areas between which translocations take place (e.g. Wilson &amp; Smith., 2008; Gittenberger, 2014; MEC, 2015). For example, if high risk non-native species (based on a pre-established species list) are detected</p>	<p>uncertainty remains however in relation to the detectability of <i>M. lateralis</i> individuals during routine inspections by industry standards and the degree of compliance with legislation and codes of conduct at the EU scale.</p>
--	--	---	---

	<p><i>Ruditapes philippinarum</i>. Both species are naturalised in parts of the RA area.</p>	<p>during transportation, the import stops and bivalves are not relayed. They may be returned to the harvesting area or placed in quarantine. If IAS are detected on a relaying site, the plots must be cleaned and the mussels placed in quarantine.</p> <p>Any cleaning or removal procedure during transportation on board a dredger vessel (e.g. washing over a certain sieve size to remove larvae and juveniles, hand-picking of adults) would not guarantee the complete removal/eradication of risk organisms.</p>	
<p><b>Reducing spread</b></p>	<p><b>Managing the pathway “Bilge water”</b>  Bilge water is generally defined as any seawater that accumulates within the hull of a vessel, including uncontained water on the deck area. Bilge water volumes in recreational vessels can range between &lt;1l for small motorboats to &gt;200l for a large catamaran (Fletcher et al., 2017) and are typically pumped out of the vessel untreated. Discharge of bilge water for large commercial vessels is regulated under Marpol Annex I (MEPC.1/Circ.642), which requires an integrated bilge water treatment system (IMO, 2008).</p> <p>There are currently no legal acts or official guidance for the prevention of NIS transportation with bilge water by small vessels.</p>	<p>Requiring discharge within the source region seems the most practical option available, with no associated costs and minimal logistical constraints. Desirable vessel operator behaviours can be promoted through awareness campaigns to educate boaters about possible risks from bilge water, e.g. the “Check Clean Dry” campaign already implemented in the UK in relation to aquatic hitchhikers.</p> <p><a href="http://www.nonnativespecies.org//checkcleandry/index.cfm?">http://www.nonnativespecies.org//checkcleandry/index.cfm?</a></p>	<p>Low</p> <p>These methods are not currently practiced in the marine environment and are based on expert opinion.</p>

	<p>Potential mitigation measures (Fletcher et al., 2017):</p> <ul style="list-style-type: none"> <li>• Restrictions on the location of discharge.</li> <li>• Retention of bilge water for subsequent disposal.</li> <li>• Treatment of bilge water prior to discharge.</li> <li>• Awareness campaigns to boaters.</li> <li>• Industry codes of practice.</li> </ul>		
<p><b>Methods to achieve early detection<sup>6</sup></b></p>	<p><b>Monitoring and early detection</b></p> <p>In order to reach Good Environmental Status targets with reference to Descriptor D2 for alien species (i.e. “Non-indigenous species introduced by human activities are at levels that do not adversely alter the ecosystems”), most EU states are already designing or implementing national/regional NIS-targeted monitoring programs (see ICES, (2017) for national reports in France, Germany, Sweden, Denmark, Norway; see Minchin (2014) for Ireland). Monitoring should focus on introduction hotspots (e.g., ports, marinas, aquaculture plots, aggregate extraction sites) and specific natural hotspots on a yearly basis (ICES, 2017). Molecular tools and DNA barcoding of zooplankton samples may represent a further early</p>	<p>One of the potential caveats of monitoring based on morphological identification, especially if it’s not specifically targeting IAS, is the long processing times needed to analyse large amounts of samples (Klunder et al., 2019). On the other hand, Rapid Assessment Surveys carried out by experienced specialists with the appropriate methods and targeted species lists, can prove effective at early NIS detection even in subtidal soft sediments (Buschbaum et al., 2012). Nevertheless, the efficacy of early detection methods in detecting <i>M. lateralis</i> (including early life stages) at monitoring hotspots for new introduction events, will be the highest if eDNA methodologies are implemented for ballast and sea water samples and sediments, as well as potentially contaminated aggregates. This would be particularly effective in detecting new introductions via dredger vessels with EU home ports returning from the native area, as the potential donor regions where such operations take place are very specific (i.e. eastern coast of Mexico and Bay of St. Lawrence, Canada).</p>	<p>Medium</p> <p>Monitoring of dredging activities and equipment specifically for the purposed of NIS detection has not been implemented. The logistics, effectiveness and uptake of proposed methods are unknown.</p>

	<p>detection approach that could be extended to ballast water, hopper water and bilge water monitoring (Zaiko et al., 2015; Fletcher et al., 2017). Furthermore, eDNA methodologies for the detection of macro-organisms in sediments are continuously being developed and refined (Xie et al., 2018; Sakata et al., 2020) and could be applied to ballast tank sediments, and port sediments, as well as dredged material.</p>	<p>Additionally, the complete mitochondrial genome of <i>M. lateralis</i> has been sequenced and is available for the development of specific assays (Liu et al., 2020). With regards to the cost of monitoring, an indicative estimate comes from Denmark, where the cost of a proposed hotspot monitoring program for all marine NIS (covering 13 ports and three areas with discharges of cooling water) was estimated at approximately €125k for the period 2015-2017 (Andersen et al., 2014). In the UK, a broad initial estimate of monitoring costs for MSFD D2 alone (considering that existing or new surveys for other descriptors will also contribute to the monitoring of NIS) suggests that they would be less than €961k over 10 years (DEFRA, 2012), with an additional €100k for drafting legislation and guidance. In New Zealand, surveillance of 11 ports for high risk NIS every six months cost approximately NZ\$ 2 million annually (Arthur et al., 2015). The costs of eDNA methodologies can vary considerably depending on the approach employed (e.g. Borrell et al., 2017) but generally nucleic acids-based tools are more cost-efficient compared to traditional sampling and morphological identification approaches (Darling &amp; Frederick, 2018), provided that the necessary infrastructure is already available and the method is established and sensitive. These are general monitoring costs and not specific to <i>M. lateralis</i>.</p>	
--	---	--	--

	<p><b>Early warning systems / awareness raising</b></p> <p>Citizen scientist observation networks are a suitable platform for this species, which can be found intertidally, is frequently washed up on the shore, and attracts the attention of shell collectors. Early warning systems to inform shellfish growers should be designed due to the potential danger <i>M. lateralis</i> poses for the spread of <i>Perkinsus</i> parasites.</p>	<p>Its small size and similarity with common native species mean that <i>M. lateralis</i> can get easily misidentified by non-experts at the juvenile stage.</p> <p>On the other hand, many of the recent Belgian records refer to adult individuals from citizen scientist observations through a well organised reporting and validation platform (Waarnemingen, 2021). However, if individuals of the species have been washed up on the shore and are grown enough to be identifiable by the public, this likely means that the population is already established.</p>	Medium
<p><b>Methods to achieve eradication<sup>7</sup></b></p>	<p><b>Mechanical removal</b></p> <p>This could be attempted with different types of towed bottom gears, such as trawls and dredges. Different types of trawls have been used to sample <i>M. lateralis</i> in scientific surveys (e.g. Reguero &amp; Raz-Guzman, 2018) and dredges used for commercial clam species could also be employed.</p>	<p><i>Mulinia lateralis</i> is not commercially harvested, hence information on the effectiveness of different fishing gears in removing the species was not found. <i>Mulinia</i> however is generally small (up to 21 mm in the invaded range - Craeymeersch et al., 2019) and a considerable proportion of the population would be expected to pass through typical commercial gear. Given the very small size at which it can reproduce (3 mm – Calabrese, 1969) and the ability of the species to rapidly colonise defaunated habitats (Flint &amp; Younk, 1983), eradication is very unlikely to be achieved. On the contrary, by removing competition, dredging may allow the remaining <i>M. lateralis</i> individuals to opportunistically and rapidly re-colonise the dredged area, possibly reaching even higher densities.</p> <p>Moreover, dredging outside commercial operations and cultured bivalve beds is likely to have serious negative impacts on local species and habitats. Finally, the use of this measure will likely require special permits or</p>	Medium

		changes in fisheries regulations (local spatial/temporal restrictions) and is unlikely to be allowed in protected areas due to potential damage to protected features.	
	<p><b>Physical/chemical methods</b> Other methods that are commonly considered for the eradication and/or population control of marine organisms involve chemical treatment with a variety of substances (from salt, to chlorine, to specialised biocides) and physical methods such as the application of heated water, sometimes in combination with physical containment (i.e. plastic sheets) (see McEnnulty et al., 2001).</p>	None of these methods are applicable to <i>Mulinia lateralis</i> because of its infaunal existence in open water habitats (as opposed to the majority of bivalve species for which such control methods have been applied which are either freshwater and/or biofouling species). The broadcast application of chemicals has detrimental effects on native species while containment with physical barriers is only realistic for visible organisms with limited/clustered distribution.	Low
<b>Methods to achieve management<sup>8</sup></b>	<p><b>Population removal</b> Dredging would be the best option if population removals were attempted. In the case where <i>M. lateralis</i> infected with the parasite <i>Perkinsus</i> were detected among cultivated or harvested bivalve beds the recommended action would be close monitoring of all clam species for infection and the early harvesting of clams, alongside the invader (Andrews &amp; Ray, 1988).</p>	As in the previous section, population control efforts in the wild are regarded as ineffective.	Low

## Guidelines for Completing the Annex

1 Provide a brief summary description of the most cost-effective methods drawing on the reviews in the detailed assessments

2 Provide a description of the potential method. This should be based on the available key scientific evidence which should be gathered from sources including articles and reviews in technical and scientific journals, internet searches, online databases, grey literature and relevant books and personal communications from scientists, stakeholders, conservation practitioners and governmental bodies. This information should include a full bibliographic list detailing the literature and sources considered.

3 Provide an assessment of the likely cost and effectiveness of the method. Where information is available, consider the following range of questions, accepting that not all questions will be appropriate in all circumstances.

- How effective has this approach proven to be in the past or in an analogous situation?
- How publically acceptable is the approach likely to be?
- Over what period of time would this approach need to be applied to be effective?
- What is the direct cost of implementing this approach?
- How likely are the methods used in the approach to be available?
- How likely is it that relevant licences or other approvals to undertake the approach would be difficult to obtain?
- How likely is it that health and safety issues would prevent the use of this approach?
- How significant is the environmental harm caused by this approach?
- How significant is the economic harm caused by this approach?
- How significant is the social harm caused by this approach?
- How likely is it that the approach will be criticised on welfare grounds?
- How likely is it that the approach will be acceptable to other stakeholders?

Where available, factual information on the costs of specialist equipment, or case studies of management costs from across the Union or third countries should be provided. When describing case studies, if the information is available then provide both total cost and the area over which control was undertaken so that a cost per unit area might be derived. Where such quantitative information is not available, then any qualitative information from the literature is acceptable to help guide decision making. It is accepted that in the majority of cases the information required to assess the potential total cost of management at a member state level is unlikely to be available. This would normally require information on the extent and abundance of the species which is beyond the scope of this assessment. Assessors are not expected to extrapolate the potential total costs of management at a member state level, only to report on the information provided within the literature.

4 Provide an overall assessment of the confidence that can be applied to the information provided for this method. This confidence should relate to the quality of the available information using the guidance below. It should NOT relate to the confidence in the effectiveness of the method

The confidence scores are:

- **High:** Information comes from published material, or current practices based on expert experience applied in one of the EU countries or third country with similar environmental, economic and social conditions.
- **Medium:** Information comes from published data or expert opinion, but it is not commonly applied, or it is applied in regions that may be too different from Europe (e.g. tropical regions) to guarantee that the results will be transposable.
- **Low:** data are not published in reliable information sources and methods are not commonly practiced or are based solely on opinion; This is for example the case of a novel situation where there is little evidence on which to base an assessment.

If there are further factors beyond these that have determined the chosen level of confidence, then provide a brief written description to support the choice of the level of confidence.

5 Measures for preventing the species being introduced intentionally or unintentionally into the territory of a Member State (cf. Articles 7(1)(a), 7(2), 13, 15), i.e. preventing a species entering by blocking its pathways, including pre-border prevention and prevention of escape or release into the environment and secondary spread whenever relevant. Measures for preventing the species reproducing while in containment should be included, if appropriate. Consider all methods that might be applied, including any that have not proven useful. Provide a description of each method in turn, using separate rows to consider each method.

6 Measures to run an effective surveillance system for achieving an early detection of a new occurrence (cf. Article 16). This section assumes that the species is not currently present in a Member State, or part of a Member State's territory.

7 Measures to achieve eradication. Preferably, but not exclusively, used at an early stage of invasion, after an early detection of a new occurrence (cf. Article 17). Consider all methods that might be applied, including any that have not proven useful. Provide a description of each method in turn, using separate rows to consider each method.

8 Measures to achieve management of the species once it has become widely spread within a Member State territory (cf. Article 19). These measures can be aimed at eradication, population control or containment of a population of the species. Consider all methods that might be applied, including any that have not proven useful. Provide a description of each method in turn, using separate rows to consider each method.

The development and completion of this template forms part of the EU project **No 07.0202/2020/834529/ETU/ENV.D.2** Study on Invasive Alien Species – Development of risk assessments to tackle priority species and enhance prevention.

**Risk assessment template developed under the "Study on Invasive Alien Species – Development of risk assessments to tackle priority species and enhance prevention"  
Contract No 07.0202/2020/834529/ETU/ENV.D.2<sup>1</sup>**

**Name of organism:** *Obama nungara* Carbayo, Álvarez-Presas, Jones & Riutort, 2016

**Author(s) of the assessment:**

Archie K. Murchie, Agri-Food & Biosciences Institute, Belfast, BT9 5PX

Leigh Winsor, College of Science and Engineering, James Cook University, Townsville, QLD, Australia

Jean-Lou Justine, ISYEB (Institut de Systématique, Évolution, Biodiversité), Muséum National d'Histoire Naturelle, Paris, France

Björn Beckmann, Centre for Ecology & Hydrology, Penicuik, EH26 0QB

**Risk Assessment Area:** The risk assessment area is the territory of the European Union 27 and the United Kingdom, excluding the EU-outermost regions.

**Peer review 1:** Dr Richard Shaw, CABI, Egham, UK

**Peer review 2:** Dr Brian Boag, James Hutton Institute, Invergowrie Dundee, UK

**Date of completion:** 15/10/2021

---

<sup>1</sup> This template is based on the Great Britain non-native species risk assessment scheme (GBNNRA). A number of amendments have been introduced to ensure compliance with Regulation (EU) 1143/2014 on IAS and relevant legislation, including the Delegated Regulation (EU) 2018/968 of 30 April 2018, supplementing Regulation (EU) No 1143/2014 of the European Parliament and of the Council with regard to risk assessments in relation to invasive alien species (see <https://eur-lex.europa.eu/legal-content/en/TXT/?uri=CELEX%3A32018R0968>).

## SECTION A – Organism Information and Screening

### **A1. Identify the organism. Is it clearly a single taxonomic entity and can it be adequately distinguished from other entities of the same rank?**

including the following elements:

- the taxonomic family, order and class to which the species belongs;
- the scientific name and author of the species, as well as a list of the most common synonym names;
- names used in commerce (if any)
- a list of the most common subspecies, lower taxa, varieties, breeds or hybrids

As a general rule, one risk assessment should be developed for a single species. However, there may be cases where it may be justified to develop one risk assessment covering more than one species (e.g. species belonging to the same genus with comparable or identical features and impact). It shall be clearly stated if the risk assessment covers more than one species, or if it excludes or only includes certain subspecies, lower taxa, hybrids, varieties or breeds (and if so, which subspecies, lower taxa, hybrids, varieties or breeds). Any such choice must be properly justified.

Response: *Obama nungara* Carbayo, Álvarez-Presas, Jones & Riutort, 2016

Phylum Platyhelminthes, Class Rhabditophora (previously Turbellaria), Order Tricladida, Family Geoplanidae, Subfamily Geoplaninae

Synonyms: *Obama marmorata pro parte*

This species was originally mistaken as *Obama marmorata* when first found in Europe (Lago-Barcia *et al.*, 2015) but subsequently identified as a new species *Obama nungara* (Carbayo *et al.*, 2016).

The organism is a single taxonomic entity. There are no known varieties, breeds or hybrids. Through molecular analyses of the COI gene, Justine *et al.* (2020) found *O. nungara* to be composed of three clades. They termed these: ‘Brazil’ - currently confined to Brazil, ‘Argentina 2’ - found in Argentina and Spain; ‘Argentina 1’ - found in Argentina and in Spain, Portugal, France, UK, Italy, Belgium, and Switzerland. As to date there is no information on morphological or physiological differences between the clades, this risk assessment will apply to all

Common names: The ‘Obama flatworm’. Note there is no connection to the former US President Barack Obama. The genus name *Obama* comes from the Tupi language and means leaf-animal. In French, ‘Marron plate’.

### **A2. Provide information on the existence of other species that look very similar [that may be detected in the risk assessment area, either in the environment, in confinement or associated with a pathway of introduction]**

Include both native and non-native species that could be confused with the species being assessed, including the following elements:

- other alien species with similar invasive characteristics, to be avoided as substitute species (in this case preparing a risk assessment for more than one species together may be considered);

- other alien species without similar invasive characteristics, potential substitute species;
- native species, potential misidentification and mis-targeting

Response: *Obama nungara* was formally described in 2016 as a new species (Carbayo *et al.*, 2016). The flatworm measures typically 50 – 80 mm in length and 5 mm in width, with brown dorsal colouration, with multiple longitudinal black striae giving a ‘netted’, reticulated appearance, and a beige sole (Justine *et al.*, 2020; Soors *et al.*, 2019). The dorsal colour is variable ranging from orange to almost black. Multiple eyes extend in a lateral band on each side of the body, one third of the flatworm’s body width (Carbayo *et al.*, 2016). Justine *et al.* (2020) gives detailed descriptions suitable for the non-specialist along with photographs of the different colour forms. Egg cocoons are shiny spheroidal capsules which are red when newly laid, turning dark brown to black within a few days (Justine *et al.*, 2020). They measure c. 5 mm in diameter. Juveniles are light cream in colour with fine dark brown stipling (Justine *et al.*, 2020).

*Obama nungara* may be confused with other terrestrial flatworms. Superficially, this may include small native species and invasive alien species such as *Arthurdendyus triangulatus* and *Bipalium kewense*. Native flatworm species are mostly small (< 50 mm length), innocuous animals whereas *O. nungara* can be distinguished from alien flatworms by dorsal colouration (e.g., the pale marginal edge of *A. triangulatus*) and body/head shape (e.g., the shovelhead shape of *Bipalium* spp.).

Justine *et al.* (2020), on the experience of citizen science records, says that *O. nungara* may be confused with: 1) *Parakontikia ventrolineata*, an alien species native to Australia, but this species is smaller and has longitudinal lines on its back and belly; 2) *Platydemus manokwari* but the body shape is different and *P. manokwari* has a clear, pale single longitudinal line on its back and two conspicuous eyes.

*Obama nungara* may be confused with other *Obama* spp., in particular *Obama marmorata* but this species has not been found within the risk assessment area. *Obama marmorata* is up to 100 mm long, 10 mm wide, with the dorsum covered with green brown longitudinal striae on an orange to ivory background (Carbayo *et al.*, 2016).

**A3. Does a relevant earlier risk assessment exist? Give details of any previous risk assessment, including the final scores and its validity in relation to the risk assessment area.**

Response: There is no quantitative or qualitative risk assessment for *O. nungara*.

**A4. Where is the organism native?**

including the following elements:

- an indication of the continent or part of a continent, climatic zone and habitat where the species is naturally occurring
- if applicable, indicate whether the species could naturally spread into the risk assessment area

Response: *Obama nungara* is native to South America, and particularly to Argentina, south-eastern Brazil and Uruguay (Carbayo *et al.*, 2016; Lago-Barcia *et al.*, 2015; Negrete *et al.*, 2020). The specimens found in Europe show most affinity to the Argentinian clade (Justine *et al.*, 2020).

As with other invasive flatworms, *O. nungara* is synanthropic, found in gardens and other modified habitats in its native range (Lago-Barcia *et al.*, 2019; Negrete *et al.*, 2020; Carbayo *et al.*, 2016). In a study on the coexistence of several terrestrial flatworm species in South American Atlantic Forest, *O. nungara* was found in human-disturbed areas (Boll and Leal-Zanchet, 2016). Similarly *O. nungara* has also been collected from human-disturbed native forest habitats (Lago-Barcia *et al.*, 2019). However, Negrete *et al.* (2020) collected many specimens in undisturbed native forests from Tucumán Province, north-western Argentina. It is possible that this is close to the natural habitat of *O. nungara*. However, L. Negrete (2021, pers. comm.) commented that this area is very close to routes with intense trade between provinces, which could suggest *O. nungara* may have been introduced there and has found ideal conditions for establishment. In that same area (Tucumán) large number *Bipalium kewense* (a definite introduction) were found, which would support this conjecture. It is not therefore clear exactly what and where is the native habitat of *O. nungara*.

*Obama nungara* is a predatory, soil-dwelling organism that naturally disperses by creeping on the substrate surface. In common with other terrestrial flatworms, especially these of a synanthropic nature, it is usually found under wood, rocks and debris on the soil surface. It could not naturally spread into the risk assessment area.

**A5. What is the global non-native distribution of the organism outside the risk assessment area?**

Response: *Obama nungara* is native to South America and has been recorded from Argentina, Brazil, Uruguay and Chile, with the latter likely to be an introduction. Outside of South America, *O. nungara* has only been recorded in Europe and two records from the USA in 2020, in North Carolina ([www.inaturalist.org/observations/68472771](http://www.inaturalist.org/observations/68472771)) and South Carolina (L. Winsor 2021, unpubl.). Most records in Europe are from the risk assessment area but *O. nungara* has established in the wild also in Guernsey (Álvarez-Presas *et al.*, 2014; Carbayo *et al.*, 2016; Webster, 2020), Madeira Island and São Miguel in the Azores (Lago-Barcia *et al.*, 2020; Justine *et al.*, 2020) and Switzerland (Justine *et al.*, 2020).

**A6. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species been recorded and where is it established? The information needs to be given separately for recorded (including casual or transient occurrences) and established occurrences. “Established” means the process of an alien species successfully producing viable offspring with the likelihood of continued survival<sup>2</sup>.**

<sup>2</sup> Convention on Biological Diversity, Decision VI/23

**A6a. Recorded: List regions**

**A6b. Established: List regions**

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

- Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea.

Comment on the sources of information on which the response is based and discuss any uncertainty in the response.

For delimitation of EU biogeographical regions please refer to <https://www.eea.europa.eu/data-and-maps/figures/biogeographical-regions-in-europe-2> (see also Annex VI).

For delimitation of EU marine regions and subregions consider the Marine Strategy Framework Directive areas; please refer to <https://www.eea.europa.eu/data-and-maps/data/msfd-regions-and-subregions/technical-document/pdf> (see also Annex VI).

Response (6a): *Obama nungara* has been recorded in the Atlantic, Continental and Mediterranean biogeographic regions (see A.8 for references).

Response (6b): *Obama nungara* has also established in the Atlantic, Continental and Mediterranean biogeographic regions (see A.8 for references).

**A7. In which biogeographic region(s) or marine subregion(s) in the risk assessment area could the species establish in the future under current climate and under foreseeable climate change? The information needs be given separately for current climate and under foreseeable climate change conditions.**

**A7a. Current climate: List regions**

**A7b. Future climate: List regions**

With regard to EU biogeographic and marine (sub)regions, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

Response (7a): *Obama nungara* is predicted to have a potentially wide distribution in Europe. Under the current climate it could establish in the Atlantic, Mediterranean and Black Sea biogeographical regions and to a lesser extent in the Continental region, with small incursions into Pannonian and Alpine regions (see Annex VIII ‘Projection of environmental suitability for *Obama nungara* establishment in Europe’).

Response (7b): Under climate change scenarios RCP 2.6 (likely range of 0.4-1.6°C global warming increase) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase), *O. nungara* could establish in greater areas of the Atlantic and Continental regions as its range increases northwards and eastwards. The Pannonian region is also markedly more vulnerable to flatworm establishment. However, the Black Sea region only shows a slight increase in the area suitable for *O. nungara* under these climate change scenarios, whilst the flatworm’s range in the Mediterranean declines in the southern localities (see Annex VIII ‘Projection of environmental suitability for *Obama nungara* establishment in Europe’)

**A8. In which EU Member States has the species been recorded and in which EU Member States has it established? List them with an indication of the timeline of observations. The information needs be given separately for recorded and established occurrences.**

**A8a. Recorded: List Member States**

**A8b. Established: List Member States**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden

The description of the invasion history of the species shall include information on countries invaded and an indication of the timeline of the first observations, establishment and spread.

Response (8a): *Obama nungara* has been recorded in the wild or as interceptions in the following Member States:

Austria (J-L Justine 2020, unpubl.), Belgium (Soors *et al.*, 2019), France (Justine *et al.*, 2020), Germany (J-L Justine 2020, unpubl.; Kutschera and Ehnes, 2021), Ireland (Justine *et al.*, 2020), Italy (Carbayo *et al.*, 2016), Netherlands (Justine *et al.*, 2020; Aldred, 2016), Portugal (Justine *et al.*, 2020), Slovakia (L. Winsor 2021, unpubl.) and Spain (Carbayo *et al.*, 2016).

Response (8b): *Obama nungara* has established in France, Belgium, Spain, Portugal and Italy (Justine and Winsor, 2020), and almost certainly in other countries adjoining these but this has not been confirmed to date.

Before being described as a separate species, *O. nungara* was first recorded as an unknown species in Guernsey, the Channel Islands, in 2008 and England, in 2009 (Carbayo *et al.*, 2016). It was subsequently found in Spain in 2010 (Álvarez-Presas *et al.*, 2014), where it was initially misidentified as *Obama marmorata* (Lago-Barcia *et al.*, 2015). Carbayo *et al.* (2016) described the flatworm specimens as a new species, *O. nungara*, listing many additional records from Spain, principally from two regions, Asturias and Cantabria on Spain's Atlantic coast, and from the Catalonia region on Spain's north-east Mediterranean coast, as well as detailing a record from Italy (2012). Lago-Barcia *et al.* (2019) extended the known distribution on the Iberian Peninsula, collecting specimens from the Porto region, Portugal. In 2016, there was a record of *O. nungara* being intercepted in the UK on plants that came from the Netherlands (Aldred, 2016).

The most comprehensive study of *O. nungara* distribution is from France (Justine *et al.*, 2020), where 530 records were collected through citizen science from 2013-2018, and the flatworm has established in 72 of the 96 administrative Departments in Metropolitan France, as well as Corsica. From these 530 citizen science records, *O. nungara* was the most recorded flatworm species in France. *Obama nungara* was found established in Belgium in 2017 (Soors *et al.*, 2019).

**A9. In which EU Member States could the species establish in the future under current climate and under foreseeable climate change? The information needs be given separately for current climate and under foreseeable climate change conditions.**

**A9a. Current climate: List Member States**

**A9b. Future climate: List Member States**

With regard to EU Member States, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

Response (9a): There have been no experimental assessments on the environmental requirements of *O. nungara*. The most comprehensive study of *O. nungara* distribution in Europe is from Metropolitan France (Justine *et al.*, 2020), where the species has achieved a widespread distribution especially along the Atlantic and Mediterranean coasts. There were fewer records in the central plains and mountainous regions of France and none from above 500 m altitude, which the authors attribute to the likelihood of freezing. However, *O. nungara* was found above 500 m at a location on São Miguel in the Azores (Lago-Barcia *et al.*, 2020). Given the wide distribution in France, Soors *et al.* (2019) commented that *O. nungara* has a broad temperature tolerance within a temperate climate.

Using species occurrence data, Negrete *et al.* (2020) modelled and mapped the potential distribution of *O. nungara* using MaxEnt software, under both current and climate change scenarios. They found that the most important factors determining the distribution of *O. nungara* (accounting for 60% of the variance) were annual mean temperature (moderate probability of establishment 9 - 17°C), temperature range, temperature seasonality and precipitation of the coldest quarter (moderate probability of establishment 140 - 330 mm). In Europe, *O. nungara* was most suited to the climate type Cfb (temperate, oceanic) of the Köppen-Geiger climate classification; whereas in South America Cfa (humid, subtropical) fitted best with the flatworm's distribution. The model predicted that under the current climate, *O. nungara* has the potential to expand its range in Europe, to establish in Luxembourg, the Netherlands, Germany, and Denmark, as well as regions of Croatia and Greece on the east coast of the Adriatic.

The model developed as part of this risk assessment is presented in detail in Annex VIII. The model is an ensemble of six algorithms. The factors that most strongly predicted *O. nungara* distribution were minimum temperature of the coldest month (38% of variation), human influence index (24%), mean temperature of the warmest quarter (18%), annual precipitation (11%), precipitation seasonality (5%)

and climatic moisture index (4%). The flatworm is predicted capable of establishing in large areas (>50% of the region) in Belgium, France, Italy, Luxembourg, the Netherlands and Portugal. Significant areas (>20%) of Croatia, Germany, Greece and Spain, as well as the United Kingdom, are also at risk of this species establishing (Annex VIII).

Response (9b): Negrete *et al.* (2020) modelled the distribution of *O. nungara* under RCP 2.6 and RCP 8.5 climate change scenarios. Under both RCP 2.6 and 8.5, *O. nungara* was predicted to expand its current potential range in Europe by 35%, which would include the following Member States: Luxembourg, the Netherlands, Denmark, Ireland, Croatia, and Greece.

The species distribution model predictions (Annex VIII) under RCP 2.6 and RCP 4.5 show a similar expansion of range to the north and east as with the Negrete *et al.* (2020) under both climate change scenarios, with Austria, the Czech Republic, Denmark, Hungary and Ireland at significant risk with >20% of area suitable for *O. nungara* establishment. Conversely, some Mediterranean countries (Greece, Italy, Portugal and Spain) may see the areas suitable for *O. nungara* establishment decline under both climate change scenarios. Predictions under RCP 2.6 and 8.5, gave the same general trends with the RCP 8.5 predictions more pronounced.

**A10. Is the organism known to be invasive (i.e. to threaten or adversely impact upon biodiversity and related ecosystem services) anywhere outside the risk assessment area?**

Response: No evidence of impact is available for *O. nungara* so far, despite other species of alien flatworms being known for their invasive potential due to their predatory impact on soil fauna, but this may be due to the relatively small initial populations.

Outside of the risk assessment area, *O. nungara* has established in the wild in Guernsey (Álvarez-Presas *et al.*, 2014; Carbayo *et al.*, 2016; Webster, 2020), Madeira Island and in São Miguel in the Azores (Lago-Barcia *et al.*, 2020; Justine *et al.*, 2020), Switzerland (Justine *et al.*, 2020), Chile and the US.

**A11. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea

Response: No evidence of impact is available for the species so far in any EU biogeographical region. *Obama nungara* is a predator of soil invertebrates including earthworms and molluscs (Boll and Leal-Zanchet, 2016). To date, there have been no studies assessing the impact of *O. nungara*. Consequently, it is not yet known whether *O. nungara* will have a negative effect on European soil fauna (Negrete *et al.*, 2020). The greatest densities found so far are in populations occurring within the Atlantic biogeographical region (Justine *et al.*, 2020).

**A12. In which EU Member States has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden

Response: No evidence of impact is available for the species so far in any EU Member State (please see Qu. A11). High numbers of *O. nungara* have been collected by gardeners in France. In one garden, 944 specimens were collected from May to August from an area of c. 300 m<sup>2</sup>; whereas in another 1,442 were collected from November to May from a garden of c. 175 m<sup>2</sup> (Justine *et al.*, 2020). However, the impact of *O. nungara* on soil fauna has not been assessed.

**A13. Describe any known socio-economic benefits of the organism.**

including the following elements:

- Description of known uses for the species, including a list and description of known uses in the risk assessment area and third countries, if relevant.
- Description of social and economic benefits deriving from those uses, including a description of the environmental, social and economic relevance of each of those uses and an indication of associated beneficiaries, quantitatively and/or qualitatively depending on what information is available.

If the information available is not sufficient to provide a description of those benefits for the entire risk assessment area, qualitative data or different case studies from across the risk assessment area or third countries shall be used, if available.

Response: There are no known socio-economic benefits. *Obama nungara* could possibly benefit gardeners and farmers by feeding on pest snails and slugs. However, experience with other snail-feeding flatworms such as *P. manokwari*, suggests that the long-term deleterious effects on native mollusc biodiversity outweighs any benefits (Gerlach *et al.*, 2020). Similarly, *O. nungara* will feed on other flatworm species (e.g. *Dolichoplana carvalhoi*) (Boll and Leal-Zanchet, 2016) and therefore there is the tentative possibility of biocontrol of other invasive flatworm species but this remains to be tested and, as above, there is potential for significant non-target effects on indigenous flatworm species.

## SECTION B – Detailed assessment

### Important instructions:

- In the case of lack of information the assessors are requested to use a standardized answer: “No information has been found.” In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable).
- With regard to the scoring of the likelihood of events or the magnitude of impacts see Annexes I and II.
- With regard to the confidence levels, see Annex III.
- Highlight the selected response score and confidence level in **bold** but keep the other scores in normal text (so that the selected score is evident in the final document).

## 1 PROBABILITY OF INTRODUCTION AND ENTRY

### Important instructions:

- **Introduction** is the movement of the species into the risk assessment area (it may be either in captive conditions and/or in the environment, depending on the relevant pathways).
- **Entry** is the release/escape/arrival in the environment, i.e. occurrence in the wild
- Introduction and entry may coincide for species entering through pathways such as “corridor” or “unaided”, but it also may differ. If different, please consider all relevant pathways, both for the introduction into the risk assessment area and the entry in the environment.
- The classification of pathways developed by the Convention of Biological Diversity (CBD) should be used (see Annex IV). For detailed explanations of the CBD pathway classification scheme consult the IUCN/CEH guidance document<sup>3</sup> and the provided key to pathways<sup>4</sup>.
- For organisms which are already present (recorded or established) in the risk assessment area, the likelihood of introduction and entry should be scored as “very likely” by default.
- Repeated (independent) introductions and entries at separate locations in the risk assessment area should be considered here (see Qu. 1.7).

**Qu. 1.1. List relevant pathways through which the organism could be introduced into the risk assessment area and/or enter into the environment. Where possible give details about the specific origins and end points of the pathways as well as a description of any associated commodities.**

For each pathway answer questions 1.2 to 1.8 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 1.2a, 1.3a, etc. and then 1.2b, 1.3b etc. for the next pathway.

In this context a pathway is the route or mechanism of introduction and/or entry of the species.

<sup>3</sup> <https://circabc.europa.eu/sd/a/7e5f0bd4-34e8-4719-a2f7-c0cd7ec6a86e/2020-CBD-pathways-interpretation.pdf>

<sup>4</sup> <https://circabc.europa.eu/sd/a/0aeba7f1-c8c2-45a1-9ba3-bcb91a9f039d/TSSR-2016-010%20CBD%20pathways%20key%20full%20only.pdf>

The description of commodities with which the introduction of the species is generally associated shall include a list and description of commodities with an indication of associated risks (e.g. the volume of trade; the likelihood of a commodity being contaminated or acting as vector).

If there are no active pathways or potential future pathways this should be stated explicitly here, and there is no need to answer the questions 1.2-1.9.

A main pathway described in this risk assessment for *O. nungara* is “contaminant nursery material” (unintentional) because of the species being considered as associate to the plant trade, the flatworm has been found in nurseries and the recognition of nursery material as a pathway for other invasive flatworms. There is no evidence in the literature of any other pathway being significant for introduction to the risk assessment area. Some thought was given as to whether botanical gardens (unintentional) should also be considered as a pathway as they have been implicated in the introduction of other flatworm species, e.g. *Bipalium kewense* (Winsor, 1983), *Platydemus manokwari* (Justine *et al.*, 2014) and *Arthurdendyus triangulatus* (Boag and Neilson, 2014). However, the pathways are very similar and represent unintentional introduction via trade and movement of living plants, which may be ultimately to a garden centre or botanic garden (in some cases, the same site may function as both). This is different from a plant species being intentionally brought into a botanical garden and escaping into the wild, as under the CBD ‘escape from confinement’ pathways. There is a suggestion of importation to the island of São Miguel on soil on machinery (Lago-Barcia *et al.*, 2020), but this pathway is considered here not active for introduction or entry into the risk assessment area and will be considered under spread within the risk assessment area. EU restrictions on the movement of soil (e.g. under EU Commission Implementing Regulation (EU) 2019/2072) and phytosanitary procedures for the cleansing of imported machinery make this pathway more pertinent within the risk assessment area, where such restrictions are not in place.

Pathway name: **Contaminant nursery material**

It is not known how *O. nungara* was introduced to the risk assessment area but terrestrial flatworms are most commonly introduced via accidental importation in plants for planting (nursery stock) (Sluys, 2016) and this would seem the most likely pathway (Lago-Barcia *et al.*, 2019). The proximity of early records to garden centres, nurseries and gardens (Carbayo *et al.*, 2016; Justine *et al.*, 2020; Álvarez-Presas *et al.*, 2014) strongly support this contention.

**Qu. 1.2a. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	intentional	<b>CONFIDENCE</b>	low
	<b>unintentional</b>		medium
			<b>high</b>

Response: This pathway is unintentional. Terrestrial flatworms have been intercepted in the UK on plant material, particularly tree ferns (*Dicksonia* spp.), from Australia and New Zealand (Matthews, 2005; Cannon and Baker, 2007). Although within the risk assessment area, there is a record of *O. nungara*

being intercepted in the UK on plants that came from the Netherlands (Aldred, 2016), which serves as another example of this potential pathway for introduction.

**Qu. 1.3a. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Terrestrial flatworms are cryptic, nocturnal animals that shelter under debris on the soil surface during the day. Some species, such as *O. nungara*, are synanthropic, being found in man-disturbed habitats, which includes gardens and nurseries. It is postulated that *O. nungara* likely sheltered in plant containers or plant material that was exported from Argentina to Europe (Justine *et al.*, 2020; Lago-Barcia *et al.*, 2019; Justine and Winsor, 2020). Experience with other invasive flatworms would suggest that the number of individuals would be low and sporadic, with one or two individual flatworms in a contaminated shipment. Flatworm egg cocoons may also be present and they could give rise to several individuals; in theory, a single egg cocoon could give rise to a population. As *O. nungara* is not associated with a particular host plant but is rather an opportune contaminant, it is difficult to determine which nursery plant species are likely to be contaminated with flatworms and thus form the precise pathway of introduction. Europe imported US \$32 million worth of plants for planting from South America in 2002 (van Uffelen and de Groot, 2005). It is also difficult to determine if *O. nungara* was repeatedly imported with nursery material from South America or arrived only once and was then disseminated throughout Europe. There are two genetically distinct clades of *O. nungara* found in Europe. One found only in Spain and the other much more widespread being found in Spain, Portugal, France, UK, Italy, Belgium, and Switzerland (Justine *et al.*, 2020). This would suggest at least two separate introductions. It should also be considered that phytosanitary procedures in the EU have changed with the adoption in 2019 of EU Commission Implementing Regulation (EU) 2019/2072. The current procedures should minimise the likelihood of contamination with invasive alien flatworms but much depends on compliance, inspection and policing of these phytosanitary requirements.

**Qu. 1.4a. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Within a potted plant or enclosed in a plant’s root ball, *O. nungara* would be in a ‘protected’ environment and able to survive for extended periods. The conditions necessary to keep the plant healthy would presumably match those of the source location and therefore be amenable to the flatworm. Other invasive flatworm species such as *A. triangulatus* and *P. manokwari* can survive long periods (months) without food as they metabolise their own tissues and degrow but it is not confirmed that *O. nungara* can do likewise. Egg cocoons may be more tolerant of physical disruption and desiccation than adult flatworms during transportation, although this has not been tested for *O. nungara* or other flatworm species.

**Qu. 1.5a. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Plant health inspection and phytosanitary measures are the most practical means of preventing invasion by cryptic flatworm species. Legislation in the EU requires that growing media must be free from soil or subjected to suitable treatment to ensure freedom from pests (EU Commission Implementing Regulation (EU) 2019/2072). However, legislation is dependent on plant health certification by exporting producers and only a small proportion of the plant trade can be directly inspected by the importing country.

Aside from plant health inspection, there are no existing management practices implemented against invasive flatworms. Hot water treatment has been suggested for flatworm management for imported plants for planting (Justine *et al.*, 2014; Murchie and Moore, 1998; Sugiura, 2008a), but has not been used for this specific purpose.

If *O. nungara* makes it into a plant consignment shipment undetected, it is likely that it will survive the onward journey.

**Qu. 1.6a. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: *Obama nungara* has already been introduced into the risk assessment area undetected. Terrestrial flatworms are cryptic animals that shelter in crevices in plant material or within root balls and growing media. *Obama nungara* is brown to black and would be difficult to detect in transit. Egg cocoons are similarly dark-coloured and at c. 5 mm diameter (Justine *et al.*, 2020), smaller than the adult flatworms and difficult to see. In most cases, terrestrial flatworms have been detected by gardeners post-introduction (Justine *et al.*, 2020), underneath plant pots, plastic and other items on the soil surface in their own gardens. However, laypeople or nursery workers may not be able to detect the species if they are not familiar with this group.

**Qu. 1.7a. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: Plants transported for nursery stock are mostly imported to wholesalers and then disseminated to multiple retail points. Most large towns would have several garden centres or nurseries. Assuming that infested plants are bought and then planted in the consumers’ gardens, potentially, there would be many thousands of possible points of introduction into the environment within the risk assessment area.

**Qu. 1.8a. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
-----------------	---------------	-------------------	-----

	unlikely moderately likely likely <b>very likely</b>		<b>medium</b> high
--	---	--	-----------------------

Response: *Obama nungara* has already been introduced at multiple localities within the risk assessment area including on both continental areas and islands, e.g. in Corsica (and outside the risk assessment area, the islands of Guernsey, Madeira and São Miguel). Such a pattern of introduction is indicative of importation via the plant trade. Whilst no one knows for certain how *O. nungara* was introduced to the risk assessment area, there is agreement amongst researchers that plant trade was involved (Justine and Winsor, 2020; Negrete *et al.*, 2020; Justine *et al.*, 2020; Soors *et al.*, 2019). Therefore, the likelihood of introduction through this pathway is considered very likely and confidence is scored as medium due to the lack of data on the specific pathway of introduction.

**Qu. 1.9. Estimate the overall likelihood of introduction into the risk assessment area or entry into the environment based on all pathways and specify if different in relevant biogeographical regions in current conditions.**

Provide a thorough assessment of the risk of introduction in relevant biogeographical regions in current conditions: providing insight in to the risk of introduction into the risk assessment area.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: *Obama nungara* has already been introduced to several countries in the risk assessment area (in particular France, Spain and Belgium) therefore it is scored as very likely with high confidence. This flatworm has been found at nurseries and garden centres, and in domestic gardens (Carbayo *et al.*, 2016; Justine *et al.*, 2020; Álvarez-Presas *et al.*, 2014), which supports the view that traded live plants were the initial pathway of introduction into the risk assessment area and of entry into the environment.

The first records of *O. nungara* in Europe were from 2008 (Guernsey) and from 2010 in the risk assessment area (Spain) (Carbayo *et al.*, 2016). Eschen *et al.* (2015) commented that previously the EU permitted sufficient soil to maintain plants-for-planting in transit, but did not specify quantities, which in effect allowed a whole ecosystem to be transplanted, leading to a high risk of non-native organisms to be accidentally introduced. Plant health legislation has been updated recently (EU Commission Implementing Regulation (EU) 2019/2072) and there are requirements for plants-for-planting to be bare-rooted or treated to ensure freedom from pests and diseases. If this legislation is comprehensively implemented, the likelihood of inadvertently importing *O. nungara* should be minimal. However, the volume and diversity of trade in plants, and the limited capacities of biosecurity authorities in the EU,

makes it almost impossible to monitor, police and completely ensure that consignments are flatworm-free.

**Qu. 1.10. Estimate the overall likelihood of introduction into the risk assessment area or entry into the environment based on all pathways in foreseeable climate change conditions?**

Thorough assessment of the risk of introduction in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of introduction (e.g. change in trade or user preferences)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely introduction within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: *Obama nungara* has already been introduced to the risk assessment area and the likelihood is that climate change will increase the risk of this species being introduced to more regions in the future. There are two reasons for this. First, climate change will enable the flatworm to establish in more regions and countries around the world (e.g. North America), some of which will export plants to the risk assessment area. Models predicted an 83% increase of the suitable area at a global level for *O. nungara* under the RCP 2.6 compared to the current predicted distribution (Negrete *et al.*, 2020). Second, as the climate within Europe changes, the planting preferences of gardeners will likely adjust, potentially increasing the market for sub-tropical plant species native to South America within Europe. Relating the likelihood of this happening with the RCP 2.6 and the RCP 4.5 is difficult because of the many interacting and unknown factors involved, hence the confidence level is ‘low’.

## 2 PROBABILITY OF ESTABLISHMENT

### Important instructions:

- For organisms which are already established in parts of the risk assessment area or have previously been eradicated, the likelihood of establishment should be scored as “very likely” by default.
- Discuss the risk also for those parts of the risk assessment area, where the species is not yet established.

**Qu. 2.1. How likely is it that the organism will be able to establish in the risk assessment area based on similarity of climatic and abiotic conditions in its distribution elsewhere in the world?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: As *Obama nungara* has already established in the risk assessment area, in France, Belgium, Spain, Portugal and Italy (Justine and Winsor, 2020) the response is that establishment in the risk assessment area is very likely and confidence is high. It is likely that it has established in other countries in the risk assessment area where it has been introduced, but there is no published evidence available for those countries. The Species Distribution Model (Annex VIII) demonstrates that significant regions of the risk assessment are climatically suitable for establishment of *O. nungara*.

**Qu. 2.2. How widespread are habitats or species necessary for the survival, development and multiplication of the organism in the risk assessment area? Consider if the organism specifically requires another species to complete its life cycle.**

<b>RESPONSE</b>	very isolated isolated moderately widespread <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: *Obama nungara* has been found most often in gardens and disturbed habitats (Justine *et al.*, 2020; Lago-Barcia *et al.*, 2019; Negrete *et al.*, 2020). So, the habitats necessary for the survival, development and multiplication of the organism are widespread in the risk assessment area. The habitat preferences and natural locations of *O. nungara* are unknown, so it is difficult to specify details beyond

this. In the UK and Ireland, *A. triangulatus* was initially found mostly in gardens but migrated out from these to surrounding farmland, in particular pasture (Murchie *et al.*, 2003). Flatworms may be unlikely to establish widely in arable cropping habitats due the likelihood of physical damage when the soil is cultivated.

The flatworm is a generalist predator, recorded as feeding on snails, slugs, earthworms and other flatworms, in Brazil (Boll and Leal-Zanchet, 2016). *Obama nungara*'s prey range within Europe has not been fully assessed but Justine *et al.* (2020) reported *O. nungara* feeding on a snail (*Theba pisana*) and an unidentified earthworm species in France. *Obama nungara* fed on an unidentified earthworm, the snail *Cochlicella acuta* and part of a defrosted cockroach in the laboratory (Carbayo *et al.*, 2016). Given the presumably wide prey range, it is assumed that prey availability will not be a limiting factor in the flatworm's establishment.

**Qu. 2.3. How likely is it that establishment will occur despite competition from existing species in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: *Obama nungara* is actually established in the risk assessment area despite potential competitors so the response is very likely with a high confidence. Indigenous *Microplana* spp. flatworms in the risk assessment area are smaller than *O. nungara* and there is no evidence that they can outcompete alien flatworm species. Where invasive flatworms have established, they have often become the dominant flatworm species. This would seem to be the case with *O. nungara*, e.g. in a citizen science survey of flatworms in France, *O. nungara* was the most recorded species (Justine *et al.*, 2020). The potentially broad prey range of *O. nungara* (see Qu. 2.2) also makes it less vulnerable to competition with existing, more specialized predators.

There is a theory that invasive flatworms in Europe may be exploiting an underdeveloped predatory niche, given the comparatively rich native flatworm fauna in Asia, South America and Australasia (Boag and Yeates, 2001; Boag *et al.*, 2010).

**Qu. 2.4. How likely is it that establishment will occur despite predators, parasites or pathogens already present in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

	likely <b>very likely</b>		
--	------------------------------	--	--

Response: Terrestrial flatworms are generally considered unpalatable to vertebrate predators. Although birds and shrews have been found feeding on other species of terrestrial flatworm in the risk assessment area (Cannon *et al.*, 1999; Justine *et al.*, 2014), they are not specialist predators and are unlikely to prevent establishment. Predatory beetles and other generalist invertebrate predators may also attack terrestrial flatworms (Gibson *et al.*, 1997) but their impact at the population level remains unknown. There have been no specific studies on which species predate *O. nungara* so a medium confidence is given.

**Qu. 2.5. How likely is the organism to establish despite existing management practices in the risk assessment area? Explain if existing management practices could facilitate establishment.**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: *Obama nungara* is already established in the risk assessment area. As *O. nungara* is synanthropic, disturbance of the habitat and the provision of refuges on the soil surface through gardening or building activities will likely benefit this species. However, direct cultivation of the soil is likely to be harmful to flatworms and limits their establishment. In terms of management of flatworm species, there are no specific management methods widely practiced in the risk assessment area.

**Qu. 2.6. How likely is it that biological properties of the organism would allow it to survive eradication campaigns in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: *Obama nungara* has already established in many regions in the risk assessment area. *Obama nungara* is a cryptic soil-dwelling animal and difficult to target for eradication as they are hidden in the soil or under refuges on the soil surface and hard to detect. Flatworms are hermaphrodites and produce egg cocoons containing multiple offspring, so a single surviving egg cocoon could give rise to a

population. There have been no formal large-scale eradication programmes for terrestrial flatworm species anywhere in the world. Local eradication of *A. triangulatus* by lay-persons has been attempted but not been successful (A.K. Murchie 2021, unpubl.).

**Qu. 2.7. How likely are the biological characteristics of the organism to facilitate its establishment in the risk assessment area?**

including the following elements:

- a list and description of the reproduction mechanisms of the species in relation to the environmental conditions in the risk assessment area
- an indication of the propagule pressure of the species (e.g. number of gametes, seeds, eggs or propagules, number of reproductive cycles per year) of each of those reproduction mechanisms in relation to the environmental conditions in the risk assessment area.
- If relevant, comment on the likelihood of establishment based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in establishment whereas for others high propagule pressure (many thousands of individuals) may not.
- If relevant, comment on the adaptability of the organism to facilitate its establishment and if low genetic diversity in the founder population would have an influence on establishment.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: *Obama nungara* is hermaphrodite and reproduces sexually via egg cocoons, which typically measure c. 3-5 mm diameter and each contain 3-6 offspring (Negrete *et al.*, 2020; Justine *et al.*, 2020). A single cocoon could give rise to a population. The impact of limited genetic diversity on the ability of *O. nungara* to establish is unknown. Inbreeding depression has been observed in freshwater flatworms (Benazzi and Forli, 2009). However, in an exclusively self-fertilising flatworm, no effect was found on fitness (Benazzi, 1991). Justine and Winsor (2020) commented that *O. nungara* reproduces very quickly and numbers can build up rapidly, e.g. 1,442 specimens were collected from a garden area of c. 175 m<sup>2</sup> within 7 months (Justine *et al.*, 2020). However, there has been no specific research on *O. nungara*'s fecundity.

Other invasive flatworm species such as *A. triangulatus* and *P. manokwari* can reabsorb tissues when food is scarce, to enable them to survive long periods (months) of starvation. Flatworms can also retreat deep into the soil or within rotten logs during dry periods, where they survive in mucus lined chambers. It seems very likely that *O. nungara* will have similar survival characteristics but this is not been studied.

**Qu. 2.8. If the organism does not establish, then how likely is it that casual populations will continue to occur?**

Consider, for example, a species which cannot reproduce in the risk assessment area, because of unsuitable climatic conditions or host plants, but is present because of recurring introduction, entry and release events. This may also apply for long-living organisms.

<b>RESPONSE</b>	N/A very unlikely unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low medium high
-----------------	--	-------------------	-----------------------

Response: *Obama nungara* has already established in many regions in the risk assessment area.

**Qu. 2.9. Estimate the overall likelihood of establishment in the risk assessment area under current climatic conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under current climatic conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in current conditions: providing insight in the risk of establishment in (new areas in) the risk assessment area.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: *Obama nungara* has already established in the risk assessment area, in many regions of France, Spain and parts of Portugal, Belgium and Italy so the response is very likely with high confidence. The flatworm has established predominantly in the Atlantic and Mediterranean biogeographical regions, and to a lesser extent in the Continental biogeographical region. The Species Distribution Model (SDM) also predicted that *O. nungara* could establish in the Black Sea biogeographical region (Annex VIII). The SDM predicted that 48% of the Atlantic biogeographical region, 38% of the Mediterranean, 9% of the Continental and 29% of the Black Sea region would be suitable for establishment. This is bearing in mind that the Continental biogeographical region is considerably larger than, for example, the Atlantic biogeographical region.

**Qu. 2.10. Estimate the overall likelihood of establishment in the risk assessment area under foreseeable climate change conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under foreseeable climate change conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of establishment (e.g. increase in average winter temperature, increase in drought periods)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely establishment within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: Under climate change scenarios, *O. nungara* has the potential to increase its range northwards and eastwards into areas of Austria, the Czech Republic, Denmark, Germany, Hungary and Ireland (Annex VIII ‘Projection of environmental suitability for *Obama nungara* establishment in Europe’). Under RCP 4.5, *O. nungara* could potentially establish in southern Sweden. Some Mediterranean countries (Greece, Italy, Portugal and Spain) may become less suitable for *O. nungara* establishment under climate change. The climatic suitability for *O. nungara* was most strongly determined by temperature, human influence and precipitation. Increased annual temperatures will benefit this species and allow northward range expansion, provided soil moisture is maintained. The reduction in the southern range around the Mediterranean is likely due to changes in patterns of precipitation, with correspondingly drier and more arid conditions, which would prohibit *O. nungara* survival.

### 3 PROBABILITY OF SPREAD

**Important instructions:**

- Spread is defined as the expansion of the geographical distribution of an alien species within the risk assessment area.
- Repeated releases at separate locations do not represent continuous spread and should be considered in the probability of introduction and entry section (Qu. 1.7).

**Qu. 3.1. How important is the expected spread of this organism within the risk assessment area by natural means? (List and comment on each of the mechanisms for natural spread.)**

including the following elements:

- a list and description of the natural spread mechanisms of the species in relation to the environmental conditions in the risk assessment area.
- an indication of the rate of spread discussed in relation to the species biology and the environmental conditions in the risk assessment area.

The description of spread patterns here refers to the CBD pathway category “Unaided (Natural Spread)”. It should include elements of the species life history and behavioural traits able to explain its ability to spread, including: reproduction or growth strategy, dispersal capacity, longevity, dietary requirements, environmental and climatic requirements, specialist or generalist characteristics.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: Terrestrial flatworms move by creeping on the soil surface. *Obama nungara*'s life stages (egg cocoon, juvenile and adult) are all soil-bound and there is no specific dispersal phase. The general pattern of dispersal of invasive terrestrial flatworms is that of man-made spread via movement of infested potted plants by nurseries, garden centers and gardeners, followed by local colonization of the surrounding area by natural movement. This appears to be what is happening in France (Justine and Winsor, 2020). The exact rate of natural movement by *O. nungara* is not known (has not been studied) and aside from locomotory dispersal, there is no evidence of natural movement by other means (e.g. birds or water). However, for a comparable flatworm such as *A. triangulatus* movement was assessed by tracking the spread of established populations in transects of traps. The maximum rate of movement in the wild was 15 m in 7 days, whereas Gibson and Cosens (1998) found the flatworm to disperse 17 m in 30 days. Such movement is random and represents the locomotory capability of the species. The moving front of invasion into a new area for *P. manokwari* was found to be c. 20-30 m per year in a garden setting (Winsor, 1990) and this might be a more appropriate measure than the ability of individuals to disperse. Either way the importance of natural spread is considered minor with high confidence.

**Qu. 3.2a. List and describe relevant pathways of spread other than "unaided". For each pathway answer questions 3.3 to 3.9 (copy and paste additional rows at the end of this section**

**as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 3.3a, 3.4a, etc. and then 3.3b, 3.4b etc. for the next pathway.**

including the following elements:

- a list and description of pathways of spread with an indication of their importance and associated risks (e.g. the likelihood of spread in the risk assessment area, based on these pathways; likelihood of survival, or reproduction, or increase during transport and storage; ability and likelihood of transfer from the pathway to a suitable habitat or host) in relation to the environmental conditions in the risk assessment area.
- an indication of the rate of spread for each pathway discussed in relation to the species biology and the environmental conditions in the risk assessment area.
- All relevant pathways of spread (except “Unaided (Natural Spread)”, which is assessed in Qu. 3.1) should be considered. The classification of pathways developed by the Convention of Biological Diversity shall be used (see Annex IV).

The principal pathway for spread of *O. nungara* is likely to be movement of ‘contaminated nursery material’ (unintentional) from nurseries, garden centres, DIY stores, supermarkets and between gardeners. *Obama nungara* was first found at garden centres and nurseries in Guernsey (Carbayo *et al.*, 2016) and a specimen of *O. nungara* was discovered at a garden centre in Oxfordshire (UK), crawling out of a *Heuchera* plant pot imported from the Netherlands (Aldred, 2016). An example pathway is as follows. A flatworm infested consignment of potted plants from South America is disseminated to wholesalers in the risk assessment area and then to retail outlets. The flatworms may establish within premises along the way where they can shelter in new material, or be transported onwards in the original material. Contaminated stock is bought by gardeners, who may then move plants amongst premises. There was some discussion as to whether this pathway overlaps with the ‘contaminant on plants’ pathway. For example, a gardener may buy infested nursery stock from a garden centre, which allows *O. nungara* to establish and proliferate in their garden. They then move plants from their garden to another site, inadvertently carrying flatworms in the plant’s root balls. However, the flatworms are not attached to the plants in the manner of a phytophagous insect pest but are sheltering within the root ball, soil attached to the plant, or within plant pots.

Flatworms may also be moved in contaminated soil, either on its own (‘transportation of habitat material’ - unintentional) or stuck to machinery as stowaway on “machinery/equipment” (unintentional).

**Pathway name: Contaminant nursery material**

**Qu. 3.3a. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional	<b>CONFIDENCE</b>	low
	<b>unintentional</b>		medium
			<b>high</b>

Response: This pathway is unintentional. The association of *O. nungara* with nurseries and gardens indicates inadvertent transfer along this pathway within the risk assessment area. Gardeners do not want to buy nursery material that contains flatworms. This is non-intentional transfer and if known it can adversely affect the reputation of the business or botanic garden concerned (Boag and Neilson, 2014).

**Qu. 3.4a. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Trade in plants within countries offers numerous opportunities for spread of *O. nungara*. A single fertilised flatworm or an egg cocoon could give rise to a population. As dispersal by this pathway is unintentional, flatworms are usually unnoticed until they have established at a premises or in gardens. Therefore, it is difficult to assess the numbers being spread at any one time. This is particularly so if gardeners move plants between different locations or informally pass them on to neighbours and fellow gardeners. The apparently rapid spread of *O. nungara* in France (Justine *et al.*, 2020) and the discovery of *O. nungara* at nurseries in other countries suggests this is the major route of dissemination. As the timeframe is just one year then the highest likelihood category is not justified and confidence is only medium.

**Qu. 3.5a. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: If *O. nungara* is transferred with nursery plants containing growing media within the risk assessment area, and providing these plants are not exposed to temperature extremes (e.g. direct sunlight, frost), it is likely that flatworms will survive. Reproduction is probably unlikely during transit or storage as mating may be disturbed but there are no barriers to fertilised flatworms laying egg cocoons and these being transported. During storage in the garden centres or nurseries the species is also well able to survive and reproduce.

**Qu. 3.6a. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: National phytosanitary measures within Member States may be implemented at nurseries / garden centres to control flatworms, if a consignment is suspected to be contaminated, but are rarely executed in practice. In such a case, use of hot-water treatment shows promise for flatworm management (Sugiura, 2008a; Murchie and Moore, 1998; Justine *et al.*, 2014). However, we know of no instances where any routine management is practiced against invasive flatworms. As existing management practices are not widely applied in the risk assessment area, it is likely that the flatworm’s survival would not be affected.

**Qu. 3.7a. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: *Obama nungara* is a cryptic, nocturnal soil-dwelling species. It can shelter within plant pots, root balls and within plant material making it very difficult to detect unless the plants are uprooted and the growing media and root balls examined directly by qualified personnel. The spread in France was largely undetected until flatworms had established in gardens. It is very likely that its spread would be undetected and confidence is high.

**Qu. 3.8a. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: *Obama nungara* is a synanthropic species, often found in man-made and disturbed habitats (Lago-Barcia *et al.*, 2019; Negrete *et al.*, 2020; Carbayo *et al.*, 2016) and a polyphagous predator (Boll and Leal-Zanchet, 2016). Gardens would seem to provide an ideal habitat (Justine *et al.*, 2020). It is very likely that *O. nungara* is unintentionally spread with infested nursery stock to domestic gardens, botanic gardens, parks and landscaped areas. This is essentially direct transfer to the environment and has been demonstrated widely in France.

**Qu. 3.9a. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area. (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly slowly moderately <b>rapidly</b> very rapidly	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: *Obama nungara* could spread rapidly through the plant trade network but there are no explicit quantitative data (studies have not been conducted). The flatworms are opportunistic contaminants that do not require a specific host plant. This means that if they infested a nursery or garden centre, then there is great opportunity for secondary spread. Most large towns in Europe have plant nurseries, garden centres or DIY stores that sell containerised plants. The rate of spread is difficult to predict as although most garden centres will operate locally, some may trade on the internet, whilst customers may purchase plants on holiday or travelling. A record of *O. nungara* in Scotland was due to a gardener buying a contaminated plant in southern England (H. Jones 2021, pers. comm.). Therefore, although such spread is likely to be mostly localised, there will be some with random long-distance transfers.

As transfer of plants is human-mediated and likely to be via cars and vans, environmental conditions are unlikely to have an impact on this means of transfer *per se* and the environmental conditions in the risk assessment area where the potted plants are likely to end up are very likely to pose no restrictions on this rapid spread.

**Pathway name: Transportation of habitat material (soil, vegetation,...)**

**Qu. 3.3b. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional	<b>CONFIDENCE</b>	Low
	<b>unintentional</b>		medium <b>high</b>

Response: Terrestrial flatworms may be spread with contaminated soil or material left on the soil surface or plant material that they have sheltered beneath. Such transport is unintentional.

**Qu. 3.4b. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	<b>Low</b>
	unlikely		medium
	moderately likely		high
	<b>likely</b>		
	very likely		

Response: Movement of topsoil and compost have spread other terrestrial flatworms, such as *A. triangulatus* (Cannon *et al.*, 1999; Christensen and Mather, 1998; Moore *et al.*, 1998). Although there is no specific data for *O. nungara*, as it shelters under soil refuges in the same way as *A. triangulatus*, including items such as bagged soil / compost, it is reasonable to assume that this flatworm species could be spread in a similar manner. Compost heaps in gardens may have a rich invertebrate fauna including earthworms and molluscs that *O. nungara* may be attracted to and prey on. Mature compost is a valuable growing media and soil conditioner in domestic gardens. As such, it is likely to be distributed in the garden and may be moved to other sites or given to neighbours.

**Qu. 3.5b. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	Low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Soil can provide a microhabitat that retains moisture and buffers temperature fluctuations. *Obama nungara* would likely survive transport and storage in soil especially if the volume is large. Reproduction is less likely due to the disturbance, so flatworms would probably not mate in transit but fertilised adults could lay egg cocoons. *Obama nungara* is likely to survive storage of soil if it is left outdoors and retains moisture. If the soil is kept indoors it may dry out over time, which would be detrimental for the flatworms.

**Qu. 3.6b. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	Low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: If soil is sterilised by steaming *O. nungara* would be killed. This is sometimes used for large quantities of commercial topsoil but would not be a commonplace approach for domestic soil/compost or for smaller quantities moved within a region. It has also been suggested that soil or compost could be heated by placing in a glasshouse to kill *A. triangulatus* (A.K. Murchie 2021, unpubl.). However, this has not been tested. Subsequent sieving or cultivation of the soil would be detrimental to *O. nungara* as the flatworm could be physically damaged. These options for management along this pathway can only be applied if a consignment is known to be contaminated, rather than as a routine preventive measure.

**Qu. 3.7b. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: *Obama nungara* has mostly been detected in the wild after it has established, or intercepted emerging from containerised plants (Justine *et al.*, 2020; Aldred, 2016). Detecting *O. nungara* in a contaminated consignment of soil / compost would be very difficult and laypersons may not recognise the flatworms, even if seen. It is likely that the flatworm will be buried in cracks and crevices within the soil / compost, and being a nocturnal, brown and cryptic species, they are not easily noticed. Their egg cocoons are black and c. 5 mm in diameter, so even more difficult to detect. Environmental DNA technologies could be used to detect invasive flatworms in soil but this has not been tested as yet.

**Qu. 3.8b. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The movement of contaminated topsoil or compost between gardens and in landscaping would directly transfer *O. nungara* into a suitable habitat. This is providing that the habitat contained suitable refuges on the soil surface (stones, wood, plant pots, plastic sheeting etc.) and prey (e.g. earthworms, slugs, snails). Transfer is therefore, very likely with high confidence.

**Qu. 3.9b. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly slowly moderately <b>rapidly</b> very rapidly	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: This pathway can be quite diverse and vary from movement of contaminated compost between neighbouring gardeners to large quantities of topsoil moved for landscaping purposes onto new construction developments. Larger quantities of topsoil and compost can be split into multiple sub-lots and disseminated extensively to different recipients. Due to the diverse nature of this pathway, it is difficult to quantify the potential for spread of *O. nungara*. So far, we have no direct reports of movement along this pathway for *O. nungara*, but evidence from other invasive alien flatworms suggests it is a significant risk (Moore *et al.*, 1998; Christensen and Mather, 1998). It is however, likely that the environmental conditions in the receiving area along with the large volume of soil likely to be transported will mean spread will not be limited by environmental conditions.

**Pathway name: machinery/equipment (transport-stowaway)**

**Qu. 3.3c. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response: Transfer along this pathway is unintentional. Terrestrial flatworms and flatworm egg cocoons can be carried in soil remnants left on machinery or equipment. In addition, flatworms are covered in mucus and may adhere directly to machinery and equipment.

**Qu. 3.4c. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: *Obama nungara* was found on São Miguel in the Azores, in an area free from imported plants, which led Lago-Barcia *et al.* (2020) to suggest that it was transported with machinery used in building work or with tourists visiting the nearby beauty spot. Other invasive flatworms are reported to have been translocated in soil on machinery, boots or stuck to farming materials and equipment (Sugiura *et al.*, 2006; Okochi *et al.*, 2004; Moore *et al.*, 1998; Boag *et al.*, 1999). This is random and sporadic spread. There are no data available to estimate the propagule pressure, although in theory a single egg cocoon could spawn a population. The rate of spread along this pathway will be determined by the volume of movement of machines or equipment.

**Qu. 3.5c. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: The longer the distance travelled the less likely flatworms will survive as they will be subject to mechanical damage and desiccation. Reproduction is unlikely. Egg cocoons embedded in soil on machinery are more likely to survive than adults, being smaller and immobile. Adult flatworms only may survive short-range transport along this pathway. These limitations mean that survival and reproduction are unlikely in this pathway but confidence remains low as there has been no research to date.

**Qu. 3.6c. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

For general biosecurity purposes, machinery should be washed clear of soil when moving between locations. However, this is only likely to occur where there is significant distance involved or movement over state boundaries. Power-washing should dislodge flatworms and may physically damage them. Therefore cleaning equipment and machinery should be straightforward but much depends on how often it is implemented and how thorough the washing. These management practices, if implemented, would make survival on this pathway unlikely.

**Qu. 3.7c. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: *Obama nungara* is a cryptic nocturnal species, so will hide away during the day. It is brown and therefore may be difficult to detect on machinery or equipment carrying soil. Laypersons may not recognise the species as problematic. Egg capsules are 5 mm diameter and black, so are also difficult to detect unless examined close-up. Other flatworms have been detected on farming machinery. For example, *A. triangulatus* has been seen on hay and silage bales and the equipment used to move these (Boag *et al.*, 1999; Moore *et al.*, 1998).

**Qu. 3.8c. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low medium high
-----------------	--	-------------------	-----------------------

Response: Machinery and equipment used for horticultural or agricultural purposes are likely to be moving between similar habitats and may transport *O. nungara* directly to new habitats. For example, an egg cocoon embedded in soil in the tread of a tractor could be dropped off as soon as the tractor starts working in a new area. *Obama nungara* has mostly been found in gardens within the risk assessment area (Justine *et al.*, 2020) but there seems no reason why they could not establish in horticultural sites or on the margins of agricultural land and being subsequently further spread with machinery. However, terrestrial flatworms are susceptible to physical damage so would not survive intensive cultivation practices or longer transport or storage periods.

**Qu. 3.9c. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly <b>slowly</b> moderately rapidly very rapidly	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: Agricultural and horticultural machinery and equipment are predominantly used locally, although sometimes they can be moved over long distances between sites. Aside from the suggestion that contaminated building machinery may have been the source of *O. nungara* on São Miguel in the Azores (Lago-Barcia *et al.*, 2020), there are no quantitative data on the spread of *O. nungara* along this pathway. As with the other pathways above, it is likely to be random and sporadic but more limited in nature.

**Qu. 3.10. Within the risk assessment area, how difficult would it be to contain the organism in relation to these pathways of spread?**

<b>RESPONSE</b>	very easy easy with some difficulty difficult <b>very difficult</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: *Obama nungara* shelters during the day under debris / materials on the soil surface, including plant pots and containers (terrestrial flatworms seem to have a particular affinity for plastic as it retains moisture and provide a smooth resting place). The flatworm is not therefore associated with a particular host plant or commodity but is inadvertently moved around as a contaminant of potted and containerised plants, soil or compost and machinery / material where it has sheltered. The possibilities for spread within the risk assessment area are therefore large and include the plant trade, domestic movement of plants, movement of soil / compost, and potentially any machinery or material that has been left on the soil surface. The potential individual routes and commodities within pathways are numerous and are both commercial and domestic. The flatworms are difficult to detect and there are no universal control measures that could be applied to bulk quantities of either plants, soil or compost.

**Qu. 3.11. Estimate the overall potential rate of spread in relevant biogeographical regions under current conditions for this organism in the risk assessment area (indicate any key issues and provide quantitative data where possible).**

Thorough assessment of the risk of spread in relevant biogeographical regions in current conditions, providing insight in the risk of spread into (new areas in) the risk assessment area.

<b>RESPONSE</b>	very slowly slowly moderately <b>rapidly</b> very rapidly	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: *Obama nungara* was first detected in France in 2013 but is now established in 72 of the 96 administrative Departments in Metropolitan France in the Atlantic, Continental and Mediterranean Regions (Justine *et al.*, 2020). It may be that the flatworm was present for some time before its first detection. For example, the highly noticeable non-native flatworms *Bipalium* spp. and *Diversibipalium* spp. escaped attention for 20 years in France (Justine *et al.*, 2018). However, the pattern of spread in France and the notification of this species from surrounding countries do indicate that spread has been

rapid. This is principally driven by human movement of contaminated materials but local natural movement from gardens to surrounding farmland and wild areas is probable.

**Qu. 3.12. Estimate the overall potential rate of spread in relevant biogeographical regions in foreseeable climate change conditions (provide quantitative data where possible).**

Thorough assessment of the risk of spread in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk, specifically if rates of spread are likely slowed down or accelerated.

<b>RESPONSE</b>	very slowly slowly moderately <b>rapidly</b> very rapidly	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: As spread is mostly man-made, there is little reason to suggest that the potential rate of spread will slow due to climate change. Indeed, it seems likely in the areas affected that plant trade in exotic ornamentals may increase as the region's climate becomes hotter and wetter. It is feasible that gardeners may seek out new plant species and varieties to grow as the climate changes. In addition, milder, wetter conditions may facilitate the natural spread of *O. nungara* from gardens to the surrounding habitat. The Atlantic biogeographical region would be most affected by this scenario under current and future climatic conditions.

## 4 MAGNITUDE OF IMPACT

Important instructions:

- Questions 4.1-4.5 relate to biodiversity and ecosystem impacts, 4.6-4.8 to impacts on ecosystem services, 4.9-4.13 to economic impact, 4.14-4.15 to social and human health impact, and 4.16-4.18 to other impacts. These impacts can be interlinked, for example, a disease may cause impacts on biodiversity and/or ecosystem functioning that leads to impacts on ecosystem services and finally economic impacts. In such cases the assessor should try to note the different impacts where most appropriate, cross-referencing between questions when needed.
- Each set of questions starts with the impact elsewhere in the world, then considers impacts in the risk assessment area (=EU excluding outermost regions) separating known impacts to date (i.e. past and current impacts) from potential future impacts (including foreseeable climate change).
- Only negative impacts are considered in this section (socio-economic benefits are considered in Qu. A.7)
- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable).

### Biodiversity and ecosystem impacts

**Qu. 4.1. How important is the impact of the organism on biodiversity at all levels of organisation caused by the organism in its non-native range excluding the risk assessment area?**

including the following elements:

- Biodiversity means the variability among living organisms from all sources, including terrestrial, marine and other aquatic ecosystems and the ecological complexes of which they are part; this includes diversity within species, between species and of ecosystems
- impacted chemical, physical or structural characteristics and functioning of ecosystems

RESPONSE	N/A	CONFIDENCE	low medium high
	minimal minor moderate major massive		

Response: No information has been found on the issue. Outside of its native range and the risk assessment area, *O. nungara* has established in the wild in Guernsey (Álvarez-Présas *et al.*, 2014; Carbayo *et al.*, 2016; Webster, 2020), Madeira Island and in São Miguel in the Azores, Switzerland (Lago-Barcia *et al.*, 2020; Justine *et al.*, 2020), Chile and the US. Whilst there is concern expressed in the literature that *O. nungara* will impact on native species, there have been no studies to assess this to date (Justine and Winsor, 2020; Justine *et al.*, 2020; Negrete *et al.*, 2020). These concerns relate to how

similar species of invasive flatworms such as *A. triangulatus* and *P. manokwari* have negatively impacted on earthworm and snail biodiversity, respectively, through predation (Murchie and Gordon, 2013; Gerlach *et al.*, 2020). Given *O. nungara*'s broad prey range and potential to establish in large areas of the risk assessment, these concerns are justified.

**Qu. 4.2. How important is the current known impact of the organism on biodiversity at all levels of organisation (e.g. decline in native species, changes in native species communities, hybridisation) in the risk assessment area (include any past impact in your response)?**

Discuss impacts that are currently occurring or are likely occurring or have occurred in the past in the risk assessment area. Where there is no direct evidence of impact in the risk assessment area (for example no studies have been conducted), evidence from outside of the risk assessment area can be used to infer impacts within the risk assessment area.

<b>RESPONSE</b>	N/A	<b>CONFIDENCE</b>	low
	minimal		medium
	minor		high
	moderate		
	major		
	massive		

Response: *Obama nungara* has established in France, Belgium, Spain, Portugal and Italy (Justine and Winsor, 2020). As a potentially numerous predator in the soil ecosystem, there is much concern that it will impact upon native species. The prey range of *O. nungara* has been assessed in Brazil, where it fed on snails, slugs, earthworms and other flatworms, when they were presented to flatworms in the laboratory (Boll and Leal-Zanchet, 2016). However, there have been no studies assessing the impact of *O. nungara* predation in the field in the risk assessment area. Other earthworm-feeding and snail-feeding flatworms such as *A. triangulatus* and *P. manokwari* have had demonstrable negative effects on soil fauna. For example, *A. triangulatus* reduced anecic earthworm biomass by 74% in a field study in Northern Ireland (Murchie and Gordon, 2013), whilst *P. manokwari* has been implicated in the extinction of indigenous snail fauna on Pacific islands (Sugiura, 2008b). Due to the lack of data on *O. nungara*, this question has been scored 'N/A', as it refers to 'current known impact' rather than potential impact (please see Qu. 4.3 below).

**Qu. 4.3. How important is the potential future impact of the organism on biodiversity at all levels of organisation likely to be in the risk assessment area?**

See comment above. The potential future impact shall be assessed only for the risk assessment area. A potential increase in the distribution range due to climate change does not *per se* justify a higher impact score.

<b>RESPONSE</b>	minimal	<b>CONFIDENCE</b>	low
-----------------	---------	-------------------	-----

	minor <b>moderate</b> major massive		medium high
--	--	--	----------------

Response: There are no specific data on the future impact of *O. nungara* on soil biodiversity in the risk assessment area. However, there are relevant examples from other invasive alien flatworms which have had negative effects on soil biodiversity where they have established, and that are reported here as example of the potential future impact of *O. nungara*. *Arthurdendyus triangulatus* is a predator of earthworms. In field experiments where flatworm density was manipulated, *A. triangulatus* at 0.8 individuals per m<sup>2</sup> reduced earthworm biomass by 20%. *Arthurdendyus triangulatus* predation had a disproportionate impact on *Lumbricus terrestris* whose biomass was reduced by 74% (Murchie and Gordon, 2013). Similarly, the snail predator *P. manokwari* has had devastating impacts on endemic snail species on Pacific islands where it has been introduced and potentially could impact snail biodiversity in the risk assessment area (Murchie and Beckmann, 2020). Both snails and earthworms are important food resources for other species, including many birds and mammals, so predation on these invertebrates by *O. nungara* would have consequences further up the food chain.

It has to be expected that *O. nungara*, as a generalist predator feeding on earthworms and molluscs, would have a similar impact such as *A. triangulatus* and *P. manokwari*. High numbers of *O. nungara* are likely to outcompete other soil predators, including indigenous flatworms but no data are available on such an impact. Justine *et al.* (2020) commented that the ecological impact of *O. nungara* was likely to be high, based on the impact of other flatworms, *O. nungara*'s broad prey range and the locally high population densities in France, but this has yet to be studied. The score of moderate is based on expert opinion in the absence of hard data so the confidence is set as low.

**Qu. 4.4. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism currently in the risk assessment area?**

including the following elements:

- native species impacted, including red list species, endemic species and species listed in the Birds and Habitats directives
- protected sites impacted, in particular Natura 2000
- habitats impacted, in particular habitats listed in the Habitats Directive, or red list habitats
- the ecological status of water bodies according to the Water Framework Directive and environmental status of the marine environment according to the Marine Strategy Framework Directive

<b>RESPONSE</b>	minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	--	-------------------	-----------------------

Response: There are no data on the decline in conservation value caused by presence of *O. nungara*. At the present time, *O. nungara* is mostly restricted to gardens. However, there is one record of *O. nungara* from a high value natural ecosystem in Spain (Lago-Barcia *et al.*, 2020) and as a generalist predator of earthworms and snails, *O. nungara* has the potential to impact on endemic and conservation value species.

**Qu. 4.5. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.3. and 4.4.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: *Obama nungara* is a predator of earthworms, terrestrial gastropods and other soil-dwelling invertebrates. In the European region, 22% of the 2,469 native species of gastropods (snails and slugs) are considered threatened (critically endangered, endangered or vulnerable), with 97 species critically endangered (European Commission, 2020). *Obama nungara* has already established in the Mediterranean region, which includes areas of high snail endemicity (Cuttelod *et al.*, 2011) and therefore the flatworm could have a future impact on indigenous snail species. For earthworms, there is no comparable Europe-wide red list and the conservation status of most species is unknown. The only assessment is by the Federal Agency for Nature Conservation (Bundesamt für Naturschutz) who produced an earthworm red list for Germany, with 14 of the 47 earthworm species assessed as ‘extremely rare’ (Phillips *et al.*, 2017). As with snails, there is therefore a potential for *O. nungara* predation to have an impact on rare earthworm species but data are lacking. The score of moderate is based on expert opinion in the absence of hard data so the confidence is set as low.

**Ecosystem Services impacts**

**Qu. 4.6. How important is the impact of the organism on provisioning, regulating, and cultural services in its non-native range excluding the risk assessment area?**

- For a list of services use the CICES classification V5.1 provided in Annex V.
- Impacts on ecosystem services build on the observed impacts on biodiversity (habitat, species, genetic, functional) but focus exclusively on reflecting these changes in relation to their links with socio-economic well-being.
- Quantitative data should be provided whenever available and references duly reported.

<b>RESPONSE</b>	N/A minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: No information has been found on the issue.

Outside of its native range and the risk assessment area, *O. nungara* has established in the wild in Guernsey (Álvarez-Presas *et al.*, 2014; Carbayo *et al.*, 2016; Webster, 2020), Madeira Island and in São Miguel in the Azores, Switzerland (Lago-Barcia *et al.*, 2020; Justine *et al.*, 2020), Chile and the US. As these records are comparatively recent, no impacts on ecosystem services have been reported so far but likewise, there have been no specific studies on this issue. Please see Qu. 4.8 below for potential future impacts.

**Qu. 4.7. How important is the impact of the organism on provisioning, regulating, and cultural services currently in the different biogeographic regions or marine sub-regions where the species has established in the risk assessment area (include any past impact in your response)?**

- See guidance to Qu. 4.6.

<b>RESPONSE</b>	N/A minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: No information has been found on the issue.

Most records of *O. nungara* in the risk assessment area are from France and the impact on ecosystem services has not been evaluated (Justine *et al.*, 2020). Please see Qu. 4.8 below for potential future impacts.

**Qu. 4.8. How important is the impact of the organism on provisioning, regulating, and cultural services likely to be in the different biogeographic regions or marine sub-regions where the species can establish in the risk assessment area in the future?**

- See guidance to Qu. 4.6.

<b>RESPONSE</b>	minimal	<b>CONFIDENCE</b>	low
-----------------	---------	-------------------	-----

	minor moderate <b>major</b> massive		medium high
--	--	--	----------------

Response: There are no data on the impact of *O. nungara* on ecosystem services. However, where established, the flatworm can build up large population levels (Justine *et al.*, 2020) and as a generalist, apex predator in the soil ecosystem, there is future potential that *O. nungara* could have a significant impact on other soil fauna, with knock-on effects on ecosystem services.

If *O. nungara* predation reduces earthworm densities in the future this will have an effect on ‘soil quality regulation’. Earthworms perform a valuable role in aerating and draining the soil, as well as recycling nutrients for plant growth (Edwards and Bohlen, 1996). ‘Water conditions’ could also be potentially affected if reduced earthworm densities change the hydrological aspects of the soil and increase run-off to neighbouring waterways. Snail predation could have an impact on populations of wild snails used as food (‘wild animals used for nutritional purposes’). The presence of invasive alien flatworms can also cause distress to gardeners and others working on the soil, and impact upon their ‘physical and experiential interactions with natural environment’. Especially if present in large numbers, the flatworms are viewed as undesirable, harmful and uncontrollable species. There are numerous examples on social media of people exclaiming upset at having found an invasive alien flatworm in their locality.

## Economic impacts

**Qu. 4.9. How great is the overall economic cost caused by the organism within its current area of distribution (excluding the risk assessment area), including both costs of / loss due to damage and the cost of current management.**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the world these should be reported here. The assessment of the potential costs of / loss due to damage shall describe those costs quantitatively and/or qualitatively depending on what information is available. Cost of / loss due to damage within different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage. As far as possible, it would be useful to separate costs of / loss due to the organism from costs of current management.

<b>RESPONSE</b>	N/A minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: No information has been found on the issue.

*Obama nungara* is not considered a pest within its native South American distribution range. Outside of that and the risk assessment area, *O. nungara* has established in Guernsey (Álvarez-Presas *et al.*, 2014; Carbayo *et al.*, 2016; Webster, 2020), Madeira Island and in São Miguel in the Azores, Switzerland (Lago-Barcia *et al.*, 2020; Justine *et al.*, 2020), Chile and the US. At the present time, there are no reports of any economic damage or costs associated with management.

**Qu. 4.10. How great is the economic cost of / loss due to damage (excluding costs of management) of the organism currently in the risk assessment area (include any past costs in your response)?**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the EU these should be reported here. Assessment of the potential costs of damage on human health, safety, and the economy, including the cost of non-action. A full economic assessment at EU scale might not be possible, but qualitative data or different case studies from across the EU (or third countries if relevant) may provide useful information to inform decision making. In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable). Cost of / loss due to damage within different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: *Obama nungara* has established in France, Belgium, Spain, Portugal and Italy (Justine and Winsor, 2020). At the present time, there are no reports of any economic damage. However, one online retailer denied the presence of *O. nungara* in a shipment despite expert assessment, presumably to safeguard their reputation (H. Jones 2021, unpubl.). Gardeners and consumers are increasingly aware of invasive alien flatworms through magazine articles and online fora, and contamination of products with flatworms could have a potentially serious economic impact on gardening businesses but there are no studies on this or quantitative data available. These possible reputational costs coupled with the extra time spent dealing with investigations of possible contamination are unlikely at present to exceed 100,000 euros per year so a score of minor with low confidence is given.

**Qu. 4.11. How great is the economic cost of / loss due to damage (excluding costs of management) of the organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.10.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: *Obama nungara* is a predator of molluscs and earthworms. Predation on snails may cause biodiversity losses but could also impact on heliciculture (snail farming). Within some parts of Europe, snails (*Cornu aspersum* and *Helix pomatia*, and others) are farmed and collected from the wild as food (Conte, 2015; Waldhorn, 2020). It is feasible that if *O. nungara* spread and established in snail farming / collecting regions, it could impact on snail production for food. Predation on earthworms could have knock-on effects on crop yield. *Arthurdendyus triangulatus* is a flatworm species that predaes upon earthworms, and has established in the UK, Ireland and the Faroe Islands. Using figures of a 20% decline in earthworm biomass caused by flatworm predation (Murchie and Gordon, 2013) times the contribution of earthworms to ryegrass above ground biomass of 34% (van Groenigen *et al.*, 2014), the predicted decline in grass yield was 7% in Northern Ireland (Murchie, 2018). The economic impact in Northern Ireland would be in the region of €17 per ha per annum as pasture underpins large dairy and beef production. The concern is that *O. nungara* could be an equivalent predator of earthworms to *A. triangulatus*, and cause similar losses but, unlike *A. triangulatus*, has already established extensively in gardens in France and continental Europe. Permanent grassland covers c. 50 million ha in the EU27 (Huyghe *et al.*, 2014). If *O. nungara* had a similar effect as *A. triangulatus* across pasture production in the EU27, the economic impact could potentially run into several 100 million euros. Nonetheless a moderate score is given for the immediate future as recorded costs are likely to be much lower and no data exist on the impact of *O. nungara* on earthworms.

**Qu. 4.12. How great are the economic costs / losses associated with managing this organism currently in the risk assessment area (include any past costs in your response)?**

- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable).

<b>RESPONSE</b>	N/A minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: No information has been found on the issue.

As far as we are aware there have been no management practices implemented aside from actions taken by local gardeners to physically collect and destroy *O. nungara* (Justine *et al.*, 2020).

**Qu. 4.13. How great are the economic costs / losses associated with managing this organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.12.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: If *O. nungara* were to cause significant problems that necessitated widespread management the costs would be substantial. The flatworm is widely established in gardens and as a soil-dwelling species difficult to target with treatments. In addition, there are no known pesticide treatments or biological control agents. Management therefore would rely on greater plant health inspections to prevent further spread, and physical barriers and heat treatment at nurseries and garden centres, as has been recommended for *A. triangulatus* (EPPO, 2001). Research would also be required into novel approaches for management. This would likely be more than 1m euros across the risk assessment area each year.

## Social and human health impacts

**Qu. 4.14. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism for the risk assessment area and for third countries, if relevant (e.g. with similar eco-climatic conditions).**

The description of the known impact and the assessment of potential future impact on human health, safety and the economy, shall, if relevant, include information on

- illnesses, allergies or other affections to humans that may derive directly or indirectly from a species;
- damages provoked directly or indirectly by a species with consequences for the safety of people, property or infrastructure;
- direct or indirect disruption of, or other consequences for, an economic or social activity due to the presence of a species.

Social and human health impacts can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: The presence of *O. nungara* in gardens would be distressing to gardeners in a local affected area, as they see this species as a harmful and insidious alien species. This would be a mild short-term upset in most cases. Presence of *O. nungara* in nursery produce could result in reputational damage for nurseries or garden centres.

**Qu. 4.15. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism in the future for the risk assessment area.**

- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable).

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: Another snail-eating flatworm, *P. manokwari*, is a paratenic host of parasitic nematodes, *Angiostrongylus* spp. (rat lungworms) (Asato *et al.*, 2004) which have snails as their intermediate host, so there is potential that *O. nungara* could also host and transmit parasites (Negrete *et al.*, 2020). Flatworms, as snail predators, may bioaccumulate nematodes in their tissues and if consumed by humans lead to the potentially fatal condition of angiostrongyliasis. However, human angiostrongyliasis is recorded mainly in tropical and subtropical regions (Barratt *et al.*, 2016) and there is no evidence to date (no studies) that *O. nungara* has hosted lungworm parasites.

Terrestrial flatworms feed by secreting neurotoxins to subdue prey (Stokes *et al.*, 2014) and digestive enzymes to break down prey tissue. Exposure to these through handling of flatworms may cause skin irritation (Blackshaw and Stewart, 1992). However, this is felt mostly as mild dermabrasion.

Due to the lack of data on this topic and that angiostrongyliasis is mainly a tropical disease, which is unlikely to arise in the risk assessment area, the score is ‘minor’ with ‘low’ confidence.

**Other impacts**

**Qu. 4.16. How important is the organism in facilitating other damaging organisms (e.g. diseases) as food source, a host, a symbiont or a vector etc.?**

<b>RESPONSE</b>	N/A minimal minor	<b>CONFIDENCE</b>	low medium high
-----------------	-------------------------	-------------------	-----------------------

	moderate major massive		
--	------------------------------	--	--

Response: No information has been found on the issue.

As mentioned in Qu. 4.15, *O. nungara* could potentially carry nematodes and other parasitic organisms (Negrete *et al.*, 2020). It is possible that flatworms could increase the likelihood of heart lungworm in dogs (*Angiostrongylus vasorum*) but there is no evidence or information for this.

**Qu. 4.17. How important might other impacts not already covered by previous questions be resulting from introduction of the organism?**

<b>RESPONSE</b>	N/A minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: No information has been found on the issue.

**Qu. 4.18. How important are the expected impacts of the organism despite any natural control by other organisms, such as predators, parasites or pathogens that may already be present in the risk assessment area?**

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: *Obama nungara* may be predated upon by native birds, shrews and insects, but there are no specific predators likely to provide population control (Justine and Winsor, 2020). Similarly, there are no known parasites or pathogens capable of limiting *O. nungara* populations, that we are aware of, either in the flatworm's natural range or in the invaded regions.

There is a lack of data on the impact of *O. nungara* and the score of 'major' is based on expert opinion and hence confidence is 'low'.

**Qu. 4.19. Estimate the overall impact in the risk assessment area under current climate conditions. In addition, details of overall impact in relevant biogeographical regions should be provided.**

Thorough assessment of the overall impact on biodiversity and ecosystem services, with impacts on economy as well as social and human health as aggravating factors, in current conditions.

<b>RESPONSE</b>	Minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: *Obama nungara* was first discovered in Europe in 2008 but the species was only described in 2016 (Carbayo *et al.*, 2016). The most comprehensive assessment of *O. nungara*'s distribution in Europe was published in 2020 (Justine *et al.*, 2020). There are therefore relatively few scientific papers on *O. nungara* compared to other flatworm species such as *A. triangulatus*, *P. manokwari* and *B. kewense*.

Aside from a laboratory assessment of *O. nungara*'s predatory capabilities from Brazil (Boll and Leal-Zanchet, 2016), there are no European or field assessments of the impact on soil fauna by *O. nungara*. Assessing the impact of *O. nungara* on biodiversity and ecosystem services, the economy and human health, therefore relies heavily on information from other similar species, principally *A. triangulatus* and *P. manokwari*.

Some factors are however clear. *Obama nungara* is well established in the risk assessment area and is spreading. *Obama nungara* is synanthropic and ecologically suited to man-disturbed habitats. The flatworm can achieve high local densities. One gardener in south-western France collected 924 specimens from an area of c. 300 m<sup>2</sup> over the course of the summer; whereas another gardener in north-western France collected 1,442 specimens from 175 m<sup>2</sup> (Justine *et al.*, 2020). *Obama nungara* is a predator of molluscs and earthworms (Boll and Leal-Zanchet, 2016) and this flexibility of prey utilization may allow greater niche expansion than if it was limited to just one food source. This broad prey range could either alleviate the predatory impact of *O. nungara* on any particular species or worsen it. If *O. nungara* feeds on many prey species then the impact on any one particular species may be lessened. Alternatively, *A. triangulatus* preferentially predate anecic earthworms but was able to sustain itself on other earthworm species, thereby circumventing the normal predator / prey cycles, and having a greater impact on the anecic earthworm species (Murchie and Gordon, 2013).

Whilst data are very limited, there is potential that *O. nungara* could have the same impact in continental Europe as *A. triangulatus* has had in regions of the UK, Ireland and Faroe Islands. This is very likely to lead to a decline in earthworm species, with knock-on effects on pasture yield and earthworm feeding wildlife as well as other soil fauna that fall within its prey range. This is likely to be most damaging in the Atlantic biogeographic region, as this region is most suited to flatworm establishment coupled with a relatively high proportion of permanent grassland. *Obama nungara* also has potential to impact on endemic snails, particularly in the Mediterranean biogeographic region, with a potential extinction risk

Scoring the impact of *O. nungara* in the risk assessment area is problematic due to the relatively recent introduction of the flatworm and the lack of scientific studies on it in the field in Europe. Given the densities that can be achieved by *O. nungara* in France, its broad prey range and the known impacts of other similar flatworm species with particular reference to rare and highly-localised endemic species (snails, slugs and earthworms species) that could be driven to extinction, expert opinion assessed the impact as ‘major’ but with ‘low’ confidence.

**Qu. 4.20. Estimate the overall impact in the risk assessment area in foreseeable climate change conditions. In addition, details of overall impact in relevant biogeographical regions should be provided.**

Thorough assessment of the overall impact on biodiversity and ecosystem services, with impacts on economy as well as social and human health as aggravating factors, under future conditions.

- See also guidance to Qu. 4.3.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: Climate change predictions suggest that *O. nungara* could establish in substantially more regions of the risk assessment area and extend its range northwards and eastwards (Annex VIII). In the Atlantic biogeographic region this may enable more pasture to be affected (including in Germany, the Netherlands and Denmark). There is some contraction of the predicted range in southern regions but it is comparatively small compared to the expansion. The impacts on biodiversity, ecosystem services and human health are likely to increase under climate change and mostly occur in the same biogeographic regions.

<b>RISK SUMMARIES</b>			
	<b>RESPONSE</b>	<b>CONFIDENCE</b>	<b>COMMENT</b>
<b>Summarise Introduction and Entry*</b>	very unlikely unlikely moderately likely likely likely <b>very likely</b>	low medium <b>high</b>	<i>Obama nungara</i> has already been introduced to the risk assessment area. The most likely pathway was the plant trade, in particular plants for planting.
<b>Summarise Establishment*</b>	very unlikely unlikely moderately likely likely likely <b>very likely</b>	low medium <b>high</b>	<i>Obama nungara</i> has definitely established in France, Belgium, Spain, Portugal and Italy, and probably other countries in the risk assessment area. Climate change will substantially increase the regions in the risk assessment area suitable for flatworm establishment.
<b>Summarise Spread*</b>	very slowly slowly moderately <b>rapidly</b> very rapidly	low <b>medium</b> high	<i>Obama nungara</i> is spread by human-assisted transport followed by natural dispersal. Flatworms can be inadvertently spread with plants for planting, soil or compost, and equipment that has been in contact with the soil surface. First detected in France in 2013, <i>O. nungara</i> has spread to 72 of the 96 administrative Departments in Metropolitan France within less than a decade.
<b>Summarise Impact*</b>	minimal minor moderate <b>major</b> massive	<b>low</b> medium high	Little is known about the impact of <i>O. nungara</i> as a predator of soil fauna, given its comparatively recent establishment in Europe. <i>Obama nungara</i> is a predator of earthworms and molluscs, and can occur in large numbers. The species therefore could potentially reduce both mollusc and earthworm biodiversity and densities, including endemic European species, with a risk of extinction of rare isolated species. Reductions of earthworm densities can have negative effect on ecosystem services and knock-on effects on pasture productivity. Climate change will probably increase the impact of <i>O. nungara</i> in the risk assessment area.
<b>Conclusion of the risk assessment (overall risk)</b>	low moderate <b>high</b>	low <b>medium</b> high	<i>Obama nungara</i> has established in the risk assessment area and is spreading. In some domestic gardens it has achieved high densities. It is a predator of molluscs and earthworms with no known natural enemies or means of control other than phytosanitary measures. There is a high risk that <i>O. nungara</i> could impact

			<p>biodiversity in a similar way to the invasive flatworm <i>Arthurdendyus triangulatus</i> and deplete native/endemic snail and earthworm populations within the risk assessment area with possible extinctions of rare species. However, there have been no studies on this to date.</p>

## **ANNEX I Scoring of Likelihoods of Events**

(taken from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

<b>Score</b>	<b>Description</b>	<b>Frequency</b>
Very unlikely	This sort of event is theoretically possible, but is never known to have occurred and is not expected to occur	1 in 10,000 years
Unlikely	This sort of event has occurred somewhere at least once in the last millennium	1 in 1,000 years
Moderately likely	This sort of event has occurred somewhere at least once in the last century	1 in 100 years
Likely	This sort of event has happened on several occasions elsewhere, or on at least once in the last decade	1 in 10 years
Very likely	This sort of event happens continually and would be expected to occur	Once a year

## ANNEX II Scoring of Magnitude of Impacts

(modified from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

Score	Biodiversity and ecosystem impact	Ecosystem Services impact	Economic impact (Monetary loss and response costs per year)	Social and human health impact, and other impacts
	<i>Question 5.1-5</i>	<i>Question 5.6-8</i>	<i>Question 5.9-13</i>	<i>Question 5.14-18</i>
Minimal	Local, short-term population loss, no significant ecosystem effect	No services affected <sup>5</sup>	Up to 10,000 Euro	No social disruption. Local, mild, short-term reversible effects to individuals.
Minor	Some ecosystem impact, reversible changes, localised	Local and temporary, reversible effects to one or few services	10,000-100,000 Euro	Significant concern expressed at local level. Mild short-term reversible effects to identifiable groups, localised.
Moderate	Measureable long-term damage to populations and ecosystem, but reversible; little spread, no extinction	Measureable, temporary, local and reversible effects on one or several services	100,000-1,000,000 Euro	Temporary changes to normal activities at local level. Minor irreversible effects and/or larger numbers covered by reversible effects, localised.
Major	Long-term irreversible ecosystem change, spreading beyond local area	Local and irreversible or widespread and reversible effects on one / several services	1,000,000-10,000,000 Euro	Some permanent change of activity locally, concern expressed over wider area. Significant irreversible effects locally or reversible effects over large area.
Massive	Widespread, long-term population loss or extinction, affecting several species with serious ecosystem effects	Widespread and irreversible effects on one / several services	Above 10,000,000 Euro	Long-term social change, significant loss of employment, migration from affected area. Widespread, severe, long-term, irreversible health effects.

<sup>5</sup> Not to be confused with “no impact”.

## ANNEX III Scoring of Confidence Levels

(modified from Bacher et al. 2017)

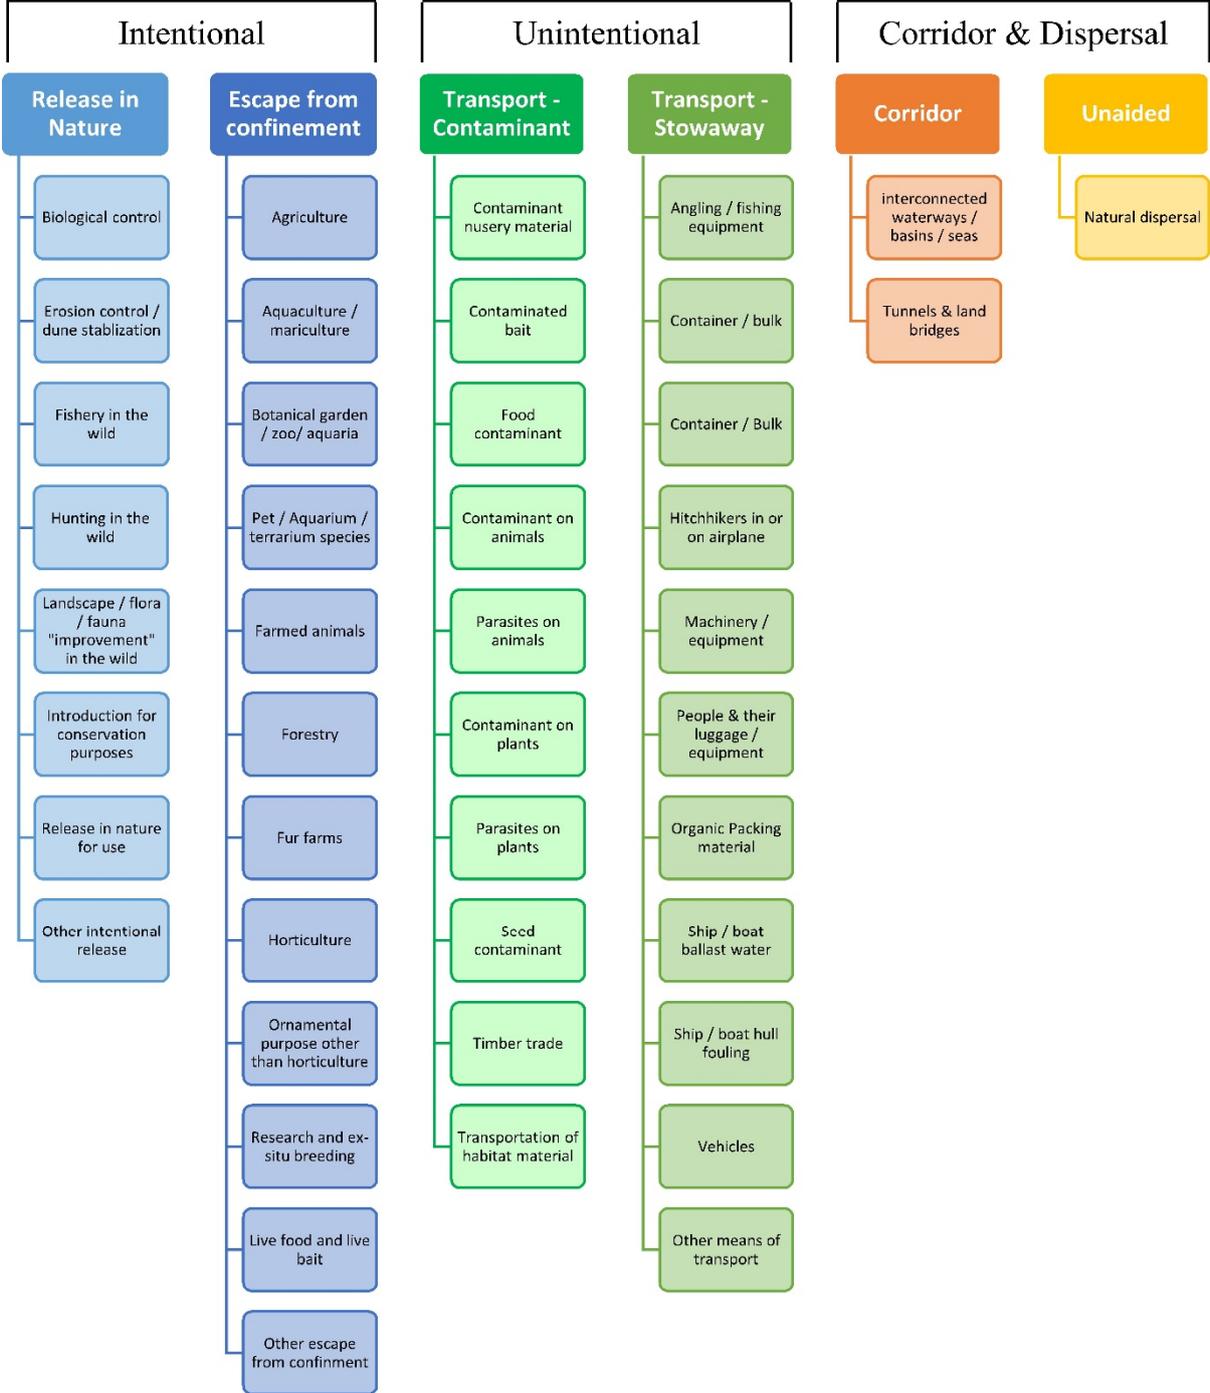

Each answer provided in the risk assessment must include an assessment of the level of confidence attached to that answer, reflecting the possibility that information needed for the answer is not available or is insufficient or available but conflicting.

The responses in the risk assessment should clearly support the choice of the confidence level.

<b>Confidence level</b>	<b>Description</b>
Low	There is no direct observational evidence to support the assessment, e.g. only inferred data have been used as supporting evidence <i>and/or</i> Impacts are recorded at a spatial scale which is unlikely to be relevant to the assessment area <i>and/or</i> Evidence is poor and difficult to interpret, e.g. because it is strongly ambiguous <i>and/or</i> The information sources are considered to be of low quality or contain information that is unreliable.
Medium	There is some direct observational evidence to support the assessment, but some information is inferred <i>and/or</i> Impacts are recorded at a small spatial scale, but rescaling of the data to relevant scales of the assessment area is considered reliable, or to embrace little uncertainty <i>and/or</i> The interpretation of the data is to some extent ambiguous or contradictory.
High	There is direct relevant observational evidence to support the assessment (including causality) <i>and</i> Impacts are recorded at a comparable scale <i>and/or</i> There are reliable/good quality data sources on impacts of the taxa <i>and</i> The interpretation of data/information is straightforward <i>and/or</i> Data/information are not controversial or contradictory.

# ANNEX IV CBD pathway categorisation scheme

Overview of CBD pathway categorisation scheme showing how the 44 pathways relate to the six main pathway categories. All of the pathways can be broadly classified into 1) those that involve intentional transport (blue), 2) those in which the taxa are unintentionally transported (green) and 3) those where taxa moved between regions without direct transportation by humans and/or via artificial corridors (orange and yellow). **Note that the pathways in the category “Escape from confinement” can be considered intentional for the introduction into the risk assessment area and unintentional for the entry into the environment.**

## ANNEX V Ecosystem services classification (CICES V5.1, simplified) and examples

For the purposes of this risk assessment, please feel free to use what seems as the most appropriate category / level / combination of impact (Section – Division – Group), reflecting information available.

Section	Division	Group	Examples (i.e. relevant CICES “classes”)
Provisioning	Biomass	<b>Cultivated <i>terrestrial</i> plants</b>	<p>Cultivated terrestrial plants (including fungi, algae) grown for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from cultivated plants, fungi, algae and bacteria for direct use or processing (excluding genetic materials);            Cultivated plants (including fungi, algae) grown as a <u>source of energy</u></p> <p><i>Example: negative impacts of non-native organisms to crops, orchards, timber etc.</i></p>
		<b>Cultivated <i>aquatic</i> plants</b>	<p>Plants cultivated by in- situ aquaculture grown for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from in-situ aquaculture for direct use or processing (excluding genetic materials);            Plants cultivated by in- situ aquaculture grown as an <u>energy source</u>.</p> <p><i>Example: negative impacts of non-native organisms to aquatic plants cultivated for nutrition, gardening etc. purposes.</i></p>
		<b>Reared animals</b>	<p>Animals reared for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from reared animals for direct use or processing (excluding genetic materials);            Animals reared to provide <u>energy</u> (including mechanical)</p> <p><i>Example: negative impacts of non-native organisms to livestock</i></p>
		<b>Reared <i>aquatic</i> animals</b>	<p>Animals reared by in-situ aquaculture for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from animals grown by in-situ aquaculture for direct use or processing (excluding genetic materials);            Animals reared by in-situ aquaculture as an <u>energy source</u></p> <p><i>Example: negative impacts of non-native organisms to fish farming</i></p>
		<b>Wild plants (terrestrial and aquatic)</b>	<p>Wild plants (terrestrial and aquatic, including fungi, algae) used for <u>nutrition</u>;  <u>Fibres and other materials</u> from wild plants for direct use or processing (excluding genetic materials);            Wild plants (terrestrial and aquatic, including fungi, algae) used as a <u>source of energy</u></p> <p><i>Example: reduction in the availability of wild plants (e.g. wild berries, ornamentals) due to non-native organisms (competition, spread of disease etc.)</i></p>
		<b>Wild animals (terrestrial and aquatic)</b>	<p>Wild animals (terrestrial and aquatic) used for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from wild animals for direct use or processing (excluding genetic materials);            Wild animals (terrestrial and aquatic) used as a <u>source of energy</u></p>

			<i>Example: reduction in the availability of wild animals (e.g. fish stocks, game) due to non-native organisms (competition, predations, spread of disease etc.)</i>
	<b>Genetic material</b> from all biota	<b>Genetic material</b> from plants, algae or fungi	<u>Seeds, spores and other plant materials</u> collected for maintaining or establishing a population; Higher and lower plants (whole organisms) used to <u>breed new strains or varieties</u> ; Individual genes extracted from higher and lower plants for the <u>design and construction of new biological entities</u>  <i>Example: negative impacts of non-native organisms due to interbreeding</i>
		<b>Genetic material</b> from animals	Animal material collected for the purposes of maintaining or establishing a population; Wild animals (whole organisms) used to breed new strains or varieties; Individual genes extracted from organisms for the design and construction of new biological entities  <i>Example: negative impacts of non-native organisms due to interbreeding</i>
	<b>Water</b> <sup>6</sup>	<b>Surface water</b> used for nutrition, materials or energy	Surface water for <u>drinking</u> ; Surface water used as a material ( <u>non-drinking purposes</u> ); Freshwater surface water, coastal and marine water used as an <u>energy source</u>  <i>Example: loss of access to surface water due to spread of non-native organisms</i>
		<b>Ground water</b> for used for nutrition, materials or energy	Ground (and subsurface) water for <u>drinking</u> ; Ground water (and subsurface) used as a material ( <u>non-drinking purposes</u> ); Ground water (and subsurface) used as an <u>energy source</u>  <i>Example: reduced availability of ground water due to spread of non-native organisms and associated increase of ground water consumption by vegetation.</i>
<b>Regulation &amp; Maintenance</b>	<b>Transformation</b> of biochemical or physical inputs to ecosystems	<b>Mediation of wastes or toxic substances</b> of anthropogenic origin by living processes	<u>Bio-remediation</u> by micro-organisms, algae, plants, and animals; <u>Filtration/sequestration/storage/accumulation</u> by micro-organisms, algae, plants, and animals  <i>Example: changes caused by non-native organisms to ecosystem functioning and ability to filtrate etc. waste or toxics</i>
		<b>Mediation of nuisances</b> of anthropogenic origin	<u>Smell reduction</u> ; <u>noise attenuation</u> ; <u>visual screening</u> (e.g. by means of green infrastructure)  <i>Example: changes caused by non-native organisms to ecosystem structure, leading to reduced ability to mediate nuisances.</i>
	<b>Regulation</b> of physical, chemical, biological conditions	<b>Baseline flows and extreme event</b> regulation	Control of <u>erosion</u> rates; Buffering and attenuation of <u>mass movement</u> ; <u>Hydrological cycle and water flow regulation</u> (Including flood control, and coastal protection); <u>Wind</u> protection; <u>Fire</u> protection

<sup>6</sup> Note: in the CICES classification provisioning of water is considered as an abiotic service whereas the rest of ecosystem services listed here are considered biotic.

			<p><i>Example: changes caused by non-native organisms to ecosystem functioning or structure leading to, for example, destabilisation of soil, increased risk or intensity of wild fires etc.</i></p>
		<p><b>Lifecycle maintenance, habitat and gene pool protection</b></p>	<p>Pollination (or 'gamete' dispersal in a marine context); <u>Seed dispersal</u>; Maintaining <u>nursery populations and habitats</u> (Including gene pool protection)</p> <p><i>Example: changes caused by non-native organisms to the abundance and/or distribution of wild pollinators; changes to the availability / quality of nursery habitats for fisheries</i></p>
		<p><b>Pest and disease control</b></p>	<p>Pest control; Disease control</p> <p><i>Example: changes caused by non-native organisms to the abundance and/or distribution of pests</i></p>
		<p><b>Soil quality regulation</b></p>	<p><u>Weathering processes</u> and their effect on soil quality; <u>Decomposition and fixing processes</u> and their effect on soil quality</p> <p><i>Example: changes caused by non-native organisms to vegetation structure and/or soil fauna leading to reduced soil quality</i></p>
		<p><b>Water conditions</b></p>	<p>Regulation of the <u>chemical condition</u> of freshwaters by living processes; Regulation of the chemical condition of salt waters by living processes</p> <p><i>Example: changes caused by non-native organisms to buffer strips along water courses that remove nutrients in runoff and/or fish communities that regulate the resilience and resistance of water bodies to eutrophication</i></p>
		<p><b>Atmospheric composition and conditions</b></p>	<p>Regulation of <u>chemical composition</u> of atmosphere and oceans; Regulation of <u>temperature and humidity</u>, including ventilation and transpiration</p> <p><i>Example: changes caused by non-native organisms to ecosystems' ability to sequester carbon and/or evaporative cooling (e.g. by urban trees)</i></p>
<b>Cultural</b>	<b>Direct, in-situ and outdoor interactions</b> with living systems that depend on presence in the environmental setting	<p><b>Physical and experiential</b> interactions with natural environment</p>	<p>Characteristics of living systems that that enable activities promoting health, recuperation or enjoyment through <u>active or immersive interactions</u>;</p> <p>Characteristics of living systems that enable activities promoting health, recuperation or enjoyment through <u>passive or observational interactions</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that make it attractive for recreation, wild life watching etc.</i></p>
		<p><b>Intellectual and representative</b> interactions with natural environment</p>	<p>Characteristics of living systems that enable <u>scientific investigation</u> or the creation of traditional ecological knowledge;</p> <p>Characteristics of living systems that enable <u>education and training</u>;</p> <p>Characteristics of living systems that are resonant in terms of <u>culture or heritage</u>;</p> <p>Characteristics of living systems that enable <u>aesthetic experiences</u></p>

			<i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have cultural importance</i>
	<b>Indirect, remote, often indoor interactions</b> with living systems that do not require presence in the environmental setting	<b>Spiritual, symbolic</b> and other interactions with natural environment	<p>Elements of living systems that have <u>symbolic meaning</u>;</p> <p>Elements of living systems that have <u>sacred or religious meaning</u>;</p> <p>Elements of living systems used for <u>entertainment or representation</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have sacred or religious meaning</i></p>
		Other biotic characteristics that have a <b>non-use value</b>	<p>Characteristics or features of living systems that have an <u>existence value</u>;</p> <p>Characteristics or features of living systems that have an <u>option or bequest value</u></p> <p><i>Example: changes caused by non-native organisms to ecosystems designated as wilderness areas, habitats of endangered species etc.</i></p>

## **ANNEX VIII Projection of environmental suitability for *Obama nungara* establishment in Europe**

Björn Beckmann, Archie Murchie, Leigh Winsor, Jean-Lou Justine and Dan Chapman

21 September 2021

### *Aim*

To project the suitability for potential establishment of *Obama nungara* in Europe, under current and predicted future climatic conditions.

### *Data for modelling*

Species occurrence data were obtained from the Global Biodiversity Information Facility (GBIF) (543 records), iNaturalist (79 records), and additional records from the risk assessment team. We scrutinised occurrence records from regions where the species is not known to be established and removed any dubious records or where the georeferencing was too imprecise (e.g. records referenced to a country or island centroid) or outside of the coverage of the predictor layers (e.g. small island or coastal occurrences). The remaining records were gridded at a 0.25 x 0.25 degree resolution for modelling, yielding 233 grid cells with occurrences (Figure 1a). As a proxy for recording effort, the density of Platyhelminthes records held by GBIF was also compiled on the same grid (Figure 1b).

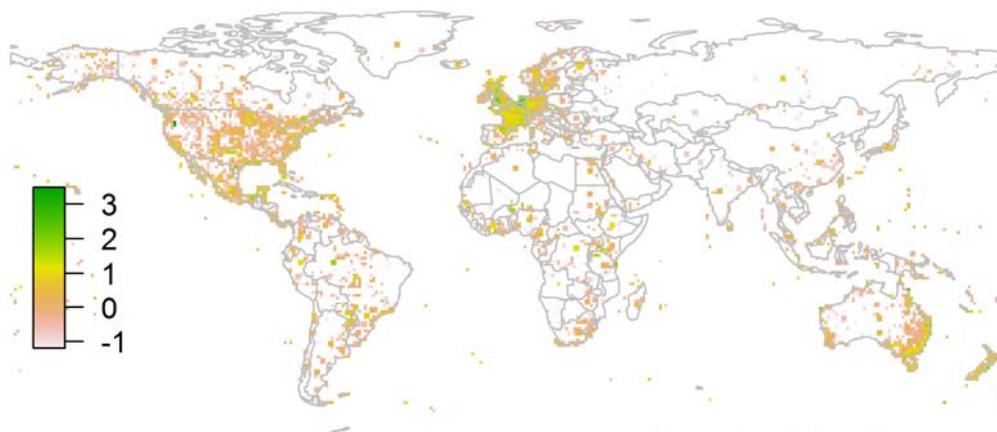

[Page Break](#)

**Figure 1.** (a) Occurrence records obtained for *Obama nungara* and used in the modelling, showing native and invaded distributions. (b) The recording density of Platyhelminthes on GBIF, which was used as a proxy for recording effort.

(a) Species distribution used in modelling

(b) Estimated recording effort (log10-scaled)

Climate data were selected from the 'Bioclim' variables contained within the WorldClim database (Hijmans et al., 2005), originally at 5 arcminute resolution (0.083 x 0.083 degrees of longitude/latitude) and aggregated to a 0.25 x 0.25 degree grid for use in the model.

Based on the biology of *Obama nungara*, the following climate variables were used in the modelling:

- Minimum temperature of the coldest month (Bio6)
- Mean temperature of the warmest quarter (Bio10)
- Annual precipitation (Bio12)
- Precipitation seasonality (Bio15)
- Climatic moisture index (CMI): ratio of mean annual precipitation to potential evapotranspiration, log+1 transformed. For its calculation, monthly potential evapotranspirations were estimated from the WorldClim monthly temperature data and solar

radiation using the simple method of Zomer et al. (2008) which is based on the Hargreaves evapotranspiration equation (Hargreaves, 1994).

To estimate the effect of climate change on the potential distribution, equivalent modelled future climate conditions for the 2070s under the Representative Concentration Pathways (RCP) 2.6 and 4.5 were also obtained. These represent low and medium emissions scenarios, respectively. The above variables were obtained as averages of outputs of eight Global Climate Models (BCC-CSM1-1, CCSM4, GISS-E2-R, HadGEM2-AO, IPSL-CM5A-LR, MIROC-ESM, MRI-CGCM3, NorESM1-M), downscaled and calibrated against the WorldClim baseline (see [http://www.worldclim.org/cmip5\\_5m](http://www.worldclim.org/cmip5_5m)).

The following habitat layers were also used:

- Human influence index (HII): As many non-native invasive species associate with anthropogenically disturbed habitats. We used the Global Human Influence Index Dataset of the Last of the Wild Project (Wildlife Conservation Society - WCS & Center for International Earth Science Information Network - CIESIN - Columbia University, 2005), which is developed from nine global data layers covering human population pressure (population density), human land use and infrastructure (built-up areas, nighttime lights, land use/land cover) and human access (coastlines, roads, railroads, navigable rivers). The index ranges between 0 and 1 and was  $\ln+1$  transformed for the modelling to improve normality.

### *Species distribution model*

A presence-background (presence-only) ensemble modelling strategy was employed using the BIOMOD2 R package version 3.4.6 (Thuiller et al., 2020, Thuiller et al., 2009). These models contrast the environment at the species' occurrence locations against a random sample of the global background environmental conditions (often termed 'pseudo-absences') in order to characterise and project suitability for occurrence. This approach has been developed for distributions that are in equilibrium with the environment. Because invasive species' distributions are not at equilibrium and subject to dispersal constraints at a global scale, we took care to minimise the inclusion of locations suitable for the species but where it has not been able to disperse to (Chapman et al. 2019).

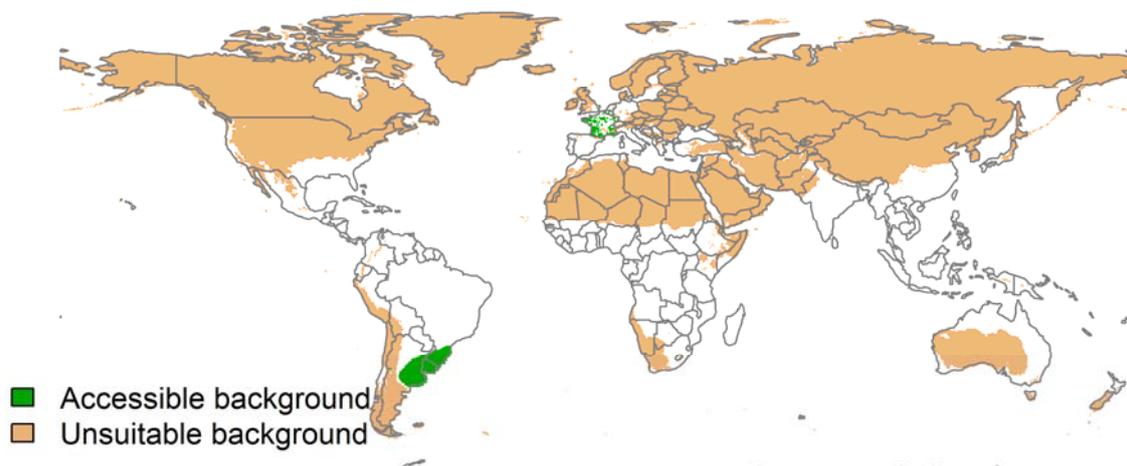

Therefore the background sampling region included:

- The area accessible by native *Obama nungara* populations, in which the species is likely to have had sufficient time to disperse to all locations. Based on presumed maximum dispersal distances, the accessible region was defined as a 300km buffer around the native range occurrences; AND
- A 30km buffer around the non-native occurrences, encompassing regions likely to have had high propagule pressure for introduction by humans and/or dispersal of the species; AND
- Regions where we have an *a priori* expectation of high unsuitability for the species so that absence is assumed irrespective of dispersal constraints (see Figure 2). The following rules were applied to define a region expected to be highly unsuitable for *Obama nungara* at the spatial scale of the model:
  - Minimum temperature of the coldest month (Bio6) < -4°C
  - Mean temperature of the warmest quarter (Bio10) < 15.5°C
  - Annual precipitation (Bio12) < 350mm

Altogether, 0.9% of occurrence grid cells were located in the unsuitable background region.

Within the unsuitable background region, 10 samples of 5000 randomly sampled grid cells were obtained. In the accessible background (comprising the accessible areas around native and non-native occurrences as detailed above), the same number of pseudo-absence samples were drawn as there were presence records (233), weighting the sampling by a proxy for recording effort (Figure 1(b)).

**Figure 2.** The background from which pseudo-absence samples were taken in the modelling of *Obama nungara*. Samples were taken from a 300km buffer around the native range and a 30km buffer around non-native occurrences (together forming the accessible background), and from areas expected to be highly unsuitable for the species (the unsuitable background region). Samples from the accessible background were weighted by a proxy for recording effort (Figure 1(b)).

Each dataset (i.e. combination of the presences and the individual background samples) was randomly split into 80% for model training and 20% for model evaluation. With each training dataset, seven statistical algorithms were fitted with the default BIOMOD2 settings and rescaled using logistic regression, except where specified below:

- Generalised linear model (GLM)
- Generalised boosting model (GBM)
- Generalised additive model (GAM) with a maximum of four degrees of freedom per smoothing spline
- Artificial neural network (ANN)
- Multivariate adaptive regression splines (MARS)
- Random forest (RF)
- Maxent

Since the total background sample was larger than the number of occurrences, prevalence fitting weights were applied to give equal overall importance to the occurrences and the background. Normalised variable importance was assessed and variable response functions were produced using BIOMOD2's default procedure.

Model predictive performance was assessed by the following three measures:

- AUC, the area under the receiver operating characteristic curve (Fielding & Bell 1997). Predictions of presence-absence models can be compared with a subset of records set aside for model evaluation (here 20%) by constructing a confusion matrix with the number of true positive, false positive, false negative and true negative cases. For models generating non-dichotomous scores (as here) a threshold can be applied to transform the scores into a dichotomous set of presence-absence predictions. Two measures that can be derived from the confusion matrix are sensitivity (the proportion of observed presences that are predicted as such, quantifying omission errors), and specificity (the proportion of observed absences that are predicted as such, quantifying commission errors). A receiver operating characteristic (ROC) curve can be constructed by using all possible thresholds to classify the scores into confusion matrices, obtaining sensitivity and specificity for each matrix, and plotting sensitivity against the corresponding proportion of false positives (equal to  $1 - \text{specificity}$ ). The use of all possible thresholds avoids the need for a selection of a single threshold, which is often arbitrary, and allows appreciation of the trade-off between sensitivity and specificity. The area under the ROC curve (AUC) is often used as a single threshold-independent measure for model performance (Manel et al. 2001). AUC is the probability that a randomly selected presence has a higher model-predicted suitability than a randomly selected absence (Allouche et al. 2006).
- Cohen's Kappa (Cohen 1960). This measure corrects the overall accuracy of model predictions (ratio of the sum of true presences plus true absences to the total number of records) by the accuracy expected to occur by chance. The Kappa statistic ranges from -1 to +1, where +1 indicates perfect agreement and values of zero or less indicate a performance no better than random. Advantages of Kappa are its simplicity, the fact that both commission and omission errors are accounted for in one parameter, and its relative tolerance to zero values in the confusion matrix (Manel et al. 2001). However, Kappa has been criticised for being sensitive to prevalence (the proportion of sites in which the species was recorded as present) and may therefore be inappropriate for comparisons of model accuracy between species or regions (McPherson et al. 2004, Allouche et al. 2006).
- TSS, the true skill statistic (Allouche et al. 2006). TSS is defined as sensitivity + specificity - 1, and corrects for Kappa's dependency on prevalence. TSS compares the number of correct forecasts, minus those attributable to random guessing, to that of a hypothetical set of perfect forecasts. Like Kappa, TSS takes into account both omission and commission errors, and success as a result of random guessing, and ranges from -1 to +1, where +1 indicates perfect agreement and values of zero or less indicate a performance no better than random (Allouche et al. 2006).

An ensemble model was created by first rejecting poorly performing algorithms with relatively extreme low AUC values and then averaging the predictions of the remaining algorithms, weighted by their AUC. To identify poorly performing algorithms, AUC values were converted into modified z-scores based on their difference to the median and the median absolute deviation across all algorithms (Iglewicz & Hoaglin 1993). Algorithms with  $z < -2$  were rejected. In this way, ensemble projections were made for each dataset and then averaged to give an overall suitability, as well as its standard deviation.

Projections were classified into suitable and unsuitable regions using a “lowest presence threshold” (Pearson et al. 2007), setting the cut-off as the lowest value at which 98% of all presence records are classified correctly under the current climate (here 0.71). In order to express the sensitivity of classifications to the choice of this threshold, thresholds at which 95% and 99% of records are classified correctly (here 0.79 and 0.62 respectively) were used in the calculation of error bars in Figures 9 and 10 below in addition to taking account of uncertainty in the projections themselves.

We also produced a limiting factor map for Europe following Elith et al. (2010). For this, projections were made separately with each individual variable fixed at a near-optimal value. These were chosen as the median values at the occurrence grid cells. Then, the most strongly limiting factors were identified as the ones resulting in the highest increase in suitability in each grid cell.

[Page Break](#)

## Results

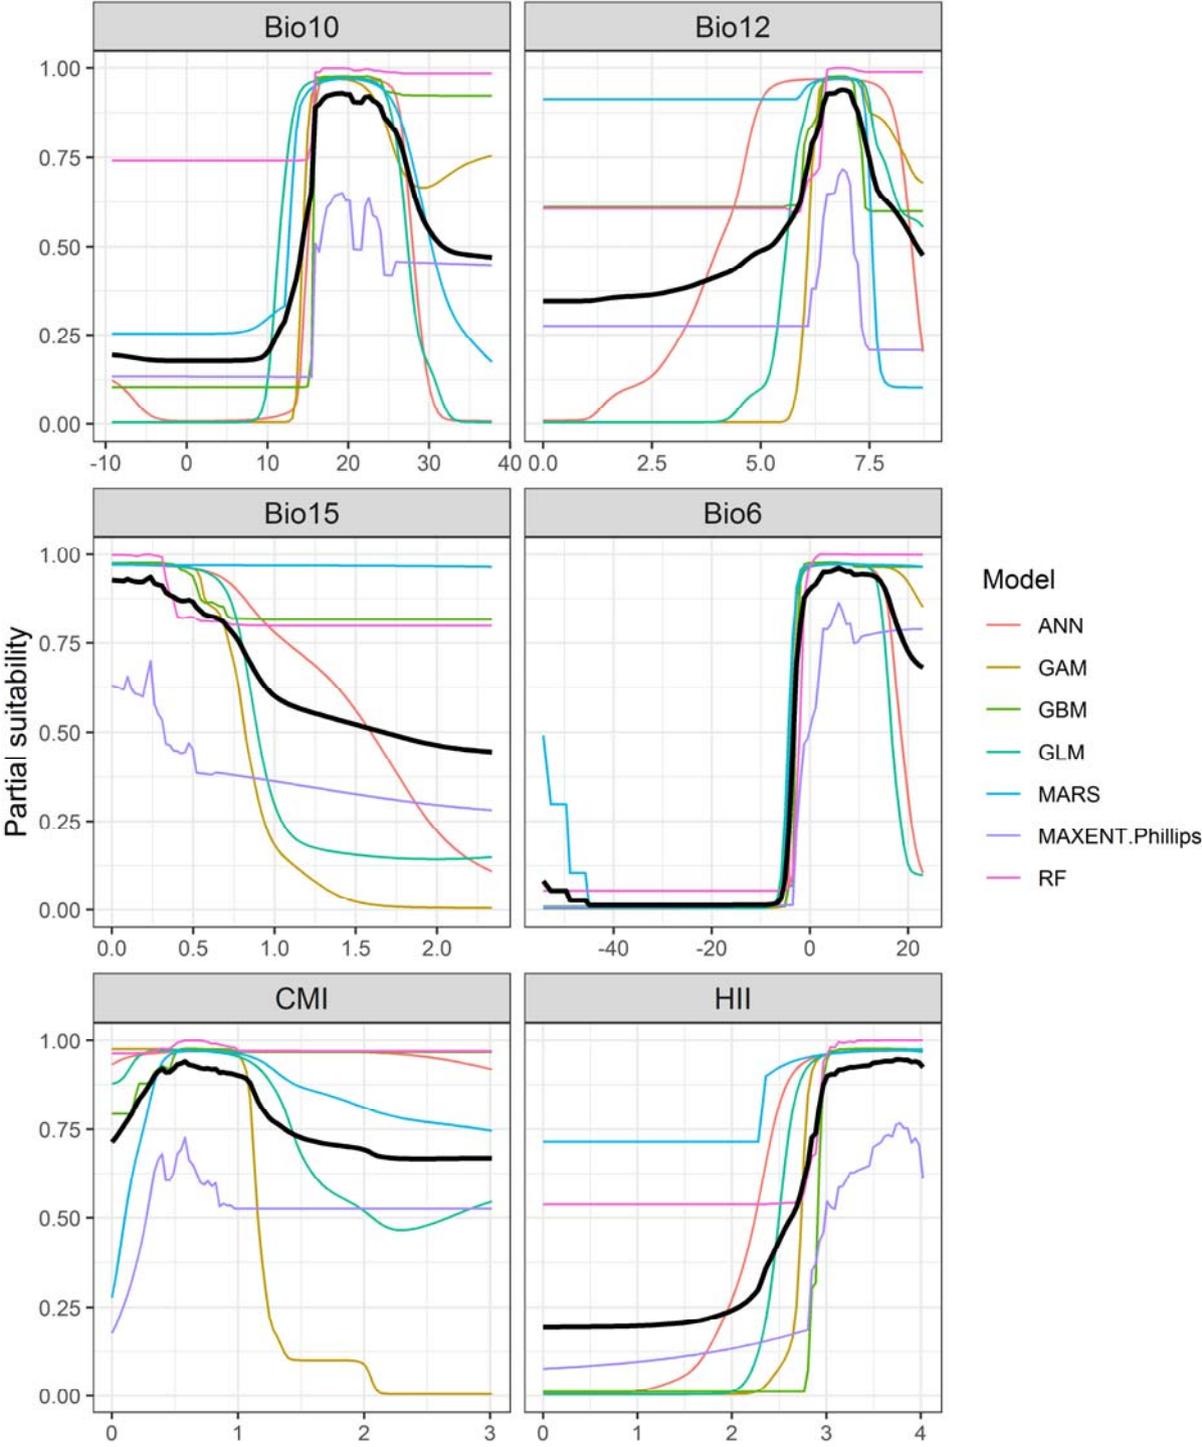

The ensemble model suggested that suitability for *Obama nungara* was most strongly determined by Minimum temperature of the coldest month (Bio6), accounting for 42.3% of variation explained, followed by Human influence index (HII) (21.8%), Mean temperature of the warmest quarter (Bio10) (15.9%), Annual precipitation (Bio12) (11.8%), Climatic moisture index (CMI) (5.1%) and Precipitation seasonality (Bio15) (3.2%) (Table 1, Figure 3).

**Table 1.** Summary of the cross-validation predictive performance (AUC, Kappa, TSS) and variable importance of the fitted model algorithms and the ensemble (AUC-weighted average of the best performing algorithms). Results are the average from models fitted to 10 different background samples of the data.

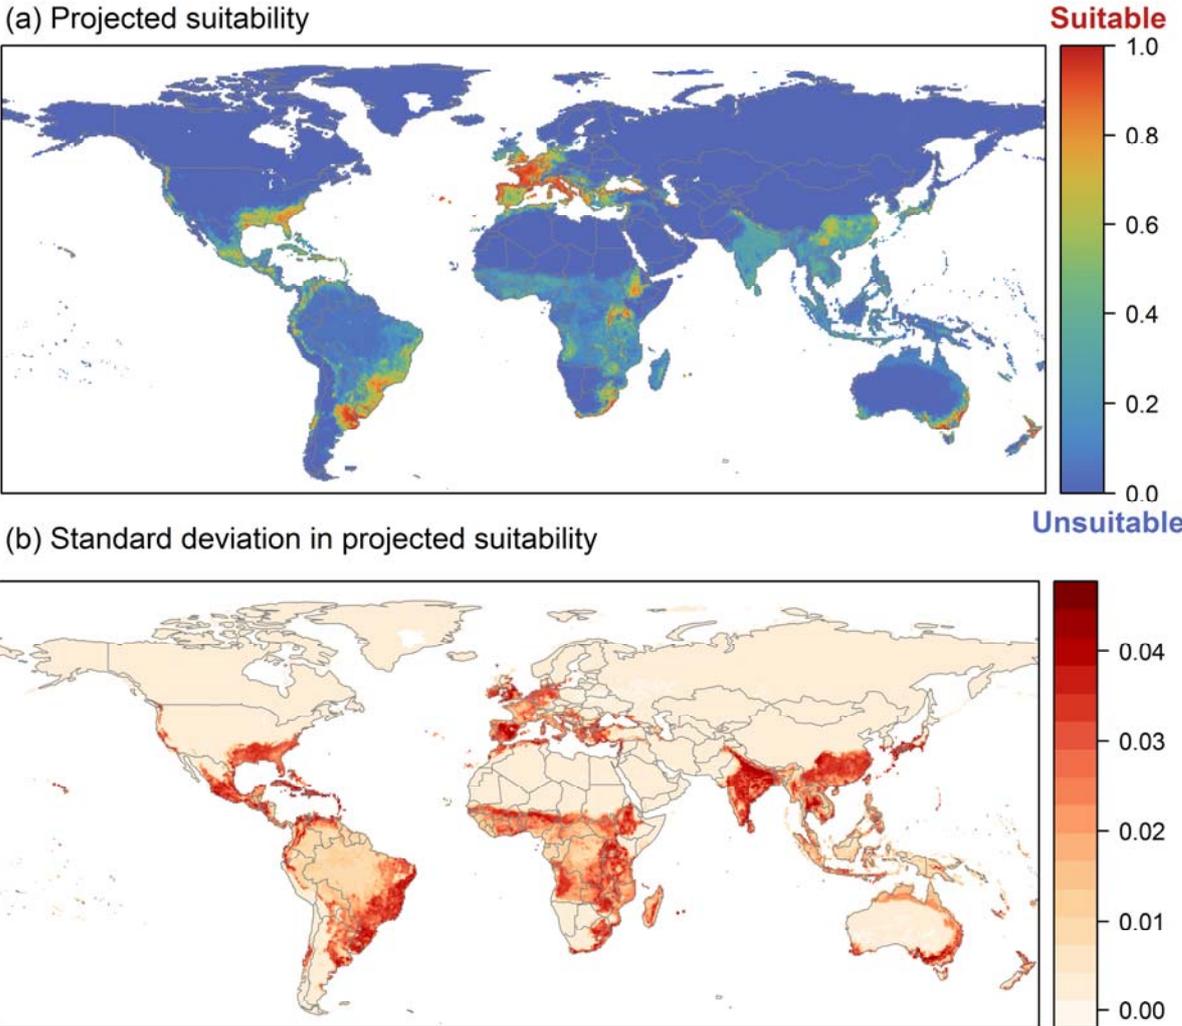

Algorithm	AUC	Kappa	TSS	Used in the ensemble	Variable importance (%)					
					Minimum temperature of the coldest month (Bio6)	Human influence index (HII)	Mean temperature of the warmest quarter (Bio10)	Annual precipitation (Bio12)	Climatic moisture index (CMI)	Precipitation seasonality (Bio15)
GLM	0.979	0.655	0.939	yes	37	26	16	14	3	5

**Figure 3.** Partial response plots from the fitted models. Thin coloured lines show responses from the algorithms in the ensemble, while the thick black line is their ensemble. In each plot, other model variables are held at their median value in the training data. Some of the divergence among algorithms is because of their different treatment of interactions among variables.

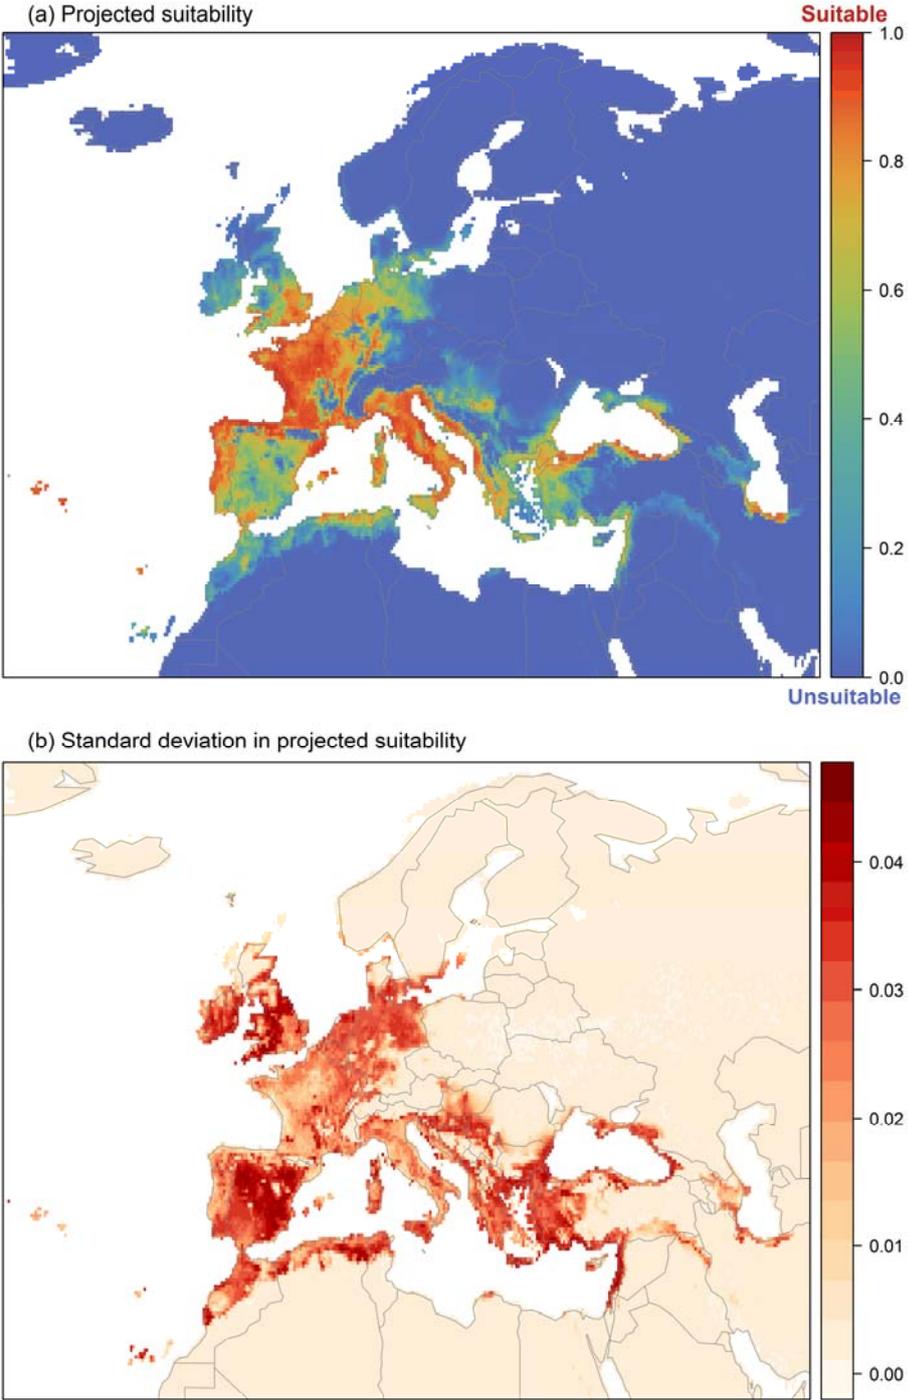

**Figure 4.** (a) Projected global suitability for *Obama nungara* establishment in the current climate. For visualisation, the projection has been aggregated to a 0.5 x 0.5 degree resolution, by taking the maximum suitability of constituent higher resolution grid cells. Values > 0.71 are suitable for the species, with 98% of global presence records above this threshold. Values below 0.71 indicate lower relative suitability. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

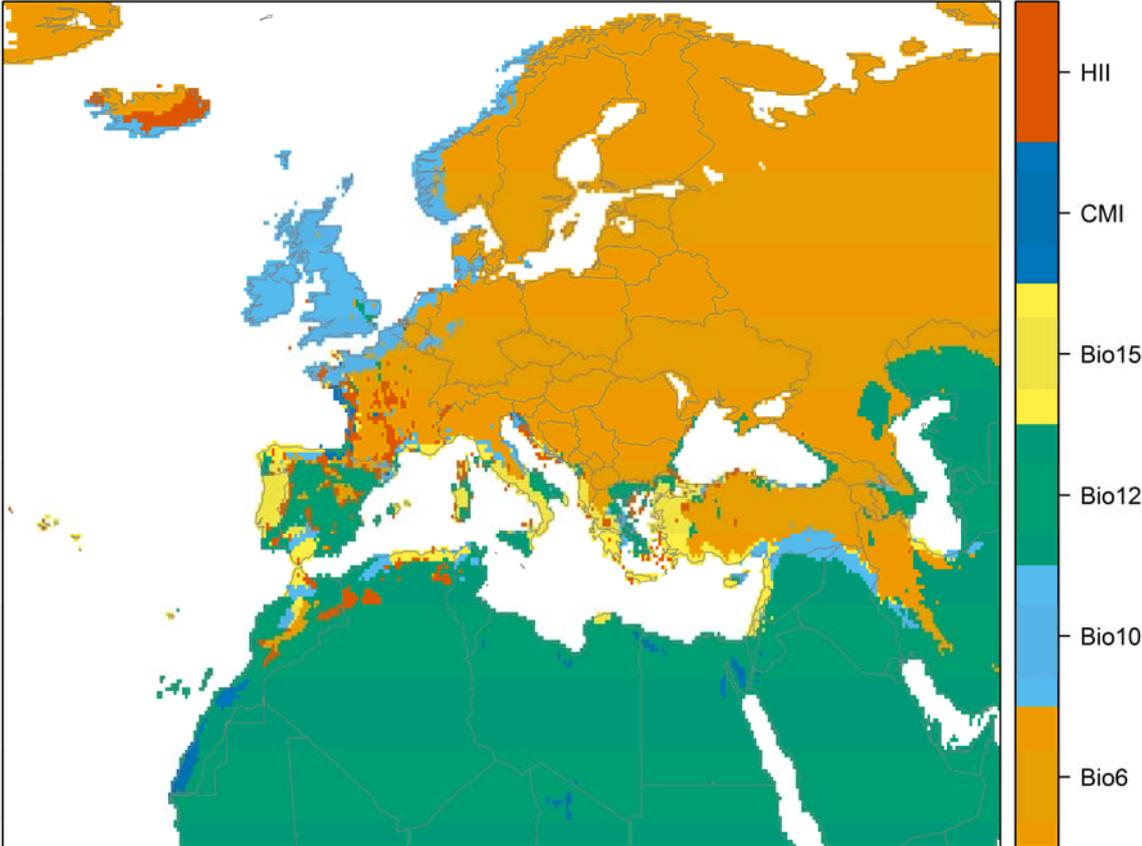

Page Break

**Figure 5.** (a) Projected current suitability for *Obama nungara* establishment in Europe and the Mediterranean region. Values > 0.71 are suitable for the species, with 98% of global presence records above this threshold. Values below 0.71 indicate lower relative suitability. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

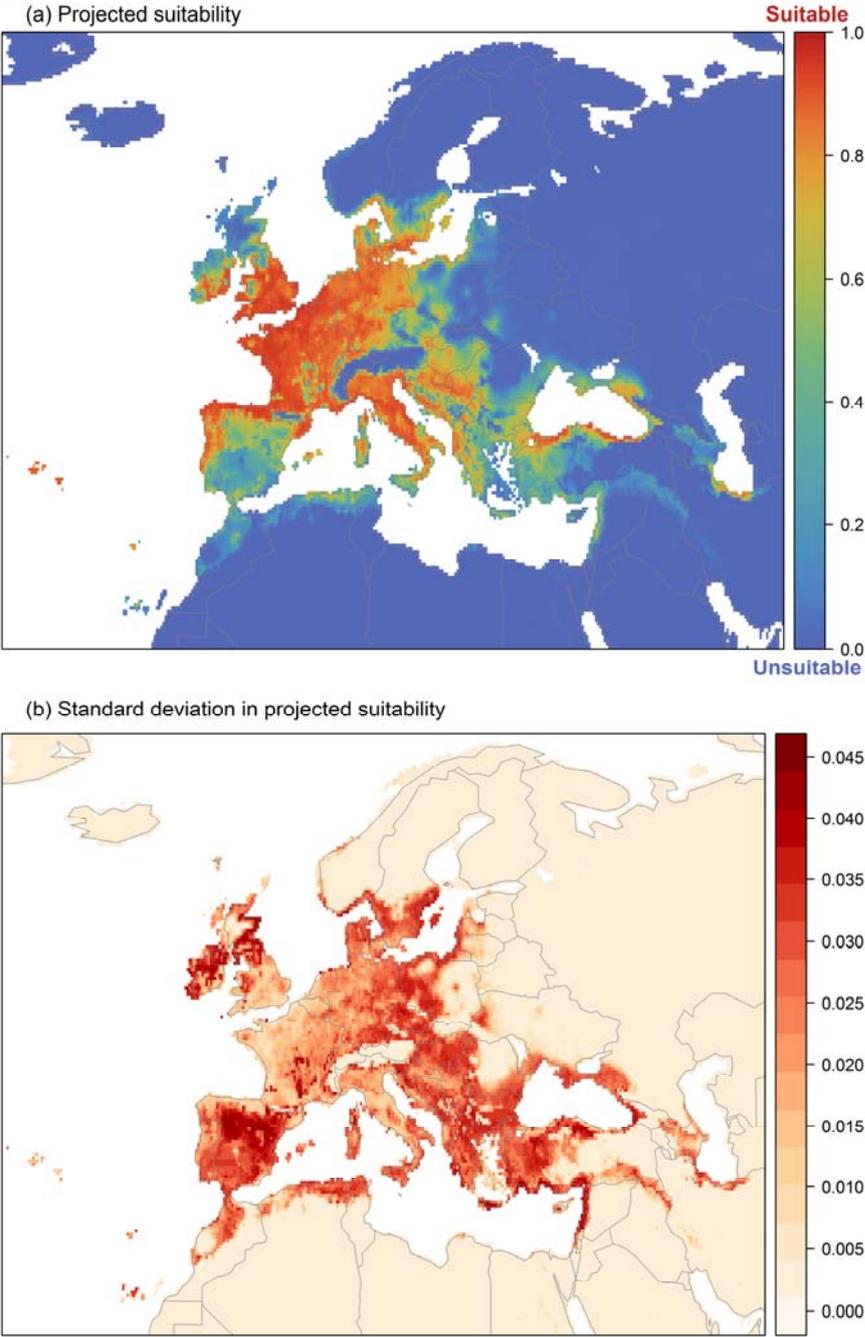

**Figure 6.** The most strongly limiting factors for *Obama nungara* establishment estimated by the model in Europe and the Mediterranean region in current climatic conditions.

### *Caveats to the modelling*

To remove spatial recording biases, the selection of the background sample from the accessible background was weighted by the density of Platyhelminthes records on the Global Biodiversity Information Facility (GBIF). While this is preferable to not accounting for recording bias at all, it may not provide the perfect measure of recording bias.

There was substantial variation among modelling algorithms in the partial response plots (Figure 3). In part this will reflect their different treatment of interactions among variables. Since partial plots are made with other variables held at their median, there may be values of a particular variable at which this does not provide a realistic combination of variables to predict from.

Other variables potentially affecting the distribution of the species, such as types of land cover were not included in the model.

## Annex with evidence on measures and their implementation cost and cost-effectiveness

<b>Species (scientific name)</b>	<b><i>Obama nungara</i> Carbayo, Álvarez-Presas, Jones &amp; Riutort, 2016</b>
<b>Species (common name)</b>	<b>Obama flatworm</b>
<b>Author(s)</b>	<b>Archie K. Murchie, Leigh Winsor, Jean-Lou Justine</b>
<b>Reviewer</b>	<b>Brian Boag, Richard Shaw</b>
<b>Date completed</b>	<b>15/10/2021</b>

### Summary<sup>1</sup>

Highlight of measures that provide the most cost-effective options to prevent the introduction, achieve early detection, rapidly eradicate and manage the species, including significant gaps in information or knowledge to identify cost-effective measures.

*Obama nungara* is an alien terrestrial flatworm, originally from South America, that has established in France, Belgium, Spain, Portugal and Italy (Justine and Winsor, 2020). It has been recorded most often from domestic gardens. *Obama nungara* is a potentially problematic species because it is a predator of earthworms, snails and other invertebrates found in the soil. If established in a region, eradication and management options are very limited. Prevention of introduction, prevention of establishment and prevention of spread are by far the best options.

Unintentional introduction: Legislative control and phytosanitary practices at exporting plant producers would be the first step to prevent introduction of *O. nungara*. If *O. nungara* is found, detention notices should be enforced to prevent further stock movement. Plants from the same consignment should be traced and thoroughly examined for flatworms. Good biosecurity practices should be in place. Machinery and equipment should be hosed down with water to remove soil before moving between sites. Gardeners and others should not move soil, compost or plants from infested sites.

Detection: An education and awareness programme should be implemented to raise the profile of *O. nungara* and the potential risk it poses to the environment within the industry. Importing nurseries, botanic gardens or garden centres should inspect their stock regularly for non-indigenous flatworms. Pictorial guides should be produced to enable identification by laypersons.

Eradication: Eradication is only likely to be feasible in very small, controlled areas before the species has entered the wild. If on concrete, biocides could be used, but on a soil-base, removal and scorching would be necessary. If *O. nungara* spreads to the wild, eradication will be virtually impossible.

Long-term Management: Management options are limited. There are no chemical or classical biological control methods currently available for invasive alien flatworms. Spread may be limited by good biosecurity measures, cleaning machinery and equipment before moving between sites. Soil, compost and rooted plants should not be moved from infested gardens or other sites.

Detailed assessment			
	Description of measures <sup>2</sup>	Assessment of implementation cost and cost-effectiveness (per measure) <sup>3</sup>	Level of confidence <sup>4</sup>
<b>Methods to achieve prevention of intentional and unintentional introduction<sup>5</sup></b>	<p><b>Plant health inspection</b> Terrestrial flatworms are mostly introduced via inadvertent transport by the plant trade, particularly plants-for-planting. Regular plant health inspections and surveillance are necessary to prevent establishment. Current EU Commission Implementing Regulation (EU) 2019/2072 stipulates the special requirements for growing medium attached to plants to sustain them and this largely prohibits soil but includes plants imported bare root or maintained on an artificial media. If implemented correctly, this should reduce the likelihood of <i>O. nungara</i> being carried in plant containers. Legislation to guarantee that exported plants are free from infestation by invasive flatworms is required.</p> <p>EPPO (2001) guidelines for <i>Arthurdendyus triangulatus</i> specify that:</p>	<p><b>Plant health inspection</b> Plant health inspections and surveillance are important universal controls for crop pests and pathogens, as well as preventing incursion of invasive species. They are widely accepted and expected across the horticulture sector therefore any inspections for <i>O. nungara</i> will probably be accepted by stakeholders with minimal objections. It is likely that surveillance for <i>O. nungara</i> would be incorporated into routine surveillance. However, examination for soil-borne or cryptic pests such as <i>O. nungara</i> is likely to be very time-consuming, expensive and inaccurate. Plant inspections at source would be more effective than portal inspections. Environmental DNA technologies could aid in detection but have not been developed as yet.</p> <p>There would be an incremental cost from increasing the level of plant health inspection at ports of entry as well as the cost of training inspectors in new monitoring and control</p>	<p>Medium</p> <p>(some information from published sources on terrestrial flatworms but not applied to <i>O. nungara</i>)</p>

	<p>1) Plants are grown on slatted benches  2) The consignment must come from a place of production found free from flatworms  3) The consignment must have been subjected to a disinfestation treatment to eliminate flatworms.</p> <p><b>Hot-water treatment</b>  Hot water treatment may be used to phytosanitise plants for terrestrial flatworms, either by immersion (Sugiura, 2008; Murchie and Moore, 1998) or as a drench (Justine <i>et al.</i>, 2014). The temperature will depend on the flatworm species. For <i>A. triangulatus</i>, immersion in water at 34°C, resulted in death after 5 minutes (Murchie and Moore, 1998). No data are available for <i>O. nungara</i>. Treatment at source would be preferable, as this would meet the requirement that the consignment has been subject to disinfestation treatment (as above). The guidelines above can be stipulated by importers and National Plant Protection Organisations.</p>	<p>measures which could be passed on to the industry.</p> <p><b>Hot-water treatment</b>  Hot water treatment is used for nematode control and could be effective for <i>O. nungara</i>. The method is likely acceptable to the public for <i>O. nungara</i> management as these measures have been agreed for other invasive flatworms and hot water is the recommended method of euthanising them when found in domestic settings. However, on a commercial scale it requires specialist equipment and risks damaging the plants. There may be some health and safety implications of hot water treatment such as scalding but these are likely to be routine. Justine <i>et al.</i> (2014) considered that drenching may be more practical in a commercial setting. There is little information on whether hot-water treatment has been used for flatworm control at any nurseries or producers. Placing compost in glasshouses to raise the temperature has been occasionally used against <i>A. triangulatus</i> but its effectiveness against <i>O. nungara</i>, a sub-tropical species, would be smaller. There are few environmental implications for heat-treatment control as measures will take place in a managed environment at a local scale. However, any washings must be filtered or reheated before disposal to prevent any contamination from plant</p>	
--	--	---	--

		<p>pathogens to the surrounding environment. Eradication at site would need to be implemented as rapidly as possible.</p>	
<p><b>Methods to achieve early detection<sup>6</sup></b></p>	<p><b>Awareness and education (detection by industry and public)</b></p> <p>UK and Irish guidelines (MAFF, 1996; Kelly, 2012) for nurseries and garden centres suggest the following methods to detect terrestrial flatworms:</p> <ol style="list-style-type: none"> <li>1) Check regularly under matting or pots standing directly on the ground for flatworms or their egg cocoons.</li> <li>2) Lift plants from their pots frequently to check for the presence of flatworms or their egg cocoons. Standing potted plants in water overnight has been practised by some gardeners as a means of detecting <i>A. triangulatus</i> (B. Boag 2005, pers. comm.).</li> <li>3) Set traps (e.g. gravel or sand filled polythene bags) along the edges of the holding especially where it adjoins private gardens. Regularly check these for the presence of flatworms or their egg cocoons.</li> <li>4) Inspect all outgoing consignments of plants carefully whether for export or not.</li> </ol> <p>For <i>A. triangulatus</i>, pictorial identification guides have been produced and it is</p>	<p><b>Awareness and education (detection by industry and public)</b></p> <p>As <i>O. nungara</i> is likely to be spread from nurseries, garden centres and botanic gardens, detection at these sites would be most cost-effective. Raising awareness of invasive flatworms and their potential impact to industry and consumers, would be one of the most effective ways to detect this species. The methods proposed are low-cost and easily implemented as part of normal nursery practice. Awareness and vigilance are key. If a nursery or garden centre were found to disseminate <i>O. nungara</i> in their plants, this would cause significant reputational damage with consequent loss in consumer confidence. There is therefore a clear commercial incentive for producers to be involved.</p> <p>Citizen science approaches have been used to map the spread of invasive flatworms, including <i>O. nungara</i> (Moore <i>et al.</i>, 1998; Justine <i>et al.</i>, 2020; Justine <i>et al.</i>, 2015). This is a valuable approach that has become increasingly effective with the development of mobile phone cameras and online recording applications.</p>	<p>High</p> <p>(professionally produced guidelines for effective invasive flatworm detection published and available on several websites)</p>

	<p>recommended that similar was done for <i>O. nungara</i>. Environmental DNA (eDNA) technologies could be used for detection by, for example, analysing water samples passed through growing media held in plant pots.</p>	<p>Large adult flatworms are distinctive from other soil organisms such as earthworms and insect larvae. However, for species identification specialist training would be required. A citizen science approach would cost tens of thousands of euros, but this would comprise many hours of individual unpaid activity, rather than direct costs to government or industry. There are environmental benefits of engaging the public in this process, as it aids in the overall awareness of invasive species and other issues. The health and safety and welfare issues are minimal. However, members of the public should handle flatworms wearing gloves or using forceps in case of skin irritation.</p> <p>Detection is likely if industry and the public can be proactively engaged. As <i>O. nungara</i> has not established in all its potential European range, ongoing vigilance is required, and refresher messages should be disseminated to promote continued engagement.</p>	
<p><b>Methods to achieve eradication<sup>7</sup></b></p>	<p><b>Eradication</b> There are no reports in the literature about any attempts at eradication of <i>O. nungara</i>. For other flatworms (e.g. <i>A. triangulatus</i>), removal trapping (Cannon <i>et al.</i>, 1999; Blackshaw <i>et al.</i>, 1996), and soil removal and scorching (Murchie, 2017) have been suggested.</p>	<p><b>Scorching / soil removal</b> Murchie (2017) considered that soil removal and scorching could eradicate invasive flatworms from a small area. However, such techniques have not been tested against flatworms and may not be effective if flatworms hide deep in the soil. Furthermore, any removed soil would also have to</p>	<p>Medium  (no evidence in the literature of successful eradication of an invasive terrestrial flatworm)</p>

	<p>Eradication is likely only to be possible in a small, controlled area, following intensive treatments such as soil removal, chemical treatments, heat treatment and soil scorching (but these have not been attempted for alien flatworms). Once established in the wider environment, eradication of <i>O. nungara</i> is unlikely. Removal trapping was not successful for <i>A. triangulatus</i>, as shelter traps did not capture a sufficiently high proportion of the population and also it was very labour intensive.</p>	<p>be treated to eliminate flatworms therein, most likely with a form of heat treatment or freezing. Scorching and / or soil removal is only effective for very small areas (10s of m<sup>2</sup>) and at the very early stages of detection. Even so, the likely costs for small-scale eradication at a suspected nursery / garden site would be in the tens of thousands of euros if soil needed to be removed and monitoring implemented. Scorching and soil removal would have health and safety implications and need to be carried out by professional operators. The environmental impact would be highly localised. Stakeholders are generally likely to be supportive but may call for financial support to fund the eradication process or seek compensation for damaged produce and / or facilities. Eradication will be rapid if techniques are successful but these are untested.</p>	
<p><b>Methods to achieve management<sup>8</sup></b></p>	<p><b>Management options</b> There are no reports of any management methods being deployed against free-living <i>O. nungara</i>. In general, prevention of spread through the measures detailed in the ‘prevention of introduction’ section (above) would be valuable, particularly education and awareness, coupled with good biosecurity/phytosanitary measures and limitations on the movement of infested soil or plants.</p>	<p><b>Management options</b> Management options for <i>O. nungara</i> are extremely limited and none have been used in the field. Chemical control will depend on identifying a suitable active ingredient and applying it in a way that minimises any effects on earthworms, slugs and snails. Even if this could be done, widespread use of pesticides in natural environments is likely to be met with public scrutiny and possible stakeholder rejection (e.g. organic nurseries) and could have other environmental consequences (e.g. non-target</p>	<p>Medium  (little evidence of successful management techniques described in the literature)</p>

	<p>Trapping and hand collection of <i>A. triangulatus</i> have been used by domestic gardeners but the effectiveness of these techniques are unknown. Similarly, flooding and hand collection have been used to manage <i>Bipalium kewense</i> in earthworm beds in Australia (Winsor, 1998).</p> <p>Cultivation may physically damage terrestrial flatworms and could be used for management purposes within a horticultural or arable location. However, cultivation will also impact on earthworm and snail species, which are similarly vulnerable to physical damage.</p> <p>If native species are threatened by the presence of flatworms, species conservation measures may be required. For earthworms, this may entail methods to enhance their populations such as minimum-till cultivation (compare with above comments on cultivation) and application of farmyard manure. At the extreme level, rare and endemic species may need to be removed and captive breeding programmes initiated. Exclusion of predatory flatworms may be possible using physical or chemical barriers, but there is no information on this.</p>	<p>impacts, water pollution, etc.). In France, pesticides are restricted for personal use in gardens, so would not be a viable option in the most affected (to date) European country.</p> <p>Hand collection of flatworms may be possible within a limited area but is labour-intensive and gloves or forceps should also be used to prevent skin irritation or possible allergic reactions.</p> <p>It is probable that native predatory beetles and some birds will feed upon <i>O. nungara</i> in Europe and their activity should be encouraged through land management practices and judicious use of pesticides. However, terrestrial flatworms are generally distasteful and native predation may be insufficient to negate the flatworm's impacts. Protection and enhancement of earthworms and snail populations through conservation measures may mitigate some flatworm damage. For example, pasture earthworm species benefit from the application of farmyard manure, whilst endemic snail populations have been conserved through captive breeding programmes (Murray <i>et al.</i>, 1988) (albeit an extreme measure). Conservation measures are a long-term and costly commitment, although they would be a beneficial approach irrespective of the flatworm threat.</p>	
--	--	--	--

	<p>Chemical control has not been used against terrestrial flatworms. No pesticides are approved for control and it is difficult to target flatworms on the soil, whilst avoiding impacts on non-target organisms. Fumigation may be a possibility for containerised plants providing phytotoxic effects were kept to a minimum; however, this has not been assessed. B. Boag quoted in Murchie (2017) reported that slug pellets (metaldehyde) had an impact on <i>A. triangulatus</i> sheltering under refuges on the soil surface. Veterinary anti-helminthics could potentially target invasive alien flatworms but this has not been tested and there would be significant regulatory hurdles to widespread environmental use.</p> <p>No specific predators, parasitoids or pathogens have been documented as potential biocontrol agents for <i>O. nungara</i>.</p>	<p>The large-scale management of such a cryptic and inaccessible pest species is impractical and unproven and would probably be limited to preventing further local spread. It is unlikely that a full-blown invasion could be managed effectively and the costs would be very high.</p>

## Guidelines for Completing the Annex

1 Provide a brief summary description of the most cost-effective methods drawing on the reviews in the detailed assessments

2 Provide a description of the potential method. This should be based on the available key scientific evidence which should be gathered from sources including articles and reviews in technical and scientific journals, internet searches, online databases, grey literature and relevant books and personal communications from scientists, stakeholders, conservation practitioners and governmental bodies. This information should include a full bibliographic list detailing the literature and sources considered.

3 Provide an assessment of the likely cost and effectiveness of the method. Where information is available, consider the following range of questions, accepting that not all questions will be appropriate in all circumstances.

- How effective has this approach proven to be in the past or in an analogous situation?
- How publically acceptable is the approach likely to be?
- Over what period of time would this approach need to be applied to be effective?
- What is the direct cost of implementing this approach?
- How likely are the methods used in the approach to be available?
- How likely is it that relevant licences or other approvals to undertake the approach would be difficult to obtain?
- How likely is it that health and safety issues would prevent the use of this approach?
- How significant is the environmental harm caused by this approach?
- How significant is the economic harm caused by this approach?
- How significant is the social harm caused by this approach?
- How likely is it that the approach will be criticised on welfare grounds?
- How likely is it that the approach will be acceptable to other stakeholders?

Where available, factual information on the costs of specialist equipment, or case studies of management costs from across the Union or third countries should be provided. When describing case studies, if the information is available then provide both total cost and the area over which control was undertaken so that a cost per unit area might be derived. Where such quantitative information is not available, then any qualitative information from the literature is acceptable to help guide decision making. It is accepted that in the majority of cases the information required to assess the potential total cost of management at a member state level is unlikely to be available. This would normally require information on the extent and abundance of the species which is beyond the scope of this assessment. Assessors are not expected to extrapolate the potential total costs of management at a member state level, only to report on the information provided within the literature.

4 Provide an overall assessment of the confidence that can be applied to the information provided for this method. This confidence should relate to the quality of the available information using the guidance below. It should NOT relate to the confidence in the effectiveness of the method

The confidence scores are:

- **High:** Information comes from published material, or current practices based on expert experience applied in one of the EU countries or third country with similar environmental, economic and social conditions.
- **Medium:** Information comes from published data or expert opinion, but it is not commonly applied, or it is applied in regions that may be too different from Europe (e.g. tropical regions) to guarantee that the results will be transposable.
- **Low:** data are not published in reliable information sources and methods are not commonly practiced or are based solely on opinion; This is for example the case of a novel situation where there is little evidence on which to base an assessment.

If there are further factors beyond these that have determined the chosen level of confidence, then provide a brief written description to support the choice of the level of confidence.

5 Measures for preventing the species being introduced intentionally or unintentionally into the territory of a Member State (cf. Articles 7(1)(a), 7(2), 13, 15), i.e. preventing a species entering by blocking its pathways, including pre-border prevention and prevention of escape or release into the environment and secondary spread whenever relevant. Measures for preventing the species reproducing while in containment should be included, if appropriate. Consider all methods that might be applied, including any that have not proven useful. Provide a description of each method in turn, using separate rows to consider each method.

6 Measures to run an effective surveillance system for achieving an early detection of a new occurrence (cf. Article 16). This section assumes that the species is not currently present in a Member State, or part of a Member State's territory.

7 Measures to achieve eradication. Preferably, but not exclusively, used at an early stage of invasion, after an early detection of a new occurrence (cf. Article 17). Consider all methods that might be applied, including any that have not proven useful. Provide a description of each method in turn, using separate rows to consider each method.

8 Measures to achieve management of the species once it has become widely spread within a Member State territory (cf. Article 19). These measures can be aimed at eradication, population control or containment of a population of the species. Consider all methods that might be applied, including any that have not proven useful. Provide a description of each method in turn, using separate rows to consider each method.

The development and completion of this template forms part of the EU project **No 07.0202/2020/834529/ETU/ENV.D.2** Study on Invasive Alien Species – Development of risk assessments to tackle priority species and enhance prevention.

**Risk assessment template developed under the "Study on Invasive Alien Species – Development of risk assessments to tackle priority species and enhance prevention"  
Contract No 07.0202/2020/834529/ETU/ENV.D.2<sup>1</sup>**

**Name of organism:** *Pycnonotus jocosus* (Linnaeus, 1758), red-whiskered bulbul

**Author(s) of the assessment:**

- *Tim Adriaens, Institute for Nature and Forest Research (INBO), Brussels, Belgium*
- *Bram D'hondt, Institute for Nature and Forest Research (INBO), Brussels, Belgium*
- *Riccardo Scalera, IUCN SSC Invasive Species Specialist Group, Rome, Italy*
- *Björn Beckmann, Centre for Ecology and Hydrology (CEH), Wallingford, United Kingdom*
- *Peter Robertson, Newcastle University, United Kingdom*

**Risk Assessment Area:** The risk assessment area is the territory of the European Union 27 and the United Kingdom, excluding the EU-outermost regions.

**Peer review 1:** *Tom Evans, Institute of Biology Berlin University, Berlin, Germany*

**Peer review 2:** *Enrique Murgui, Grupo para el Estudio de las Aves, Valencia, Spain*

**Acknowledgments:** We thank Antonio Polo for sharing information on the species in Valencia province and Chris Feare for information on the eradication campaign in the Seychelles.

**Date of completion:** 15/10/2021

<sup>1</sup> This template is based on the Great Britain non-native species risk assessment scheme (GBNNRA). A number of amendments have been introduced to ensure compliance with Regulation (EU) 1143/2014 on IAS and relevant legislation, including the Delegated Regulation (EU) 2018/968 of 30 April 2018, supplementing Regulation (EU) No 1143/2014 of the European Parliament and of the Council with regard to risk assessments in relation to invasive alien species (see <https://eur-lex.europa.eu/legal-content/en/TXT/?uri=CELEX%3A32018R0968> ).

## SECTION A – Organism Information and Screening

### A1. Identify the organism. Is it clearly a single taxonomic entity and can it be adequately distinguished from other entities of the same rank?

including the following elements:

- the taxonomic family, order and class to which the species belongs;
- the scientific name and author of the species, as well as a list of the most common synonym names;
- names used in commerce (if any)
- a list of the most common subspecies, lower taxa, varieties, breeds or hybrids

As a general rule, one risk assessment should be developed for a single species. However, there may be cases where it may be justified to develop one risk assessment covering more than one species (e.g. species belonging to the same genus with comparable or identical features and impact). It shall be clearly stated if the risk assessment covers more than one species, or if it excludes or only includes certain subspecies, lower taxa, hybrids, varieties or breeds (and if so, which subspecies, lower taxa, hybrids, varieties or breeds). Any such choice must be properly justified.

This risk assessment covers one species, the red-whiskered bulbul *Pycnonotus jocosus* (Linnaeus, 1758), sometimes also called crested bulbul, red-eared bulbul or Persian nightingale. *Lanius jocosus* is an older synonym. This medium-sized passerine songbird (class Aves, order Passeriformes) from Asia belongs to the bulbul family (Pycnonotidae).

Common names regularly used within the risk assessment area include bulbul Orfeo and bulbul orfeu (Spanish/Catalan), roodoorbuulbuul (Dutch), Rotohrbülbul (German), bulbul orphée, condé or merle de Maurice (French), tuta-de-faces-vermelhas (Portuguese), bulbul baffirossi, bulbul dai mustacchi rossi, bulbul mustacchi rossi (Italian).

Nine subspecies of the red-whiskered bulbul are currently recognized (Clements 2007), some of which were originally described as separate species (*P. j. fuscicaudatus* under the genus *Otocampsa*, *P. j. emeria* under the genus *Motacilla*, *P. j. pyrrhotis* and *P. j. monticola* under the genus *Ixos*) (Avibase, <https://avibase.bsc-eoc.org/>):

- *P. j. abuensis* (Whistler, 1931): north-western India
- *P. j. fuscicaudatus* (Gould, 1866): western and central India.
- *P. j. pyrrhotis* (Bonaparte, 1850): northern India and Nepal.
- *P. j. emeria* (Linnaeus, 1758): eastern India to south-western Thailand, Bangladesh and Myanmar.
- *P. j. whistleri* (Deignan, 1948): Andaman Islands.
- *P. j. monticola* (Horsfield, 1840): eastern Himalayas, north-eastern India, southern Tibet, northern Myanmar and southern China.

- *P. j. pattani* (Deignan, 1948): southern Myanmar, Thailand, northern peninsular Malaysian, Laos and southern Indochina.
- *P. j. jocosus* (Linnaeus, 1758): south-eastern China.
- *P. j. hainanensis* (Hachisuka, 1939): northern Vietnam and south-eastern China.

A number of hybrids with the red-whiskered bulbul have been identified: *P. jocosus* x *cafer*, *P. jocosus* x *melanicterus*, *P. jocosus* x *xanthorrhous*, *P. jocosus* x *xanthopygos*, *P. jocosus* x *leucotis*, *P. jocosus* x *leucogenis* (Avibase, <https://avibase.bsc-eoc.org/>). This risk assessment deals with *Pycnonotus jocosus* sensu lato (i.e. including all described subspecies). We do not exclude *P. jocosus* hybrids though information on impacts is lacking for hybrids.

**A2. Provide information on the existence of other species that look very similar [that may be detected in the risk assessment area, either in the environment, in confinement or associated with a pathway of introduction]**

Include both native and non-native species that could be confused with the species being assessed, including the following elements:

- other alien species with similar invasive characteristics, to be avoided as substitute species (in this case preparing a risk assessment for more than one species together may be considered);
- other alien species without similar invasive characteristics, potential substitute species;
- native species, potential misidentification and mis-targeting
