The red-whiskered bulbul is a dark, medium-sized, rather slender bulbul species. It is almost unmistakable due to the combination of its conspicuous black head tuft, usually held vertically, the white and red cheeks and the red undertail-coverts. With a length of 18-20.5 cm the species is about the size of a song thrush *Turdus philomelos* or a European starling *Sturnus vulgaris*. Adults have a black head with an erect spiky crest and ear coverts have red whiskers behind the eyes above a white patch, separated from the white chin and throat by a narrow black malar (Brazil 2009). The throat is white and surrounded by extensions of the crest. The back, wings and tail are of a uniform dusky grey-brown colour but nape and neck-sides are black. The belly is whitish, with cream-coloured sides. The beak is black with the upper mandible somewhat curved and the eyes are dark brown. There is no clear sexual dimorphism between male and female. Juveniles have a shorter, browner crest, lack the red postocular patch and have a duller orange or bullfish-pink vent (Robson 2000). The red-whiskered bulbul has a pleasant song consisting of rich warbled phrases. Calls include high-pitched pips, a long buzzy note, and a sharp “*pik-pik-a-wew*” (Islam and Williams 2020). The vocalisation could potentially be confused with that of Iberian grey shrike (*Lanius meridionalis*) and great grey shrike (*L. excubitor*). These species also occur in Iberia but are not commonly found in the urban green areas (unless as rare winter visitors) around Valencia where red-whiskered bulbul is established (personal communication E. Murgui, September 2021).

Other species of *Pycnonotus* have been recorded in the risk assessment area, such as the brown bulbul (*P. barbatus*), the red-vented bulbul (*P. cafer*), and rarely the white-eared bulbul (*P. leucotis*), the Arabian bulbul (*P. xanthopygos*) and the bimaculate bulbul (*P. bimaculatus*) (Santos 2015). None of

these species have a conspicuous crest, nor do they have red and white cheeks (Mo 2015). The white-eared bulbul has white cheeks, but its caudal undertail-coverts are not red but yellow. The red-vented bulbul does have red caudal undertail-coverts and has a small crest but it does not have white cheeks. The other bulbul species have neither white cheeks nor red caudal undertail-coverts, which are mostly white or yellow. The brown-breasted bulbul *P. xanthorrous*, a species from China, Burma and northern Indochina which has not been observed in the risk assessment area, superficially resembles red-whiskered bulbul but equally lacks the red and white cheeks and its vent is ochre to yellow (Robson 2000).

In Australia, the Department of Primary Industries and Regional Development (2018) reported possible confusion with the native eastern whippbird *Psophodes olivaceus*. This species does however not occur in the risk assessment area and confusion with any crested native European bird is unlikely.

The only native bulbul species that somewhat resembles the red-whiskered bulbul and that therefore could be misidentified as such is the common bulbul (*P. barbatus*). This species is one of the commonest birds in Africa (including in the Spanish enclaves of Ceuta and Melilla, where it is common) in well-vegetated areas in dry landscapes such as gardens, orchards, and oases but is still very rare in the wild in the risk assessment area. In recent years (since 2013), common bulbul has bred in Tarifa (Cádiz, Andalusia, Spain) (van den Berg and Haas 2013). However, common bulbul is a rather dull, nondescript brown bird with a darker face and throat. The belly is pallid and the undertail white (north part of its range) or yellow (south part of its range) and is therefore unlikely to be confused with the red-whiskered bulbul.

The identification of hybrids which other Pycnonotus species might be more problematic. First and second generation hybrids often show intermediate characteristics, but further third and fourth generation hybrids acquired through further back crossing are often indistinguishable from pure-bred red-whiskered bulbul. Red-whiskered bulbuls are also sometimes cross-bred with stripe-throated bulbul *P. finlaysoni* and black-crested bulbul *Rubigula flaviventris* (McCarthy 2006; Techachoochert and Round 2013). Techachoochert and Round (2013) further report cross-breeding of red-whiskered bulbul with yellow-vented bulbul *P. goaivier* is common in Thailand. Hybrids are usually backcrosses with red-whiskered bulbuls from which they are almost indistinguishable (Techachoochert and Round 2013).

**A3. Does a relevant earlier risk assessment exist? Give details of any previous risk assessment, including the final scores and its validity in relation to the risk assessment area.**

No existing risk assessments with direct relevance for the risk assessment area were found. A scientific risk assessment conducted by the Department of Primary Industries and Regional Development, Western Australia and endorsed by the national Invasive Plants and Animals Committee, indicates that the red-whiskered bulbul poses a serious threat (the second highest of four categories) to Australia (Department of Primary Industries and Regional Development 2018). The species does not occur in Western Australia but has the legal status of a Prohibited Declared Pest species and may only be imported and kept subject to permits available to research organisations or similarly secure institutions. Part of the assessment showed that the climates of the bulbul's overseas range and areas of Australia are very similar. The current distribution of the species in Australia along

the east coast is in humid subtropical and oceanic climate (Köppen–Geiger climate classification Cfa and Cfb respectively, e.g. Sydney, see A5).

In Mexico, the red-whiskered bulbul was scored as a high risk species using the Método de Evaluación Rápida de Invasividad (MERI) scoring system (Comisión Nacional para el Conocimiento y Uso de la Biodiversidad (2020). The species was officially listed as an invasive species for the country (Secretaría del Medio Ambiente y Recursos Naturales 2016).

Evans et al. (2016), in their global assessment of the impacts of alien birds using the Environmental Impact Classification for Alien Taxa (EICAT) protocol, classified the species as having a Major (MR) environmental impact with low confidence, with predation being the most important impact mechanism. Martin-Albarracín et al. (2015), in a global analysis of alien bird impact for 39 bird species, identified the red-whiskered bulbul as one of the three species with the highest global impact because of high local impact and a strong intrinsic ability to affect ecosystems. In this risk assessment the red-whiskered bulbul received a higher impact score than the related red-vented bulbul *P. cafer* for the impact criteria competition and interactions with other non-native organisms (for more details see Qu. 4.1).

#### **A4. Where is the organism native?**

including the following elements:

- an indication of the continent or part of a continent, climatic zone and habitat where the species is naturally occurring
- if applicable, indicate whether the species could naturally spread into the risk assessment area

The red-whiskered bulbul is native to tropical Asia. It has a very large range and occurs from Pakistan throughout India and southwest to China. Its natural range is from India to Southeast Asia and northeast into southern China (Guangdong, southern Jiangxi and southern Fujian) (Robson 2000; Brazil 2009). Islands and countries within the native range include: Andaman islands, Bangladesh, Bhutan, Cambodia, China, India, Laos, Myanmar, northern Malaysia, Nepal, Thailand and Vietnam (Hart 2020). According to BirdLife International (2017, 2021b) the species is least concern on the Red List but shows a decreasing population trend. Fishpool and Tobias (2017) report red-whiskered bulbul is in decline following local declines and extinctions owing to hunting and trapping pressure. For instance, in Thailand, Techachoochert and Round (2013) report the species is much in demand due to its sweet, chuckling song, and is possibly the most widely kept native cage-bird species in the country, but has nearly vanished from most of its Thai range due to the illegal trapping of wild birds for sale. Also, the practice of cross-breeding red-whiskered bulbul with yellow-vented bulbul *P. goaivier* presents a possible threat. Breeders believe the hybrids are more aggressive and sing more vigorously giving them an advantage in bird-singing competitions. The global population size has not been quantified, but the species is described as common in many areas, abundant in south and west India and very common in Hong Kong (Fishpool and Tobias 2017). National population sizes have been estimated at c.10,000-100,000 breeding pairs in China and c.100-10,000 introduced breeding pairs in Japan (Brazil 2009; BirdLife International 2017, 2021b).

The species occupies a range of lowland (< 2.000 m) habitats. Red-whiskered bulbul is a resident (non-migratory) species which is mostly closely associated with human habitation in native and introduced ranges (Islam and Williams 2000). It often occurs in wooded habitats (forest edges, mangrove, secondary forest), reed beds, near habitation, in villages, (sub)urban parks and gardens, orchards, scrubland and agricultural habitats where it usually occurs in pairs or small groups (Grimmet et al. 2001; Brazil 2009; Hart 2020). It tends to avoid densely vegetated areas such as continuous forest and their preferred habitat consists of well-watered, open wooded areas (Robson 2000). The species shows communal roosting behavior outside of the breeding season and was reported roosting in various species of trees (*Pinus*, *Casuarina*, *Ficus*) in Florida (Carleton and Owre 1975).

#### **A5. What is the global non-native distribution of the organism outside the risk assessment area?**

The red-whiskered bulbul has been introduced to many regions of the world as a cage bird and with ritual releases, including in Europe within the risk assessment area (Spain) and on the Canary Islands (Tenerife) outside the risk assessment area. It is widely kept as a cage bird and was introduced to many places, including Australia, Madagascar, Hawaii, Japan, the Seychelles, Indonesia, the Arabian Peninsula, Zimbabwe, South Africa, islands in the Indian Ocean and North America (California and Florida) (Dyer et al. 2017). It has established populations in Australia, Borneo, the Canary Islands, Hawaii, Hong Kong, Indonesia, Japan, Juan de Nova Island, southern Malaysia, Mauritius, Nicobar Islands, Oman, Réunion, Saudi Arabia, Singapore, Spain, Taiwan, the United Arab Emirates and the USA (Hart 2020 and references therein).

In **Taiwan** the species was first observed in 1985 with nesting documented since 2010 at two localities in Taipei City (Walther 2011).

On the **Canary Islands** a small population was established on Tenerife in the urban area Los Realejos (Barranco Godines) before some of those birds were removed in 2007 (Santos 2015). The species has only been observed on the island of Tenerife (Lorenzo 2010). The first observation was performed in 1997 in the locality of Las Casas de la Cumbrilla, in Anaga. Later, the species was recorded in Los Realejos, where it formed a breeding nucleus. Solitary individuals were observed here in 1998, in 2000 and in 2001, when a juvenile was accidentally captured, indicating reproduction. Further observations followed: two individuals in 2001, ten individuals in 2003, including a juvenile, and two individuals in 2003, including a juvenile, two in 2005, one of them carrying nest material. Around 2006 a population of more than 15 individuals was estimated in Los Realejos. Between 2006 and 2007 some control measures were carried out on this population (Santos 2015). The control action, commissioned by the Cabildo de Tenerife, succeeded in reducing the initial population from 15 individuals (using air rifles mostly but with one bird trapped in a trap with a female decoy – mist netting proved ineffective) to just three. It is thought that this nucleus has disappeared now.

The red-whiskered bulbul established in **Japan** (Hyogo, Tottori, and Kanagawa prefectures (National Institute for Environmental Studies 2017)) (Eguchi and Amano 2004a, b). The species is reported being scarce (i.e. between 100-10.000 breeding pairs) in Japan.

The red-whiskered bulbul has been reported from **South Africa** and **Zimbabwe** but is not currently considered established anywhere on continental Africa (Hart 2020).

The species has been introduced to several Indian Ocean islands: Mauritius, Reunion (France), Mayotte (Comoros), Juan de Nova (France) and Assumption (Seychelles). It has been a very successful invader on Mauritius and Réunion. On the **Mascarene Islands**, expansion appeared to be fast. Bulbuls were introduced in 1892 to northern Mauritius (Carié 1910), and 18 years later were abundant throughout the 1865 km<sup>2</sup> island (Clergeau and Mandon-Dalger 2001). Since then the red-whiskered bulbul became one of the most abundant birds on the island. On Assumption island (Seychelles) it was introduced in the 1970s and reached a population of over a thousand birds, but was recently successfully eradicated. Soon after the start of the Assumption eradication campaign, in early 2012, birds also invaded the neighbouring Aldabra Atoll (Bunbury et al. 2019). Both islands are however considered bulbul free again. Cruz and Reynolds (2019) and Bunbury et al. (2019) report 5279 red-whiskered bulbuls removed by 2014 from Assumption and a single bird from Aldabra. A combination of mist-netting and shooting was used to target the bulbuls over a 3-year period starting 2011-2012.

In **Réunion** it was introduced in 1972 (Barau 1978) and is now widely distributed in almost all parts of the 2515 km<sup>2</sup> island, occupying areas of native forest. In Nicobar, the species was introduced at the end of the 19th century on the island of Camorta, and was later introduced to other islands such as Nancowry, Trinkat, Katchall, Teressa and Car Nicobar (Mo 2015, Lever 2005).

In **Australia** there are four established populations on the east coast and the populations in Queensland and New South Wales are expanding (Department of Primary Industries and Regional Development 2018). These are all located in temperate climate zones of Australia. Interestingly, despite abundance in suburbia and colonisation of semi-rural districts (especially orchards), the red-whiskered bulbul also expanded its range further north and seemed not limited by low fruit abundance (Mo 2015). Peri-urban populations might act as bridgehead for invasion into other areas. In Sydney the species was introduced in the late 19th century. The red-whiskered bulbul became common and widespread in the suburban areas of Sydney in the 1920s with flocks of up to 100 birds (MacPherson 1921, 1923) and now occupies a large area, occurring particularly in peri-urban areas (Mo 2015). The species was introduced to Melbourne (Victoria) as early as the beginning of the 19th century, and to Coffs Harbour (New South Wales) and Mackay (Queensland) in the 1970s-80s. There are also records of introductions and breeding in other parts of the country (Mo 2015).

The species was introduced to the **United States** during the 1960s in the states of Florida and California. In Florida, the population could number several thousands of birds. Carleton and Owre (1975) provide a detailed account of the invasion history of the species in the United States. Red-whiskered bulbuls were first detected in Miami in 1960, when a few birds escaped while being transferred from one aviary to another; these birds were shipped to Miami from Calcutta, India. By fall 1961 they had spread about 56 km southwest of Miami and the first proof of reproduction was reported. In 1963, a flock of 23 birds was seen in Kendall, which increased to between 40 and 50 by 1964 (Banks and Laybourne 1968). During that first decade, Carleton (1971) estimated an annual increase of 30-40% in the total population. By winter of 1969-1970, total population was estimated at <250, and it was hypothesized that between 5 and 10 breeding pairs were the founders of this population, which occupied 8.2 km<sup>2</sup> of suburban Kendall (Carleton and Owre 1975). By 1973, the population had doubled to about 500 and continued to increase and expand in a southerly direction (Lever 1987). In California, where the species maintains only two small populations, red-whiskered bulbuls became established around 1968 from aviary escapees in Los Angeles at the Los Angeles Arboretum and Huntington Gardens. These birds were either deliberately or accidentally released (Hardy 1973, Lever 1987). Because this population increased substantially and became a threat to the

local citrus crop, the California Department of Agriculture initiated an eradication program that has been only partially successful (Long 1981).

In **Hawaii**, the red-whiskered bulbul was introduced to the island of Oahu in the 1960s and is now established in the southeast of the island, mainly in urban areas, favoured by the cultivation of exotic fruit trees such as papaya. In contrast to the Californian population population which grew in number but appears to remain limited in distribution, populations on Hawaii have undergone growth and range expansion, although the red-whiskered bulbul has shown a less dramatic increase in numbers and range than the red-vented bulbul (Islam and Williams 2000).

**A6. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species been recorded and where is it established? The information needs be given separately for recorded (including casual or transient occurrences) and established occurrences. “Established” means the process of an alien species successfully producing viable offspring with the likelihood of continued survival<sup>2</sup>.**

**A6a. Recorded: List regions**

**A6b. Established: List regions**

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

- Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea.

Comment on the sources of information on which the response is based and discuss any uncertainty in the response.

For delimitation of EU biogeographical regions please refer to <https://www.eea.europa.eu/data-and-maps/figures/biogeographical-regions-in-europe-2> (see also Annex VI).

For delimitation of EU marine regions and subregions consider the Marine Strategy Framework Directive areas; please refer to <https://www.eea.europa.eu/data-and-maps/data/msfd-regions-and-subregions/technical-document/pdf> (see also Annex VI).

Response (6a - recorded): Mediterranean, Atlantic, Continental

The red-whiskered bulbul was recorded in the Mediterranean, Atlantic and Continental biogeographic regions with proof of these being escaped birds. Presumably a similar situation might occur in all of the other biogeographic regions.

---

<sup>2</sup> Convention on Biological Diversity, Decision VI/23

Response (6b - established): Mediterranean

The red-whiskered bulbul is known to be established in Spain in a river valley around Valencia in the Mediterranean biogeographic region where a breeding population of 100-150 birds exists (see A8 for more detail).

**A7. In which biogeographic region(s) or marine subregion(s) in the risk assessment area could the species establish in the future under current climate and under foreseeable climate change? The information needs be given separately for current climate and under foreseeable climate change conditions.**

**A7a. Current climate: List regions**

**A7b. Future climate: List regions**

With regard to EU biogeographic and marine (sub)regions, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

Response (7a – current climate):

The species distribution model (Annex VIII) indicates suitable areas in the Mediterranean, Atlantic, Black Sea (and Anatolian) biogeographic regions under current climate. In the Mediterranean, the model predicts about 48% (26%-29%) of the surface area as suitable for establishment. For the Atlantic 9% (2%-50%) and for the Black Sea 8% (0%-26%) of the biogeographic region is predicted suitable under current climate. The Pannonian, Steppic, Continental, Alpine and Boreal biogeographic regions are not predicted to be at risk under current climate.

The ensemble model suggested that the climatic and environmental suitability for red-whiskered bulbul was most strongly determined by Annual mean temperature (Bio1), accounting for 41% of the variation explained, followed by Minimum temperature of the coldest month (Bio6) (21%), and Precipitation of the wettest month (Bio13) (9%). Annual precipitation (Bio12) and Climatic moisture index (CMI) all account for 7% of the variation, Mean temperature of the warmest quarter (Bio10) for 6%. The other variables included in the model had less explanatory power. Human influence index (HII) accounts for 5%; Precipitation of the driest month (Bio14) for 4% and Global tree cover (Tree) only explained about 1%. For more details, see Annex VIII.

Compared to the range of the red-vented bulbul *P. cafer*, the native distribution area of the red-whiskered bulbul is more extensive, especially across southeast Asia, and spans a bigger range of climate types including tropical, arid and temperate climate zones.

Response (7b – future climate):

Under future climate, the modeled suitability for establishment is predicted to increase in the Mediterranean biogeographic region from 48% (26%-69%) to 63% (39%-80%) and 67% (44%-85%) under RCP 2.6 and RCP 4.5 respectively by 2070. Note that there is considerable uncertainty on the predictions and potentially under climate change the suitable region in the Mediterranean could go up to 85% by 2070. In the Black Sea biogeographic region the proportion suitable increases from 8% (0%-26%) to 25% (4%-45%) and 32% (12%-55%) under both future emission scenarios with an upper limit of 55% of the region becoming suitable by 2070. In the Atlantic biogeographic region, where regular escaped birds are reported, the proportion of grid cells classified as suitable for establishment increases from 9% (5%-50%) to 20% (4%-78%) under RCP 2.6 and 25% (6%-85%) under RCP 4.5 by 2070. Also, here, there is considerable uncertainty on the predictions with a central estimate of 25%, but an upper range of 85% of the Atlantic biogeographic region becoming suitable by 2070. As for the other regions that were predicted unsuitable under current climate, only the Continental and Pannonian biogeographic regions are predicted to become suitable considering an upper estimate of 13% and 41% becoming suitable under RCP 4.5 by 2070, respectively (Annex VIII).

**A8. In which EU Member States has the species been recorded and in which EU Member States has it established? List them with an indication of the timeline of observations. The information needs be given separately for recorded and established occurrences.**

**A8a. Recorded: List Member States**

**A8b. Established: List Member States**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden.

The description of the invasion history of the species shall include information on countries invaded and an indication of the timeline of the first observations, establishment and spread.

Response (8a - recorded):

The red-whiskered bulbul has been observed in several EU Member States that have well established birding communities. In **Germany**, a singing male was reported in July 1994 in the area of Lake Constance (Heine et al. 1999); a further two observations have been reported, a calling adult in Wedel along the Elbe near Hamburg in 2012 (D. Eichstedt, naturgucker.de) and in 2019 an adult male reported as a probable escape from Heidelberg Zoo (C. Stepf, naturgucker.de). In **Belgium**, there are several observations of individual birds since 1994 in at least nine locations, including an observation with photo in 2019 in Namur province (I. Volont, waarnemingen.be), with a maximum number of two birds seen together in an apple tree in Broechem (Antwerp) and Ukkel (resp. D. van Tulder and A. De

Broyer, waarnemingen.be). Sometimes birds hang around for some time, such as the bird in Uccle that was present from February 1998 until December 1999 and was often heard singing (A. De Broyer, waarnemingen.be). In **The Netherlands**, observations of at least 11 birds were reported through the online recording system waarneming.nl since 1990 across the country, mostly in (sub)urban areas, suggesting captive origin. Most of these birds were present for at least a few weeks and observed by several people. At least one bird survived the winter of 2005-2006 (B. van herk, waarneming.nl).

Additionally, the species has been observed in **Denmark**, the **United Kingdom** and **Switzerland** (Santos et al. 2007). In **Portugal**, an individual was recorded in Cascais in 2007 (T. Martins).

Outside the core population around Valencia, in **Spain**, isolated birds have also been reported in the province of Alicante and in Catalonia. In the province of Alicante, a bird was detected in 2003 in the town of Albir, in Altea. In 1993 a single bird was observed at the mouth of the river Tordera, between the provinces of Barcelona and Girona (Grupo de Aves Exóticas, unpublished). In 2008 a verified sighting was performed in a suburban area in the outskirts of Benidorm bordering the natural parc Serra Gelada (obs. Mathieu Woldhuis, observation.org), about 100 km south of the established population in the Turia river basin, and again in the same neighbourhood, in 2014, two escaped birds were reported (obs. R. Effern, observation.org).

In **Italy**, Andreotti et al. (2001) listed the species as a Category 4 species i.e. the red-whiskered bulbul has been recorded breeding in Italy but is not listed as a regular breeding bird in the country. This status is based on Brichetti and Massa (1998). There are however no recent sightings of the species on the recording platform ornitho.it. The species is not in the updated Italian bird checklist (Baccetti et al. 2020) and there are no recent sightings (personal communication E. Caprio, May 2021; A. Andreotti and L. Serra, June 2021).

Response (8b - established):

The red-whiskered bulbul is known to be established in **Spain** with one breeding population in a river valley near the city of Valencia, centred around the town of Paterna, where the species was originally introduced. Here, it occupies suburban habitats, generally residential areas with an abundance of parks and gardens. It is always found in the vicinity of a river valley, in its lower part, which it uses to disperse and expand its range. The red-whiskered bulbul established here shortly after the first observation of two birds in 2003 in the town of La Canyada (Paterna), in the lower Rio Turia basin area (Santos 2015; Polo-Aparisi and Polo-Aparisi 2021). Detailed impact studies or recent (post 2016) population estimates for Spain are lacking. The introduction of the species is probably due to the accidental escape or deliberate release from captivity. According to Santos (2015), the species is able to withstand natural population fluctuations, and its population is expanding.

In 2005 a group of twelve birds was observed in the rio Turia area, indicating breeding success of this core population. This was later confirmed by the presence of juveniles (Grupo de Aves Exóticas 2007). The red-whiskered bulbul then began to expand and progressively colonised other municipalities (Santos 2015). Heading west, the species was observed for the first time in San Antonio de Benagéber in 2004, in L'Elia in 2006, in Riba-roja de Túria in 2011, in Bétera in 2013 and in La Pobla de Vallbona in 2014. In an easterly direction, it was observed for the first time in Burjassot in 2012, in Mislata in 2013 and in Valencia in 2014. Currently red-whiskered bulbul can be found in La Cañada, La Vallesa and El Plantío (Paterna), Colinas de Sant Antoni (San Antonio de Benagéber), Entrepins, Los Almendros, Montesol y Mas del Carmen (L'Elia), Mas de Traver (Riba-roja de

Túria), Montesano (Bétera), Montecolorado and Vista Calderona (La Pobla de Vallbona), el Park of La Granja (Burjassot), the Military Hospital and the Park of La Canaleta (Mislata), and the Parque de Cabecera and the Botanical Gardens (Valencia). Despite this expansion, more numerous groups of birds, to a maximum of twelve birds, have only been recorded in the municipalities of Paterna, San Antonio de Benagéber and L'Eliana. Observations in other municipalities tend to correspond to solitary or paired individuals. It is very likely, however that in the future the species will continue to expand and colonise other localities along the Turia valley (Santos 2015). The recent breeding bird atlas of Valencia province (with data until 2016) describes the expansion in the Turia area from the first records in Paterna in 2003. Currently (up till 2016), during the breeding period the species was observed in six 5km<sup>2</sup> squares (UTM grid), during winter in seven 5km<sup>2</sup> squares, never in groups of more than 12 birds flocking together (Polo-Aparisi and Polo-Aparisi 2021). Its current distribution mostly involves (sub)urban areas where the birds nest and feed in private gardens and public green areas. The red-whiskered bulbul feeds here on a wide array of fruits and other plant resources, both exotic and native plant species (see also Qu. 4.3). It also consumes invertebrates. The breeding population has been estimated at 58 (range 26-130) breeding pairs and a wintering population of 258 (137-465) individuals. Polo-Aparisi and Polo-Aparisi (2021) state that the species will probably increase its range and population in the forthcoming years.

In Valencia city, the first records were made in 2013. Since then, the red-whiskered bulbul has been appearing regularly but never abundantly. Monthly surveys in Valencia city parks showed yearly records of maximum 8 birds (unpublished data E. Murgui). A small breeding population is now confined to a few urban parks in the west of the city (Parc de Benicalap, Parc de Polífil, Parc de Capçalera) which are relatively close to the river Turia that probably acts as a dispersal corridor. Currently, the population here is small (2-3 breeding pairs) and is not perceived as a threat (Murgui, in press). The birds were observed capturing invertebrates and consuming fruits of *Cotoneaster* spp., mastic *Pistacia lentiscus* and pomegranate *Punica granatum* (Murgui, in press).

Outside the Valencia area, there are several documented observations of red-whiskered bulbul elsewhere in Spain (see A8a).

**A9. In which EU Member States could the species establish in the future under current climate and under foreseeable climate change? The information needs be given separately for current climate and under foreseeable climate change conditions.**

**A9a. Current climate: List Member States**

**A9b. Future climate: List Member States**

With regard to EU Member States, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate

change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

(9a) Under current climate, suitable area for establishment of the red-vented bulbul is estimated to be present in Mediterranean Member States including Spain (35% (16%-53%) of the grid cells in the country predicted suitable), Portugal (96%, 86%-100%), Cyprus (100%, 75%-100%), Greece (49%, 29%-73%) and Italy (39%, 19%-65%). Suitable area is also predicted to a lesser extent in Ireland (20%), Croatia (13%) and France (10%) (Annex VIII). There is uncertainty on the predicted suitability under current climate in southwest Iberia, the eastern Mediterranean and the west coast of Ireland. Particularly in Iberia, some areas in southwest Iberia (Andalucia, Extremadura and nearby regions of Portugal) which have a mesomediterranean climate with hot, dry summers and cold, rainy winters, and some in northwest Iberia with colder climates (e.g. Galicia) seem less suitable to the red-whiskered bulbul (personal communication E. Murgui, September 2021) The presence of suitable area on Malta is likely, as similar conditions are present as in other Mediterranean Member States, but Malta was excluded from the distribution model because the Human Influence Index lacks coverage for the country.

(9b) Under foreseeable climate change conditions, by 2070, Portugal and Cyprus are still predicted 100% suitable for the establishment of the red-whiskered bulbul. In Greece and Italy the proportion suitable area for establishment is predicted to increase under RCP 2.6 and to almost double under RCP 4.5 to about 75%. In Spain, 44% and 47% of the area would be suitable under RCP 2.6 and RCP 4.5 respectively (but potentially going up to 75% of the territory under RCP 4.5), in Croatia 25%. In France, the suitable area for establishment would increase from 10% to 22% and 29% under RCP 2.6 and RCP 4.5 respectively. In Ireland these proportions could go up to 63% and 67% under RCP 2.6 and RCP 4.5 respectively yet with considerable uncertainty on the predictions (0%-100%). Also, under climate change, additional Member States suitable for establishment include Slovenia, Bulgaria and the United Kingdom (Annex VIII). There is some uncertainty on the predicted suitability under foreseeable climate change in southwest Iberia, the eastern Mediterranean and the west coast of Ireland (see also 9a).

**A10. Is the organism known to be invasive (i.e. to threaten or adversely impact upon biodiversity and related ecosystem services) anywhere outside the risk assessment area?**

The red-whiskered bulbul is known to be invasive on the Seychelles, Mauritius and on Hawaii. Environmental impacts are documented through the dispersal of seeds of invasive plants, interspecific competition with native birds and predation on reptiles, insects, spiders and other invertebrates (Hawaii Invasive Species Council 2017; Cottrell 2017). It is also a pest of agriculture and gardens, feeding on fruits, vegetables, flower buds and insects.

On the Nicobar Islands, competition by red-whiskered bulbul has been implicated in the decline of the endemic Nicobar bulbul *Ixos nicobariensis* together with habitat loss and (Sankaran 1998; BirdLife International 2021a). In Australia, the species may be aggressive to other bird species, either defensively (Wood 1999) or in competition for resources. Agonistic responses toward flocks of silvereye *Zosterops lateralis* and rosellas *Platycercus* spp. feeding on camphor laurel *Cinnamomum camphora* fruits in Sydney have been reported (MacPherson 1921, 1923). In Hawaii, red-whiskered bulbul chases native birds, competing with them for food and space (Hawaii Invasive Species Council 2017). In Mauritius, where the species was introduced in the late 1800s and became the most abundant bird species, the red-whiskered bulbul contributed to population declines of native white-eyes (*Zosterops*) and the endemic Mauritius bulbul *Hypsipetes olivaceus* through resource competition (Linnebjerg et al. 2010). Islam and Williams (2000) report that populations of geckos are severely depressed on Mauritius probably because of predation by bulbuls on young geckos. It also represents a threat to native invertebrates, and caused the disappearance of orb-web spiders (*Nephila inaurata*) by predation (Islam and Williams 2000). It facilitated the spread of invasive plant species such as *Ligustrum robustum*, *Lantana camara* and *Cordia interrupta*, which, prior to the introduction of the red-whiskered bulbul, were quiescent sleeper weeds (Linnebjerg et al. 2009, 2010). Linnebjerg et al. (2010) in an analysis of faecal pellets found the diet to consist primarily of fleshy fruits with seeds of ten plant species being present in 92% of all faecal pellets six of which were notorious invasive plant species on Mauritius (*Clidemia hirta*, *Ligustrum robustum*, *Litsea glutinosa*, *Psidium cattleianum*, *Rubus alceifolius* and *R. rosifolius*). Gut passage of seeds by the red-whiskered bulbul improved the germination success of the invasive plants *Clidemia hirta* (Linnebjerg et al. 2009), and *Schinus terebinthifolius* (Mandon-Dalger et al. 2004), on Mauritius and Réunion, respectively. In Hawaii, the red-whiskered bulbul spreads the seeds of invasive plants such as *Miconia calvescens*, ivy (*Hedera*), gourd and false kava (*Piper auritum*). Mo (2015) also identified the spread of exotic weeds as the main impact. In Florida, the red-whiskered bulbul's diet overlaps with the northern mockingbird *Mimus polyglottos* resulting in competition for mango, christmasberry, fig (*Ficus* spp.), day hessamine, lantana (*Lantana* spp.) and jasmine, especially during winter when insects are scarce (*Jasminum* spp.) (Carleton 1971; Gore and Doubilet 1976).

**A11. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea

No information was found on invasiveness of the established population of red-whiskered bulbul in the Mediterranean biogeographic region within the risk assessment area (Valencia, Spain).

**A12. In which EU Member States has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden.

The red-whiskered bulbul is established in one area in Spain (see A8b) and no information was found on its invasiveness there.

**A13. Describe any known socio-economic benefits of the organism.**

including the following elements:

- Description of known uses for the species, including a list and description of known uses in the risk assessment area and third countries, if relevant.
- Description of social and economic benefits deriving from those uses, including a description of the environmental, social and economic relevance of each of those uses and an indication of associated beneficiaries, quantitatively and/or qualitatively depending on what information is available.

If the information available is not sufficient to provide a description of those benefits for the entire risk assessment area, qualitative data or different case studies from across the risk assessment area or third countries shall be used, if available.

The red-whiskered bulbul is widely kept as a cage bird both in private collections and in zoos, and therefore represents economic, ornamental, sentimental, educational and aesthetic value as a pet, zoo animal and companion animal. Prices advertised by online shops range from 300-350 US\$ per bird (<https://www.softbillsforsale.com/sale/red-whiskered-bulbul.asp>). In their native range, red-whiskered bulbuls are also commonly bought and released for religious ceremonial purposes (prayer release i.e. religious practice in which captive wildlife are released as a demonstration of compassion and kindness in order to receive merit or good karma (Severinghaus and Chi 1999)) although no data could be found on the extent of this practice within the risk assessment area. Also, in the native range, red-whiskered bulbuls are used in bird singing competitions (Techachoochert and Round 2013). Mo (2015) mentions the species is appreciated as a predator of some invertebrate pests but without further details on species or regions.

## SECTION B – Detailed assessment

### Important instructions:

- In the case of lack of information the assessors are requested to use a standardized answer: “No information has been found.” In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable).
- With regard to the scoring of the likelihood of events or the magnitude of impacts see Annexes I and II.
- With regard to the confidence levels, see Annex III.
- Highlight the selected response score and confidence level in **bold** but keep the other scores in normal text (so that the selected score is evident in the final document).

## 1 PROBABILITY OF INTRODUCTION AND ENTRY

### Important instructions:

- **Introduction** is the movement of the species into the risk assessment area (it may be either in captive conditions and/or in the environment, depending on the relevant pathways).
- **Entry** is the release/escape/arrival in the environment, i.e. occurrence in the wild
- Introduction and entry may coincide for species entering through pathways such as “corridor” or “unaided”, but it also may differ. If different, please consider all relevant pathways, both for the introduction into the risk assessment area and the entry in the environment.
- The classification of pathways developed by the Convention of Biological Diversity (CBD) should be used (see Annex IV). For detailed explanations of the CBD pathway classification scheme consult the IUCN/CEH guidance document<sup>3</sup> and the provided key to pathways<sup>4</sup>.
- For organisms which are already present (recorded or established) in the risk assessment area, the likelihood of introduction and entry should be scored as “very likely” by default.
- Repeated (independent) introductions and entries at separate locations in the risk assessment area should be considered here (see Qu. 1.7).

**Qu. 1.1. List relevant pathways through which the organism could be introduced into the risk assessment area and/or enter into the environment. Where possible give details about the specific origins and end points of the pathways as well as a description of any associated commodities.**

For each pathway answer questions 1.2 to 1.8 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 1.2a, 1.3a, etc. and then 1.2b, 1.3b etc. for the next pathway.

In this context a pathway is the route or mechanism of introduction and/or entry of the species.

The description of commodities with which the introduction of the species is generally associated shall include a list and description of commodities with an indication of associated risks (e.g. the

<sup>3</sup> <https://circabc.europa.eu/sd/a/7e5f0bd4-34e8-4719-a2f7-c0cd7ec6a86e/2020-CBD-pathways-interpretation.pdf>

<sup>4</sup> <https://circabc.europa.eu/sd/a/0aeba7f1-c8c2-45a1-9ba3-bcb91a9f039d/TSSR-2016-010%20CBD%20pathways%20key%20full%20only.pdf>

volume of trade; the likelihood of a commodity being contaminated or acting as vector).

If there are no active pathways or potential future pathways this should be stated explicitly here, and there is no need to answer the questions 1.2-1.9.

Pathway names:

- a. ESCAPE from confinement: Pet/aquarium/terrarium species (including live food for such species)
- b. ESCAPE from confinement: Botanical garden/zoo/aquaria (excluding domestic aquaria)
- c. RELEASE in nature: Other intentional release

Specifically, these pathways refer to (a.) pet escapes, (b.) escapes from zoos, and (c.) releases for religious purposes respectively.

For the congeneric species *P. cafer*, sightings of birds along coastlines of islands have led to the suggestion of hitchhikers on boats contributing to new introductions (Islam and Williams 2000). No such suggestions were made for the red-whiskered bulbul, so the pathway “TRANSPORT – stowaway: hitchhikers on ship/boat (excluding ballast water and hull fouling)” is not considered active in the Risk assessment area and is not dealt with here.

### **ESCAPE from confinement: Pet/aquarium/terrarium species (including live food for such species)**

**Qu. 1.2a. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)? --**

<b>RESPONSE</b>	<b>intentional</b> unintentional	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Red-whiskered bulbuls are intentionally introduced in the risk assessment area for the pet trade. Also their release is intentional. The escape of animals kept as pets, by itself, qualifies as unintentional.

**Qu. 1.3a. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.

- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

The red-whiskered bulbul is among the most popular bulbul species to be held as cagebirds by hobbyists. Wild caught bird trade (as opposed to captive bred) has been suspended in the EU since 2005, when a temporary ban on wild bird imports was installed to prevent the spread of avian influenza (Reino et al., 2017). The ban was made permanent in 2007 and considers all wild caught bird imports regardless of species' conservation status. This ban has been effective in reducing propagule pressure (Cardador et al., 2019). Given the European wild bird trade ban, the legal circuit of captive the red-whiskered bulbuls exclusively consists of animals bred and raised in confinement, which are known to have lower invasive potential than wild-caught birds due to changes in behavioral and physiological traits which lower their chances of successful establishment (Cabezas et al., 2013; Carrete and Tella 2015). Red-whiskered bulbuls are usually kept in pairs, not as solitary birds, nor in groups. The species is easily found on hobbyist websites for exchange (individuals for sale, or requested), with prices generally around 80-120 € per bird and 180 € to 400 € per pair (e.g. <https://www.softbillsforsale.com/sale/red-whiskered-bulbul.asp>, <https://www.prachtfinkenfreunde.de/>).

However, there are no official figures on the size of the captive population or trade volumes in the risk assessment area. There are also no formal figures on their risk of escaping, although of the 11 bird families considered, alien Pycnonotidae were found to be among the families with a significantly higher probability of escaping captivity than the overall escape rate in Taiwan (Shieh et al. 2006). Similar figures for Europe are lacking. Since the animals are usually kept in pairs, there is a fairly high chance of reproduction if the environment proves suitable.

Despite a lack in figures, outside the risk assessment area entry events of the red-whiskered bulbul are commonly attributed to escape or unauthorised release of privately owned cagebirds (Hardy 1973; Islam and Williams 2000; Eguchi and Amano 2004a,b; Clergeau and Mandon-Dalger 2001; Mo 2015; Cruz and Reynolds 2019). The same is true for the suspected origin of birds observed within the risk assessment area (Santos 2015; see Qu. A8. for an overview of observations).

**Qu. 1.4a. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Birds kept as pets are usually taken care of, with animal welfare and reproduction being of interest to the owner. There are specialist groups of hobbyists that specialize in the keeping of bulbuls. For example, in the Netherlands, the species is kept and bred by members of a bird breeders association specialized in insect and fruit-eating species who adopted a code of best practice for keeping red-vented bulbuls (NBvB 2014). It is known as a species which likes spacious aviaries with appropriate planting and it is mentioned that they are winter hardy. Also, they are known to be sociable birds which like the company of conspecifics or other tropical birds (NBvB 2014). We scored the likelihood and confidence lower in comparison with Qu. 1.4b (holdings in zoos), since holding conditions under private ownership are much more varied.

**Qu. 1.5a. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

There are no known management practices for birds kept as pets. Control mechanisms should however be in place to ensure the adherence to legislation on animal welfare. In case of an infringement, authorities may decide to seize birds, for them to be re-homed or euthanised (both are considered moderately likely). There is however also the possibility of birds being illegally traded, for example on online platforms, with little or no control.

**Qu. 1.6a. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: If the red-whiskered bulbul would escape from a privately owned cage or aviary, it is unlikely that this would go unnoticed as private owners are well aware of the number of birds they possess. Yet, in comparison with Qu. 1.6b (holdings in zoos), its likelihood is scored higher (moderately likely), and the confidence lower, since less control mechanisms are in place to ascertain discovery. It is also questionable if pet owners will (or can) take the necessary efforts to retrieve birds following an escape.

**Qu. 1.7a. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

See Qu. 1.3c. As the red-whiskered bulbul is considered a fairly popular cagebird, it can be assumed that private holdings are widespread in the risk assessment area. Formal numbers are lacking but there is good observational evidence of regular and widespread escapes within the risk assessment area (see Qu. A8), hence the confidence on this response is medium.

**Qu. 1.8a. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Worldwide, the entry of the red-whiskered bulbul into the environment is commonly attributed to escape (or unauthorised release) of cagebirds. The many observations of individual escaped birds illustrate this happens quite frequently across the risk assessment area (see A8a). As this is also the suggested pathway that led to the established population in Spain (Santos 2015), the likelihood is considered very likely (in accordance with the instructions). Because there is direct observational evidence of escapes across the risk assessment area we scored high confidence.

*End of pathway assessment, repeat Qu. 1.2 to 1.8 as necessary using separate identifier.*

**ESCAPE from confinement: Botanical garden/zoo/aquaria (excluding domestic aquaria)**

**Qu. 1.2b. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	intentional unintentional	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	------------------------------	-------------------	------------------------------

Red-whiskered bulbuls are intentionally introduced in the risk assessment area to be put on display in zoos. s

**Qu. 1.3b. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

It is difficult to assess the exact extent to which the red-whiskered bulbul is kept in zoological collections within the risk assessment area. Information provided by the database *zootierliste.de* (accessed 17 May 2021) shows that the species is present (or was recently present, considering some lag in website updates) in a considerable number of collections. In total, 67 holdings of red-whiskered bulbul (incl. *P. jocosus jocosus*) are mentioned, in Belgium (1), Denmark (4), Germany (30), France (3), Greece (1), the Netherlands (9), Austria (1), Poland (2), Slovakia (1), Spain (2, one of which is on Tenerife), Czechia (4), Hungary (1), and the United Kingdom (8). No information is available on the number of birds kept in other, non-EAZA (cf. <https://www.eaza.net/>) associated or private zoos, nor on trends in the captive population. By comparison, the red-vented bulbul, an aesthetically less

attractive species, is on display in a much lower (<10) number of EAZA zoos in the risk assessment area (*zootierliste.de*). There are examples of historic escapes from a collection where the red-whiskered bulbul was on display, for example in Miami where birds escaped from the Miami Rare Bird Farm, a working breeding farm as well as tourist attraction, in 1960 (Owre 1973; Kenward 2009). Nowadays, zoological collections on public display are set within tight legal frameworks (Council Directive 1999/22/EC of 29 March 1999 on the keeping of wild animals in zoos), with the risk of escape being of prime importance. Nonetheless, the risk of escapes can never be fully excluded as illustrated by the suspected escape from a German zoo in 2019 (see Qu. A8). As that risk is generally well-monitored by holding owners and public authorities, the likelihood for entry in the environment through escape from such collections can be considered unlikely, at least for EAZA associated zoos which are usually characterized by very high standards. The risk may however be higher for other facilities, like private backyards or illegal holdings (Cassey and Hogg 2015) and it is known that not all facilities are associated to EAZA.

**Qu. 1.4b. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

When birds are put on display in living collections, care is taken by holding owners to keep birds in good condition both during transport and storage. Holding would typically also include a possibility for reproduction as zoo keepers would actively encourage breeding to maintain a captive population for display.

**Qu. 1.5b. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Management practices of birds in zoological collections are likely to increase the prospects of survival. Control mechanisms should be in place to ensure the adherence to legislation on animal display and welfare.

**Qu. 1.6b. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

If the red-whiskered bulbul would escape from zoological collections, it is unlikely that this would go unnoticed. Although some time lag between the actual escape and its discovery may exist, the species is conspicuous, easy to identify, and the coverage by birdwatchers is fairly good so the species is unlikely to be unnoticed for a very long time. Also, zoos are likely to have to report on escapes (more than private people keeping birds as pets) (Council Directive 1999/22/EC of 29 March 1999 on the keeping of wild animals in zoos) and are known to sometimes initiate recapture efforts in case of accidental escapes. Such mechanisms might however not be adhered to by a lot of the non-official zoos that might not be up standard with the housing of birds. It is noteworthy that birds have a lower retrieval rate than escaped mammals and reptiles in such cases (Cassey and Hogg 2015).

**Qu. 1.7b. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

See Qu. 1.3b. There is a considerable geographic spread of zoological facilities within the risk assessment area.

**Qu. 1.8b. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Documented escapes of red-whiskered bulbul from zoological collections (on display to the wider public, as opposed to the next pathway) are scarce but do exist (e.g. in Germany, California, Florida, see A5, A8a). There are also numerous examples of other bird species escaping such facilities. For example, after storm damage in Planckendael zoo (Belgium) in february 2020, after which however most of the 45 escaped birds could be retrieved (this could be more difficult with small passerine birds like bulbuls). The risk of escape from zoological collections with high housing standards can be considered small. There are however many other types of facilities across the RA area with relatively poor standards. Also, Cassey and Hogg (2015) showed that compared to mammals and reptiles, bird escapes were significantly less likely to be retrieved, and more likely to remain undetected. Considering that both official and non-official holdings are relatively widespread (and considering that observations of escapes were regularly reported since 1990 (see A8a), even if they cannot unequivocally be attributed to escapes from zoos), the overall risk of at least one entry event happening within the risk assessment area within the next 10 years was scored likely, with medium confidence because there is direct observational evidence.

### **RELEASE in nature: Other intentional release (i.e. prayer release)**

**Qu. 1.2c. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	<b>intentional</b> unintentional	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

By definition, prayer release is intentionally performed in the belief that one can accrue merits by freeing captive animals into the wild (Severinghaus and Chi 1999). The importance of such releases as a pathway of introduction was stressed for a variety of taxa but especially for birds including bulbuls (Gilbert et al. 2012; Magellan 2019).

**Qu. 1.3c. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent

establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

The ritual of animal release is regularly performed in Buddhist practice (Shiu and Stokes 2008). It is thus most prevalent in Asia, where the practice may to a limited extent also be performed by people that adhere to other religions. The species may be local or exotic, and bred or wild-caught. For Taiwan, *Pycnonotus sinensis* is known to be used in prayer release (Severinghaus and Chi 1999), and given that the red-whiskered bulbul is sold in shops (Su et al. 2014; 2016), it probably is too.

There is proof that prayer release is also performed by Buddhist groups in Western countries, with the local frequencies of release being as high as once per month (United States, Campbell et al. 2021; Canada and Australia, Shiu and Stokes 2008). However, the species pool used is very diverse (including invertebrates and fishes), with awareness on the environmental concerns and legal restrictions having grown considerably (Shiu and Stokes 2008).

No data could be found on the extent of prayer release within the risk assessment area, but given the above, the overall volume of entry is probably limited. In contrast to Asia, there are no supply chains dedicated to the practice. Therefore, for the red-whiskered bulbul in particular, entry into the European environment through this pathway is deemed unlikely, overall.

**Qu. 1.4c. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

As prayer release is centered around the respect for lives of beings, care is taken by practitioners to keep captive birds alive and in good condition until the moment of release. The same would be expected from actors earlier in the supply chain (breeders, sellers), since the birds would be of commercial interest to them.

**Qu. 1.5c. How likely is the organism to survive existing management practices before and**

**during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

There are no known management practices for birds subject to prayer release, maybe except for law enforcement measures on intended (illegal) release, in which case seized birds may become re-homed or euthanised depending on the authorities (both are considered moderately likely).

**Qu. 1.6c. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

See Qu. 1.2a. As prayer release is intentional by definition, neither introduction nor entry would happen undetected, except for the theoretical scenario in which birds escape the cage environment prior to release.

**Qu. 1.7c. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated widespread ubiquitous	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--------------------------------------	-------------------	------------------------------

There is no information on religious groups, notably Buddhist groups, in the risk assessment area that perform prayer release, let alone release involving the red-whiskered bulbul. Given that this religion is less prevalent, and given legal constraints, environmental awareness and the lack of supply chains dedicated to this purpose, the possible points of introduction for this pathway would anyhow be (very) limited in number in the risk assessment area.

**Qu. 1.8c. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

In Eastern Asia, prayer release of *P. jocusus* poses a real risk (Severinghaus and Chi 1999; Su et al. 2014; Campbell et al. 2021). Although prayer release is known to have occurred in Western countries outside Europe, and may thus occur in the risk assessment area too, the likelihood for it involving this species is however deemed very small. For it to happen, the pathway would need to coincidentally bring together planned releases with the trade in red-whiskered bulbul.

**Qu. 1.9. Estimate the overall likelihood of introduction into the risk assessment area or entry into the environment based on all pathways and specify if different in relevant biogeographical regions in current conditions.**

Provide a thorough assessment of the risk of introduction in relevant biogeographical regions in current conditions: providing insight in to the risk of introduction into the risk assessment area.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Introduction into the risk assessment area has occurred (since the species is kept in zoos and as a pet bird), and the same is true for entry into the environment (given that the species is recorded in multiple countries, and locally established). The escape of pet birds from confinement is considered to be the prime pathway, in line with the species' invasion history outside of the risk assessment area. Further escapes or unauthorised releases are very likely to occur in the future, but the expected frequency is unclear. The contribution of prayer release is considered negligible, in contrast to the situation in Eastern Asia.

There is no evident geographical variation in holdings of red-whiskered bulbul (in zoos or as pets) throughout the risk assessment area. In terms of introduction and entry, we therefore consider all biogeographical regions to be equally prone. From the information available, it can be assumed that there are more red-whiskered bulbuls in zoos and collections than red-vented bulbuls. We scored very

likely with high confidence because the interpretation of information is straightforward and not controversial/contradictory (see A8).

**Qu. 1.10. Estimate the overall likelihood of introduction into the risk assessment area or entry into the environment based on all pathways in foreseeable climate change conditions?**

Thorough assessment of the risk of introduction in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of introduction (e.g. change in trade or user preferences)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely introduction within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Climate change is not expected to alter patterns of introduction in the risk assessment area, nor of entry into the environment (for any of the three pathways described). The response and its confidence are therefore scored equal to Qu. 1.9.

## 2 PROBABILITY OF ESTABLISHMENT

### Important instructions:

- For organisms which are already established in parts of the risk assessment area or have previously been eradicated, the likelihood of establishment should be scored as “very likely” by default.
- Discuss the risk also for those parts of the risk assessment area, where the species is not yet established.

**Qu. 2.1. How likely is it that the organism will be able to establish in the risk assessment area based on similarity of climatic and abiotic conditions in its distribution elsewhere in the world?**

RESPONSE		CONFIDENCE	
	very unlikely		low
	unlikely		medium
	moderately likely		<b>high</b>
	likely		
	<b>very likely</b>		

See also Qu. A7 and Annex VIII. The red-whiskered bulbul is already established in Spain so suitable climatic and abiotic conditions are present in the risk assessment area. Using the climate matching methodology of Faulkner et al. (2014), and using the available validated distribution data (N = 7,208) of *P. cafer* in the native and invaded range gathered for the species distribution model (Annex VIII), we determined the degree (%) overlap with Köppen Geiger climate classification classes (Rubel and Kottek 2010; Beck et al. 2018) present in the risk assessment area. This shows that under current climate (2001-2025), there are similarly suitable climates for the red-whiskered bulbul in the risk assessment area, primarily humid subtropical climate (Cfa, 36% overlap), temperate oceanic climate (Cfb, 16% overlap), to a lesser extent other climates such as hot-summer Mediterranean climate (Csa, 3% overlap) which are present in a number of EU Member States (cf.

<https://www.plantmaps.com/koppen-climate-classification-map-europe.php>). This rough climate matching is refined and corroborated by the species distribution model (Annex VIII). Apart from climatological overlap, the species is associated with human influenced landscapes and can occupy a range of lowland habitats (forest edges, reed beds, gardens, orchards, scrubland, agricultural areas) (Hart 2020) which are not rare in Europe (see A4). The species distribution model (SDM), based on worldwide occurrence data, indicates suitable area in the Mediterranean, Black Sea and Atlantic biogeographic regions. The surface area suitable for establishment is about 48%, 8% and 9% respectively.

**Qu. 2.2. How widespread are habitats or species necessary for the survival, development and multiplication of the organism in the risk assessment area? Consider if the organism specifically requires another species to complete its life cycle.**

RESPONSE		CONFIDENCE	
	very isolated		low
	isolated		<b>medium</b>
	moderately widespread		high
	<b>widespread</b>		
	ubiquitous		

See Qu. A7, and Annex VIII. The SDM suggests that human influence on the environment is a poorer predictor for the occurrence of the red-whiskered bulbul than climate variables are. Nonetheless, the species is described as being associated with human habitation, preferring (semi)open vegetation (e.g. parks, gardens, orchards) in its native and introduced range (Islam and Williams 2000). Such (sub)urban landscapes are widespread in each of the biogeographic regions mentioned under Qu. 2.1.

The red-whiskered bulbul has a broad diet, consisting primarily of plants (petals, stamens, nectar, leaves, fleshy fruits), and secondarily of invertebrates (Islam and Williams 2000; Linnebjerg et al. 2009). Therefore, there is supposedly no dietary constraint for the species' establishment in the above biogeographic regions. But since no dietary studies have been performed within the risk assessment area, this conclusion comes with some uncertainty.

**Qu. 2.3. How likely is it that establishment will occur despite competition from existing species in the risk assessment area?**

RESPONSE		CONFIDENCE	
	very unlikely		low
	unlikely		medium
	moderately likely		<b>high</b>
	likely		
	<b>very likely</b>		

Following entry into the environment, the red-whiskered bulbul would probably compete for food (see Qu. 2.2.) and space (e.g. for nesting) with other bird species. Concerning food, however, the species' broad diet and the abundance of food items (e.g. leaves, fruits) would provide plenty of opportunity for niche differentiation with other omnivorous species.

The nests are open cups, and are generally well concealed in dense foliage. Height ranges described in literature are 0.6–2.4 m (Carleton and Owre, 1975), 1.5–3.6 m (van Riper et al., 1979), 0.9–3.8 m (Li et al., 2015) and 0.6–2.1 m (Khan and Naher, 2020). Li et al. (2015) found nests in 50 different plant species in China. Of the species mentioned by Islam and Williams (2000), *Nerium* (oleander) and *Hedera* (ivy) are widespread in the risk assessment area. House sparrow *Passer domesticus* has been frequently observed in association with the red-whiskered bulbul roosts in Florida, but without evident signs of direct competition (Islam and Williams 2000).

On Oahu (Hawaii), both the red-whiskered and the red-vented bulbul were introduced on year apart. Their population growth rates did not differ, but *P. cafer* became the more abundant species, which is attributed to a wider availability of dry habitats in favour of *P. cafer* (Williams and Giddings, 1984).

The existing literature suggests that the species is able to establish in new environments and to compete with a range of bird species there (see Qu. 4.1). Also, the current population in the risk assessment area established in a wet, riparian urban green area, which probably also attracts a good number of native songbirds. Yet, this did not hamper successful establishment. We therefore scored very likely with high confidence.

**Qu. 2.4. How likely is it that establishment will occur despite predators, parasites or pathogens already present in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Predators: Potential predators (of relevance to the risk assessment area) of the red-whiskered bulbul are rats, cats, snakes (e.g. *Coluber* spp.), magpies (*Pica pica*), and birds of prey (e.g. *Falco* spp.; Carleton and Owre, 1975; Islam and Williams 2000; Li et al. 2015). Li et al. (2015) report relatively high rates of nest predation in the species’ native range in China. From a comparison of population expanse across tropical islands, Clergeau and Mandon-Dalger (2001) estimate predation to be less important as a constraint than inter-specific competition.

Parasites: Two ixodid tick species (*Haemaphysalis spinigera*, *H. wellingtoni*) were described on the red-whiskered bulbul from an Indian forest, both of which were highly abundant across the local pool of bird species (Rajagopalan, 1972). Furthermore, toxoplasmosis and three species of *Haemoproteus*, a blood parasite, have been detected (references within Islam and Williams, 2000).

Pathogens: The avian malaria parasite *Plasmodium (Novyella) jiangi* was first described from the red-whiskered bulbul (He and Huang, 1993), but its identity is doubtful (Valkiūnas and Iezhova 2018).

There is no reason to assume that predators, parasites or pathogens in the risk assessment area will cause a disproportionately high mortality during establishment of the red-whiskered bulbul. The species is already established in the risk assessment area (see A8b).

**Qu. 2.5. How likely is the organism to establish despite existing management practices in the risk assessment area? Explain if existing management practices could facilitate establishment.**

<b>RESPONSE</b>	very unlikely unlikely moderately likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

	likely <b>very likely</b>		
--	------------------------------	--	--

There are currently no dedicated management schemes (directed toward the species or its habitat) in place to prevent the red-whiskered bulbul from establishing. Hunting is unlikely to hamper establishment as hunting small passerines is a rather rare activity in the risk assessment area (especially also near human settlements). The species thrives in cultivated landscapes such as in agricultural areas or smaller scale vegetable gardens that can provide food. Birds are opportunistic in using natural and man-made nest material and can nest in hedges, shrubs and trees (Carleton and Owre 1975) therefore it is unlikely that commonly applied park and garden management is going to hamper successful establishment across the risk assessment area.

**Qu. 2.6. How likely is it that biological properties of the organism would allow it to survive eradication campaigns in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Red-whiskered bulbul have several (2-3) broods per year, a rather high (70-80% depending on the habitat) nesting success and low (10-17%) chick mortality in their native range (Hart 2020). Despite this, a well designed eradication campaign should be able to eradicate the red-whiskered bulbul in early stages of invasion, considering elements of visibility, the popularity of birdwatching (cf. citizen science), and the species' communal roosting behaviour which facilitates the mist-net catch along flight lines towards roosts. Also, the birds have a habit of vocalising from prominent perches which makes them conspicuous during eradication campaigns, for example when locating them for targeting of the last few birds through shooting campaigns (Bunbury et al., 2019). Different techniques have proven effective, such as mist-netting (Bunbury et al., 2019), trapping (Clergeau et al., 2002), and shooting (Clark, 1976). This is exemplified by successful campaigns in California (Clark, 1976), on Assumption and Aldabra (Seychelles; Bunbury et al. 2019), and on Tenerife (Cruz and Reynolds, 2019). Nonetheless, the time frame for (cost)effective eradication may be as short as five years following entry into the environment, as the species may rapidly spread in some situations (Clergeau and Mandon-Dalger, 2001). Considering these elements and examples of successful eradications, we scored moderately likely with medium confidence.

**Qu. 2.7. How likely are the biological characteristics of the organism to facilitate its establishment in the risk assessment area?**

including the following elements:

- a list and description of the reproduction mechanisms of the species in relation to the environmental conditions in the risk assessment area

- an indication of the propagule pressure of the species (e.g. number of gametes, seeds, eggs or propagules, number of reproductive cycles per year) of each of those reproduction mechanisms in relation to the environmental conditions in the risk assessment area.
- If relevant, comment on the likelihood of establishment based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in establishment whereas for others high propagule pressure (many thousands of individuals) may not.
- If relevant, comment on the adaptability of the organism to facilitate its establishment and if low genetic diversity in the founder population would have an influence on establishment.

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Populations of the red-whiskered bulbul may develop from as little as a few breeding pairs (e.g. Pranty, 2010; Mo, 2015). A population could establish from just one single pair given that genetic diversity in founder birds is sufficiently high. For example, in Florida, the size of the founding population was reported small from “a few birds” (Fisk, 1966; Rand, 1980), “between 5 and 10 breeding pairs” (Carleton and Owre, 1975), or “five to ten” birds (Robertson and Woolfenden, 1992).

There is considerable variation in the species’ fecundity throughout its range. There is generally one brood per year, such as in China, with a mean clutch size of 2.5 eggs (Li et al., 2015). However, two and even three broods per year are described in parts of its native and non-native range, e.g. India and Hawaii (Islam and Williams, 2000; Mo, 2015; Li et al., 2015; and references therein). Clutch size generally varies between two and five eggs.

Since the species performs well close to human populations, with requirements for food and nesting that are easily fulfilled, its characteristics fit well with the environment it is most likely to enter in first. This makes survival at the very first stage likely. Climate (see Qu. 2.1.) and mortality events through competition (see Qu. 2.3.), predation or disease (see Qu. 2.4.) or human intervention (see Qu. 2.5. and 2.6.) subsequently are critical factors for initial population build-up. As stated above, only climate stands out as a structural constraint at that stage, whereas the others may prove a constraint only by their stochastic nature.

In general, the species shows behavioural flexibility, generalism (e.g. an opportunistic diet), has multiple broods throughout its lifespan and shows human commensalism (i.e. a propensity to living in close association with humans). These traits have been shown to link to invasion success in birds (Cassey et al. 2004; Callaghan et al. 2019; Sol et al. 2002).

**Qu. 2.8. If the organism does not establish, then how likely is it that casual populations will continue to occur?**

Consider, for example, a species which cannot reproduce in the risk assessment area, because of unsuitable climatic conditions or host plants, but is present because of recurring introduction, entry

and release events. This may also apply for long-living organisms.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

See section B1. Since the red-whiskered bulbul is kept as a popular pet bird, has a rather long expected lifespan of 15-25 years in captivity (Pangsuban and Thavarorith 2021), and is kept in zoological collections, there is a continuous risk of escape or unauthorised release. In the biogeographic regions that are not climatically suited (see Qu. 2.1.), casual records would be expected on a (close to) yearly basis as they currently already do (see Qu. A8a).

**Qu. 2.9. Estimate the overall likelihood of establishment in the risk assessment area under current climatic conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under current climatic conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in current conditions: providing insight in the risk of establishment in (new areas in) the risk assessment area.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

The red-whiskered bulbul is already established in the risk assessment area (in Spain, see Qu. A8b). Despite some uncertainties on the model predictions in specific areas in the risk assessment area (see Qu. 9a), biogeographical regions predicted suitable for establishment are the Mediterranean (48% surface area), Black Sea (8%) and Atlantic (9%) biogeographic regions (see Qu. A7 and Annex VIII). This is exemplified by the presence of the established population near Valencia (Mediterranean, Qu. A8). Countries of the risk assessment area particularly at risk are Spain, Portugal, Cyprus, Greece, Italy and Malta (with France and Croatia to a lesser extent; see Qu. A9 and Annex VIII).

Competition (see Qu. 2.3.), predation or disease (see Qu. 2.4.) and current management (see Qu. 2.5. and 2.6.) are not considered constraints for establishment. They are expected to contribute to failed establishment in the first stages by chance only. In line with the guidance, as the species is already established in parts of the risk assessment area, the likelihood of establishment is scored as very likely.

**Qu. 2.10. Estimate the overall likelihood of establishment in the risk assessment area under**

**foreseeable climate change conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under foreseeable climate change conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of establishment (e.g. increase in average winter temperature, increase in drought periods)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely establishment within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided.

However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Under foreseeable climate change conditions, the suitability of already-suitable biogeographic regions would increase, i.e. the Mediterranean ( $\pm 60\%$  surface area), Black Sea ( $\pm 25\%$ ), Atlantic ( $\pm 20\%$ ) biogeographic regions (see Qu. A7 and Annex VIII). This results in the same countries particularly at risk (Spain, Portugal, Cyprus, Greece, Italy, Malta, France, Croatia, Ireland), with the addition of Slovenia, Bulgaria and the United Kingdom under foreseeable climate change conditions (see Qu. A9 and Annex VIII).

### 3 PROBABILITY OF SPREAD

**Important instructions:**

- Spread is defined as the expansion of the geographical distribution of an alien species within the risk assessment area.
- Repeated releases at separate locations do not represent continuous spread and should be considered in the probability of introduction and entry section (Qu. 1.7).

**Qu. 3.1. How important is the expected spread of this organism within the risk assessment area by natural means? (List and comment on each of the mechanisms for natural spread.)**

including the following elements:

- a list and description of the natural spread mechanisms of the species in relation to the environmental conditions in the risk assessment area.
- an indication of the rate of spread discussed in relation to the species biology and the environmental conditions in the risk assessment area.

The description of spread patterns here refers to the CBD pathway category “Unaided (Natural Spread)”. It should include elements of the species life history and behavioural traits able to explain its ability to spread, including: reproduction or growth strategy, dispersal capacity, longevity, dietary requirements, environmental and climatic requirements, specialist or generalist characteristics.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Invasion histories within and outside the risk assessment area illustrate the red-whiskered bulbul is a mobile bird species with a capacity for natural spread (e.g. Clergeau and Mandon-Dalger, 2001; Mo, 2015; Santos 2015; Polo-Aparisi and Polo-Aparisi 2021). There is however considerable variation in reported spread rates for invasion histories outside the risk assessment area (Clergeau and Mandon-Dalger, 2001). Pranty (2010) describes the red-whiskered bulbul as “by far the most range-restricted exotic bird” established in Florida state, despite a 50-year presence. Also, in the risk assessment area, the established population around Valencia showed relatively moderate expansion from its original introduction point in 2003. In 15 years (2003-2019) the species has spread to only a few adjacent municipalities not very far from the original introduction area (Paterna). The spread has occurred mostly along the course of the river Turia which could act as a dispersal corridor, suggesting spread is influenced by landscape features. By 2016 it covered an area of seven 5km<sup>2</sup> squares (Polo-Aparisi and Polo-Aparisi 2021) (see Qu A8b). In contrast, the species has spread much faster elsewhere, as evidenced by patterns from Hawaii (Oahu) and the Mascarenes (Mauritius and Réunion). There, the red-whiskered bulbul colonized the entire area considered suitable within a few decades. This led Clergeau and Mandon-Dalger (2001) to estimate dispersion rates in continental areas to be about 3 km in ten years, but on islands, to be up to 30 km in ten years. Their data suggest that the rate of expansion is slower within the first five years after introduction. Clergeau and Mandon-Dalger (2001) note that the rate of spread on Réunion was most likely determined by habitat suitability, as bulbuls

first colonized the wet eastern coast, and then dry habitats and high altitudes (Mandon-Dalger et al. 1999). Within ten years of their initial introduction, bulbuls occupied ca 380 km<sup>2</sup>. Although the speed of dispersal was not the same in all directions, they estimated an average dispersion rate of ca 6.2 km/yr during the first ten years, and 14.7 km/yr between 1985 and 1995. A limited spread rate overall has been attributed in part to the species' preference for communal roosting (Mo, 2015). The higher spread on islands has been suggested to be due to the smaller size of their bird communities, thus limiting competition (Clergeau and Mandon-Dalger, 2001).

Given contrasting evidence, and a limited insight into how local species pools and habitat suitability may constrain the spread rate of the red-whiskered bulbul within the risk assessment area, we estimate spread to be moderate, with a medium confidence since there is documented evidence available.

**Qu. 3.2a. List and describe relevant pathways of spread other than "unaided". For each pathway answer questions 3.3 to 3.9 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 3.3a, 3.4a, etc. and then 3.3b, 3.4b etc. for the next pathway.**

including the following elements:

- a list and description of pathways of spread with an indication of their importance and associated risks (e.g. the likelihood of spread in the risk assessment area, based on these pathways; likelihood of survival, or reproduction, or increase during transport and storage; ability and likelihood of transfer from the pathway to a suitable habitat or host) in relation to the environmental conditions in the risk assessment area.
- an indication of the rate of spread for each pathway discussed in relation to the species biology and the environmental conditions in the risk assessment area.
- All relevant pathways of spread (except "Unaided (Natural Spread)", which is assessed in Qu. 3.1) should be considered. The classification of pathways developed by the Convention of Biological Diversity shall be used (see Annex IV).

Pathway name: Following entry into the environment through any of the pathways addressed under Section B1, and disregarding range expansion through multiple entries by the same pathways, spread is expected to occur only unaided, i.e. natural spread through bird flight. No indication for other spread pathways is found in literature.

**Qu. 3.3a. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional	<b>CONFIDENCE</b>	low
	unintentional		medium high

N/A (see Qu. 3.2a.).

**Qu. 3.4a. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low medium high

**Qu. 3.10. Within the risk assessment area, how difficult would it be to contain the organism in relation to these pathways of spread?**

<b>RESPONSE</b>	very easy easy <b>with some difficulty</b> difficult very difficult	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

As spread is considered to be driven only by natural dispersal, efforts to contain the red-whiskered bulbul would translate into measures for early detection and rapid eradication around sites of entry. Some of the species' characteristics are favourable for such campaigns, e.g. its visibility, vocal nature, and communal roosting behaviour. Possible techniques include mist-netting (Bunbury et al., 2019), trapping (Clergeau et al., 2002), and shooting (Clark, 1976). Some campaigns have led to successful eradication (see Qu. 2.6.; Clark, 1976; Bunbury et al. 2019; Cruz and Reynolds, 2019).

Containment campaigns would thus be easy, in a relative sense to other introduced animal species. Yet, the human environment may also bring some drawbacks, such as public opposition or legal restrictions (e.g. on shooting). Given that the rate of spread can vary considerably (see Qu. 3.1.), the window of opportunity for rapid response campaigns is not so clear but would best be conceived as less than five years (Clergeau and Mandon-Dalger, 2001). We therefore classify the difficulty as moderate.

**Qu. 3.11. Estimate the overall potential rate of spread in relevant biogeographical regions under current conditions for this organism in the risk assessment area (indicate any key issues and provide quantitative data where possible).**

Thorough assessment of the risk of spread in relevant biogeographical regions in current conditions, providing insight in the risk of spread into (new areas in) the risk assessment area.

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

As spread is considered to be driven only by natural dispersal, the response is set as equal to that of Qu. 3.1. There is no established link between red-whiskered bulbul fecundity and climate, though the number of broods per year may be hypothesized to correlate with warmer regions and lower

seasonality (e.g. China versus India, Li et al., 2015; Florida versus Hawaii, Islam and Williams, 2001). If this is the case, the rate of spread may be higher in e.g. the Mediterranean biogeographic region as compared to the Atlantic biogeographic region.

**Qu. 3.12. Estimate the overall potential rate of spread in relevant biogeographical regions in foreseeable climate change conditions (provide quantitative data where possible).**

Thorough assessment of the risk of spread in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk, specifically if rates of spread are likely slowed down or accelerated.

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Only through the hypothesized relation between fecundity and climate, under Qu. 3.11, would an increased rate of spread be expected under climate change conditions. Given foreseeable change, we nonetheless expect that the increase would be marginal (i.e. no consistent increase to two broods per year).

## 4 MAGNITUDE OF IMPACT

Important instructions:

- Questions 4.1-4.5 relate to biodiversity and ecosystem impacts, 4.6-4.8 to impacts on ecosystem services, 4.9-4.13 to economic impact, 4.14-4.15 to social and human health impact, and 4.16-4.18 to other impacts. These impacts can be interlinked, for example, a disease may cause impacts on biodiversity and/or ecosystem functioning that leads to impacts on ecosystem services and finally economic impacts. In such cases the assessor should try to note the different impacts where most appropriate, cross-referencing between questions when needed.
- Each set of questions starts with the impact elsewhere in the world, then considers impacts in the risk assessment area (=EU excluding outermost regions) separating known impacts to date (i.e. past and current impacts) from potential future impacts (including foreseeable climate change).
- Only negative impacts are considered in this section (socio-economic benefits are considered in Qu. A.7)
- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable).

### Biodiversity and ecosystem impacts

**Qu. 4.1. How important is the impact of the organism on biodiversity at all levels of organisation caused by the organism in its non-native range excluding the risk assessment area?**

including the following elements:

- Biodiversity means the variability among living organisms from all sources, including terrestrial, marine and other aquatic ecosystems and the ecological complexes of which they are part; this includes diversity within species, between species and of ecosystems
- Impacted chemical, physical or structural characteristics and functioning of ecosystems

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

The red-whiskered bulbul impacts species and ecosystems through a number of impact mechanisms which are discussed below. Apart from impacts on individual species with documented cases of extinctions and declines in native species in the invaded range, the species can also exert ecosystem-level impacts through the facilitation of plant invasions and changes in species compositions in natural areas. As these changes are probably irreversible without severe management interventions and because of the documented local extinctions of native species, we scored major impact. This is in line with Evans et al. (2016) who classified the species as having a Major (MR) environmental impact

using the Environmental Impact Classification for Alien Taxa (EICAT) protocol with predation being the most severe impact mechanism (see also A.3). Martin-Albarracin et al. (2015), in a global analysis of alien bird impacts for 39 bird species, identified the red-whiskered bulbul as one of the three species with the highest global impact because of severe local impacts and a strong intrinsic ability to affect ecosystems. Note that in this risk assessment the red-whiskered bulbul received a higher impact score than the related red-vented bulbul *P. cafer* for the impact criteria competition and interactions with other non-native organisms based on the evidence provided in Carleton and Owre (1975) for Florida and the studies of Linnebjerg et al. (2009, 2010), Tassin et al. (2007) and Jones (1996) for Indian ocean populations. According to their scoring system used (an adapted scheme based on Kumschick and Nentwig (2010) and Blackburn et al. (2014), where 0 indicates no impact detected and 5 massive impact), the red-whiskered bulbul received a score of 4 on competition (i.e. *competition with many native species, several declining in population size, competition for food and/or space, behavioural changes in out-competed species*) and 5 on interactions with other non-native organisms (i.e. *Dispersal of seeds of non-native plants facilitates replacement or local extinction of one or several native species, and produces irreversible changes in community composition that would not have occurred in the absence of the species*) (Martin-Albarracin et al. 2015). Baker et al. (2014), in a global analysis of alien bird impacts, also report interference competition and predation as impact mechanisms for the species.

#### Impact mechanisms:

##### 1: Frugivory (spreading the fruit/seeds of alien plants)

Red-whiskered bulbul are frugivorous and are notorious for spreading invasive weeds including *Lantana* spp., *Rubus* spp., *Phytolacca* spp., *Chrysanthemoides* spp. and *Ligustrum* spp. in Mediterranean parts of Australia and this is considered their biggest impact on ecosystems (Mo 2015). Of particular concern is the movement of the birds between plantations and natural forest areas which alters the plant species composition of natural areas (Linnebjerg 2009). Invasions of the species could therefore facilitate invasive plants (Traveset, 2006; Traveset and Richardson 2014; MacFarlane et al., 2016). On Mauritius, the red-whiskered bulbul facilitated the spread of invasive plant species like *Ligustrum robustum*, *Lantana camara* and *Cordia interrupta*, which, prior to the introduction of the red-whiskered bulbul, were sleeper weeds (Linnebjerg et al. 2009, 2010). Linnebjerg et al. (2010) in an analysis of faecal pellets found the diet to consist primarily of fleshy fruits with seeds of ten plant species being present in 92% of all faecal pellets six of which were notorious invasive plant species on Mauritius (*Clidemia hirta*, *Ligustrum robustum*, *Litsea glutinosa*, *Psidium cattleianum*, *Rubus alceifolius* and *R. rosifolius*). Gut passage of seeds by the red-whiskered bulbul improved the germination success of the invasive plants *Clidemia hirta* (Linnebjerg et al., 2009), and *Schinus terebinthifolius* (Mandon-Dalger et al., 2004), on Mauritius and Réunion, respectively. In Hawaii, the species spreads the seeds of invasive *Miconia calvescens*, ivy (*Hedera*), gourd and false kava (*Piper auritum*). On Réunion, involvement of the red-whiskered bulbul in facilitating plant invasions was reported by Clergeau and Mandon-Dalger (2001) and Mandon-Dalger et al. (2004). There, red-whiskered bulbul was implicated in invasion of Brazilian pepper tree *S. terebinthifolius* and the birds were suspected to form satellite foci of plant infestations. Although the authors note consequences of long distance dispersal of this invasive shrub through ornithochorie by red-whiskered bulbul for ecological restoration, they note that the recruitment of *S. terebinthifolius* is also dependent on the soaking of fruits in water to activate germination after deposition and early seedling development. In Australia, red-whiskered bulbul has been implicated in the establishment of African Olive *Olea europaea cuspidata* in western Sydney, which is considered an environmental weed in eastern

Australia (Cuneo and Leishman 2006). Other noxious weeds that red-whiskered bulbul was reported feeding on in Australia include Lantana *L. camara*, inkweed *Phytolacca octandra*, bitou bush *Chrysanthemoides monilifera* and Chinese privet *Ligustrum sinense* (see Mo 2015 and references therein).

## 2: Competition

In Florida, red-whiskered bulbul overlaps in diet with northern mockingbird *Mimus polyglottos* and competes with this native species for fruits of mango, christmasberry, fig (*Ficus* spp.), day hessamine, lantana (*Lantana* spp.) and jasmine (*Jasminum* spp.), especially during winter when insects are scarce (Carleton 1971; Gore and Doubilet 1976). In Hong Kong, where both species have long been abundant residents and co-occur in the same habitats and have similar food and environmental requirements, red-whiskered bulbul has replaced Chinese bulbul (*P. sinensis*) in urban and suburban contexts and caused the Chinese bulbul to retreat in more rural areas including mountains, mangroves and forests (Chan 2004). Chan (2004) hypothesizes red-whiskered bulbul is a better competitor for food and nesting sites in human-modified habitats. The same happened on the Nicobar islands where the species, after it was introduced from the Andaman islands in the late 1800s, displaced the endemic Nicobar bulbul (*Ixos nicobariensis*) (Sankaran 1998) which is now considered near threatened (Goyal 2020). In Sydney, agonistic responses toward flocks of silvereye *Zosterops lateralis* and rosellas *Platycercus* spp. feeding on camphor laurel *Cinnamomum camphora* fruits have been reported (MacPherson 1923). However, Mo (2015) states that concerns over interspecific competition would be most relevant to invasions of islands and that despite field observations, there is no evidence that interspecific competition is ecologically significant in Australia.

## 3: Hybridisation

Red-whiskered bulbuls have been hybridized with several other bulbul species in captivity to increase their qualities as a pet (McCarthy 2006; Techachoochert and Round 2013) (see A1, A2). Techachoochert and Round (2013) point out this practice might represent a genetic risk to wild native populations of the red-whiskered bulbul. It also highlights a potential risk of the species (or their hybrids) interbreeding with other native bulbul species (Hart 2020).

## 4: Predation

The Red-whiskered Bulbul preys on arthropods such as cicadas, flies, aphids (MacPherson 1921, 1923), ants, moths and their larvae (Chisholm 1933, Chaffer 1933) and spiders (Islam and Williams 2000). Xiaohua (1992) found arthropods comprising approximately 28% of the diet in southern China. It is also known to be a predator of smaller (or juvenile) vertebrates like geckos and lizards (Mo 2015). Islam and Williams (2000) report that populations of geckos severely declined on Mauritius probably because of predation by bulbuls on young geckos. There have also been instances of predation of chicks of other bird species, for instance on the Mascarene islands (Philippe and Mandon-Dalger 2001) and Assumption (Roberts 1988) although it was unclear whether these represented real predation events or rather aggressive interactions (Baker et al. 2014). Red-whiskered bulbuls are known to display intra- and interspecific territorial aggression year-round which intensifies during their nesting period (Hart 2020). The red-whiskered bulbul also represents a threat to native invertebrates, and caused the extinction of native orb-web spiders (*Nephila inaurata*) on Mauritius by predation (Islam and Williams 2000). Such impact could also have indirect effects on prey species or other native predators through cascading effects. On Hawaii, predation by red-whiskered bulbul on

larvae and adults of the iconic monarch butterfly *Danaus plexippus* (Lepidoptera: Nymphalidae) led to changes in the proportions of colour morphs in the population (Stimson and Kasuya 2000). Bulbuls are not deterred by the cardiac glycosides in the monarchs' tissues and can exert heavy predation on larvae feeding on their host plant milkweed (Stimson and Berman 1990). However, we could find no evidence of population level impacts on these species.

#### 5: Pathogen transmission

Red-whiskered bulbuls are a potential reservoir of avian malaria (He and Huang 1993, Think et al. 2012) (see Qu 2.4, Qu. 4.16), which is a well-known threat to native forest birds, such as on Hawaii (Samuel et al. 2011). In India, red-whiskered bulbuls carry several species of birdlice (Arya et al. 2010, Saxena et al. 2012). Hart (2020) notes that it is likely that other parasites and diseases are hosted by red-whiskered bulbul and that given their interspecies roosting behaviour they could be important reservoirs of avian pathogens.

**Qu. 4.2. How important is the current known impact of the organism on biodiversity at all levels of organisation (e.g. decline in native species, changes in native species communities, hybridisation) in the risk assessment area (include any past impact in your response)?**

Discuss impacts that are currently occurring or are likely occurring or have occurred in the past in the risk assessment area. Where there is no direct evidence of impact in the risk assessment area (for example no studies have been conducted), evidence from outside of the risk assessment area can be used to infer impacts within the risk assessment area.

<b>RESPONSE</b>		<b>CONFIDENCE</b>	
	minimal		<b>low</b>
	<b>minor</b>		medium
	moderate		high
	major		
	massive		

Although there is evidence of the red-whiskered bulbul foraging on non-native plants (see Qu 4.3), no studies have been found quantifying the impact of red-whiskered bulbul in the risk assessment area (Spain). Recent population estimates are lacking but in 2016 the population in Valencia was estimated at 100-150 individuals (Santos 2015). Since this established population is presumably still fairly small, impact can be assumed to be minor but with low confidence due to the lack of impact studies. Also, the Spanish population is likely interacting with relatively common native species. Although hybridization with the co-occurring non-native red-vented bulbul could theoretically occur in the risk assessment area, there are currently no native bulbul species in the area so impact would occur through other impact mechanisms (predation, frugivory, competition with native bird species).

**Qu. 4.3. How important is the potential future impact of the organism on biodiversity at all levels of organisation likely to be in the risk assessment area?**

See comment above. The potential future impact shall be assessed only for the risk assessment area. A potential increase in the distribution range due to climate change does not *per se* justify a higher impact score.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

#### 1: Frugivory (spreading the fruit/seeds of alien plants)

In Spain, red-whiskered bulbuls have been reported feeding on seeds and fruits of native as well as non-native plant species e.g. kurrajong (*Brachychiton populneus*), fig (*Ficus carica*), strawberry tree (*Arbutus unedo*), loquat (*Eriobotrya japonica*), privet (*Ligustrum vulgare*), chinaberry tree (*Melia azedarach*), pomegranate (*Punica granatum*), Peruvian pepper (*Schinus molle*), date palm (*Phoenix dactylifera*), oleander (*Nerium oleander*) flowers, feijoa (*Acca sellowiana*) and yucca (*Yucca* sp.) (Santos 2015; Polo-Aparisi and Polo-Aparisi 2021). Spread of typical garden ornamentals by red-whiskered bulbul could be an issue in the Mediterranean considering the habitat preference of the species for gardens and man-made habitat, for example *Trachycarpus fortunei*, *Mahonia aquifolium*, non-native *Ribes* sp., *Parthenocissus* sp., *Cotoneaster* sp., *Rosa* sp., *Elaeagnus* sp., *Ziziphus jujuba*, *Morus* sp., *Pittosporum* sp., *Myoporum* sp., *Mirabilis jalapa*, *Opuntia* sp., *Lycium* sp., *Lonicera* sp., *Aralia* sp. and *Hedera* sp. With regards to IAS of Union concern (Union list as it stands in April 2021), *Persicaria perfoliata* is the only listed species that produces berry-like fruits (personal communication G. Brundu, 23/10/2019). This Union list species has however not been found across the EU by 2017 (Tsiamis et al. 2017). American pokeweed (*Phytolacca americana*) and oriental bittersweet (*Celastrus orbiculatus*) are relevant to mention as candidate species proposed for uptake on the Union List in 2022. Both species occur in open, disturbed habitats and are popular with berry eating birds (McDonnell et al., 1984; Beringen et al., 2017). It should be noted that these alien plants can also be spread by native birds (e.g. thrushes) and there is currently no information suggesting red-whiskered bulbul would do this to a greater extent.

It is well known that island ecosystems are especially sensitive to the impacts of invasive alien species because of high levels of endemism (e.g. Tershy et al., 2015; Bellard et al., 2016). The Mediterranean basin is particularly vulnerable to invasive alien plant invasions because its climatic conditions potentially allow the establishment of sub-tropical and tropical plant species (Lloret et al., 2005; Vila et al., 2006, 2008; Hulme et al., 2008; Lambdon et al., 2008; Brunel et al., 2010; Brundu 2015). A number of established and emerging invasive alien plants for Mediterranean countries produce fleshy fruits and could therefore potentially be spread by birds such as the red-whiskered bulbul in the risk assessment area (cf. Gosper et al., 2005; Spotswood et al., 2012, 2013). American pokeweed (*Phytolacca americana*) and Indian pokeweed (*P. acinosa*) produce fleshy purple berries that are spread by birds (McDonnell et al., 1984). Other examples of (potentially) invasive alien plants that might be spread by red-whiskered bulbuls in the risk assessment area include Brazilian peppertree (*Schinus terebinthifolius*), a commonly planted ornamental in the Mediterranean which is reported to

be spread by the red-vented bulbul (Thibault et al., 2018), silver-leaved nightshade (*Solanum elaeagnifolium*), a common agricultural weed (Brunel et al., 2010), sticky nightshade (*S. sisymbriifolium*), a weed of pastures and irrigated crops, roseleaf bramble (*Rubus rosifolius*), Chinese privet (*Ligustrum sinense*) and garden privet (*L. ovalifolium*) (Tanner 2017). Some of these species typically occur in human-modified areas such as parks, gardens and ruderal terrains and red-whiskered bulbul is currently also confined to this kind of habitat.

## 2: Competition

Impact on native bird species could occur through competition for food or space including harassment of native birds (mostly passerine birds, see Qu 4.1) by (groups of) red-whiskered bulbul, which is reported as an aggressive species in the invaded range through territorial interactions. Where the species occurs in urban, human influenced landscapes, most of the passerine species it would compete with are relatively common (e.g. blackcap *Sylvia atricapilla*, Sardinian warbler *S. melanocephala*, common blackbird *Turdus merula*) and the presence of the bulbul is expected to lead mostly to niche contraction rather than declines or extinctions, at least on larger land masses. Competition for food would likely occur with bird species that exploit similar resources such as species of Turdidae, Sylviidae and Sturnidae that occur in urban, wasteland and farmland areas. Also, several common species with broad diets such as great tit (*Parus major*), greenfinch (*Chloris chloris*) or wood pigeon (*Columba palumbus*) could be impacted yet the population level impact on these very common species would probably be small. However, based on evidence elsewhere in the invaded range (see Qu 4.1), the impact on small populations on islands might be severe.

## 3: Hybridisation

Hybridisation is unlikely to be an issue, as the only native species, common bulbul (*P. barbatus*), is currently still a very rare bird in the risk assessment area yet might increase its distribution with climate change.

## 4: Predation

The Red-whiskered Bulbul might have an impact on arthropods such as cicadas, flies, aphids, ants, moths and their larvae and spiders (see Qu 4.1). In Valencia the species was observed catching insects in flight on trees (Santos 2015; Polo-Aparisi and Polo-Aparisi 2021). It is also known to be a predator of smaller (or juvenile) vertebrate prey like geckos and lizards and possibly chicks of songbirds. Depending on the population size and the subsequent levels of predation exerted on populations, this could represent a problem for small populations of rare prey species of red-whiskered bulbul. Populations on islands (including isolated habitats which can be relatively species-poor), could be severely impacted should bulbuls establish and develop a feeding preference for such species. In extreme cases this could also lead to (local) extinctions (cf. the disappearance of *Nephila* orb-web spiders on Mauritius, see A10 and Qu 4.1). To exemplify a few sensitive receptors of conservation concern, we compiled a list of lizards and geckos that could potentially be predated upon using Speybroeck et al. (2016) and data compiled on native reptiles on Mediterranean islands by Ficetola et al. (2014). A lot of those have restricted, endemic ranges within Mediterranean islands. These include: Greek Algyroides (*Algyroides moreoticus*) (endemic), Dalmatian Algyroides (*A. nigropunctatus*) and Peloponnese slow worm (*Anguis cephalonica*) on Ionian islands; Sicilian wall lizard (*Podarcis waglerianus*) (endemic) on Sicily and the threatened Aeolian wall lizard (*Podarcis raffoneae*) (endemic) on some smaller Aeolian islets; Milos wall lizard (*Podarcis milensis*) (endemic), Balkan

green lizard (*Lacerta trilineata hansschweizeri*) (endemic subspecies), Skyros wall lizard (*Podarcis gaigeae*) (endemic) and Erhard’s wall lizard (*Podarcis erhardii*) on the Aegean islands; Cretan wall lizard (*Podarcis cretensis*) (endemic), Kotschy’s gecko (*Mediodactylus kotschyi bartoni*) (endemic subspecies), Balkan green lizard (*L. trilineata polylepidota*) (endemic subspecies) and Pori wall lizard (*Podarcis levendis*) (endemic) on Crete; Pygmy algyroides (*A. fitzingeri*) (endemic), Tyrrhenian wall lizard (*Podarcis tiliguerta*) (endemic) and European leaf-toad gecko (*Euleptes europaea*) (endemic) on the Thyrrenian islands; Ibiza wall lizard (*Podarcis pityusensis*) (endemic) and Lilford’s wall lizard (*Podarcis lilfordi*) (endemic) on the Balearic islands; Kotschy’s gecko (*Mediodactylus kotschyi*) on Cyprus and the eastern Mediterranean. Likewise, the list of insects (Lepidoptera, Coleoptera, Orthoptera) that could be predated upon by bulbuls is very long. Considering documented predation on monarch butterfly (*Danaus plexippus*) on Hawaii (see Q 5.1), this species could also be impacted in southern Spain where it is established yet rare (Gil 2006; Lafranchis 2004). Also similar species of Nymphalidae (and other families such as Papilionidae) with conspicuous colours and/or conspicuous larvae could be impacted in Spain and the Mediterranean, such as the African queen (*Danaus chrysippus*) but documented information is lacking for the risk assessment area. Because there is evidence of local extinctions, and because the species has a wide ecological amplitude which is not confined to urban or rural habitats, in line with current assessments of alien bird impacts (e.g. Martin-Albarracin et al. 2015, Evans et al. 2016), we scored major but with low confidence because impacts are inferred from other areas.

**Qu. 4.4. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism currently in the risk assessment area?**

including the following elements:

- native species impacted, including red list species, endemic species and species listed in the Birds and Habitats directives
- protected sites impacted, in particular Natura 2000
- habitats impacted, in particular habitats listed in the Habitats Directive, or red list habitats
- the ecological status of water bodies according to the Water Framework Directive and environmental status of the marine environment according to the Marine Strategy Framework Directive

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

We found no documented impact information for the population around Valencia. Currently, in the risk assessment area, there is no evidence that red-whiskered bulbul occurs or is spreading in high conservation value habitats. The part of the Rio Turia basin in Valencia, where the species currently has its main stronghold in only a small part of the lower course of the river (but seems to be spreading, see A8a), is an important suburban green space for the city with cultural value (e.g. the Garden of the

Turia which was developed over the old course of the river close to the river's mouth) and flood defence functions provided by an artificial canal developed after the severe floods in 1950. Although the area is not a NATURA2000 site, it is a part of the Turia Natural Park, which encompasses 4,680 ha of protected land along the river, with valuable Mediterranean riparian forest, stands of Aleppo pine (*Pinus halepensis*), Mediterranean scrub and typical Valencian agricultural landscapes rich in biodiversity and traditional values (<https://www.valenciaturisme.org/en/parquenatural/parque-natural-del-rio-turia/>). As the species is currently limited in distribution and numbers, and confined to only a small part of the Rio Turia basin, we scored minor impact. The confidence on this response is low in the absence of studies on the subject.

**Qu. 4.5. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.3 and 4.4.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Based on what is known of its ecological amplitude and habitat characteristics, the red-whiskered bulbul could potentially establish and spread in a variety of habitats, mostly (peri)urban habitats as is the case Valencia, but the species is known to cross the barrier between man-made and natural (forest) areas. Currently, the red-whiskered bulbul rarely occurs outside urban areas in the risk assessment area, and most of the landscape around the currently invaded area consists of irrigated orange grove and row crop farmland which are probably mostly unsuitable for the species. More inland areas consist of dry cultivation areas (olive, almond, carob trees, vineyards) and natural habitats consisting of dry treeless shrubland and pine woods where the red-whiskered bulbul would probably also have a hard time finding food (pers. comm. E. Murgui, September 2021). However, in other parts of the risk assessment area, the landscape context might be different. In (sub)urban and rural-agricultural areas, impact (e.g. through competition) would occur on rather common species (see Qu. 5.3). However, if the species becomes more widespread, also conservation value habitats could be invaded where the bulbuls could affect species of concern. Moreover, they could also have more systemic, irreversible ecosystem-level effects through the spread of invasive plant species from ruderal to natural areas (see Qu. 4.1). Habitats protected by the Habitats Directive which could potentially be invaded and impacted upon through seed dispersal of invasive alien plants include sub-Mediterranean and temperate scrub, Mediterranean arborescent matorral (maquis), Mediterranean sclerophyllous forests (e.g. wild olive woodland, cork-oak forests), garrigue (also known as phrygana in the eastern Mediterranean) and maquis shrubland, which is a complex of several possible vegetation types but characterized by densely growing evergreen shrubs. Several of these vegetation types have unique representation as specific habitats of the Habitats Directive on islands in the Mediterranean (e.g. Tyrrhenian islands, Ionian islands, Cyprus, Malta) (based on European Commission 2013). The

Mediterranean scrub biome is also home to a number of breeding birds that could be affected by the red-whiskered bulbul through competition for nesting space and food. These include a range of songbirds (shrikes, warblers, buntings etc.) and include many species protected by the Birds Directive as well as species listed as vulnerable on the IUCN Red List e.g. Iberian grey shrike (*Lanius meridionalis*), bunting species (*Emberiza spp.*) or commoner species of similar habitats like European stonechat (*Saxicola rubicola*). Other vertebrate species that could potentially be affected include geckos and small lizards, many of which are endemic or have very restricted ranges and are listed on the Annexes II and IV of the EU Habitats Directive (see Qu 4.3).

We scored moderate impact because, although the species is known to invade natural areas, presumably it is still primarily bound to human-influenced landscape. Confidence is low because most of the assumed future impacts on conservation values are inferred from cases outside the risk assessment area.

## Ecosystem Services impacts

### Qu. 4.6. How important is the impact of the organism on provisioning, regulating, and cultural services in its non-native range excluding the risk assessment area?

- For a list of services use the CICES classification V5.1 provided in Annex V.
- Impacts on ecosystem services build on the observed impacts on biodiversity (habitat, species, genetic, functional) but focus exclusively on reflecting these changes in relation to their links with socio-economic well-being.
- Quantitative data should be provided whenever available and references duly reported.

RESPONSE		CONFIDENCE	
	minimal		low
	minor		<b>medium</b>
	<b>moderate</b>		high
	major		
	massive		

1 / Provisioning ecosystem services: red-whiskered bulbul may have an impact on provisioning services such as cultivated terrestrial plants grown for nutritional purposes and as ornamentals and also on wild plants used for nutrition. The species is considered a pest for horticultural and agricultural produce outside its native range, especially in gardens and orchards where it impacts flowers, fruits and vegetables. It is a reported nuisance species in gardens causing damage to fruits such as peas, figs and strawberries (MacPherson 1923, Mo 2015), but also to the buds and ripening fruit of orchard crops, including guava, mango, orange, papaya, plum, raspberry, strawberry and flowers including orchids, seedlings, vegetables and ripening crops such as coffee and pea (Department of Primary Industries and Regional Development 2018). It also causes crop failure in soft-fruit and citrus orchards (Chaffer 1933), as it has in California (Islam and Williams 2000) and on Hawaii (Williams and Giddings 1984). Apart from this direct economic impact, the species impacts by spreading weeds into natural areas and the human environment (see Qu 4.1 - frugivory).

2 / Cultural ecosystem services: impacts on cultural ecosystem services may include disturbance of the heritage of isolated island ecosystems. In particular, changes in vegetation structure and species composition could be caused by seed dispersal of invasive weedy plant species (see Qu. 4.1). This may make landscapes less attractive for recreation and wildlife watching, and impact the qualities of ecosystems with cultural importance.

We scored this as moderate since impacts on provisioning services represent measureable, temporary, local (but probably reversible) effects, although loss of agricultural production might locally be irreversible. We scored confidence as medium because there is evidence from the invaded range of both types of impacts to ecosystem services.

**Qu. 4.7. How important is the impact of the organism on provisioning, regulating, and cultural services currently in the different biogeographic regions or marine sub-regions where the species has established in the risk assessment area (include any past impact in your response)?**

- See guidance to Qu. 4.6.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

No information was found on reported damages in the Valencia area where the red-whiskered bulbul is established. However, it has been reported feeding on seeds and fruits of native as well as non-native plant species there including species of nutritional and ornamental value (Santos 2015) (see Qu. 4.3). Therefore, and because the population is increasing (see A8a), it is reasonable to assume there is an actual impact on provisioning ecosystem services in that area but it is unmeasurable, hence minor impact. As no information has been found on the area where it is currently established (Valencia), the confidence on this assessment is low.

**Qu. 4.8. How important is the impact of the organism on provisioning, regulating, and cultural services likely to be in the different biogeographic regions or marine sub-regions where the species can establish in the risk assessment area in the future?**

- See guidance to Qu. 4.6.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Wherever it could potentially establish in the risk assessment area (see Annex VIII), the red-whiskered bulbul could impact upon several ecosystem services (Annex V), including:

- Provisioning - Biomass - Cultivated terrestrial plants - Cultivated terrestrial plants grown for nutritional purposes
- Regulation and Maintenance - Regulation of physical, chemical, biological conditions - Lifecycle maintenance, habitat and gene pool protection - Seed dispersal
- Cultural - Direct, in-situ and outdoor interactions with living systems that depend on presence in the environmental setting - Physical and experiential interactions with the natural environment - Characteristics of living systems that enable activities promoting health, recuperation or enjoyment through passive or observational interactions
- Cultural - Direct, in-situ and outdoor interactions with living systems that depend on presence in the environmental setting - Physical and experiential interactions with the natural environment - Intellectual and representative interactions with natural environment - Characteristics of living systems that enable aesthetic experiences
- Cultural - Indirect, remote, often indoor interactions with living systems that do not require presence in the environmental setting - Other biotic characteristics that have a non-use value - Characteristics or features of living systems that have an option or bequest value

Impacts would be comparable to other areas outside the native range (see Qu 4.6). Besides crop damage (e.g. olives, grapes, figs, peaches) or ornamental plant damage in the endangered area (Annex VIII), the red-whiskered bulbul also impacts seed dispersal and could act as a vector for seeds of invasive plant species causing changes in ecosystem structure and species composition of ecosystems; it could also lead to local extinctions of endemic species on islands, including habitat islands on the mainland (for examples see Qu. 4.3 and Qu. 4.4). This could impact on culturally valued elements of ecosystems (structure, species composition etc.) that make them attractive to ecotourism, recreation, wildlife watching, or that have cultural and intrinsic value, particularly on Mediterranean islands.

## Economic impacts

**Qu. 4.9. How great is the overall economic cost caused by the organism within its current area of distribution (excluding the risk assessment area), including both costs of / loss due to damage and the cost of current management.**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the world these should be reported here. The assessment of the potential costs of / loss due to damage shall describe those costs quantitatively and/or qualitatively depending on what information is available. Cost of / loss due to damage within different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage. As far as possible, it would be useful to separate costs of / loss due to the organism from costs of current management.

RESPONSE		CONFIDENCE	
	minimal		low
	minor		medium
	<b>moderate</b>		high
	major		
	massive		

The fruit diet of the red-whiskered bulbul may have direct economic impacts, by causing production loss of cultivated plants, or indirect impacts, by spreading weed species into the human environment that are problematic.

Regarding the first (damage by herbivory), van Riper et al. (1979) reported consumption of fruits of the following species with a commercial interest from Hawaii: date palm (*Phoenix dactylifera*), papaya (*Carica papaya*), mango (*Mangifera indica*), autograph tree (*Clusia rosea*), figs (*Ficus*), loquat (*Eriobotrya japonica*), avocado (*Persea americana*), octopus tree (*Schefflera actinophylla*), and mock orange (*Murraya exotica*). Largely the same species are mentioned for Florida, where also citrus is a suggested food item (Carleton and Owre, 1975). For Australia, reference is made to damage to guava, peas, figs, strawberries and other soft fruits (MacPherson, 1923; Chaffer 1933). The species is also reported to damage agriculture in Japan (National Institute for Environmental Studies, 2017). In accordance with such observations, the red-whiskered bulbul is widely regarded as an agricultural threat to fruit orchards, vegetable gardens, and flower nurseries in introduced and native ranges (references in Islam and Williams, 2000). However, some debate exists on the extent to which the red-whiskered bulbul is responsible for the initial damage to larger fruits. Van Riper et al. (1979) noted that birds pierced the skin of the fruits, except for mature avocados, yet also noted that prior skin tearing from fruit ripening cannot be excluded. From limited experimentation and surveys with growers, although citrus (*Citrus* spp.) and mango (*Mangifera indica*) are readily consumed by the birds, Carleton and Owre (1975) concluded that the red-whiskered bulbul only damages fruits secondarily. On the internet, video footage can be found of red-whiskered bulbul damaging and eating white and red grapes and clearly causing the primary damage to these soft fruits (e.g. [https://www.naturefootage.com/video-clips/ASHA170208\\_0012/the-red-whiskered-bulbuls-pycnonotus-jocosus-landed-on-the-branch](https://www.naturefootage.com/video-clips/ASHA170208_0012/the-red-whiskered-bulbuls-pycnonotus-jocosus-landed-on-the-branch)). Overall no studies were found that provide formal, quantitative data on production losses. Mo (2015) ranks the species' importance as an agricultural pest to be more limited in Australia as compared to e.g. Common starling (*Sturnus vulgaris*).

Regarding the second (damage by weed dispersal), the red-whiskered bulbul can disperse many weeds that are a concern to agriculture or human settlements. These have been dealt with in Qu. 4.1.

As the species is a recognized agricultural pest species in many parts of the world and there are many, although mostly anecdotal, records of economic damages (many more probably remain unreported), we assume yearly damages can easily mount up to more than € 1,00,000 per year and scored moderate with low confidence.

**Qu. 4.10. How great is the economic cost of / loss due to damage (excluding costs of management) of the organism currently in the risk assessment area (include any past costs in your response)?**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the EU these should be reported here. Assessment of the potential costs of damage on human health, safety, and the economy, including the cost of non-action. A full economic assessment at EU scale might not be possible, but qualitative data or different case studies from across the EU (or third countries if relevant) may provide useful information to inform decision making. In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable). Cost of / loss due to damage within different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>	minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	--	-------------------	-----------------------

No studies were found that quantify the economic impact of the red-whiskered bulbul in its currently established population within the risk assessment area (Spain). Since this population is presumably still fairly small (estimated at 100-150 birds in 2015 but recent estimates are lacking, see Santos 2015), the current impact is assumed to be minimal with low confidence.

**Qu. 4.11. How great is the economic cost of / loss due to damage (excluding costs of management) of the organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.10.

<b>RESPONSE</b>	minimal minor moderate	<b>CONFIDENCE</b>	low medium high
-----------------	------------------------------	-------------------	-----------------------

	major massive		
--	------------------	--	--

Given uncertainty on the extent to which the species is the causative agent of direct damage to fruits, future economic damage is expected to be limited to private (garden) or public (park) areas. In gardens the species might impact small agricultural produce of vegetables and be perceived as a nuisance species, such as in other areas of the world (e.g. Hawaii) (see Qu 4.9). Indirect economic damage, through dispersal of weeds, is harder to assess.

In a recent horizon scan for future problematic invaders in Cyprus, the red-whiskered bulbul was identified as a top ranking species in terms of future economic impacts, which is linked to favourable conditions for establishment and the presence of economically important sensitive receptor crops like citrus and grapes (Peyton et al. 2019, 2020). Spain is an important producer of fresh fruit (e.g. strawberries) and vegetables (<https://wits.worldbank.org/>), with the area of Valencia where the species is currently established as an important citrus region. More widely, the European Union produces a wide range of fruit, berries and nuts. In 2019, the EU-27 produced 13.7 million tonnes of pome fruit (apples, pears and quinces), 7.3 million tonnes of stone fruit (peaches, nectarines, apricots, cherries, plums, sloes and medlar), 2.5 million tonnes of sub-tropical and tropical fruits (such as figs, kiwis, avocados and bananas), 0.6 million tonnes of berries (excluding strawberries), and 1.1 million tonnes of nuts. In addition, the EU also produced 10.6 million tonnes of citrus fruit (such as oranges, satsumas, clementines, mandarins, lemons, limes and grapefruit) in 2019 (source: eurostat). Spain and Italy are the key producers of fruit and large parts of their territory are within the endangered area for invasion by red-whiskered bulbul (see Annex VIII). Grapes are of particular concern since red-whiskered bulbuls might find suitable habitat in vineyards and could cause damages to the wine industry.

We scored moderate because although potentially impacted crops are widely present in the risk assessment area and therefore crop production could be impacted, research has shown red-whiskered bulbuls mostly induce damages secondarily and rely on other species to break open the skin of the fruit with the exception of some fruits such as citrus, grapes and mango that are readily consumed (Carlton and Owre, 1975). Also, growers can implement risk management strategies to reduce bird damages using netting, growing indoors or using bird repellents (these however, represent a cost). Confidence is low because most of the documented cases of damage to crops are anecdotal and there is no direct evidence of damages for the risk assessment area.

**Qu. 4.12. How great are the economic costs / losses associated with managing this organism currently in the risk assessment area (include any past costs in your response)?**

- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable).

<b>RESPONSE</b>	minimal <b>minor</b>	<b>CONFIDENCE</b>	<b>low</b> medium
-----------------	-------------------------	-------------------	----------------------

	moderate major massive		high
--	------------------------------	--	------

The species is not under post-border management in Spain. However, the species is listed on the Spanish catalogue of invasive alien species (Royal Decree 630/2013 and its modifications 216/2019). This implies the species can not be kept, transported or traded (Article 7). Transition measures oblige owners to report the possession of birds acquired prior to their incorporation on this list to the competent authorities (by January 2022). There are also provisions on border controls, early warning systems and management actions which in practice have to be implemented by the regional administrations, water authorities and national parks. As the implementation of these preventive actions requires human resources and capacity, this surely represents a cost. We therefore scored minor but with low confidence because this actual cost is not documented.

**Qu. 4.13. How great are the economic costs / losses associated with managing this organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.12.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

In a future situation where the suitable area for establishment within the risk assessment area increases (see Qu. 2.10.) and the species becomes widespread over that area (see Qu. 3.12.), the overall cost of management could become substantial. For comparison, on a small island like Assumption (11.6km<sup>2</sup>), a total of 5297 birds were removed with mist netting accounting for 80% of captures and shooting the majority of the rest (Seychelles; Bunbury et al. 2019) (see also Qu. 2.6). This eradication, after some initial desktop work for planning, took three years (2012-2014) and involved a team of between 3 and 30 people (Uranie 2015). Other documented eradications include the removal of a single bird from Aldabra (Bunbury et al. 2019), seven birds from Fuerteventura (Canary Islands) (Saavedra & Reynolds, 2019) and 75 birds in California (Clark, 1976). None of these actions was documented in terms of cost, but Saavedra & Reynolds (2019) provide a long list of activities requiring human and financial resources during such interventions. As a comparison, Parkes et al. (2006) estimated that the costs to achieve eradication of common myna (*Acridotheres tristis*) from Mangaia (Cook Islands, 5180 ha) with appropriate levels of monitoring would be about NZ\$100,000 (c. € 55,000), with 80% of that budget needed for preparation and training and surveillance, including detecting surviving birds. However, here, the method proposed was toxic baiting.

Given that effective management measures exist (see Qu. 2.6), and that these are relatively easy and cost-efficient to apply, but considering the cost of eradication campaigns on other bird species, we estimate that in a worst case scenario the management costs could easily exceed 100,000€ and

therefore scored moderate. Since data on costs from the literature are not species specific, confidence is low.

## Social and human health impacts

**Qu. 4.14. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism for the risk assessment area and for third countries, if relevant (e.g. with similar eco-climatic conditions).**

The description of the known impact and the assessment of potential future impact on human health, safety and the economy, shall, if relevant, include information on

- illnesses, allergies or other affections to humans that may derive directly or indirectly from a species;
- damages provoked directly or indirectly by a species with consequences for the safety of people, property or infrastructure;
- direct or indirect disruption of, or other consequences for, an economic or social activity due to the presence of a species.

Social and human health impacts can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

No social or human health impact has been described for the red-whiskered bulbul so far. Red-whiskered bulbul, like many other bird species, is a potential host and reservoir of avian influenza (see Q4.1). Thinh et al. (2012), out of 16 birds tested in Cuc Phuong National Park (northern Vietnam, 2007), describe one virus antibody-positive individual for the H9 hemagglutinin subtype, a low pathogenic avian influenza virus subtype widespread in nature in many species of wild waterfowl and shorebirds worldwide (Alexander, 2000). Influenza A viruses (IAVs) of the H9 subtype are enzootic in Asia, the Middle East, and parts of North and Central Africa, where they cause significant economic losses to the poultry industry (In Europe, vaccination has been adopted to prevent reoccurrences especially in turkeys in Germany and Italy (Capua and Alexander 2009)). Some strains of H9N2 viruses have been linked to zoonotic episodes of mild respiratory diseases (Carnaccini and Perez, 2020). H9N2 viruses are considered of pandemic concern by the World Health Organization (WHO). Another bulbul species, the black-capped bulbul *P. melanicterus*, tested positive for the H5 subtype. Thinh et al. (2012) also point out that sociality (bulbuls often occur in small groups and display communal roosting behaviour) is thought to enhance pathogen transmission among animals, in part because transmission is density-dependent. Because there is no evidence that the red-whiskered bulbul was directly implicated in transmission of highly pathogenic influenza and because poultry farming in the risk assessment area could locally be affected but the impact mitigated through vaccination campaigns, we scored minor.

**Qu. 4.15. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism in the future for the risk assessment area.**

- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. In this case, no score and confidence should be given and the standardized “score” is N/A (not applicable).

massive	

No changes to the response in Qu. 4.14. are expected under future conditions.

## Other impacts

**Qu. 4.16. How important is the organism in facilitating other damaging organisms (e.g. diseases) as food source, a host, a symbiont or a vector etc.?**

RESPONSE	CONFIDENCE
minimal	low
minor	medium
moderate	high
major	
massive	

A limited number of ectoparasites (ticks; Rajagopalan, 1972) and endoparasites (*Haemoproteus*; Islam and Williams, 2000) have been described, none of which are exclusively or disproportionately linked to the red-whiskered bulbul. The avian malaria parasite *Plasmodium (Novyella) jiangi* is an exception, as it was newly described from the species (He and Huang, 1993). However, the identity of this taxon is doubtful (Valkiūnas and Iezhova 2018) (see also Qu. 2.4).

**Qu. 4.17. How important might other impacts not already covered by previous questions be resulting from introduction of the organism?**

RESPONSE	CONFIDENCE
N/A	low
minimal	medium
minor	high

	moderate major massive		
--	------------------------------	--	--

No other possible impacts were found.

**Qu. 4.18. How important are the expected impacts of the organism despite any natural control by other organisms, such as predators, parasites or pathogens that may already be present in the risk assessment area?**

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Potential predators described in literature, and of relevance to the risk assessment area, are rats, cats, snakes (*Coluber* spp.), and birds of prey (*Falco* spp.; Carleton and Owre, 1975; Islam and Williams 2000; Li et al. 2015) (see also Qu. 2.4). Specific predators that occur in the suitable area, and that thrive well near human settlements, may thus be House cat (*Felis catus*), Brown rat (*Rattus norvegicus*), Black rat (*Rattus rattus*), Barn owl (*Tyto alba*), Sparrowhawk (*Accipiter nisus*), Ladder snake (*Zamenis scalaris*), Stone marten (*Martes foina*), or any related species with a similar feeding ecology. However, neither predators, parasites nor pathogens in the risk assessment area are expected to constrain the expected impacts of the red-whiskered bulbul in the risk assessment area.

**Qu. 4.19. Estimate the overall impact in the risk assessment area under current climate conditions. In addition, details of overall impact in relevant biogeographical regions should be provided.**

Thorough assessment of the overall impact on biodiversity and ecosystem services, with impacts on economy as well as social and human health as aggravating factors, in current conditions.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Under current conditions and should the species firmly establish and spread in natural areas, the species could exert a major impact on biodiversity and ecosystem services through the spread of invasive alien plants and associated changes in natural species compositions, predation, competition

and to a lesser extent pathogen transmission (see Qu 4.2). This could especially be the case on islands with small populations of endemic species. The endangered area for the red-whiskered bulbul covers the Mediterranean, Black sea, Atlantic (and Anatolian) biogeographic regions (A2.1, A2.9, A2.10, Annex VIII).

**Qu. 4.20. Estimate the overall impact in the risk assessment area in foreseeable climate change conditions. In addition, details of overall impact in relevant biogeographical regions should be provided.**

Thorough assessment of the overall impact on biodiversity and ecosystem services, with impacts on economy as well as social and human health as aggravating factors, under future conditions.

See also guidance to Qu. 4.3.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Under future climate, the suitable region for establishment in the risk assessment area is predicted to almost double in the Mediterranean biogeographic region and to increase in the other biogeographic regions (Black Sea). Also, in the Atlantic biogeographic region, where regular escaped birds are reported, the suitability for establishment increases slightly (see also Qu 2.10, Annex VIII).

<b>RISK SUMMARIES</b>			
	<b>RESPONSE</b>	<b>CONFIDENCE</b>	<b>COMMENT</b>
<b>Summarise Introduction and Entry*</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	low medium <b>high</b>	The red-whiskered bulbul is present in zoos and private collections in multiple countries geographically spread within the risk assessment area, presumably in good numbers. It is the most popular bulbul species with specialised breeders and bird keepers although quantitative data on size and trends in captive population are lacking for the risk assessment area. The many confirmed observations of escaped birds across the risk assessment area confirm that continued escapes (and/or releases) are very likely.
<b>Summarise Establishment*</b>	very unlikely unlikely moderately likely	low medium <b>high</b>	The species is already established in the risk assessment area (Spain) and this population is increasing

	likely <b>very likely</b>		in abundance and spreading. Several biogeographic regions are vulnerable to invasion by red-whiskered bulbul. Predators or pathogens are unlikely to prevent successful establishment and the proportion of the area suitable for establishment is expected to increase under foreseeable climatic conditions.
<b>Summarise Spread*</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	low <b>medium</b> high	Population growth rates and geographic spread of red-whiskered bulbul outside the risk assessment area vary, with island populations showing rapid spread and mainland populations often showing longer lag times. The current established population in the risk assessment area is spreading since its introduction about two decades ago; this area however provides continuous suitable habitat to the species. Climate change could foster reproduction which might positively enhance dispersal and spread.
<b>Summarise Impact*</b>	minimal minor moderate <b>major</b> massive	low <b>medium</b> high	The red-whiskered bulbul can impact on native species and ecosystems through competition, frugivory and spreading of invasive alien plants, predation on (in)vertebrates and pathogen transmission. It is also a reported pest species impacting on garden plants, fruits and vegetables. Although the current impact in the risk assessment area is moderate, there is sufficient evidence elsewhere of ecosystem level effects through the spread of invasive plants from the urban to the natural (mostly forest) biome, competitive exclusion of other bird species and local extinction by predation.
<b>Conclusion of the risk assessment (overall risk)</b>	low moderate <b>high</b>	low <b>medium</b> high	Considering the multi-faceted potential ecological and economic impacts of the red-whiskered bulbul, its large native range in line with broad climatic and environmental amplitudes, the suitable area for establishment

			<p>which spans multiple biogeographic regions and countries, the presence of sensitive island biota, ecosystem-level effects and documented competitive exclusions and local extinctions of native species the overall risk is scored high. This score is in line with several environmental impact assessments of alien birds using established scoring protocols. There is an urgent need to provide evidence of impacts in the risk assessment area.</p>

## Distribution Summary

Please answer as follows:

- Yes if recorded, established or invasive
- if not recorded, established or invasive
- ? Unknown; data deficient

The columns refer to the answers to Questions A5 to A12 under Section A.

For data on marine species at the Member State level, delete Member States that have no marine borders. In all other cases, provide answers for all columns.

Member States and the United Kingdom

	Recorded	Established (currently)	Possible establishment (under current climate)	Possible establishment (under foreseeable climate)	Invasive (currently)
Austria	-	-	-	-	-
Belgium	Yes	-	-	-	-

## ANNEX I Scoring of Likelihoods of Events

(taken from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

<b>Score</b>	<b>Description</b>	<b>Frequency</b>
Very unlikely	This sort of event is theoretically possible, but is never known to have occurred and is not expected to occur	1 in 10,000 years
Unlikely	This sort of event has occurred somewhere at least once in the last millenium	1 in 1,000 years
Moderately likely	This sort of event has occurred somewhere at least once in the last century	1 in 100 years
Likely	This sort of event has happened on several occasions elsewhere, or on at least once in the last decade	1 in 10 years
Very likely	This sort of event happens continually and would be expected to occur	Once a year

## ANNEX II Scoring of Magnitude of Impacts

(modified from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

Score	Biodiversity and ecosystem impact	Ecosystem Services impact	Economic impact (Monetary loss and response costs per year)	Social and human health impact, and other impacts
	<i>Question 5.1-5</i>	<i>Question 5.6-8</i>	<i>Question 5.9-13</i>	<i>Question 5.14-18</i>
Minimal	Local, short-term population loss, no significant ecosystem effect	No services affected <sup>5</sup>	Up to 10,000 Euro	No social disruption. Local, mild, short-term reversible effects to individuals.
Minor	Some ecosystem impact, reversible changes, localised	Local and temporary, reversible effects to one or few services	10,000-100,000 Euro	Significant concern expressed at local level. Mild short-term reversible effects to identifiable groups, localised.
Moderate	Measureable long-term damage to populations and ecosystem, but reversible; little spread, no extinction	Measureable, temporary, local and reversible effects on one or several services	100,000-1,000,000 Euro	Temporary changes to normal activities at local level. Minor irreversible effects and/or larger numbers covered by reversible effects, localised.
Major	Long-term irreversible ecosystem change, spreading beyond local area	Local and irreversible or widespread and reversible effects on one / several services	1,000,000-10,000,000 Euro	Some permanent change of activity locally, concern expressed over wider area. Significant irreversible effects locally or reversible effects over large area.
Massive	Widespread, long-term population loss or extinction, affecting several species with serious ecosystem effects	Widespread and irreversible effects on one / several services	Above 10,000,000 Euro	Long-term social change, significant loss of employment, migration from affected area. Widespread, severe, long-term, irreversible health effects.

<sup>5</sup> Not to be confused with “no impact”.

## ANNEX III Scoring of Confidence Levels

(modified from Bacher et al. 2017)

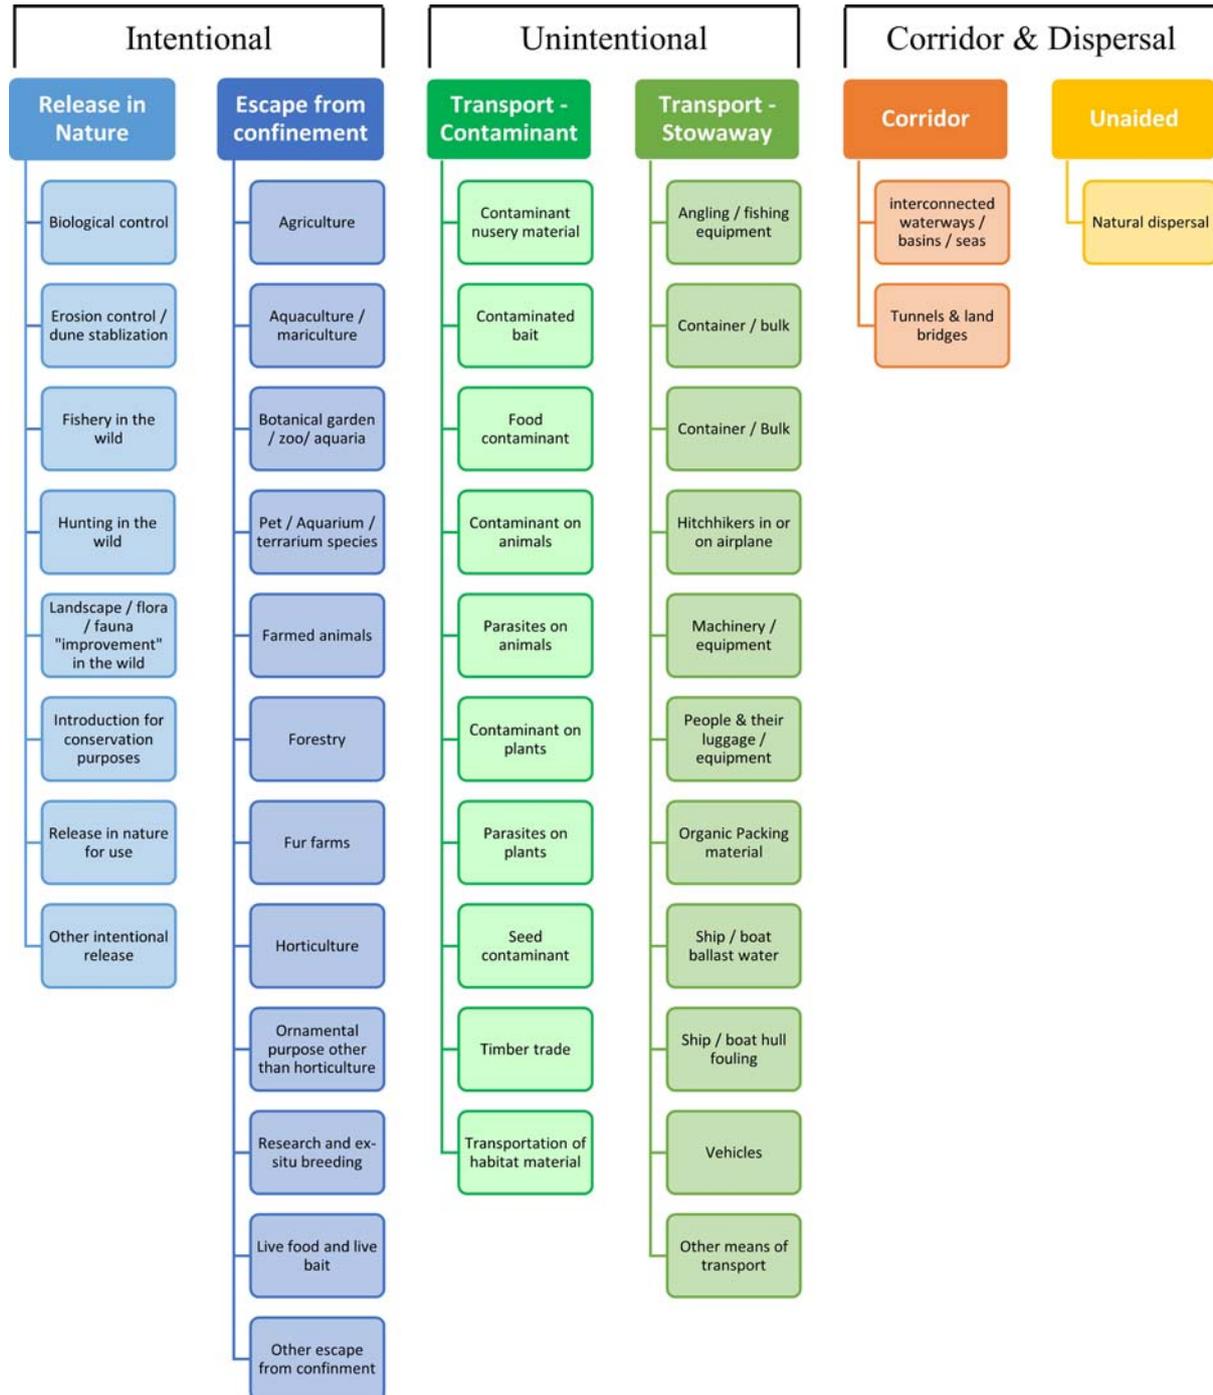

Each answer provided in the risk assessment must include an assessment of the level of confidence attached to that answer, reflecting the possibility that information needed for the answer is not available or is insufficient or available but conflicting.

The responses in the risk assessment should clearly support the choice of the confidence level.

Confidence level	Description
Low	There is no direct observational evidence to support the assessment, e.g. only inferred data have been used as supporting evidence <i>and/or</i> Impacts are recorded at a spatial scale which is unlikely to be relevant to the assessment area <i>and/or</i> Evidence is poor and difficult to interpret, e.g. because it is strongly ambiguous <i>and/or</i> The information sources are considered to be of low quality or contain information that is unreliable.
Medium	There is some direct observational evidence to support the assessment, but some information is inferred <i>and/or</i> Impacts are recorded at a small spatial scale, but rescaling of the data to relevant scales of the assessment area is considered reliable, or to embrace little uncertainty <i>and/or</i> The interpretation of the data is to some extent ambiguous or contradictory.
High	There is direct relevant observational evidence to support the assessment (including causality) <i>and</i> Impacts are recorded at a comparable scale <i>and/or</i> There are reliable/good quality data sources on impacts of the taxa <i>and</i> The interpretation of data/information is straightforward <i>and/or</i> Data/information are not controversial or contradictory.

## ANNEX IV CBD pathway categorisation scheme

Overview of CBD pathway categorisation scheme showing how the 44 pathways relate to the six main pathway categories. All of the pathways can be broadly classified into 1) those that involve intentional transport (blue), 2) those in which the taxa are unintentionally transported (green) and 3) those where taxa moved between regions without direct transportation by humans and/or via artificial corridors (orange and yellow). **Note that the pathways in the category “Escape from confinement” can be considered intentional for the introduction into the risk assessment area and unintentional for the entry into the environment.**

## ANNEX V Ecosystem services classification (CICES V5.1, simplified) and examples

For the purposes of this risk assessment, please feel free to use what seems as the most appropriate category / level / combination of impact (Section – Division – Group), reflecting information available.

Section	Division	Group	Examples (i.e. relevant CICES “classes”)
Provisioning	Biomass	<b>Cultivated <i>terrestrial</i> plants</b>	Cultivated terrestrial plants (including fungi, algae) grown for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from cultivated plants, fungi, algae and bacteria for direct use or processing (excluding genetic materials); Cultivated plants (including fungi, algae) grown as a <u>source of energy</u>  <i>Example: negative impacts of non-native organisms to crops, orchards, timber etc.</i>
		<b>Cultivated <i>aquatic</i> plants</b>	Plants cultivated by in- situ aquaculture grown for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from in-situ aquaculture for direct use or processing (excluding genetic materials); Plants cultivated by in- situ aquaculture grown as an <u>energy source</u> .  <i>Example: negative impacts of non-native organisms to aquatic plants cultivated for nutrition, gardening etc. purposes.</i>
		<b>Reared animals</b>	Animals reared for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from reared animals for direct use or processing (excluding genetic materials); Animals reared to provide <u>energy</u> (including mechanical)  <i>Example: negative impacts of non-native organisms to livestock</i>
		<b>Reared <i>aquatic</i> animals</b>	Animals reared by in-situ aquaculture for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from animals grown by in-situ aquaculture for direct use or processing (excluding genetic materials); Animals reared by in-situ aquaculture as an <u>energy source</u>  <i>Example: negative impacts of non-native organisms to fish farming</i>
		<b>Wild plants (terrestrial and aquatic)</b>	Wild plants (terrestrial and aquatic, including fungi, algae) used for <u>nutrition</u> ; <u>Fibres and other materials</u> from wild plants for direct use or processing (excluding genetic materials); Wild plants (terrestrial and aquatic, including fungi, algae) used as a <u>source of energy</u>  <i>Example: reduction in the availability of wild plants (e.g. wild berries, ornamentals) due to non-native organisms (competition, spread of disease etc.)</i>
		<b>Wild animals (terrestrial and aquatic)</b>	Wild animals (terrestrial and aquatic) used for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from wild animals for direct use or processing (excluding genetic materials); Wild animals (terrestrial and aquatic) used as a <u>source of energy</u>

			<i>Example: reduction in the availability of wild animals (e.g. fish stocks, game) due to non-native organisms (competition, predations, spread of disease etc.)</i>
	<b>Genetic material</b> from all biota	<b>Genetic material</b> from plants, algae or fungi	Seeds, spores and other plant materials collected for maintaining or establishing a population; Higher and lower plants (whole organisms) used to <u>breed new strains or varieties</u> ; Individual genes extracted from higher and lower plants for the design and construction of new biological entities  <i>Example: negative impacts of non-native organisms due to interbreeding</i>
		<b>Genetic material</b> from animals	Animal material collected for the purposes of maintaining or establishing a population; Wild animals (whole organisms) used to breed new strains or varieties; Individual genes extracted from organisms for the design and construction of new biological entities  <i>Example: negative impacts of non-native organisms due to interbreeding</i>
	<b>Water</b> <sup>6</sup>	<b>Surface water</b> used for nutrition, materials or energy	Surface water for <u>drinking</u> ; Surface water used as a material ( <u>non-drinking purposes</u> ); Freshwater surface water, coastal and marine water used as an <u>energy source</u>  <i>Example: loss of access to surface water due to spread of non-native organisms</i>
		<b>Ground water</b> for used for nutrition, materials or energy	Ground (and subsurface) water for <u>drinking</u> ; Ground water (and subsurface) used as a material ( <u>non-drinking purposes</u> ); Ground water (and subsurface) used as an <u>energy source</u>  <i>Example: reduced availability of ground water due to spread of non-native organisms and associated increase of ground water consumption by vegetation.</i>
<b>Regulation &amp; Maintenance</b>	<b>Transformation</b> of biochemical or physical inputs to ecosystems	<b>Mediation of wastes or toxic substances</b> of anthropogenic origin by living processes	<u>Bio-remediation</u> by micro-organisms, algae, plants, and animals; <u>Filtration/sequestration/storage/accumulation</u> by micro-organisms, algae, plants, and animals  <i>Example: changes caused by non-native organisms to ecosystem functioning and ability to filtrate etc. waste or toxics</i>
		<b>Mediation of nuisances</b> of anthropogenic origin	<u>Smell reduction; noise attenuation; visual screening</u> (e.g. by means of green infrastructure)  <i>Example: changes caused by non-native organisms to ecosystem structure, leading to reduced ability to mediate nuisances.</i>
	<b>Regulation</b> of physical, chemical, biological conditions	<b>Baseline flows and extreme event</b> regulation	Control of <u>erosion</u> rates; Buffering and attenuation of <u>mass movement</u> ; <u>Hydrological cycle and water flow regulation</u> (Including flood control, and coastal protection); <u>Wind</u> protection; <u>Fire</u> protection  <i>Example: changes caused by non-native organisms to ecosystem functioning or structure leading to, for example, destabilisation of soil, increased risk or intensity of wild fires</i>

<sup>6</sup> Note: in the CICES classification provisioning of water is considered as an abiotic service whereas the rest of ecosystem services listed here are considered biotic.

			etc.
		<b>Lifecycle maintenance, habitat and gene pool protection</b>	<p>Pollination (or 'gamete' dispersal in a marine context); <u>Seed dispersal</u>; Maintaining <u>nursery populations and habitats</u> (Including gene pool protection)</p> <p><i>Example: changes caused by non-native organisms to the abundance and/or distribution of wild pollinators; changes to the availability / quality of nursery habitats for fisheries</i></p>
		<b>Pest and disease control</b>	<p>Pest control; Disease control</p> <p><i>Example: changes caused by non-native organisms to the abundance and/or distribution of pests</i></p>
		<b>Soil quality regulation</b>	<p><u>Weathering processes</u> and their effect on soil quality; <u>Decomposition and fixing processes</u> and their effect on soil quality</p> <p><i>Example: changes caused by non-native organisms to vegetation structure and/or soil fauna leading to reduced soil quality</i></p>
		<b>Water conditions</b>	<p>Regulation of the <u>chemical condition</u> of freshwaters by living processes; Regulation of the chemical condition of salt waters by living processes</p> <p><i>Example: changes caused by non-native organisms to buffer strips along water courses that remove nutrients in runoff and/or fish communities that regulate the resilience and resistance of water bodies to eutrophication</i></p>
		<b>Atmospheric composition and conditions</b>	<p>Regulation of <u>chemical composition</u> of atmosphere and oceans; Regulation of <u>temperature and humidity</u>, including ventilation and transpiration</p> <p><i>Example: changes caused by non-native organisms to ecosystems' ability to sequester carbon and/or evaporative cooling (e.g. by urban trees)</i></p>
<b>Cultural</b>	<b>Direct, in-situ and outdoor interactions</b> with living systems that depend on presence in the environmental setting	<b>Physical and experiential</b> interactions with natural environment	<p>Characteristics of living systems that that enable activities promoting health, recuperation or enjoyment through <u>active or immersive interactions</u>;</p> <p>Characteristics of living systems that enable activities promoting health, recuperation or enjoyment through <u>passive or observational interactions</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that make it attractive for recreation, wild life watching etc.</i></p>
		<b>Intellectual and representative</b> interactions with natural environment	<p>Characteristics of living systems that enable <u>scientific investigation</u> or the creation of traditional ecological knowledge;</p> <p>Characteristics of living systems that enable <u>education and training</u>;</p> <p>Characteristics of living systems that are resonant in terms of <u>culture or heritage</u>;</p> <p>Characteristics of living systems that enable <u>aesthetic experiences</u></p>

			<i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have cultural importance</i>
	<b>Indirect, remote, often indoor interactions</b> with living systems that do not require presence in the environmental setting	<b>Spiritual, symbolic</b> and other interactions with natural environment	Elements of living systems that have <u>symbolic meaning</u> ; Elements of living systems that have <u>sacred or religious meaning</u> ; Elements of living systems used for <u>entertainment or representation</u>  <i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have sacred or religious meaning</i>
		Other biotic characteristics that have a <b>non-use value</b>	Characteristics or features of living systems that have an <u>existence value</u> ; Characteristics or features of living systems that have an <u>option or bequest value</u>  <i>Example: changes caused by non-native organisms to ecosystems designated as wilderness areas, habitats of endangered species etc.</i>

# **ANNEX VIII Projection of environmental suitability for the establishment of the red-whiskered bulbul *Pycnonotus jocosus* in Europe**

Björn Beckmann, Tim Adriaens, Bram D'hondt, Riccardo Scalera, Wolfgang Rabitsch and Dan Chapman

15 June 2021 (version 3)

## ***Aim***

To project the suitability for potential establishment of the red-whiskered bulbul *Pycnonotus jocosus* in Europe, under current and predicted future climatic conditions.

## ***Data for modelling***

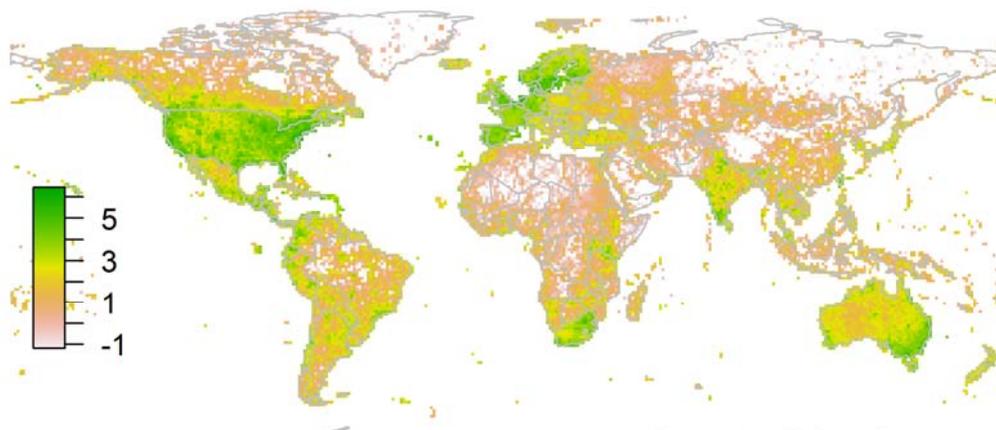

Species occurrence data were obtained from the Global Biodiversity Information Facility (GBIF) (291092 records), the Biodiversity Information Serving Our Nation database (BISON) (10458 records), iNaturalist (3915 records), the Integrated Digitized Biocollections (iDigBio) (38 records), the VertNet databases (30 records), and additional records from the risk assessment team. We scrutinised occurrence records from regions where the species is not known to be established and removed any dubious records or where the georeferencing was too imprecise (e.g. records referenced to a country or island centroid) or outside of the coverage of the predictor layers (e.g. small island or coastal occurrences). The remaining records were gridded at a 0.25 x 0.25 degree resolution for modelling, yielding 2307 grid cells with occurrences (Figure 1a). As a proxy for recording effort, the density of Aves records held by GBIF was also compiled on the same grid (Figure 1b).

**Figure 1.** (a) Occurrence records obtained for the red-whiskered bulbul and used in the modelling, showing native and invaded distributions. (b) The recording density of Aves on GBIF, which was used as a proxy for recording effort.

(a) Species distribution used in modelling

(b) Estimated recording effort (log10-scaled)

Climate data were selected from the 'Bioclim' variables contained within the WorldClim database (Hijmans et al., 2005), originally at 5 arcminute resolution (0.083 x 0.083 degrees of longitude/latitude) and aggregated to a 0.25 x 0.25 degree grid for use in the model.

Based on the biology of the red-whiskered bulbul, the following climate variables were used in the modelling:

- Annual mean temperature (Bio1)
- Minimum temperature of the coldest month (Bio6)
- Mean temperature of the warmest quarter (Bio10)
- Annual precipitation (Bio12)
- Precipitation of the wettest month (Bio13)
- Precipitation of the driest month (Bio14)

- Climatic moisture index (CMI): ratio of mean annual precipitation to potential evapotranspiration, log+1 transformed. For its calculation, monthly potential evapotranspirations were estimated from the WorldClim monthly temperature data and solar radiation using the simple method of Zomer et al. (2008) which is based on the Hargreaves evapotranspiration equation (Hargreaves, 1994).

To estimate the effect of climate change on the potential distribution, equivalent modelled future climate conditions for the 2070s under the Representative Concentration Pathways (RCP) 2.6 and 4.5 were also obtained. These represent low and medium emissions scenarios, respectively. The above variables were obtained as averages of outputs of eight Global Climate Models (BCC-CSM1-1, CCSM4, GISS-E2-R, HadGEM2-AO, IPSL-CM5A-LR, MIROC-ESM, MRI-CGCM3, NorESM1-M), downscaled and calibrated against the WorldClim baseline ([http://www.worldclim.org/cmip5\\_5m](http://www.worldclim.org/cmip5_5m)).

The following habitat layers were also used:

- Tree cover (Tree): This was estimated from the MODerate-resolution Imaging Spectroradiometer (MODIS) satellite continuous tree cover raster product, produced by the Global Land Cover Facility (<http://glcf.umd.edu/data/vcf/>). The raw product contains the percentage cover by trees in each 0.002083 x 0.002083 degree grid cell. We aggregated this to the mean cover in our 0.25 x 0.25 degree grid cells.
- Human influence index (HII): As many non-native invasive species associate with anthropogenically disturbed habitats. We used the Global Human Influence Index Dataset of the Last of the Wild Project (Wildlife Conservation Society - WCS & Center for International Earth Science Information Network - CIESIN - Columbia University, 2005), which is developed from nine global data layers covering human population pressure (population density), human land use and infrastructure (built-up areas, nighttime lights, land use/land cover) and human access (coastlines, roads, railroads, navigable rivers). The index ranges between 0 and 1 and was ln+1 transformed for the modelling to improve normality.

### ***Species distribution model***

A presence-background (presence-only) ensemble modelling strategy was employed using the BIOMOD2 R package version 3.4.6 (Thuiller et al., 2020, Thuiller et al., 2009). These models contrast the environment at the species' occurrence locations against a random sample of the global background environmental conditions (often termed 'pseudo-absences') in order to characterise and project suitability for occurrence. This approach has been developed for distributions that are in equilibrium with the environment. Because invasive species' distributions are not at equilibrium and subject to dispersal constraints at a global scale, we took care to minimise the inclusion of locations suitable for the species but where it has not been able to disperse to (Chapman et al. 2019). Therefore the background sampling region included:

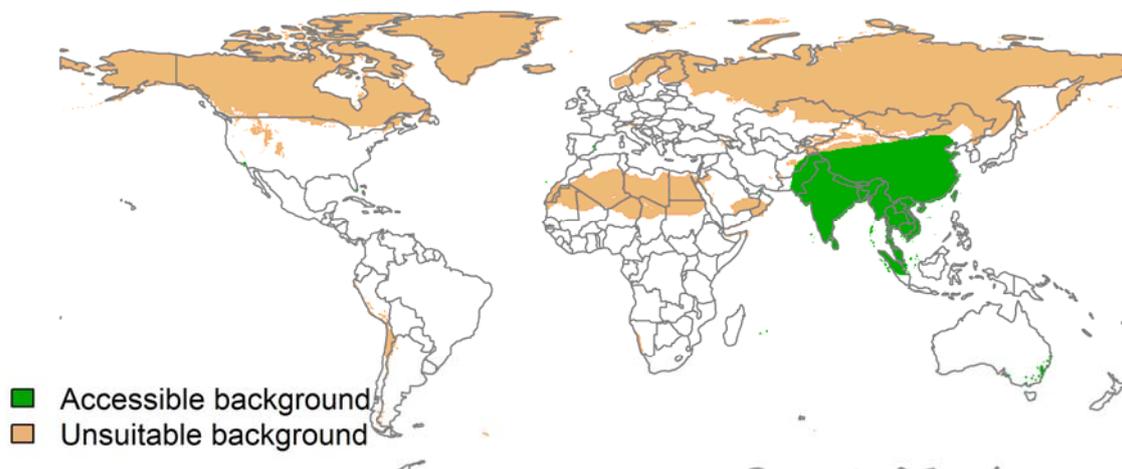

- The area accessible by native red-whiskered bulbul populations, in which the species is likely to have had sufficient time to disperse to all locations. Based on presumed maximum dispersal distances, the accessible region was defined as a 400km buffer around the native range occurrences; AND
- A 30km buffer around the non-native occurrences, encompassing regions likely to have had high propagule pressure for introduction by humans and/or dispersal of the species; AND
- Regions where we have an *a priori* expectation of high unsuitability for the species so that absence is assumed irrespective of dispersal constraints (see Figure 2). The following rules were applied to define a region expected to be highly unsuitable for the red-whiskered bulbul at the spatial scale of the model:

- Annual mean temperature (Bio1) < 4°C
- Annual precipitation (Bio12) < 55mm

Altogether, only 0.3% of occurrence grid cells were located in the unsuitable background region.

Within the unsuitable background region, 10 samples of 5000 randomly sampled grid cells were obtained. In the accessible background (comprising the accessible areas around native and non-native occurrences as detailed above), the same number of pseudo-absence samples were drawn as there were presence records (2307), weighting the sampling by a proxy for recording effort (Figure 2).

**Figure 2.** The background from which pseudo-absence samples were taken in the modelling of the red-whiskered bulbul. Samples were taken from a 400km buffer around the native range and a 30km buffer around non-native occurrences (together forming the accessible background), and from areas expected to be highly unsuitable for the species (the unsuitable background region). Samples from the accessible background were weighted by a proxy for recording effort (Figure 1(b)).

Each dataset (i.e. combination of the presences and the individual background samples) was randomly split into 80% for model training and 20% for model evaluation. With each training dataset, seven statistical algorithms were fitted with the default BIOMOD2 settings and rescaled using logistic regression, except where specified below:

- Generalised linear model (GLM)
- Generalised boosting model (GBM)
- Generalised additive model (GAM) with a maximum of four degrees of freedom per smoothing spline
- Artificial neural network (ANN)
- Multivariate adaptive regression splines (MARS)
- Random forest (RF)
- Maxent

Since the total background sample was larger than the number of occurrences, prevalence fitting weights were applied to give equal overall importance to the occurrences and the background. Normalised variable importance was assessed and variable response functions were produced using BIOMOD2's default procedure.

Model predictive performance was assessed by the following three measures:

- AUC, the area under the receiver operating characteristic curve (Fielding & Bell 1997). Predictions of presence-absence models can be compared with a subset of records set aside for model evaluation (here 20%) by constructing a confusion matrix with the number of true positive, false positive, false negative and true negative cases. For models generating non-dichotomous scores (as here) a threshold can be applied to transform the scores into a dichotomous set of presence-absence predictions. Two measures that can be derived from the confusion matrix are sensitivity (the proportion of observed presences that are predicted as such, quantifying omission errors), and specificity (the proportion of observed absences that are predicted as such, quantifying commission errors). A receiver operating characteristic (ROC) curve can be constructed by using all possible thresholds to classify the scores into confusion matrices, obtaining sensitivity and specificity for each matrix, and plotting sensitivity against the corresponding proportion of false positives (equal to  $1 - \text{specificity}$ ). The use of all possible thresholds avoids the need for a selection of a single threshold, which is often arbitrary, and allows appreciation of the trade-off between sensitivity and specificity. The area under the ROC curve (AUC) is often used as a single threshold-independent measure for model performance (Manel, Williams & Ormerod 2001). AUC is the probability that a randomly selected presence has a higher model-predicted suitability than a randomly selected absence (Allouche et al. 2006).
- Cohen's Kappa (Cohen 1960). This measure corrects the overall accuracy of model predictions (ratio of the sum of true presences plus true absences to the total number of records) by the accuracy expected to occur by chance. The kappa statistic ranges from -1 to +1, where +1 indicates perfect agreement and values of zero or less indicate a performance no better than random. Advantages of kappa are its simplicity, the fact that both commission and omission errors are accounted for in one parameter, and its relative tolerance to zero values in the confusion matrix (Manel, Williams & Ormerod 2001). However, Kappa has been criticised for being sensitive to prevalence (the proportion of sites in which the species was recorded as present) and may therefore be inappropriate for comparisons of model accuracy between species or regions (McPherson, Jetz & Rogers 2004, Allouche et al. 2006).
- TSS, the true skill statistic (Allouche et al. 2006). TSS is defined as sensitivity + specificity - 1, and corrects for Kappa's dependency on prevalence. TSS compares the number of correct forecasts, minus those attributable to random guessing, to that of a hypothetical set of perfect forecasts. Like kappa, TSS takes into account both omission and commission errors, and success as a result of random guessing, and ranges from -1 to +1, where +1 indicates perfect agreement and values of zero or less indicate a performance no better than random (Allouche et al. 2006).

An ensemble model was created by first rejecting poorly performing algorithms with relatively extreme low AUC values and then averaging the predictions of the remaining algorithms, weighted by their AUC. To identify poorly performing algorithms, AUC values were converted into modified z-scores based on their difference to the median and the median absolute deviation across all algorithms (Iglewicz & Hoaglin 1993). Algorithms with  $z < -2$  were rejected. In this way, ensemble projections were made for each dataset and then averaged to give an overall suitability, as well as its standard deviation.

Projections were classified into suitable and unsuitable regions using a "lowest presence threshold" (Pearson et al. 2007), setting the cut-off as the lowest value at which 98% of all presence records are classified correctly under the current climate (here 0.29). In order to express the sensitivity of classifications to the choice of this threshold, thresholds at which 95% and 99% of records are

classified correctly (here 0.42 and 0.2 respectively) were used in the calculation of error bars in Figs. 9 and 10 below in addition to taking account of uncertainty in the projections themselves.

We also produced a limiting factor map for Europe following Elith et al. (2010). For this, projections were made separately with each individual variable fixed at a near-optimal value. These were chosen as the median values at the occurrence grid cells. Then, the most strongly limiting factors were identified as the ones resulting in the highest increase in suitability in each grid cell.

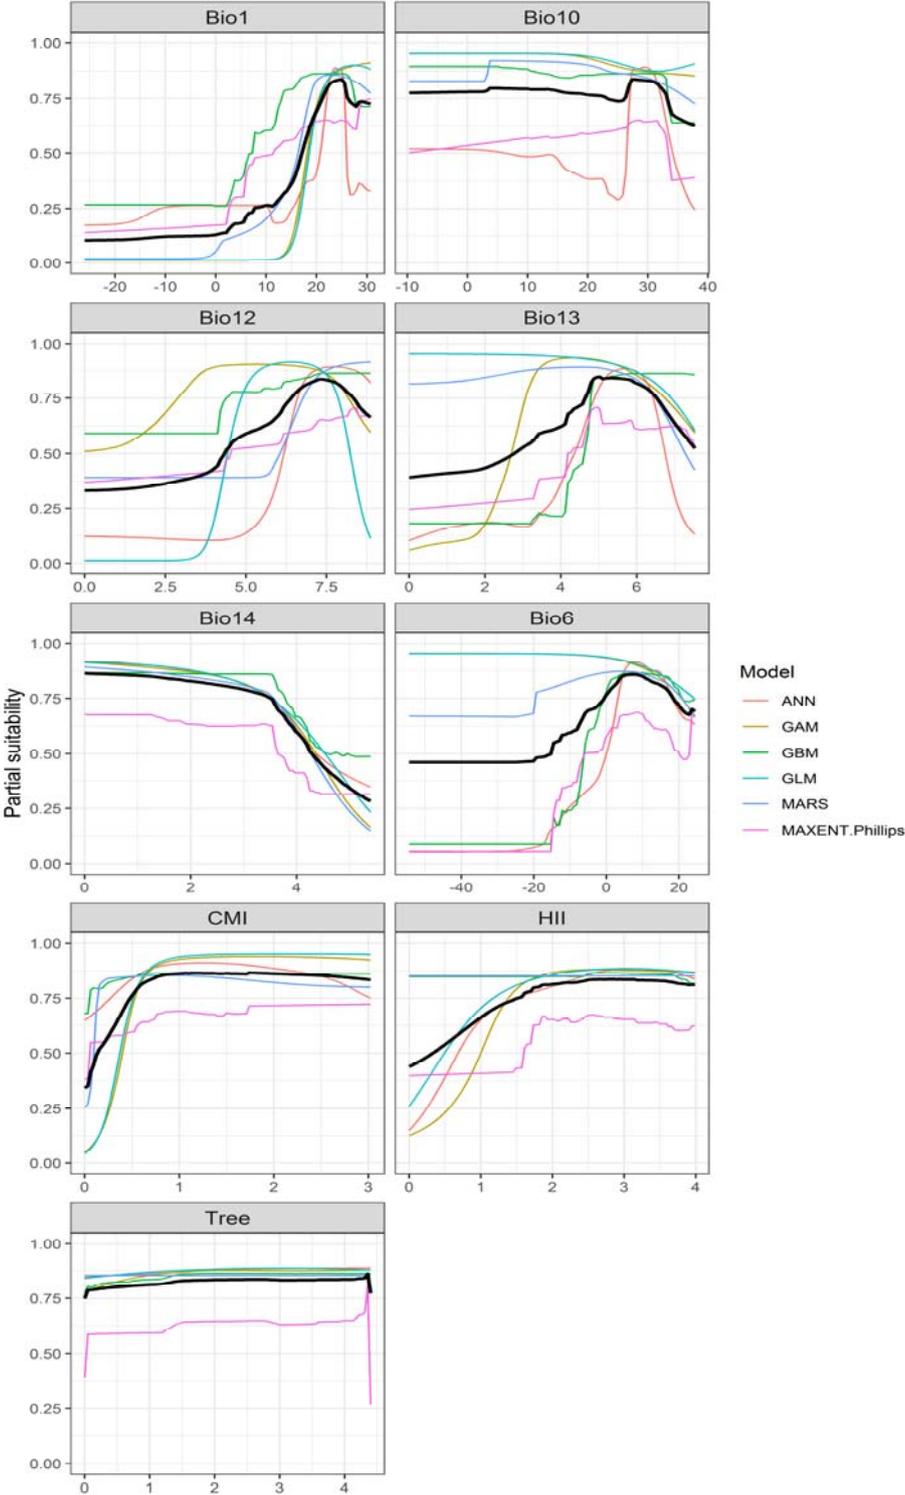

## Results

The ensemble model suggested that suitability for the red-whiskered bulbul was most strongly determined by Annual mean temperature (Bio1), accounting for 40.5% of variation explained, followed by Minimum temperature of the coldest month (Bio6) (20.8%), Precipitation of the wettest month (Bio13) (8.7%), Annual precipitation (Bio12) (7.2%), Climatic moisture index (CMI) (6.8%), Mean temperature of the warmest quarter (Bio10) (6.2%), Human influence index (HII) (4.6%), Precipitation of the driest month (Bio14) (4.2%) and Global tree cover (Tree) (1%) (Table 1, Figure 3).

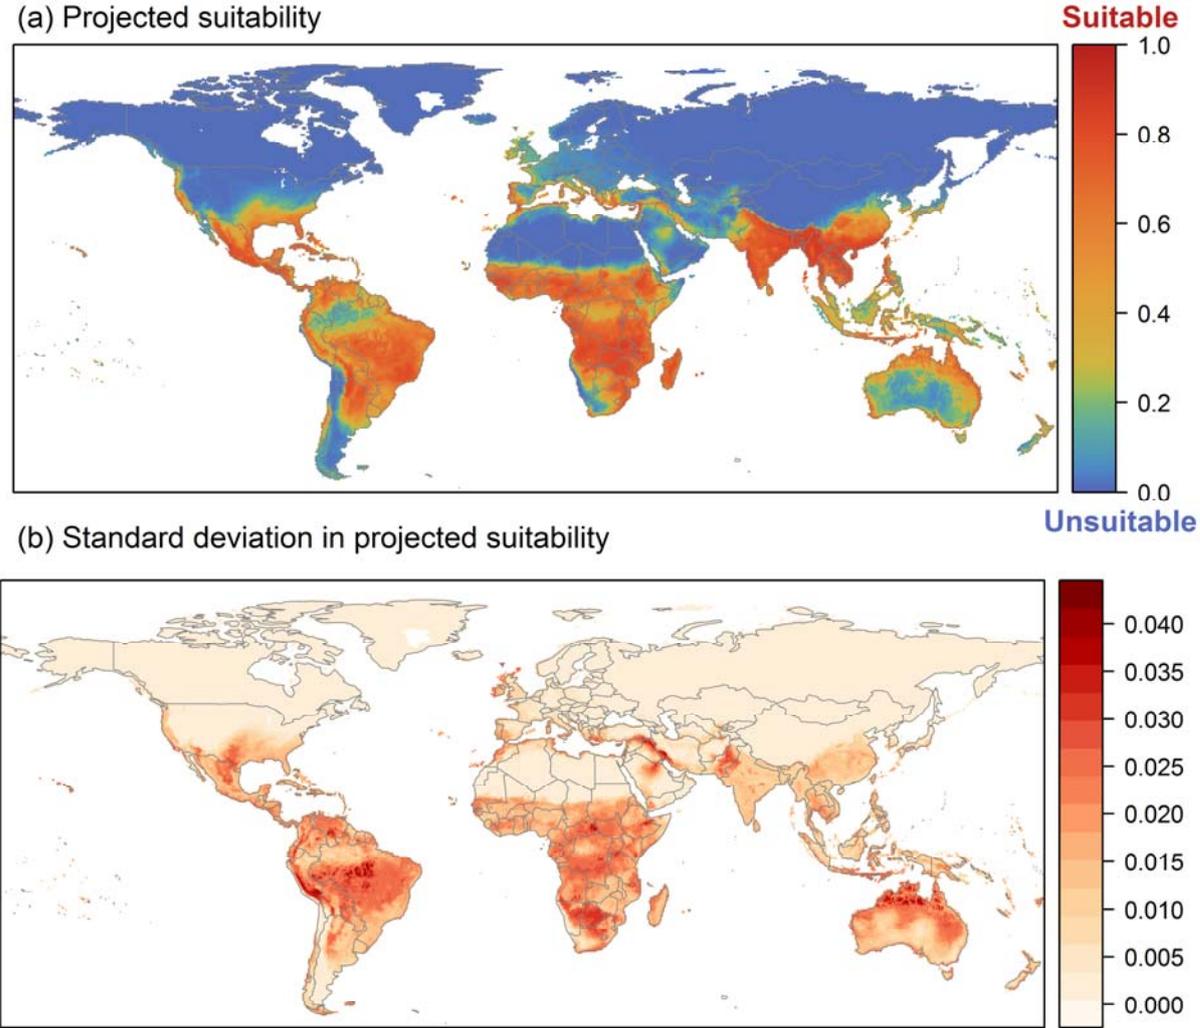

**Table 1.** Summary of the cross-validation predictive performance (AUC, Kappa, TSS) and variable importance of the fitted model algorithms and the ensemble (AUC-weighted average of the best performing algorithms). Results are the average from models fitted to 10 different background samples of the data.

Algorithm	AUC	Kappa	TSS	Used in the ensemble	Variable importance (%)								
					Annual mean temperature (Bio1)	Minimum temperature of the coldest month (Bio6)	Precipitation of the wettest month (Bio13)	Annual precipitation (Bio12)	Climatic moisture index (CMI)	Mean temperature of the warmest quarter (Bio10)	Human influence index (HII)	Precipitation of the driest month (Bio14)	Global tree cover (Tree)
GLM	0.895	0.561	0.703	yes	54	5	2	9	14	6	5	4	0
GAM	0.896	0.561	0.701	yes	57	5	4	2	12	7	8	4	1
GBM	0.897	0.571	0.699	yes	25	43	24	1	1	1	1	4	0

<b>Ensemble</b>	<b>0.903</b>	<b>0.576</b>	<b>0.703</b>		<b>41</b>	<b>21</b>	<b>9</b>	<b>7</b>	<b>7</b>	<b>6</b>	<b>5</b>	<b>4</b>	<b>1</b>

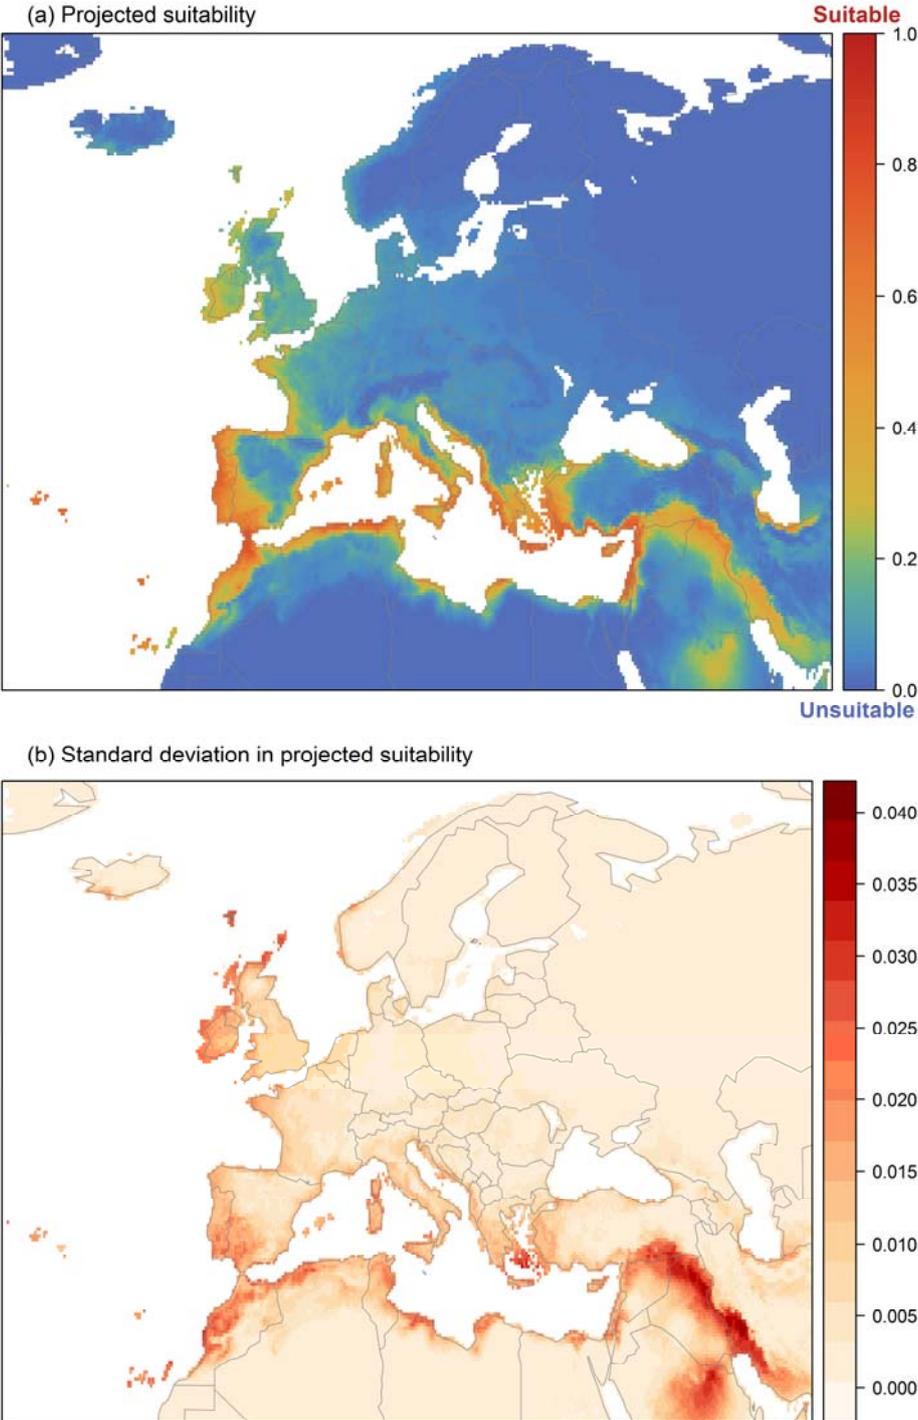

**Figure 3.** Partial response plots from the fitted models. Thin coloured lines show responses from the algorithms in the ensemble, while the thick black line is their ensemble. In each plot, other model variables are held at their median value in the training data. Some of the divergence among algorithms is because of their different treatment of interactions among variables.

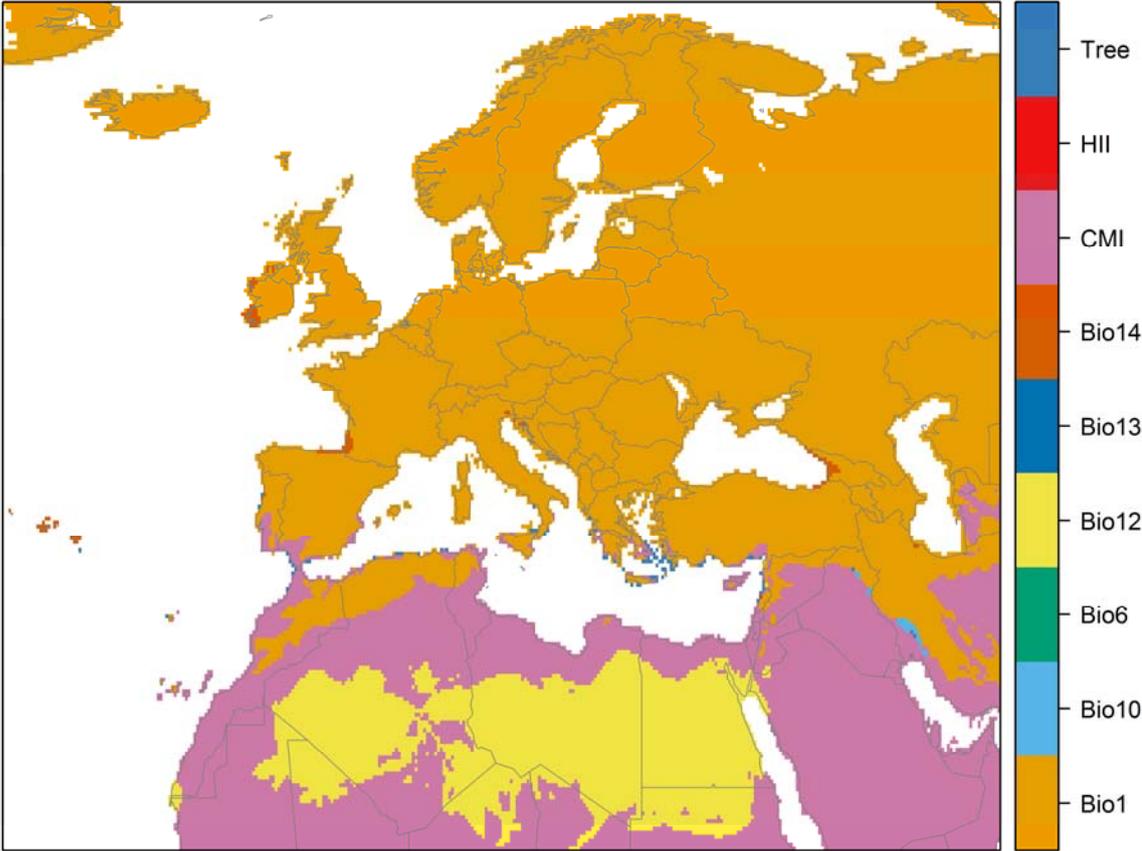

**Figure 4.** (a) Projected global suitability for the establishment of the red-whiskered bulbul in the current climate. For visualisation, the projection has been aggregated to a 0.5 x 0.5 degree resolution, by taking the maximum suitability of constituent higher resolution grid cells. Values > 0.29 are suitable for the species, with 98% of global presence records above this threshold. Values below 0.29 indicate lower relative suitability. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

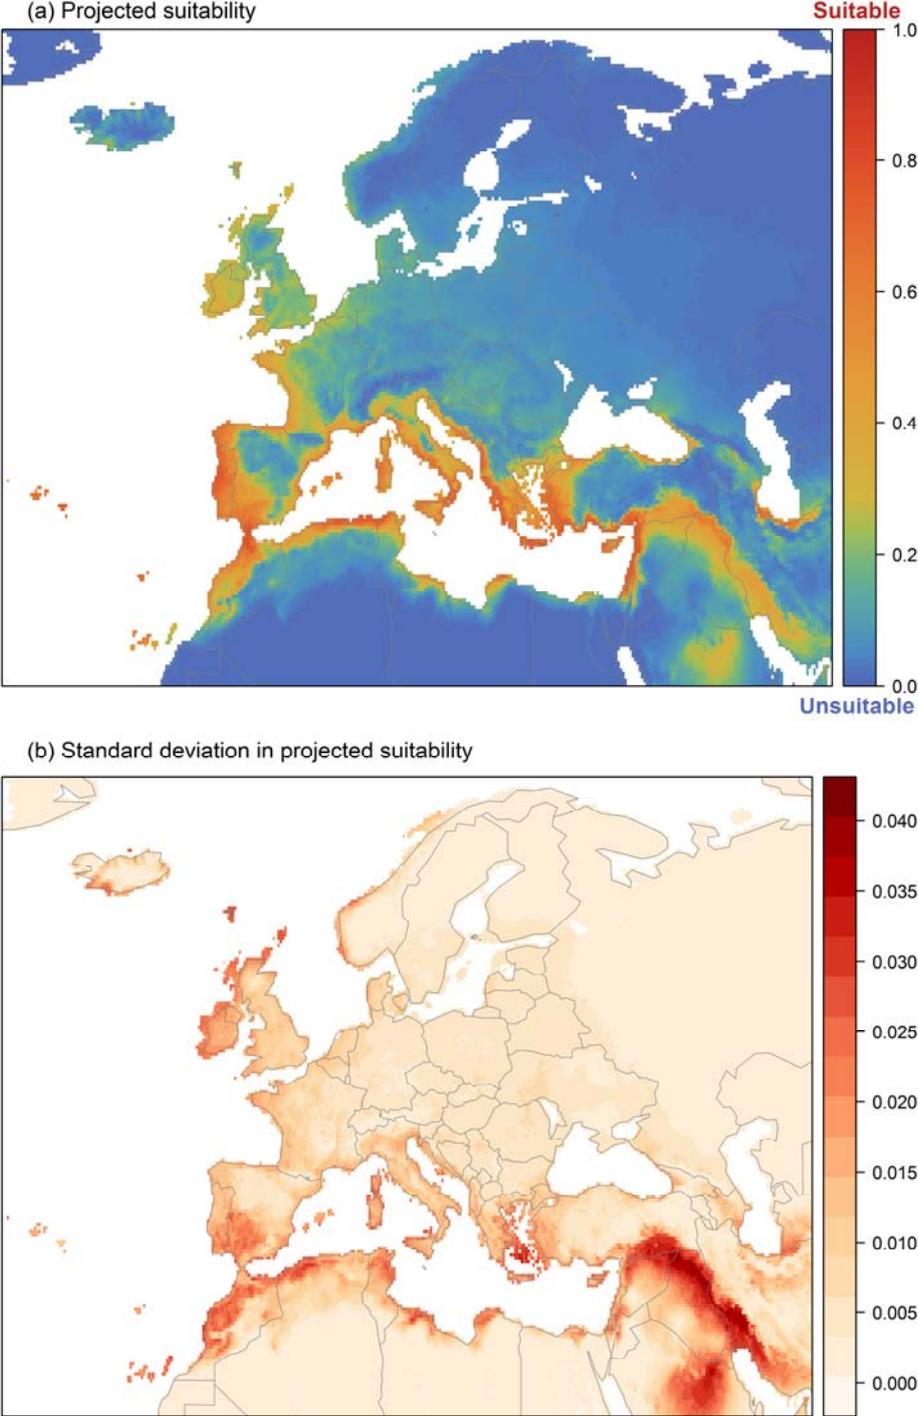

**Figure 5.** (a) Projected current suitability for the establishment of the red-whiskered bulbul in Europe and the Mediterranean region. Values  $> 0.29$  are suitable for the species, with 98% of global presence records above this threshold. Values below 0.29 indicate lower relative suitability. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

### *Caveats to the modelling*

To remove spatial recording biases, the selection of the background sample from the accessible background was weighted by the density of Aves records on the Global Biodiversity Information Facility (GBIF). While this is preferable to not accounting for recording bias at all, it may not provide the perfect measure of recording bias.

There was substantial variation among modelling algorithms in the partial response plots (Figure 3). In part this will reflect their different treatment of interactions among variables. Since partial plots are made with other variables held at their median, there may be values of a particular variable at which this does not provide a realistic combination of variables to predict from.

Other variables potentially affecting the distribution of the species, such as types of land cover other than trees were not included in the model.

## Annex with evidence on measures and their implementation cost and cost-effectiveness

<b>Species (scientific name)</b>	<i>Pycnonotus jocosus</i>
<b>Species (common name)</b>	Red-whiskered Bulbul
<b>Author(s)</b>	Peter Robertson
<b>Reviewer</b>	Thomas Evans, Enrique Murgui
<b>Date Completed</b>	15/10/2021

### Summary<sup>1</sup>

Highlight of measures that provide the most cost-effective options to prevent the introduction, achieve early detection, rapidly eradicate and manage the species, including significant gaps in information or knowledge to identify cost-effective measures.

Red-whiskered Bulbuls have been introduced through a variety of pathways, including the pet trade and escapes from captivity. Control of these pathways and public awareness raising for this species and invasive alien species in general provides the most cost-effective method of ensuring this species does not establish more widely in Europe.

This species is highly visible and not readily confused with any native European species. Given the popularity of birdwatching, early sightings are likely to arise through birdwatching reports and these provide a source of citizen science to help record this species.

Red-whiskered Bulbuls have been successfully controlled in a variety of eradication and management programmes in their introduced ranges. These programmes have typically involved a combination of mist-netting, shooting and the use of traps containing decoy birds. Given the communal roosting behaviour of this species, mist nets near the roost have been used successfully, as have searches based on their loud and distinctive calls followed by shooting. Details of suitable trap designs are also publicly available, traps containing decoy birds are particularly effective. A variety of toxins have been used to control this and similar species, but there are no currently approved avian toxins suitable for use in the EU.

A combination of mist-netting, trapping and shooting has been used to successfully eradicate this species from islands in the Seychelles, to remove small populations from Tenerife and California while the same methods are used to control established populations and their spread in Australia, Florida and Reunion. This species is often associated with human modified habitats which may aid its control as it often forms isolated populations. Eradication will be most cost effective if started quickly after reports of an established population are first received. Public concern over the control of this species may be raised, particularly if proposing to use lethal methods in urban or semi-urban environments.

This species can damage crops, particularly fruits but also plants themselves. A variety of chemical deterrents have proven to reduce foraging by similar species under experimental conditions but have not been widely used in practice. Netting may also reduce crop damage in some circumstances.

Consideration of the risk of damage when siting new orchards has been proposed as a method of reducing future conflicts.

<b>Detailed assessment</b>			
	<b>Description of measures<sup>2</sup></b>	<b>Assessment of implementation cost and cost-effectiveness (per measure)<sup>3</sup></b>	<b>Level of confidence<sup>4</sup></b>
<b>Methods to achieve prevention of intentional and unintentional introduction<sup>5</sup></b>			
<b>Managing pathways</b>	Red-whiskered Bulbuls have been introduced to new areas, probably through a variety of pathways, including the pet trade, and escapes from confinement (CABI 2019). The adoption and enforcement of appropriate legislation and codes of best practice to reduce the risks posed by these pathways should reduce the probability of further introductions.	Authorities in Australia provide advice to prevent the escape of this species, stating that it is essential that when kept, the Red-whiskered Bulbul is maintained in secure (preferably double-doored) enclosures. Unwanted birds should be surrendered to the authorities or a responsible organisation, not released into the wild (Government of Western Australia 2017). The USDA prohibits the importation of the species to the USA and its territories (CABI 2019).	High. Managing pathways is widely recognised as an effective approach to limit the establishment of new species and has already been implemented for this species
<b>Methods to achieve early detection<sup>6</sup></b>			
<b>Citizen science</b>	Red-whiskered Bulbuls are a highly visible species often found in association with human activity. Encouraging rapid reporting of new incursions increases the likely success of rapid response before the species can become established.	Citizen-science species occurrence datasets are increasingly recognized as a valid tool for monitoring the occurrence and spread of invasive species across large spatial and temporal scales (Roy et al., 2015). They are dependent on citizen-scientists who collect and upload data, typically from 'opportunistic sampling' with no underlying scientific survey design (Boakes et al., 2010) which can limit the conclusions that can be drawn from these	

		<p>data (Isaac et al., 2014). Most parts of north-west Europe have an extensive network of volunteer observers although this is less true of southern and especially eastern Europe (Boakes et al., 2010). Nevertheless the focus on native species, which is typical for monitoring activities carried out by bird-watchers, may lead to disregard the presence of non-native species, and consequently to a delay in detecting a new presence of this non native species. However, this naturalist community also provides an opportunity for developing an effective surveillance system. Unstructured citizen-science data do not reliably allow the estimation of species abundance or population trends (Kamp et al., 2016), yet in an early-warning scenario it is likely sufficient to know where a species is establishing, and these data limitations are thus of a lesser concern.</p> <p>Where the risk is considered high, more targeted approaches may be applied, actively encouraging reports from the public. In Australia, where the species has already formed local populations, the public is asked to report any members of the species in the wild where it has not been seen before (Government of Western Australia, 2017). In the 1980s, the Hawaii Department of Land and Natural Resources distributed brochures and flyers to the public requesting that any sightings be reported (CABI 2019).</p>	
<b>Raising awareness</b>	Raising public awareness of the risks posed by invasive alien species in general and Red-whiskered Bulbuls in particular. This can include the production of targeted publicity and identification material.	<p>A number of information sources and sheets are available on-line which can assist with the production of new material to raise public awareness. The Hawaii Invasive Species Council provide a handout describing the identification of the species and key information and links to other on-line sources.</p> <p><a href="https://dlnr.hawaii.gov/hisc/info/invasive-species-profiles/red-whiskered-bulbul/">https://dlnr.hawaii.gov/hisc/info/invasive-species-profiles/red-whiskered-bulbul/</a></p>	High. This method already features in the management of this species in some areas
<b>Methods to achieve eradication<sup>7</sup></b>		A number of successful eradications of Red-whiskered Bulbuls have been reported. Feare and Fries-Linnebjerg (2012). Uranie (2015) and Bunbury et al. (2019) report on the successful	

		<p>eradication of this species from Assumption (11.6km<sup>2</sup>) and the Aldabra complex of islands (155km<sup>2</sup>) in the Seychelles. A total of 5297 birds were removed from Assumption, with mist netting accounting for 80% of captures and shooting the majority of the rest. Red-whiskered bulbuls roosted communally in the early stages of the project and could be targeted with mist-nets along their flight lines towards roosts, which maximised the mist-net catch. Nocturnal shooting at the roost may have led to roost desertion, decreasing the effectiveness of mist-netting (Feare and Fries-Linnebjerg 2012). Later in the eradication, their habit of vocalising from prominent perches meant that they could be reliably located from several hundred metres away, which greatly helped in the search for and targeting of the last few birds. One bird was removed from Aldabra by mist-netting. These programmes were part of a wider eradication that included other invasive bird species, so data on effort needs to be treated with caution, but the eradications took three years and involved a team of between 3 and 30 people (Uranie 2015). A small population of seven individuals have also been eradicated from Tenerife in the Canary Islands using a combination of trapping, mist netting and shooting (Cruz and Reynolds 2019). In California, Clark (1976) reports the eradication of a Red-whiskered Bulbul population including the removal of 75 individuals. This describes stuffed decoy birds surrounded by speakers playing Red-whiskered Bulbul calls being used to lure birds within range for shooting.</p> <p>Introduced populations of Red-whiskered Bulbuls in areas such as Florida (Carleton and Owre 1975, Pranty 2010) and near Sydney in Australia (Mo 2015) have remained concentrated in areas associated with human activity, forming 'island' populations in a larger landscape. It has been suggested that this may make their eradication more feasible than is the case for more widely dispersed species in continental landscapes (Mo 2015). This</p>	
--	--	--	--

		<p>feature of their distribution may also help limit their spread, authorities in Australia have exterminated reported individuals appearing in new areas, effectively preventing new population establishment (Barrington 1985; Paton 1985). This contrasts with the situation on Reunion where the species is widespread, although the reasons for such differences remain unclear (Clergeau et al. 2002).</p> <p>Birds are popular with the public, and opposition to the control of this species may be anticipated, particularly in urban or semi-urban areas. In, particular the use of lethal methods such as shooting, or different forms of trapping may attract particular concern.</p>	
<p><b>Trapping</b></p>	<p>A wide variety of designs are available for funnel entry or walk-in traps for birds.</p> <p>Successful trap designs for Red-whiskered Bulbuls often include the use of a decoy animal or any form of wire-netting trap. The decoy birds are usually in a separate chamber and must be provided with shade, food and water (Sharp and Saunders 2004). The decoys serve to attract other birds towards the trap. Decoy birds can be used in most trap types if suitably modified. Traps must be monitored at least on a daily basis and any caught birds removed.</p> <p>Clergeau et al. (2002) describe the use of a multi-capture decoy trap on Reunion. This circular wire cage is 65cm in diameter and 20cm high, split into 8 quadrants each with a</p>	<p>Traps, in particular decoy traps, are an effective method to catch Red-whiskered Bulbuls and have been successfully used to support control programmes and eradications including the Seychelles, Reunion and Tenerife (Clergeau et al. 2002, Bunbury et al. 2019, Cruz and Reynolds 2019).</p> <p>Clergeau et al. (2002) describe the use of multi-capture decoy traps to catch Red-whiskered Bulbuls on low-lying agricultural land in Reunion. Cages baited with fruit were placed at a height of 2m, mainly within orchards and achieved capture rates of between 1.9 and 11.5 birds per cage per week. A study using 91 cage traps in three Reunion villages captured 2837 birds, with the quality of the captive decoy and the location of the trap being the main determinants of success (Georger, 2000, Amiot et al. 2007).</p> <p>Any control of a vertebrate is likely to attract some opposition, but live capture traps have been widely used in bird control programmes, for example control of the Myna, with the active cooperation of the public (Feare and Cruz 2009, Pham and van Son 2009).</p> <p>The use of decoy animals brings added complications, and potential welfare concerns. Decoys require food, water, perches, space to stretch and shelter when in the trap and care is needed</p>	<p>High - Decoy traps are widely recognised as a successful method for capturing Red-whiskered Bulbuls and have been the used to support successful eradications.</p>

	<p>separate spring-loaded entrance. In the centre of the trap is a 25cm wide enclosure for captive decoy. Most literature on suitable trap designs relates to Mynas and will probably also be suitable to catch Red-whiskered Bulbuls. However, placing traps on raised platforms has been reported as the favoured method to catch Red-whiskered Bulbuls (Clergeau et al. 2002) compared to being set on the ground for Mynas. Pham and van Son (2009), Saavedra (2010) and Feare et al. (2017) describe a variety of trap designs for use on Mynas. A wide range of myna traps based on these designs are commercially available and described on-line (search term 'myna trap').</p> <p>Captured birds can be humanely dispatched. Information on the humane dispatch of Mynas should also be applicable to Red-whiskered Bulbuls. The Pacific Island Initiative (2013) have published best practice guidelines for euthanising Common Myna. Myna trap designs have also been produced which enclose the trap in a canvas sleeve which can then be flooded with CO<sub>2</sub> to humanely kill captured birds</p>	<p>to ensure their welfare.</p> <p>Traps are simple to manufacture and the skills should be available locally after adequate training. A range of effective designs have been published and similar traps for use on Mynas are commercially available online. The main costs of their use are manpower for setting and checking. Experience of trap placement is required for their effective use and this can take time to develop. The use of decoy birds and traps may be covered by local Member State regulations. Local authorities should be asked for authorisation before their use.</p> <p>Traps are likely to also catch other birds and mammals. Care is needed to avoid non-target captures, for example through trap siting and the appropriate choice of baits. Regular checking and the release of non-target species can reduce the risks posed. Traps are a relatively safe and benign method of capture. Local authorities and regulations should be consulted before using a rtrap in a particular region. If used appropriately they do not pose particular health and safety, environmental, economic or social risks (although they can be mis-used to capture other protected species).</p>	
--	---	---	--

	(Tidemann 2005, described in Pierce 2005).		
<b>Shooting</b>	<p>Shooting can be an effective method to remove Red-whiskered Bulbuls. It is highly selective and, if used by experienced personnel, provides a humane method of despatch. It is labour intensive but has been used effectively to remove small numbers of birds during the early stages of establishment (Clark 1975), and remove dispersed birds during the latter stages of wider eradications (Bunbury et al. 2019).</p>	<p>Clark (1975) report the use of shooting as the main method used to remove at least 75 Red-whiskered Bulbuls as part of an eradication programme in California. This used recorded Red-whiskered Bulbul calls with a high degree of success to lure the birds to within shooting range or to elicit a call so they could be located. Combining this with a stuffed bird mounted on a tall pole, with speakers playing the birds' call, was also successful in luring red-whiskered Bulbuls to within shooting range. Shooting used a combination of shotguns, pellet rifles, and sling shot. Shooting has also been used in the control of this species on Assumption Island in the Seychelles, where it accounted for the removal of around 20% of the population and was particularly useful in the latter stages of the eradication (Bunbury et al. 2019). Given that the birds often perch prominently on vegetation, together with their loud and readily identifiable calls, makes the use of shooting particularly effective to remove widely dispersed individuals during the latter stages of wider eradications. However, care is needed if other bird species are attracted to the calls.</p> <p>The use of different firearms is heavily regulated and the details vary between member states. These are likely to restrict the nature of the weapon, the requirements for the operator and the times and locations where they may be used. The humaneness and effectiveness of the method is likely to be dependent on the skill and training of the operative. Local authorities must be consulted before their use.</p> <p>The use of firearms brings risks to health and safety which need to be managed. Its use in public places is likely to bring opposition and raise particular concerns which may limit its use. The use of lead projectiles has been restricted in some areas due to</p>	<p>High -Shooting has been used to remove small populations of Red-whiskered Bulbuls and to assist in the eradication of larger populations.</p>

		environmental concerns, although non-toxic alternatives are available.	
<b>Mist-nets</b>	Mist nets are fine polyester or nylon nets which are suspended between two upright poles, requiring continual monitoring and expert handling of caught birds (Sharp and Saunders, 2004).	<p>Mist nets are commonly used for the live-capture of birds for ringing. Appropriate equipment and experienced personnel should be locally available. Experience and training is required to safely extract birds from the nets and a number of EU Member States run approval and licensing schemes for their use. The use of mist nets may be covered by local member state regulations. Local authorities should be consulted before their use.</p> <p>The use of mist nets provided the main control method for the eradication of Red-whiskered Bulbuls from Assumption and Aldabra islands in the Seychelles. Bunbury et al. (2019) report that 80% of the 5279 birds removed were caught in mist nets. Nets placed on flight lines and around the communal roosts of this species proved particularly effective. Mist nets also contributed to the removal of seven birds from Tenerife (Cruz and Reynolds 2019).</p> <p>Mist nets are unselective and are likely to catch birds of a range of species. However, trained personnel should be able to extract and release any non-target species caught. Mist nets need to be used under constant supervision to quickly remove captured birds, reducing their cost-effectiveness compared to other methods, although they can be very effective at sites where birds concentrate, such as communal roosts. Mist nets are widely used for bird ringing, their use poses few risks to health and safety, the environment, economy or society.</p>	High – mist nets have proven effective for the capture of this species in a number of successful eradications, particularly when used around communal roosts.
<b>Use of toxins</b>	Spurr and Eason (1999) review the available avicides worldwide. The two most widely used compounds are Starlicide (©DCR-1339, 3-chloro-p-toluidine hydrochloride) (Ramey et al., 1994, ACVM, 2002), and the stupifactant	<p>The lack of approved compounds effectively prevents the use of toxicants for bird control in the EU. Consequently these methods are not considered in great detail in this review. Starlicide is not currently approved for use in the EU.</p> <p>In the past, Alphachloralose has been approved as an avicide and was used in a number of EU states (Ridpath et al., 1961, Spurr and Eason, 1999). However, it is not currently registered for use</p>	High – There is an existing literature on the use and effectiveness of these compounds and examples of their use on other Bulbul

	<p>Alphachloralose ((R)-1,2-0-(2,2,2-trichloroethylidene)-<math>\alpha</math>-D-glucofuranose) (Nelson, 1994; Thearle, 1969).</p> <p>Cruz and Reynolds (2019) report that Starlicide has been an effective toxicant used against Bulbuls in American Samoa. However, no products are currently approved for use in the EU.</p>	<p>as an avicide in the EU. It is currently approved for use against rodents (EU Directive 98/8/EC 2008).</p> <p>Although toxins can be an effective method of bird control, there are significant concerns regarding their non-target effects and public acceptability. Farmers on the Mascarene Islands are reported to have used use bird lime and pesticides to try and limit populations of Red-whiskered Bulbuls, although this also has an impact on non-target birds (Clergeau and Mandon-Dalger, 2001).</p>	<p>species in areas where their use has been approved.</p>
<p><b>Methods to achieve management<sup>8</sup></b></p>	<p>All of the methods described to support eradication can also be used to manage existing Red-whiskered Bulbul populations.</p>	<p>See above.</p>	<p>See above.</p>
<p><b>Protecting fruit and plants from damage.</b></p>	<p>To reduce damage to commercial fruit crops, it may be possible to apply chemical feeding deterrents. Avery (2003) reviews the methods and use of chemical bird deterrents. A cage test conducted in Hawaii on bird repellent showed that Ziram, Methiocarb and Methyl anthranilate reduced the consumption of treated papaya mash by the similar Red-vented Bulbul (Cummings et al. 1994). In an open-field test, the same authors showed that Methiocarb significantly reduced damage on orchids. Netting of valuable crops can also be used. Thibault et al. (2019) describe netting to protect tomato plants</p>	<p>Netting and the use of chemical deterrents have not been widely used to protect fruits from damage by this species, most evidence arises from scientific studies rather than their practical application. The economics of their use remain undetermined and there is only limited data available from which to assess the seriousness of any crop damage. The use of netting brings a range of issues related to practicality as nets need regular maintenance and are susceptible to damage. Nets may limit access to the crops for other species with potentially wider impacts. Chemical deterrents require licensing before use. The use of nets is likely to be acceptable to the general public, the use of chemical deterrents may raise concern if the fruits are destined for human consumption.</p>	<p>Medium – These methods have been used to reduce damage by other bird species, but there is no information related to Red-whiskered Bulbuls.</p>

	from damage by the similar Red-vented Bulbul.		
<b>Risk mapping</b>	The combination of mapping species extent, the risks of damage and the location of vulnerable resources to inform spatial decision making.	On Réunion, a multi-party working group was established to explore management practices for the widely established population of Red-whiskered Bulbuls rather than simply undertaking untargeted control. These include using planning decisions to limit their spread (for example decisions on the locations of new orchards), producing risk maps, categorising vulnerability (sanitary, social, economic and ecological) to a population of the birds, producing maps of overall vulnerability, and correlating these with maps of potential habitats for Red-whiskered Bulbuls. A comprehensive risk map was then developed to help guide control programmes (Clergeau et al., 2006).	Medium. This approach has been applied to this species, but evidence of its effectiveness is limited

## Guidelines for Completing the Annex

1 Provide a brief summary description of the most cost-effective methods drawing on the reviews in the detailed assessments

2 Provide a description of the potential method. This should be based on the available key scientific evidence which should be gathered from sources including articles and reviews in technical and scientific journals, internet searches, online databases, grey literature and relevant books and personal communications from scientists, stakeholders, conservation practitioners and governmental bodies. This information should include a full bibliographic list detailing the literature and sources considered.

3 Provide an assessment of the likely cost and effectiveness of the method. Where information is available, consider the following range of questions, accepting that not all questions will be appropriate in all circumstances.

- How effective has this approach proven to be in the past or in an analogous situation?
- How publically acceptable is the approach likely to be?
- Over what period of time would this approach need to be applied to be effective?
- What is the direct cost of implementing this approach?
- How likely are the methods used in the approach to be available?
- How likely is it that relevant licences or other approvals to undertake the approach would be difficult to obtain?
- How likely is it that health and safety issues would prevent the use of this approach?
- How significant is the environmental harm caused by this approach?
- How significant is the economic harm caused by this approach?
- How significant is the social harm caused by this approach?
- How likely is it that the approach will be criticised on welfare grounds?
- How likely is it that the approach will be acceptable to other stakeholders?

Where available, factual information on the costs of specialist equipment, or case studies of management costs from across the Union or third countries should be provided. When describing case studies, if the information is available then provide both total cost and the area over which control was undertaken so that a cost per unit area might be derived. Where such quantitative information is not available, then any qualitative information from the literature is acceptable to help guide decision making. It is accepted that in the majority of cases the information required to assess the potential total cost of management at a member state level is unlikely to be available. This would normally require information on the extent and abundance of the species which is beyond the scope of this assessment. Assessors are not expected to extrapolate the potential total costs of management at a member state level, only to report on the information provided within the literature.

4 Provide an overall assessment of the confidence that can be applied to the information provided for this method. This confidence should relate to the quality of the available information using the guidance below. It should NOT relate to the confidence in the effectiveness of the method

The confidence scores are:

- **High:** Information comes from published material, or current practices based on expert experience applied in one of the EU countries or third country with similar environmental, economic and social conditions.
- **Medium:** Information comes from published data or expert opinion, but it is not commonly applied, or it is applied in regions that may be too different from Europe (e.g. tropical regions) to guarantee that the results will be transposable.
- **Low:** data are not published in reliable information sources and methods are not commonly practiced or are based solely on opinion; This is for example the case of a novel situation where there is little evidence on which to base an assessment.

If there are further factors beyond these that have determined the chosen level of confidence, then provide a brief written description to support the choice of the level of confidence.

5 Measures for preventing the species being introduced intentionally or unintentionally into the territory of a Member State (cf. Articles 7(1)(a), 7(2), 13, 15), i.e. preventing a species entering by blocking its pathways, including pre-border prevention and prevention of escape or release into the environment and secondary spread whenever relevant. Measures for preventing the species reproducing while in containment should be included, if appropriate. Consider all methods that might be applied, including any that have not proven useful. Provide a description of each method in turn, using separate rows to consider each method.

6 Measures to run an effective surveillance system for achieving an early detection of a new occurrence (cf. Article 16). This section assumes that the species is not currently present in a Member State, or part of a Member State's territory.

7 Measures to achieve eradication. Preferably, but not exclusively, used at an early stage of invasion, after an early detection of a new occurrence (cf. Article 17). Consider all methods that might be applied, including any that have not proven useful. Provide a description of each method in turn, using separate rows to consider each method.

8 Measures to achieve management of the species once it has become widely spread within a Member State territory (cf. Article 19). These measures can be aimed at eradication, population control or containment of a population of the species. Consider all methods that might be applied, including any that have not proven useful. Provide a description of each method in turn, using separate rows to consider each method.

The development and completion of this template forms part of the EU project **No 07.0202/2020/834529/ETU/ENV.D.2** Study on Invasive Alien Species – Development of risk assessments to tackle priority species and enhance prevention.

## **Revised Risk Assessments on**

**Risk assessment template developed under the "Study on Invasive Alien Species – Development of risk assessments to tackle priority species and enhance prevention"  
Contract No 07.0202/2019/812602/ETU/ENV.D.2<sup>1</sup>**

**Name of organism:** *Asterias amurensis* Lutken, 1871

**Author(s) of the assessment:** Marika Galanidi, Ustun Energy Engineering LTD, Izmir, Turkey

**Risk Assessment Area:** The risk assessment area is the territory of the European Union 27 and the United Kingdom, excluding the EU-outermost regions.

**Peer review 1:** Jack Sewell, The Marine Biological Association, UK

**Peer review 2:** Frances Lucy, Centre for Environmental Research Innovation and Sustainability CERIS, Dept of Environmental Science, Institute of Technology Sligo, Ireland

**Date of completion:** 15/10/2020

**Date of revision:** 15/10/2021

---

<sup>1</sup> This template is based on the Great Britain non-native species risk assessment scheme (GBNNRA). A number of amendments have been introduced to ensure compliance with Regulation (EU) 1143/2014 on IAS and relevant legislation, including the Delegated Regulation (EU) 2018/968 of 30 April 2018, supplementing Regulation (EU) No 1143/2014 of the European Parliament and of the Council with regard to risk assessments in relation to invasive alien species (see <https://eur-lex.europa.eu/legal-content/en/TXT/?uri=CELEX%3A32018R0968> ).

## SECTION A – Organism Information and Screening

**A1. Identify the organism. Is it clearly a single taxonomic entity and can it be adequately distinguished from other entities of the same rank?**

including the following elements:

- the taxonomic family, order and class to which the species belongs;
- the scientific name and author of the species, as well as a list of the most common synonym names;
- names used in commerce (if any)
- a list of the most common subspecies, lower taxa, varieties, breeds or hybrids

As a general rule, one risk assessment should be developed for a single species. However, there may be cases where it may be justified to develop one risk assessment covering more than one species (e.g. species belonging to the same genus with comparable or identical features and impact). It shall be clearly stated if the risk assessment covers more than one species, or if it excludes or only includes certain subspecies, lower taxa, hybrids, varieties or breeds (and if so, which subspecies, lower taxa, hybrids, varieties or breeds). Any such choice must be properly justified.

Response: This risk assessment covers one species: *Asterias amurensis* Lutken, 1871

**Subspecies/varieties:** *Asterias amurensis f. amurensis* Lutken, 1871  
*Asterias amurensis f. robusta* Djakonov, 1950

Both subspecies are covered in the Risk Assessment.

**Phylum:** Echinodermata, **Class:** Stelleroidea, **Order:** Forcipulatida, **Family:** Asteroidea

**Synonyms:** *Allasterias migrata* Sladen, 1879  
*Allasterias rathbuni var. nortonensis* Verrill, 1909 †  
*Asteracanthion rubens var. migratum* Doderlein, 1879  
*Asterias acervispinis* Djakonov, 1950  
*Asterias amurensis f. acervispinis* Djakonov, 1950  
*Asterias amurensis f. flabellifera* Djakonov, 1950  
*Asterias amurensis f. gracilispinis* Djakonov, 1950  
*Asterias amurensis f. latissima* Djakonov, 1950  
*Asterias flabellifera* Djakonov, 1950  
*Asterias gracilispinis* Djakonov, 1950  
*Asterias latissima* Djakonov, 1950  
*Asterias pectinata* Brandt, 1835 (Synonym according to Fisher (1930))  
*Asterias rubens var. migratum* Sladen, 1879  
*Parasterias albertensis* Verrill, 1914 (Synonym according to Fisher (1930))

**Common names:** North Pacific sea star (EN); Japanese sea star (EN); Japanese starfish (EN); purple-orange sea star (EN); northern Pacific sea star (EN); flatbottom sea star (EN); Nordpazifischer Seestern (DE)

**A2. Provide information on the existence of other species that look very similar [that may be detected in the risk assessment area, either in the environment, in confinement or associated with a pathway of introduction]**

Include both native and non-native species that could be confused with the species being assessed, including the following elements:

- other alien species with similar invasive characteristics, to be avoided as substitute species (in this case preparing a risk assessment for more than one species together may be considered);
- other alien species without similar invasive characteristics, potential substitute species;
- native species, potential misidentification and mis-targeting

Response:

*Asterias amurensis* is a starfish that can grow up to 50cm in diameter. It is yellow with red and purple pigmentation on its five arms, and a small central disk. The undersides are completely yellow and arms are unevenly covered with small, jagged-edged spines. It shows a wide range of colours on its dorsal side: orange to yellow, sometimes red and purple. These spines line the groove in which the tube feet lie, and join up at the mouth in a fan-like shape (MPSC, 2015).

Similar species: According to Verrill (1914) it most resembles the species *Asterias forbesi* (North-west Atlantic) and *A. rubens* from the north-east Atlantic, which is native to the RA area. It is distinguished by its lack of interactinal plates and the evenly reticulated arrangement of the dorsal plates.

Fisher (1930) notes the following: “Differing from *A. rubens* in having, when adult, conspicuously broader rays, more numerous, usual shorter abactinal spinelets; 5 to 10 channeled or scoop-shaped superomarginal spines instead of two to five more or less terete, tapered, cylindrical, or clavate ones; in having a more nearly plane actinal surface (sharply defined by the rather thin edge of the ray, bearing a chevaux-defrise of superomarginal spines), and by having a broader, flatter actinal interradial region; intermarginal spines frequently present.

In more simple terms, a number of ‘photo-ID features’ could be used in combination to differentiate between *A. rubens* and *A. amurensis*.

- *Asterias rubens* appears to consistently display a straight row of spines along the centre of the dorsal surface of each arm. In *A. amurensis* this central, upper row is almost always irregularly arranged, waved or ‘zig-zagging’.
- In orange specimens of *A. amurensis* arm tips often appear to have been ‘dipped in purple paint’. *Asterias rubens* do not appear to display this colour pattern.
- In purple specimens of *A. Amurensis* the tip region of the arms is more densely purple than rest of arm and usually with white, yellow or pale patches/ blotches around the spines towards the central disk. *Asterias rubens* is more uniformly coloured along the length of the arms and is lacking pale blotches around the spines.

*Asterias amurensis* is very variable. While large specimens all have the same general appearance and are easily recognized, there is considerable diversity in the number, robustness and form of the spines.

The breadth of the ray increases with age in such a way as to alter very materially the appearance of the animals. Quite immature specimens are therefore unlike the adults in general appearance.”

Besides the congeneric *A. rubens*, two other, common to the RA area, starfish species present some similarities with *A. amurensis* but should not be difficult to differentiate. These are:

- *Leptasterias mueleri*: this species has a ‘rosette of spines on the dorsal surface rather than single spines. The central row of dorsal spines is arranged in a straight line, while the arm tips are white/ pale in purple specimens. This species is sometimes confused with young *A. rubens* but the common features are different in *A. amurensis* .
- *Marthasterias glacialis* often has purple tips to arms but has conspicuous knobs and large thorn-like spines arranged in straight lines and should not be mistaken for *A. amurensis*. It is also a larger species (up to 80cm across but usually smaller) and usually has a pale blue colouration, although it can also be grey, brown or white.

A number of starfish species exist in the aquarium trade (e.g. *Echinaster (Echinaster) sepositus* (Retzius, 1783), which is also native to the RA area) but they are distinctly different from *A. amurensis* and *Asterias* species in general.

**A3. Does a relevant earlier risk assessment exist? Give details of any previous risk assessment, including the final scores and its validity in relation to the risk assessment area.**

Response: Extensive work has been carried out in Australia, where the species is considered invasive since the 1990s (see McEnnulty et al., 2001). It is widely viewed as one of the most serious invasive marine pests in Australia (Hayes et al. 2005) and considerable scientific effort has been devoted to the prevention of its spread and its management (e.g. Goggin, 1998; Joint SCC/SCFA, 1999; Hayes et al., 2004; Bax et al., 2006; Aquenal, 2008; MPSC, 2015).

*Asterias amurensis* is on New Zealand’s register of unwanted and notifiable marine organisms (<http://www.environmentguide.org.nz/issues/marine/marine-biosecurity/invasive-marine-species/>).

The species was assessed with the CMIST screening-level risk assessment tool for NIS for Pacific North America in relation to the Japanese Tsunami Marine Debris JTMD (Therriault et al., 2018), and was one of the highest scoring species. Higher scores for the species may be expected in Pacific N. America, due to the higher proximity to donor regions and an already confirmed introduction event with JTMD.

It is included in the MSFD UK priority surveillance species list (version 1 – Stebbing et al., 2015) and was assessed with the MI-ISK protocol by Townhill et al. (2017) for the UK, where it was one of the highest scoring species (5<sup>th</sup> highest score out of 20, driven by high likelihood of spread and impact). The last two studies are directly relevant to the RA area (particularly Atlantic Europe), in terms of climatic conditions but also risk of introduction and spread.

Included in the marine species Horizon Scanning exercise carried out under the auspices of JRC (Tsiamis et al., 2020), and scored medium (weighed score of 31), identified as posing a threat to the NE Atlantic.

Considered as a “door knocker species” in the Nordic region (covering Sweden, Norway, Denmark, Finland, Estonia, Lithuania, Latvia, Iceland and the Faroe Islands) but was not risk assessed by the NOBANIS Horizon Scanning exercise (NOBANIS, 2015).

Assessed as a potential invader of medium impact by the Irish Horizon Scanning exercise (O’Flynn et al., 2014).

#### A4. Where is the organism native?

including the following elements:

- an indication of the continent or part of a continent, climatic zone and habitat where the species is naturally occurring
- if applicable, indicate whether the species could naturally spread into the risk assessment area

Figure 1: Occurrence records of *A. amurensis* in the native (red) and invaded (blue) range. Data points retrieved from the literature, biodiversity databases and screened as explained in A4-A6 and the modelling Annex (Annex IX). Map created by Bjorn Beckmann.

Response: *Asterias amurensis* is one of the most common northern Pacific starfish species, native to the cold-temperate, coastal waters of Korea, Russia, Japan (Lee et al. 2004) and Northern China (Li et al., 2018). It is common in the Eastern Bering Sea from the eastern Chukchi Sea to the Gulf of Alaska and British Columbia (Smith & Armistead 2014 and references therein), where it is considered cryptogenic (McLoughlin & Bax, 1993, cited in Talman et al., 1999). *Asterias amurensis* inhabits a variety of coastal habitats, from muddy, sandy, to coarser and more consolidated bottoms (Smith & Armistead, 2014), to kelp beds (Won et al., 2013) and rocky sheltered areas of intertidal zones (Aquenal, 2008). In its native range it is typically found at depths down to approximately 100m (Gabaev, 2018) but more commonly below 40-50m (Hatanaka & Kosaka, 1959; D’yakonov, 1968).

#### A5. What is the global non-native distribution of the organism outside the risk assessment area?

Response: Outside its native distribution, the species has been introduced to Tasmania and Victoria, in temperate Australia. In Tasmania it is believed to have been introduced as early as 1982 but was only correctly identified in 1992 (see Dunstan & Bax, 2007). The population in the Derwent estuary (Tasmania) was estimated in 1994 to be more than 30 million individuals (Goggin 1998). Today the species can be found all along the south and east coast of Tasmania (MPSC, 2015). In Port Phillip Bay, Victoria, it first appeared in 1995 with a few adult individuals, while spawning was confirmed in 1997 (Parry & Cohen, 2001). Within 3 years of confirmed establishment the population had reached ≈165 million individuals (Parry et al., 2004).

In Australia, it is predominantly found on shallow (<25m) soft sediment habitats and reefs, mostly limited to protected embayments and estuaries (Richardson et al., 2016; NIMPIS, 2020), as well as artificial structures, such as wharves and piers (Aqenal, 2008). It is not clear whether the narrower range of colonized habitats in the invaded range vs the native range (see previous question) is due to different habitat availability/distribution, time since colonization or other selection factors.

In Alaskan waters, where the species is considered cryptogenic, it occurs at depths down to 200m (Smith & Armistead, 2014 and references therein).

Note: Global Biodiversity Information Facility (<http://www.gbif.org>, occurrence data: [https://www.gbif.org/occurrence/search?taxon\\_key=5187508](https://www.gbif.org/occurrence/search?taxon_key=5187508)) contains a number of records based on non-validated citizen science observations from South-East Asia (Indonesia, Thailand, Philippines), southern USA (Gulf of Mexico, California) as well as various European locations (see question A6 for details). These are considered questionable (see also Byrne et al., 2016), are not included in the peer reviewed literature on the non-native range of the species and were ignored for the purposes of this Risk Assessment.

**A6. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species been recorded and where is it established? The information needs to be given separately for recorded (including casual or transient occurrences) and established occurrences. “Established” means the process of an alien species successfully producing viable offspring with the likelihood of continued survival<sup>2</sup>.**

**A6a. Recorded: List regions**

**A6b. Established: List regions**

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

- Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea.

<sup>2</sup> Convention on Biological Diversity, Decision VI/23

Comment on the sources of information on which the response is based and discuss any uncertainty in the response.

For delimitation of EU biogeographical regions please refer to <https://www.eea.europa.eu/data-and-maps/figures/biogeographical-regions-in-europe-2> (see also Annex VI).

For delimitation of EU marine regions and subregions consider the Marine Strategy Framework Directive areas; please refer to <https://www.eea.europa.eu/data-and-maps/data/msfd-regions-and-subregions/technical-document/pdf> (see also Annex VI).

Response (6a): None

Response (6b): None

Note: as above (A5), GBIF and OBIS records based on non-validated citizen science observations (besides, no photograph was supplied) were not taken into account in the answer to A6. For the RA area, these refer to records from Greece, Portugal, Spain, France, the UK, the Netherlands, corresponding to the marine regions North-East Atlantic and Mediterranean Sea. The presence of the species is not confirmed in the peer-reviewed literature (e.g. Tsiamis et al., 2020), in the European Alien Species Information Network (EASIN) or in national biodiversity databases, e.g. the NBN Atlas for the UK (<https://nbnatlas.org/>), ELNAIS for Greece (<https://elnais.hcmr.gr/>), Netherlands Soortenregister for the Netherlands (<https://www.nederlandsesoorten.nl/>), thus it is considered extremely unlikely that these observations belong to *A. amurensis*.

**A7. In which biogeographic region(s) or marine subregion(s) in the risk assessment area could the species establish in the future under current climate and under foreseeable climate change? The information needs be given separately for current climate and under foreseeable climate change conditions.**

**A7a. Current climate: List regions**

**A7b. Future climate: List regions**

With regard to EU biogeographic and marine (sub)regions, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

Response (7a): The response is based on combining physiological tolerances and the results from the distribution modeling (see Qu 2.1, Qu 2.9 and Annex VIII & IX for details). For purposes of mapping and assessing the risk of establishment, the following tolerance limits were defined:

- Average surface temperature of the warmest month < 20°C
- Average surface temperature of the coldest month > 5°C
- Minimum surface salinity > 20psu

Baltic Sea: unlikely, high confidence

Greater North Sea: likely, medium confidence

Celtic Seas: likely, medium confidence

Bay of Biscay and the Iberian coast: likely, medium confidence

Mediterranean Sea: moderately likely, low confidence

Black Sea: unlikely, high confidence (BUT moderately likely with medium confidence ONLY for the Sea of Marmara, which is outside the RA Area)

In the Black Sea and the Baltic Sea, establishment of *A. amurensis* will be prevented by low salinities (Black Sea range of 14-19 psu for surface salinity – Baltic Sea beyond the Kattegat <15 psu). The species requires salinities above 22 psu for spawning, fertilization, and embryonic development (i.e. salinity near the seabed) and above 20 psu for complete larval development, i.e. surface salinity (Kashenko, 2005). The only exception here is the Sea of Marmara (part of the Black Sea), which exhibits surface salinities > 20 psu and fully marine bottom salinities (Beşiktepe et al., 1994) and can potentially support establishment of *A. amurensis*. Establishment in the Mediterranean Sea is expected to be limited by high temperatures to the northern, cooler basins.

Response (7b): The response is based on combining physiological tolerances and the results from the distribution modeling (see Qu 2.1, Qu 2.9 and Annex VIII & IX for details). Aspects of climate change most likely to affect future distribution were considered as an increase in minimum and maximum Sea Surface Temperatures (SST). The methodology for the developed models is described in Annex IX and considers scenarios RCP 2.6 and RCP 4.5 by 2070. See also Qu. 2.10.

Baltic Sea: unlikely, high confidence

Greater North Sea: likely, medium confidence

Celtic Seas: likely, medium confidence

Bay of Biscay and the Iberian coast: moderately likely, medium confidence

Mediterranean Sea: unlikely, low confidence

Black Sea: unlikely, high confidence (Sea of Marmara: moderately likely, medium confidence)

The species distribution model predicted a very small reduction in projected suitability for *A. amurensis* for all EU marine subregions under future climate change and a small northward shift of the overall suitable area for the species. Suitable conditions in the Mediterranean are likely to become even more restricted spatially and temporally (Annex VIII – Figure 2), rendering establishment in this marine subregion unlikely. The possibility of physiological adaptations and/or introductions from southern Japan, where the sea surface temperature of the warmest month can exceed 27 C, drives the low confidence of this assessment. In the Bay of Biscay and the Iberian coast suitable conditions for establishment are expected to last for shorter time periods in the future, hence the lower likelihood score. In the Greater North Sea, an increase in sea temperature will offer suitable conditions for

spawning and larval development for prolonged periods in the south and east of the region, extending into the winter months, which under current conditions are too cold for the survival of larvae (see Annex VIII – Figure 1).

**A8. In which EU Member States has the species been recorded and in which EU Member States has it established? List them with an indication of the timeline of observations. The information needs be given separately for recorded and established occurrences.**

**A8a. Recorded: List Member States**

**A8b. Established: List Member States**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden

The description of the invasion history of the species shall include information on countries invaded and an indication of the timeline of the first observations, establishment and spread.

Response (8a): None

Response (8b): None

See also comment in Qu. A6

**A9. In which EU Member States could the species establish in the future under current climate and under foreseeable climate change? The information needs be given separately for current climate and under foreseeable climate change conditions.**

**A9a. Current climate: List Member States**

**A9b. Future climate: List Member States**

With regard to EU Member States, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

Response (9a): Belgium, Croatia, Denmark, France, Germany, Greece, Ireland, Italy, Netherlands, Portugal, Slovenia, Spain, Sweden; and the United Kingdom

Response (9b): Belgium, Denmark, France, Germany, Ireland, Netherlands, Portugal, Spain, Sweden; and the United Kingdom

The response to 9b is based on the RCP4.5 scenario for the period 2050/2070. The aspect of climate change most likely to affect the organism's ability to establish is an increase in winter sea surface temperatures. Higher winter temperatures in the Mediterranean Sea will exceed the species' upper limit for larval survival/development, particularly throughout the southern basin, while the same change will favour larvae for longer periods in the eastern North Sea. (see Annexes VIII & IX for details on modelling and future climate conditions in the RA area).

**A10. Is the organism known to be invasive (i.e. to threaten or adversely impact upon biodiversity and related ecosystem services) anywhere outside the risk assessment area?**

Response: for details and references see Qu. 4.1.

In Australia, *Asterias amurensis* reached very high densities (up to 24 individuals/m<sup>2</sup>) and developed massive populations within a relatively short time of its establishment (Byrne et al. 1997b; Grannum et al. 1996) in the two main invaded areas, where it has become the dominant benthic invertebrate predator. By the late 1990s, the adult population in Derwent was estimated at 30 million sea stars, and in Port Phillip Bay at 165 million individuals by 2003 (Parry et al., 2004).

With its voracious appetite and preference for bivalve prey, it has caused drastic population declines of (commercially important) native bivalve species and severely reduced the recruitment of juvenile bivalves to the benthos (Ross et al., 2002; 2004). It has been implicated in population declines of fish species, with which it competes for food (Parry & Hirst, 2016) and was considered responsible for the precipitous decline of the endemic fish species *Brachionichthys hirsutus* (Barrett et al., 1996, Ross et al., 1999), which was subsequently considered critically endangered. The mechanism was hypothesized to involve predation by *A. amurensis* on stalked ascidians, which form the primary spawning substrate of *B. hirsutus*, and subsequent reduction of key habitat availability (Bruce & Green, 1998; Green et al. 2012), although direct evidence for this is lacking.

**A11. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea

Response: None. *Asterias amurensis* is not present in the risk assessment area.

**A12. In which EU Member States has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden, United Kingdom

Response: None. *Asterias amurensis* is not present in the risk assessment area.

**A13. Describe any known socio-economic benefits of the organism.**

including the following elements:

- Description of known uses for the species, including a list and description of known uses in the risk assessment area and third countries, if relevant.
- Description of social and economic benefits deriving from those uses, including a description of the environmental, social and economic relevance of each of those uses and an indication of associated beneficiaries, quantitatively and/or qualitatively depending on what information is available.

If the information available is not sufficient to provide a description of those benefits for the entire risk assessment area, qualitative data or different case studies from across the risk assessment area or third countries shall be used, if available.

Response:

Species of the genus *Asterias* have been used in the past in their native range (e.g. Japan, Canada and the USA), albeit to a limited extent, for the production of fish meal, compost or fertiliser (McEnnulty et al., 2001; Barkhouse et al., 2007 and references therein). For example, in Japan, where the large amounts of *A. amurensis* by-catch from fisheries and aquaculture activities constitute a waste disposal problem, the species has been used to produce plant growth promoting compost (Line, 1994; Ishii et al., 2007). In Denmark, a starfish meal processing plant was inaugurated in 2019, utilising starfish *A. rubens* caught in an important mussel cultivation area, intended for animal feed. Similar uses can be envisaged for *A. amurensis*, in case the species is introduced to the RA area.

Preliminary research work has been conducted with *A. amurensis* in China, in order to obtain saponin (Hwang et al., 2011) and collagen (Hao and Li, 1999) from viscera or body wall for biotechnological purposes. In another area, the gametes of *A. amurensis* have been used in the assessment of marine environmental quality in Japan (Yu, 1998; Yu et al., 1998; Lee and Choi, 2003).

It is listed as a medicinal species in Asia (Goya & Youngsung, 2017), primarily in relation to its use in homeopathy.

## SECTION B – Detailed assessment

### Important instructions:

- In the case of lack of information the assessors are requested to use a standardized answer: “No information has been found.”
- With regard to the scoring of the likelihood of events or the magnitude of impacts see Annexes I and II.
- With regard to the confidence levels, see Annex III.
- Highlight the selected response score and confidence level in **bold** but keep the other scores in normal text (so that the selected score is evident in the final document).

## 1 PROBABILITY OF INTRODUCTION AND ENTRY

### Important instructions:

- **Introduction** is the movement of the species into the risk assessment area (it may be either in captive conditions and/or in the environment, depending on the relevant pathways).
- **Entry** is the release/escape/arrival in the environment, i.e. occurrence in the wild
- Introduction and entry may coincide for species entering through pathways such as “corridor” or “unaided”, but it also may differ. If different, please consider all relevant pathways, both for the introduction into the risk assessment area and the entry in the environment.
- The classification of pathways developed by the Convention of Biological Diversity (CBD) should be used (see Annex IV). For detailed explanations of the CBD pathway classification scheme consult the IUCN/CEH guidance document<sup>3</sup> and the provided key to pathways<sup>4</sup>.
- For organisms which are already present (recorded or established) in the risk assessment area, the likelihood of introduction and entry should be scored as “very likely” by default.
- Repeated (independent) introductions and entries at separate locations in the risk assessment area should be considered here (see Qu. 1.7).

**Qu. 1.1. List relevant pathways through which the organism could be introduced into the risk assessment area and/or enter into the environment. Where possible give details about the specific origins and end points of the pathways as well as a description of any associated commodities.**

For each pathway answer questions 1.2 to 1.7 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 1.2a, 1.3a, etc. and then 1.2b, 1.3b etc. for the next pathway.

In this context a pathway is the route or mechanism of introduction and/or entry of the species.

<sup>3</sup> <https://circabc.europa.eu/sd/a/738e82a8-f0a6-47c6-8f3b-aeddb535b83b/TSSR-2016-010%20CBD%20categories%20on%20pathways%20Final.pdf>

<sup>4</sup> <https://circabc.europa.eu/sd/a/0aeba7f1-c8c2-45a1-9ba3-bcb91a9f039d/TSSR-2016-010%20CBD%20pathways%20key%20full%20only.pdf>

The description of commodities with which the introduction of the species is generally associated shall include a list and description of commodities with an indication of associated risks (e.g. the volume of trade; the likelihood of a commodity being contaminated or acting as vector).

If there are no active pathways or potential future pathways this should be stated explicitly here, and there is no need to answer the questions 1.2-1.9.

Pathway name:

**a) TRANSPORT-STOWAWAY (ship/boat ballast water)**

*Asterias amurensis* is believed to have been introduced to Tasmanian waters from central Japan via ballast water discharge (Ward & Andrew, 1995). Based on a thorough evaluation of alternative pathways (Hayes et al., 2004), ballast water transfer is still considered the most plausible pathway of introduction of this species to Tasmania, as well as its subsequent spread to Victoria, mainland Australia (Dunstan & Bax, 2008).

**b) TRANSPORT-STOWAWAY Hitchhikers on ship/boat (excluding ship/boat hull fouling)**

This pathway covers specifically cases where species are transported with boat/ship in locations other than ballast water and hull fouling (namely where water is held or collected within the hull, such as sea chests, bilge water and within the hull itself – IUCN, 2017). While it is unlikely that starfish would remain attached to vessels when underway for any length of time, their translocation is possible in sheltered niche areas (Dommissie & Hough, 2004; MAF, 2011). For example, *Asterias amurensis* was observed in the sea-chest of a commercial vessel operating between the Derwent Estuary, Tasmania, and Port Phillip Bay in Australia (Thresher, pers. comm in Dommissie & Hough, 2004). Additionally, *A. amurensis* DNA was found in biofouling samples collected from internal surfaces of fishing/recreational vessels offering further support that the species can be translocated via this pathway (Hayes et al., 2004).

**c) TRANSPORT-CONTAMINANT Contaminant on animals (except parasites, species transported by host/vector)**

*Asterias amurensis* is a notorious pest in shellfish aquaculture, both in the native and the invaded range, and is known to settle on and infest oyster trays, mussel lines and scallop spat collectors, as well as salmon cages, on-shore and offshore abalone facilities and other fish-farming equipment (e.g. Gabaev, 2018; Dommissie & Hough, 2004). Even though introduction via this pathway is not documented for the species anywhere in the invaded range, it is considered possible that infested consignments of commercial bivalve species intended for aquaculture can transport it unintentionally, as a contaminant, into the RA area.

**d) TRANSPORT-STOWAWAY (ship/boat hull fouling)**

*Asterias amurensis* DNA was found in biofouling samples collected from the external surfaces of fishing and recreational vessel hulls examined in Australia, in the absence of *A. amurensis* larvae in the surrounding water, offering support that the species can be translocated via vessel fouling (Hayes et al., 2004). However, it is unlikely that starfish would remain attached to vessels when underway for any length of time (Dommissie & Hough, 2004; MAF, 2011), such that this pathway is not considered a risk for primary introductions from existing native and invasive populations and is instead discussed in conjunction with the pathway “Hitchhikers on ship/boat” only in the Risk of Spread section.

a) **TRANSPORT-STOWAWAY (ship/boat ballast water)**

**Qu. 1.2a. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	intentional	<b>CONFIDENCE</b>	low
	<b>unintentional</b>		medium
			<b>high</b>

Response: It can be stated with high certainty that this pathway is unintentional. See categorization of pathways in Annex IV and guidance notes in the beginning of this section.

**Qu. 1.3a. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
	unlikely		<b>medium</b>
	moderately likely		high
	<b>likely</b>		
	very likely		

Response: This will depend on the larval densities in the donor location, the time of the year (i.e. if uptake of ballast water coincides with the peak spawning period), as well as the densities of the adult population, which will affect the reproductive output. The highest larval densities ever recorded in the Derwent estuary, Tasmania were 1000/m<sup>3</sup> (Sutton & Greene, 2002), other studies however reported much lower densities during spawning season, in the range of 50/m<sup>3</sup> in areas with smaller adult populations (Dommissse & Hough, 2004). By the late 1990s, the adult population in Derwent was estimated at 30 million sea stars, and in Port Phillip Bay at 165 million individuals by 2003 (Parry et al., 2004). During outbreak events in China, adult *A. amurensis* densities can reach 300ind./m<sup>2</sup> (Li et

al., 2018), although much lower densities have been reported for outbreaks in Japan (i.e. 6 ind/m<sup>2</sup> – Nojima et al., 1986) and similar densities of 7 ind/m<sup>2</sup> are maintained throughout the year in Australia (MPSC, 2015); with a reproductive output of up to 19 million eggs per female (Buttermore et al., 1994), there is a very high potential for extremely high larval densities in the donor region.

According to Kaluza et al. (2010), the ports of Japan, Korea and northern China are well connected in terms of trading with the ports of the Mediterranean and Atlantic Europe (especially the Le Havre – Hamburg range) with thousands of journeys per year through the Suez Canal. With increasing sea surface temperatures (SST) and extended ice melting periods in the Arctic, some of this shipping traffic is expected to be diverted to the Northern Sea Route (Arctic passage), which is currently being used by a relatively small number of commercial vessels on a “trial” basis (Fernandez et al. 2014). However, an annual increase in traffic volume of 20% is expected over the next 25 years (Miller & Ruiz, 2014; Rosenhaim et al. 2019). Less maritime traffic takes place between temperate Australasia and the RA area (see Annex VIII for a more detailed analysis).

The lowest estimates of the volumes of ballast water taken-up, transferred and discharged into world oceans each year are around 10 billion tonnes (Interwies & Khuchua, 2017), whereas just one cubic metre of ballast water may contain from 21 up to 50,000 zooplankton specimens (Locke et al., 1991, 1993; Gollasch, 1997) and a heavy bulk carrier can carry up to more than 130,000 tonnes of ballast water (GloBallast, 2009). It is thus evident that high numbers of planktonic propagules of *A. amurensis* are likely to enter the RA area via ballast water and this remains true in the event of a possible eradication.

**Qu. 1.4a. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: Pelagic larval duration (PLD) of *A. amurensis* larvae can range between 50 and 120 days at temperatures between 19°C and 10°C respectively (Bruce et al., 1995 and references therein), while a journey from the north-west Pacific to the RA area lasts approximately 6 weeks (information retrieved from shipping companies’ itinerary pages). Despite the high PLD of the species, there is high uncertainty regarding the likelihood of survival of its larvae in ballast water when travelling through tropical regions. Ballast water temperature follows the temperature of the surrounding water with 1-2 days delay (Gollasch et al., 2000; Lenz et al., 2018). In tropical seas sea surface temperature can reach values of >30 °C in the summer and as high as 27-28 °C in the winter, far above the optimal temperature for survival of *A. amurensis* larvae as surmised by the literature (see e.g. Qu. 2.7). Nevertheless, under laboratory conditions, larvae have survived temperatures of 27.9 °C for up to 6 days but died within hours at 31.3 °C (Sagara & Ino, 1954). The dominant hypothesis about the introduction pathway to Australia is ballast water, presumably due to the sheer volume transported with international shipping and the number of larvae that could be carried in it. Even if this is indeed

the case and *A. amurensis* larvae have already survived one such trip, the time travelled through warm waters between the native region and Australia is presumably much shorter than the respective time spent in the tropics while traveling from the west Pacific to the RA area.

For vessels navigating the Northern Sea Route in the future, the transit time can be reduced by e.g. approximately 10 days for a journey between Japan and Rotterdam (ABS, 2013). Lower temperatures in the Arctic will extend larval development duration, while shorter trips will potentially increase likelihood of survival for the larvae. Reproduction is clearly not possible during ballast transport of larvae, since this would require mature adults to be present in ballast sediments and furthermore to be diverting resources to gamete production and maturation in a stressful and food poor environment.

The overall likelihood of survival with current shipping routes is assessed as moderate with low confidence.

**Qu. 1.5a. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: The International Maritime Organization (IMO) Ballast Water Management Convention (BWMC) entered into force in September 2017. It requires ships in international traffic to apply ballast water management measures, in particular:

- ballast water exchange in open seas, away from coastal areas (D-1 standard for an interim period)
- fulfil a certain discharge standard (D-2 standard according to the ship specific application schedule phased in up to 8 September 2024). D-2 standard requires the installation of a certified ballast water treatment device, which enables sterilization to avoid transfers of ballast water mediated species.

Ballast Water Exchange (BWE) is currently practiced and requires ships to exchange a minimum of 95% ballast water volume whenever possible at least 200 nautical miles (nm) from the nearest land and in water depths of at least 200 metres. When this is not possible, the BWE shall be conducted at least 50 nm from the nearest land and in waters at least 200 metres in depth (David et al., 2007 and BWMC Guideline 6). Even though BWE can reduce the concentration of live organisms in ballast by 80–95% (Ruiz & Reid 2007), its application has severe limitations, primarily dependant on shipping patterns of a port (e.g., shipping routes, length of voyages) and local specifics i.e., distance from nearest shore, water depth (David et al., 2007), particularly for EU Seas where these conditions are often not possible to meet. Also, organisms may still remain in the volume of ballast not exchanged and in ballast sediment, or BWE may not be possible due to weather conditions or other safety restrictions. The survival of zooplanktonic organisms (including *A. amurensis*) is thus not unlikely when only BWE measure are implemented.

As a result, ballast water treatment has been deemed necessary, such that ships shall discharge (in relation to the organism size range of interest for *A. amurensis*): less than 10 viable organisms per cubic metre greater than or equal to 50 micrometres in minimum dimension (IMO D-2 standard).

Ballast water treatment options include mechanical (filtration, separation), physical (heat treatment, ozone, UV light) and chemical methods (biocides). Efficiencies of various technologies utilised for ballast water treatment are reviewed in Tsolaki & Diamadopoulos (2010) and can vary with treatment method but the application of many combined methods (e.g. Filtration+UV or Hydroclone+chemical disinfectant) can decrease live zooplankton to undetectable levels, practically diminishing propagule pressure. As such, the survival of *A. amurensis* larvae in ballast water with full implementation of the D-2 standard (i.e. after 2024) is considered unlikely.

With some of the global fleet already compliant with the D2 standard, the chances of larval survival are currently assessed as moderate. Full implementation of the BWMC by 2024, despite its current operational challenges, is expected to reduce the likelihood of survival before the Arctic route becomes relevant for the species.

**Qu. 1.6a. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: After September 2017, with the BWMC coming into effect and gradually being implemented, detection of larval stages in ballast water during Port State Control inspections may be possible. According to Resolution MEPC.252(67), if initial inspections of ballast water samples indicate non-compliance with the D-2 standard, detailed inspections will be carried out. eDNA methodologies are rapidly becoming one of the fastest and most cost-efficient tools for the detection of NIS<sup>5</sup> in introduction water samples (Darling & Frederick, 2018; Borrell et al., 2017; Koziol et al., 2019) and have proven suitable for the detection of *A. amurensis* larvae specifically in port water samples as well as water samples from the internal spaces of small vessels (Hayes et al., 2004). In fact, due to their similarities with closely related species and the lack of taxonomic expertise, genetic methods are the only way to unequivocally identify *A. amurensis* larvae (Bruce et al., 1995). However, full implementation of the BWMC is not anticipated until 2024. Until then, the likelihood that *A. amurensis* will enter the RA area undetected in ballast waters remains high, particularly since eDNA methodologies are not yet widely used. On the other hand, if the species is targeted through a national monitoring programme with molecular methods, larvae in water samples from ports/harbours can be currently detected.

---

<sup>5</sup> NIS: non-indigenous species, term used in the Marine Strategy Framework Directive, synonym of “alien species” as used in the framework of Regulation (EU) 1143/2014

**Qu. 1.7a. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: In the Mediterranean Sea, potential recipient ports are relatively evenly spaced but slightly more concentrated along the central and western Mediterranean, with a small number in Malta, southern Italy and Spain acting as the main transshipment hubs (Rodrigue, 2020). Conversely, in Atlantic Europe, the main ports of entry are located within a more confined region, i.e. both coasts of the English Channel, but principally the Le Havre-Hamburg range along the north coast of continental Europe.

**Qu. 1.8a. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: *Asterias amurensis* is assumed to have been transported from central Japan to Tasmania as larvae in ballast water. The species has a very high reproductive output and can reach high densities during outbreak events, both at the seabed but also in surface waters during peak spawning periods. Despite the long PLD of the species, a number of conditions need to be met for the successful introduction of viable propagules from possible donor regions into the RA area, most importantly uptake of a sufficient number of larvae (i.e. during spawning) and transportation during the winter months, which would offer the best chances of survival during passage from tropical waters.

Out of the two main donor regions, north-western Pacific ports in Japan, Korea and China have the highest maritime connectivity with potential recipient ports in the RA area although some shipping traffic exists with southern Australia as well. Overall, the likelihood of introduction in the RA area as larvae in ballast water is judged as moderate but this applies to Atlantic Europe and primarily the Greater North Sea region. Concerning the Mediterranean Sea, considering that the primary shipping route from Asia, as well as the main transshipment hubs are located along the southern basins (Rodrigue, 2020), successful introduction and entry are considered far less likely in the Mediterranean parts of the RA area. The same applies for the Black Sea and the Baltic Sea. Concerning Arctic shipping routes, these are currently only used on a “trial” and seasonal basis with significant associated challenges and are expected to become more widely available around mid-century (Melia et al., 2017). While the increased use of the Arctic passage in the future is expected to increase the potential for introduction of *A. amurensis* (and other NIS) via ballast water, this will be of concern

further into the future, by which time it will be largely ameliorated by full implementation of the BWMC.

**b) TRANSPORT-STOWAWAY Hitchhikers on ship/boat (excluding ship/boat hull fouling)**

**Qu. 1.2b. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	intentional	<b>CONFIDENCE</b>	low
	<b>unintentional</b>		medium
			<b>high</b>

Response: It can be stated with high certainty that this pathway is unintentional. See categorization of pathways in Annex IV and guidance notes in the beginning of this section.

**Qu. 1.3b. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
	unlikely		<b>medium</b>
	<b>moderately likely</b>		high
	likely		
	very likely		

Response: The translocation of starfish is documented in sheltered niche areas of both large commercial and small recreational vessels (Dommissé & Hough, 2004; MAF, 2011). For example, *Asterias amurensis* was observed in the sea-chest of a commercial vessel operating between the Derwent Estuary, Tasmania, and Port Phillip Bay in Australia (Thresher, pers. comm in Dommissé & Hough, 2004). Additionally, *A. amurensis* DNA was found in biofouling samples collected from the internal surfaces of fishing and recreational vessel hulls, offering further support that the species can be translocated via this pathway (Hayes et al., 2004).

At this point it should be considered that DNA detected with meta-barcoding of a fouling sample may come from non-viable propagules or parts of organisms present in the stomachs of filter feeders or entrained within the fouling community. In this particular case however, fouling samples tested positive for *A. amurensis* DNA in the absence of *A. amurensis* larvae in the surrounding water, which was concurrently tested, as they were collected outside the species spawning season (Hayes et al., 2004). This does not necessarily mean that the detected DNA corresponds to viable propagules and indeed recent advances in environmental monitoring of marine pests are suggesting the combined use of eDNA and eRNA for a more accurate representation of viable communities (Pochon et al., 2017).

While it is certainly possible for the species to settle on the internal surfaces of ship/boat hulls and be transported over long distances as part of a fouling community, the likelihood of large number being transported via this pathway is not very high. Only a few such incidents are reported in the literature (see also Frey et al., 2014 for other asteroid species), and the number of individuals detected is small. On the other hand, the amount of maritime traffic between possible donor and recipient regions is very high (see Qu. 1.3a), considering both large merchant vessels as well as leisure craft. Based on the above, reinvasion after eradication is possible. Entry into the environment would require dislodgment of fouling material or active movement by the adults/juveniles. Alternatively, propagules could enter the environment in the form of gametes by at least a pair of *A. amurensis*, an event which is not considered very likely.

**Qu. 1.4b. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: If entrained in areas of the vessel with low food availability, *Asterias* species are capable of surviving prolonged periods of starvation, up to several weeks (St-Pierre & Gagnon, 2015) or even months (Vevers, 1949). If, on the other hand, starfish are transported in sea chests, where heavy fouling can accumulate (i.e. providing food resources, primarily in the form of bivalves), not only survival but also growth and maturation may be possible. For *A. amurensis*, this is attested by the survival and translocation of live individuals on debris from the Tohoku tsunami of 2011 from Japan to the west coast of North America almost a year later (Carlton et al., 2017; 2018). Reproduction would require the presence of at least a pair of adults and would be unlikely to happen under starvation conditions, when the species would mobilise its energy reserves for survival (Aguera & Byrne, 2018).

**Qu. 1.5b. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Fouling organisms such as *A. amurensis* can be transported for weeks or months in mature fouling communities or sea chests. Implementing practices to control and manage biofouling can greatly assist in reducing the risk of the transfer of invasive marine species.

While the International Convention on the Control of Harmful Anti-Fouling Systems on Ships, 2001 (AFS Convention) addresses anti-fouling systems on ships, its focus is on the prevention of adverse impacts from the use of anti-fouling systems and the biocides they may contain, rather than preventing the transfer of invasive aquatic species.

Guidelines for the control and management of ships' biofouling to minimize the transfer of invasive aquatic species were adopted on 15 July 2011 [RESOLUTION MEPC.207(62)] The Biofouling Guidelines represent a decisive step towards reducing the transfer of invasive aquatic species by ships. Especially vessel cleaning during dry-docking in a shipyard generates a very low biosecurity risk because the debris is sent to local deposit and residue water from cleaning is collected (Bohn et al., 2016). Moreover, maintenance during dry-docking involves the re-application of anti-fouling paint, which seems to be efficient for up to 1-1.5 years – thereafter heavy fouling can start occurring (Sylvester et al., 2011; Frey et al., 2014). Nevertheless, dry-docking frequency is determined by performance (fuel consumption below a certain threshold) and can range from 0.5-5 years (Bohn et al., 2016).

On the other hand, in-water cleaning (IWC) of hulls (used as an additional tool, in-between dry-dock cleaning), especially without capturing the biofouling debris, might represent a higher risk of introducing NIS relative to land based cleaning in dry-docks with land based waste disposal because physical disturbance of the fouling communities may trigger the release of propagules or viable gametes (Hopkins & Forrest, 2008). This is especially significant with *A. amurensis* as regeneration following fragmentation may result in the proliferation of individuals. High migratory distance (reported as at least 10-15 m/day in Japan – Miyoshi et al., 2018) and survival at depth mean that even offshore activity may pose a threat.

There has been a proliferation of new IWC technologies in the past decade (e.g. <https://www.ecosubsea.com/>, <http://econetsaustralia.com/>) that capture debris and render it non-viable through e.g. UV treatment, although such systems sometimes fail to contain all of the removed debris (for reviews see Zabin et al., 2016; Scianni & Georgiades, 2019).

The suite of measures described above can prove effective against *A. amurensis* and other fouling organisms, if fully implemented, although sea-chests would still remain higher risk areas and may require more frequent in-water treatment. However, anti-fouling practices are not legally required, and can be financially costly, making it likely that a number of vessels traveling between contaminated and uncontaminated marinas and ports will not have been treated, motivating a likely score for this question. Even though there does not appear to be any comprehensive analysis of the compliance levels to the MEPC 2011 biofouling guidelines, a considerable reduction in the arrival of high-risk vessels was observed in New Zealand, after biofouling management measures became mandatory (Hayes et al., 2019).

Although (as with physical hull cleaning), antifouling is not currently a legal requirement, there is potential that treatments with biocidal compounds may prove an effective method of controlling fouling and reduce the likelihood of introduction and spread.

**Qu. 1.6b. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The species is unlikely to be detected upon introduction, unless thorough inspections of fouling communities in sea chests and internal hull surfaces are carried out, which is currently not a routine practice. Even then, because of the small size of newly settled individuals, the likelihood of detection via visual inspections remains low.

In order to reach GES targets with reference to Descriptor D2, most EU states are already designing or implementing national/regional NIS-targeted monitoring programmes. Monitoring should focus on introduction hotspots (e.g. ports, marinas, aquaculture plots) and this will increase the detectability of *A. amurensis* entering the RA area through hull fouling, particularly if molecular methods are employed (Hayes et al., 2004).

**Qu. 1.7b. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: Besides the big ports, which are relevant for large commercial vessels and are described in Qu. 1.7a, marinas for recreational vessels also constitute possible points of introduction and these are much more widespread throughout the RA area. There are over 4500 marinas in Europe, of which the largest percentage is small facilities (EC, 2017), but there are some that receive leisure craft from ports outside the EU (e.g. Gittenberger et al., 2017). Additionally, there are numerous open mooring and anchoring areas for recreational vessels, particularly in touristic hotspots, attracting high numbers of vessels often during the summer months.

**Qu. 1.8b. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: *Asterias amurensis* are capable of settling on ships/boat internal surfaces and sea chests and surviving over the time period it takes for a journey from the possible donor regions to the RA area, especially considering that management measures for this pathway are not mandatory. Maritime traffic between the west Pacific and EU ports and harbours is generally high but the number of individuals transported via this pathway and entering the environment is unlikely to be high. Thus, introduction with ships/boats fouling is considered to be moderately likely.

**c) TRANSPORT-CONTAMINANT Contaminant on animals (except parasites, species transported by host/vector) mariculture**

**Qu. 1.2c. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response: It can be stated with high certainty that this pathway is unintentional. See categorization of pathways in Annex IV and guidance notes in the beginning of this section.

Even though introduction via this pathway is not documented for the species anywhere in the invaded range, it is considered possible that infested consignments of commercial bivalve species intended for aquaculture can transport it unintentionally, as a contaminant, into the RA area.

**Qu. 1.3c. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication

- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: *A. amurensis* on cultured molluscs can display high densities, e.g. in the order of 10 ind/m<sup>2</sup> on suspended scallop spat collectors (Gabaev, 2018 - for more details see Qu 4.9). The main commercial bivalve species, with which *A. amurensis* could be accidentally imported into the RA area are the oyster *Magallana gigas* and the clam *Ruditapes philippinarum*, both of which constitute preferred prey for the starfish in its native range, as well as settlement habitat in the case of *M. gigas* (see also Qu 1.5c). However, shellfish imports from countries outside the EU are not very common and are prohibited in many cases, if not requiring strict quarantine procedures.

Available information in the peer reviewed literature suggests that bivalve culture in Europe is largely dependent on harvesting/collecting wild seed from nearby locations to aquaculture plots, bivalve seed from hatcheries to a smaller extent and, when necessary, imports of seed from other EU countries (Muehlbauer et al., 2014, Robert et al., 2013; Occhipinti-Ambrogi et al., 2016; Marchini et al., 2016). Small quantities of bivalves and other cultured molluscs may still be imported from non-EU countries (e.g. small quantities of oysters *C. gigas*, up to 3-4 tonnes per year, were directly imported from Japan and Korea into the Netherlands between 2004 and 2008 – Haydar & Wolff, 2011), but more extensive information on bivalve imports from countries outside the EU could not be found. The non-native abalone species *Haliotis discus hannai*, originally imported from Japan, is cultivated in Ireland (Hannon et al., 2013) and Spain (<http://abalonbygma.com/en/abalone-exclusive-seafood/>, see also Cook, 2014), where current production takes place in closed systems and relies on local hatcheries for seed. If more stock was imported from the native range, it would be subjected to the stringent controls of COUNCIL REGULATION (EC) No 708/2007 (see Qu.1.5c), such that this species is not considered to pose additional risks for new introductions of *A. amurensis* into the RA area.

**Qu. 1.4c. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: Reproduction would not be possible considering the short duration of bivalve transfers. However, survival is very likely, given the abundance of suitable prey species and the conditions under which shellfish consignments are transported, which may actually enhance the likelihood of survival of contaminant species, as well by providing moisture and protection from harsher conditions (Minchin, 2007; Curtis et al., 2015).

**Qu. 1.5c. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: COUNCIL REGULATION (EC) No 708/2007 concerning use of alien and locally absent species in aquaculture defines the procedures to be followed that minimise the risk of introducing non-target alien species accompanying commercial shellfish spat and stocks. It requires a permit procedure, involving risk assessment for the non-target species and a quarantine period for the translocated stock.

The bivalves *Crassostrea gigas* (now *Magallana gigas*) and *Ruditapes philippinarum*, listed in Annex IV, constitute exceptions and can be moved without any risk assessment or quarantine; however local/national legislation exists that can limit the translocation possibilities of species like *M. gigas*, e.g. see WG-AS & Gittenberger (2018) for the trilateral Wadden Sea area. Additionally, if the import region is a Natura2000 area, regulations can be much stricter as they aim to protect the conservation objectives of the protected area first.

Other initiatives have produced codes of conduct for the transfer of bivalve seed/stock at the national/regional level, such as the ICES Code of Practice on the Introductions and Transfers of Marine Organisms 2005 (ICES, 2005).

The implementation of EC regulation 708/2007 (EC 2007) introduces a high biosecurity level for most bivalve transfers from areas outside the EU, that has already proven to be effective in preventing new introductions of marine alien species (Katsanevakis et al., 2013; Zenetos, 2019). However, the exemption of these two species, which both constitute common prey items of *A. amurensis* in its native (Kim, 1969) and invaded range (Dommissie & Hough, 2004), means that *M. gigas* and *R. philippinarum* consignments potentially infested with *A. amurensis* would not be subjected to mandatory control measures before being released into the wild, unless stricter national/regional regulations apply, thus increasing the risk of introduction of the species. On the other hand, shellfish growers are aware of the risks posed to bivalve stock by the introduction of *Asterias* species and would be expected to adhere to codes of conduct for thorough inspections and other additional measures if necessary.

**Qu. 1.6c. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: In situations where regular inspection of stock is a normal part of shellfish farm operations, *Asterias amurensis* can and has been detected on bivalve stock as early as recently settled juveniles of 10-15mm diameter, on e.g. mussel lines (Garnham, 1998; Martin & Proctor, 2000). Thus, early detection is not impossible, as long as there is awareness of the risk of introduction of the species and the ability to discriminate it from native species. However, *A. amurensis* is very variable in appearance, closely resembles the native common starfish *A. rubens* and even more so at the juvenile stage (See Qu. A2). Thus, inspections during aquaculture operations by unsuspecting/untrained staff could easily misidentify it.

**Qu. 1.7c. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: Concerning the two species that are exempted from the EC regulation 708/2007, i.e. *M. gigas* and *R. philippinarum*, their cultivation is widespread throughout the RA area, particularly that of *M. gigas*. *Magallana gigas* is extensively cultivated, particularly in Atlantic Europe (Muehlbauer et al., 2014) but also in some of the Mediterranean countries (Greece, Italy, Mediterranean France and Spain) to a smaller extent (Rodrigues et al., 2015). *Ruditapes philippinarum* is cultivated mainly in Italy, Spain, Portugal, France, Ireland and the UK, where the species has naturalized and developed substantial wild populations, which provide the seed for culture operations, alongside hatcheries (Moura et al., 2017). Other non-native bivalve species (potential vectors of *A. amurensis*) intended for aquaculture would be subjected to the Regulation stipulations for strict inspections, quarantine, etc, making introduction highly unlikely – This follows from Qu. 1.5c. Besides, these two are the main species that fulfil both conditions, i.e. have been/are still occasionally imported for aquaculture into the RA area and can act as vectors of *A. amurensis* as they constitute prey species and/or settlement habitat.

**Qu. 1.8c. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: The species may be introduced as pest, primarily on imported oysters *M. gigas* and clams *R. philippinarum* from the North West Pacific. Available literature suggests that shellfish imports from countries outside the EU are generally limited in the past couple of decades and well regulated. The risk of introduction is associated with a few species listed in Annex IV of Council Regulation (EC) No 708/2007 if stricter local/regional regulations are not in place (see Qu. 1.5c) and with illegal/unreported transfers. Even for the exempted species of Annex IV however, the amount imported from outside the EU is at levels low enough to render this pathway unlikely.

**Qu. 1.9. Estimate the overall likelihood of introduction into the risk assessment area or entry into the environment based on all pathways and specify if different in relevant biogeographical regions in current conditions.**

Provide a thorough assessment of the risk of introduction in relevant biogeographical regions in current conditions: providing insight in to the risk of introduction into the risk assessment area.

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

Baltic Sea: unlikely, high confidence

Greater North Sea: moderately likely, medium confidence

Celtic Seas: moderately likely, medium confidence

Bay of Biscay and the Iberian coast: moderately likely, low confidence

Mediterranean Sea: moderately likely, medium confidence

Black Sea: unlikely, high confidence

The most likely pathways of introduction of *A. amurensis* in the RA area are through shipping vectors. While ballast water can potentially transport a large number of larvae, a number of conditions need to be met for the successful introduction of viable propagules from possible donor regions into the RA area, primarily uptake and transportation during thermally suitable times of the year. Moreover, the increasing implementation of the BWMC D2 standard will gradually reduce even further the survival probability of *A. amurensis* larvae entrained in ballast water.

Entrainment in ships' sea chest and other hull internal surfaces is a plausible mode of transport but less likely to be responsible for a large number of propagules entering the RA area. Based on the maritime traffic between potential source regions and EU ports, introduction and entry of *A. amurensis* larvae is considered most likely in the Greater North Sea region (with important transshipment hubs) and less likely in the Mediterranean Sea, where most shipping traffic nowadays is concentrated along its southern parts.

**Qu. 1.10. Estimate the overall likelihood of introduction into the risk assessment area or entry into the environment based on all pathways in foreseeable climate change conditions?**

Thorough assessment of the risk of introduction in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of introduction (e.g. change in trade or user preferences)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely introduction within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: The response is based on the RCP 4.5 scenario for 2070.

Baltic Sea: unlikely, medium confidence

Greater North Sea: moderately likely, medium confidence

Celtic Seas: moderately likely, medium confidence

Bay of Biscay and the Iberian coast: moderately likely, low confidence

Mediterranean Sea: moderately likely, low confidence

Black Sea: unlikely, high confidence

A reduction in the extent and duration of ice-cover at northern latitudes under future climate conditions is likely to make the Northern Sea Route (via the Arctic Ocean) more attractive to global shipping and possibly add new ports to the potential entry points for *A. amurensis*, although big operational challenges are still associated with this (Hansen et al., 2016). Even if this happens

however, the main recipient area in the RA area where introduction is likely will remain the Greater North Sea. Increased traffic in Siberian harbours however may facilitate a stepping stone movement of *A. amurensis* larvae throughout Arctic waters towards the North-East Atlantic.

At the same time, heat waves, can cause mass mortality of aquaculture bivalves, leading to increased shellfish transfers to replete the stocks (Rodrigues et al., 2015), and this is more likely to happen in the Mediterranean Sea. More shellfish movements may be associated with a higher risk of introduction if the stocks/seed originate from areas outside the EU with a high risk of contamination with *A. amurensis* and the necessary precautions are not taken.

## 2 PROBABILITY OF ESTABLISHMENT

### Important instructions:

- For organisms which are already established in parts of the risk assessment area or have previously been eradicated, the likelihood of establishment should be scored as “very likely” by default.
- Discuss the risk also for those parts of the risk assessment area, where the species is not yet established.

**Qu. 2.1. How likely is it that the organism will be able to establish in the risk assessment area based on similarity of climatic and abiotic conditions in its distribution elsewhere in the world?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: *Asterias amurensis* is an arctic-boreal species that can survive a wide range of temperatures. In the northwestern Sea of Japan (Russia), the species overwinters under negative temperatures of -1.6 to -1.9°C, and in shallow-water bays in summer it lives at temperatures of up to 28-30°C (Gabaev, 2018 and references therein). In Alaskan waters *A. amurensis* can withstand sub-zero temperatures for weeks and it reproduces in the summer months (see also Qu. 2.7). *Asterias amurensis*, in its native range, spawns primarily in late winter-early spring, at optimal temperatures between 5°C and 17°C (Li et al., 2018) but is reported to spawn at temperatures of up to 23°C (Novikova, 1978). This upper temperature limit to spawning comes in contrast with all other published literature derived both from field studies as well as laboratory experiments (e.g. Kashenko, 2005; Lee et al., 2004; Sutton & Bruce, 1996; Byrne et al., 2016), which indicates that normal larval development can occur at a maximum temperature of 20°C.

These thermal tolerances are depicted in the global distribution of the species, combined with temperature data, retrieved from BIO-ORACLE (Assis et al., 2018, URL: <http://www.bio-oracle.org/>) and MARSPEC (Sbrocco & Barber 2013), URL: <http://www.esapubs.org/archive/ecol/E094/086/metadata.php>).

Concerning its salinity requirements, Kashenko (2003) suggests a minimum value of 22 psu for the survival of adult *A. amurensis*, based on laboratory experiments. Kashenko (2005) reports a similar tolerance to salinity during embryonic development, which is arrested at 22 psu. Other, pelagic, larval stages are able to survive salinities at an absolute minimum of 18 psu but exhibit higher survivorship above 20 psu (Kashenko, 2005). Thus, salinity limitations are expected to prevent establishment of the species in the Black Sea (surface salinities in the range of 14-19 psu), except for the Sea of Marmara with salinities > 20 psu and the Baltic Sea, except at the very entrance of the western Baltic.

For purposes of mapping and assessing risk of establishment, the following tolerance limits were defined:

- Average surface temperature of the warmest month < 20°C
- Average surface temperature of the coldest month > 5°C
- Minimum surface salinity > 20psu

Considering the above, the species is very likely to find suitable abiotic conditions for establishment throughout most of Atlantic Europe, with the exception of the Bay of Biscay, where sea surface temperatures are generally higher than 20°C in the summer months but cooler between October and June. In the Mediterranean Sea however, there are two short time windows for larval development, in April-May and November-December, depending on the donor region of larvae being Japan/Korea or Australia. Propagules arriving to the Mediterranean from China in the winter months are still likely to find suitable temperatures for development and settlement upon release. Thus, the likelihood of establishment in the Mediterranean Sea is considered as moderate (See Annexes VIII & IX for more details).

**Qu. 2.2. How widespread are habitats or species necessary for the survival, development and multiplication of the organism in the risk assessment area? Consider if the organism specifically requires another species to complete its life cycle.**

<b>RESPONSE</b>	very isolated isolated moderately widespread <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: *Asterias amurensis* inhabits a variety of coastal habitats, from muddy, sandy, to coarser and more consolidated bottoms (Smith & Armistead, 2014), to kelp beds (Won et al., 2013) and rocky sheltered areas of intertidal zones (Aquenal, 2008). In its native range it is typically found at depths down to approximately 100m (Gabaev, 2018) but more commonly below 40-50m (Hatanaka & Kosaka, 1959; D'yakonov, 1968), while in Alaskan waters it occurs at depths down to 200m (Smith & Armistead, 2014 and references therein). Some of these habitats, such as kelp beds and the rocky intertidal, are more widespread in Atlantic Europe, but the sublittoral soft and mixed sediment habitats are practically ubiquitous throughout the shallow waters (down to 200m) of all EU Seas.

The species is well known to aggregate over shellfish grounds (mostly bivalve molluscs), natural or cultivated (e.g. Paik et al., 2005; Gabaev, 2018), aquaculture equipment, such as suspended bivalve spat collectors, mussel lines and oyster trays (Dommissse & Hough, 2004; Gabaev et al., 2005) and piers/wharves (Aquenal, 2008). Such habitats are also widespread in the RA area, where extensive bivalve cultivation (and harvesting) takes place (Muehlbauer et al., 2014).

The organism does not require another species to complete its life cycle.

**Qu. 2.3. How likely is it that establishment will occur despite competition from existing species in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: In the RA area, *A. amurensis* is likely to face competition by asteroid species with a similar trophic position and functional role in the ecosystem, i.e. *A. rubens*, *Marthasterias glacialis*, as well as crab species with a similar dietary preference for bivalves, e.g. *Carcinus maenas*, *C. aestuarii*. The outcome of such interactions is difficult to predict, it is known however that subtidal starfish aggregations can consist of more than one species of asteroids, e.g. *A. rubens* and *M. glacialis* occurring together in Brittany (France) and sharing bivalve resources (Guillou, 1996) or *Leptasterias polaris* and *A. rubens* (referred to with the synonym *A. vulgaris*) in the Gulf of Saint Lawrence (North America), preying on *Mytilus edulis* (Gaymer & Himmelman, 2002). Often the outcome of such interactions is resource partitioning by prey size or depth zone, rather than competitive exclusion (Gaymer et al., 2002). As an example, in Japan, *A. amurensis* dominates the shallow waters of Sendai Bay to be gradually replaced beyond the depth of 50 m by the congeneric *A. nippon* (now *Distolasterias nippon*) (Hatanaka & Kosaka, 1959). Conversely, in Port Phillip Bay, Australia, *A. amurensis* is mostly found in water deeper than 15 m and *Coscinasterias muricata* in the shallow parts of the bay (Parry, 2015).

Even more informative is the case of co-existence of *A. rubens* with *A. forbesi* (the third boreal, closely related species of the genus *Asterias*) in parts of their range in the north-west Atlantic, where the two species display high overlap in space (geographic and bathymetric), time, mean body size, diet composition and mean prey size (Menge, 1979). Menge (1979) suggested that the two species in this region compete only infrequently and their population dynamics were controlled by storms, disease, competition and prey patchiness, in order of importance.

As regards competition with other taxonomic groups, the interaction between *C. maenas* and *A. amurensis* in Australia, where they are both introduced, appears to be one of resource competition, resulting in partitioning of bivalves according to size between predators, with *A. amurensis* consuming the large bivalves and *C. maenas* the small ones (Ross et al., 2004). On the other hand, competitive interactions with predatory crabs for bivalve prey can result in sub-lethal injuries to arm tips of *A. amurensis* (Ling & Johnson, 2013), which are more pronounced in juvenile starfish.

**Qu. 2.4. How likely is it that establishment will occur despite predators, parasites or pathogens already present in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

	likely very likely		
--	-----------------------	--	--

Response: *Asterias amurensis*, like many asteroid species, is generally considered to be a terminal consumer in food webs; it does however have some documented predators. In its native range the species is consumed by the starfish *Solaster paxillatus* and the red king crab *Paralithodes camtschaticus* (Gabaev, 2018). In Australia, predation by the native starfish *Coscinasterias muricata* is suspected to be responsible for high post-settlement mortality of *A. amurensis* juveniles in Port Phillip Bay (Parry & Cohen 2001), while in laboratory experiments *C. muricata* was identified as the most efficient predator of *A. amurensis* among a suite of species examined (Botsios 2001, in Parry 2015). Nevertheless, further research is required to determine whether such native predators have the potential to influence *A. amurensis* establishment and densities in the field (Aquenal, 2008). On the other hand, in Australia, Ling & Johnson (2013) observed a high-incidence of sub-lethal injuries to *A. amurensis* by the native spider crab *Leptomithrax gaimardi*, occurring in large aggregations, and suggested that seasonal aggregations of the large spider crab can have strong but localized effects on *A. amurensis*.

Regarding the RA area, native starfish predators of the congeneric *A. rubens* may be able to exert some predation pressure on *A. amurensis*, particularly at the post-settlement, juvenile stage. Such predators include the species *Crossaster papposus* (Castilla, 1972), the specialized echinoderm predators *Luidia ciliaris* and *L. sarsi*, which are known to control *A. rubens* populations (Guillou, 1996), possibly native species of the genus *Coscinasterias*, such as *C. tenuispina*, but also large predatory crab species. It is noteworthy that the native predator *P. camtschaticus* is introduced and invasive to Norway and currently spreading to the south and west, while smaller related stone crabs (e.g of the genus *Lithodes*, which is known to prey on asteroid species – Fuhrmann et al., 2017), may fulfil a similar role. The potential of predation by these species to limit *A. amurensis* populations is unknown, but judging from the establishment of the species in Australia in the presence of native predators, it is thought that establishment is unlikely to be prevented.

With respect to parasites and pathogens, male *A. amurensis* are liable to gonad parasitisation by the ciliate parasite *Orchitophrya stellarum* (Byrne et al., 1997a), which causes complete atrophy of the testes, leading to castration. In Japan, infestation rates were as high as 100% in some populations (Byrne et al., 1997a). This has implications for recruitment of the species, as it decreases the concentration of male gametes and, consequently, the chances of successful external fertilisation. *Orchitophrya stellarum* has a circumboreal distribution and is known to parasitize a number of asteroid species, including the native to the RA area *A. rubens*, albeit with a lower prevalence (Jangoux, 1987). It has also been found in asteroids from the Mediterranean Sea (Febvre et al., 1981 in Jangoux, 1987). Since this ciliate infests mature males, it is considered unlikely that it will affect the potential for establishment by larval propagules, it can however affect the following generations and adults entering the RA area by other vectors.

Sea star wasting disease (SSWD) can cause mass mortality events in asteroid species, accounting for strong population declines and shifts in the demography of the affected species. SSWD is an umbrella term used to describe a suit of clinical signs starting with the appearance of skin lesions which may enlarge over time to allow internal organs to protrude, leading to the animal's death (Hewson et al., 2019). While clinical signs are similar for different affected species, the etiologies vary and can range from abiotic factors to pathogens or combinations of both (Hewson et al., 2018). Such events have become more wide-spread and prevalent in the last decade but are unpredictable. Asteroid wasting

events have been documented for *A. amurensis* both in the native area (China) and in Australia (Hewson et al., 2019) but also for different species in European waters (Thorpe & Spencer, 2000; Staehli et al., 2009).

**Qu. 2.5. How likely is the organism to establish despite existing management practices in the risk assessment area? Explain if existing management practices could facilitate establishment.**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: While Ballast Water Exchange (BWE) and Ballast Water Treatment (BWT) can reduce propagule pressure and, consequently, the rate of establishment (see Q1.5a for details), these management practices are not always possible or yet in effect. On the other hand, bivalve transportations for aquaculture purposes (which constitute a pathway of spread) offer suitable habitats to *A. amurensis* in the form of the aquaculture plots themselves and, thus, facilitate establishment. Moreover, seed harvesting devices and seed relaying offer favourable substrates and conditions for settlement and growth, enhancing establishment potential. Management practices during aquaculture operations (such as the inspection of stock and removal of predators or the removal of fouling species from seed/spat before relaying to on-grow sites) can reduce establishment potential. On the other hand, management of the natural environment (e.g. MPAs with no-take zones), is likely to limit early detection and removal by stakeholders, affording some protection to early populations.

**Qu. 2.6. How likely is it that biological properties of the organism would allow it to survive eradication campaigns in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Eradication may be attempted at an early stage of invasion by manual removal with divers and/or snorkeling, i.e. targeting juveniles and adults. If the population has not yet reached sexual maturity the chances of local eradication are relatively high (see Millers, 2015; Richardson et al., 2016 and references therein for an overview of known eradication campaigns of *A. amurensis* in Australia). In the case of reproducing populations however, the very high fecundity and long pelagic larval duration of the species (see following question) would provide a high number of propagules able to disperse over long distances and negate eradication efforts. Poorly planned and executed removal

campaigns, involving chopping and fragmentation of adults may have the opposite effect, by increasing the reproducing population (see following question for details).

Size at maturity for *A. amurensis* (i.e. distance from the center of the disc to the arm tip) is reported to vary between 46-55 mm (Ino et al., 1955; Hatanaka and Kosaka 1959; Li et al., 2018) and is generally reached at one year of age. The fact that the species takes a year and grows relatively large before maturity increases the likelihood of detection before a reproductive population develops and can facilitate eradication campaigns (Crombie et al., 2007; Millers, 2015).

**Qu. 2.7. How likely are the biological characteristics of the organism to facilitate its establishment in the risk assessment area?**

including the following elements:

- a list and description of the reproduction mechanisms of the species in relation to the environmental conditions in the risk assessment area
- an indication of the propagule pressure of the species (e.g. number of gametes, seeds, eggs or propagules, number of reproductive cycles per year) of each of those reproduction mechanisms in relation to the environmental conditions in the risk assessment area.
- If relevant, comment on the likelihood of establishment based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in establishment whereas for others high propagule pressure (many thousands of individuals) may not.
- If relevant, comment on the adaptability of the organism to facilitate its establishment and if low genetic diversity in the founder population would have an influence on establishment.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

*Asterias amurensis* is a dioecious species (i.e. sexes are separate with the male and female reproductive organs being in different individuals) with external fertilization and an annual reproductive cycle (Novikova, 1978), although damaged individuals can reproduce asexually by the regeneration of arms attached to a portion of the central disc (Ward & Andrew, 1995). One-year old females produce approximately 0.4 – 2.8 million eggs and two-year old 5.3 – 15.5 million (Hatanaka & Kosaka, 1959).

Spawning is reported at different times in different locations, ranging from late January/February to July (e.g. Akkeshi Bay, Hokkaido, Japan) and at temperatures ranging from 5 °C to 23 °C (Li et al., 2018; Hatanaka & Kosaka, 1959 and references therein). Spawning takes place primarily in February-April, at temperatures between 5°C and 17°C (Lee et al., 2004; Yu et al., 1998; Kim, 1968; Hatanaka & Kosaka 1959; Kashenko, 2005), although in Alaska the species spawns in the summer (Smith & Armistead, 2014). In some locations however there are two spawning events; such is the case in China, where spawning takes place in October-November (coinciding well with the lower bottom

water temperature (14.29°C) and again in March-May (Li et al., 2018) and also in Peter the Great Bay, Russia, with spawning events in June-July and in September, at temperatures of 17°C and 23°C, respectively (Novikova, 1978). In the invaded range, *A. amurensis* spawns during the austral winter, at similar degrees of latitude, but in the southern hemisphere, indicating photoperiodic regulation of gametogenesis, as well as modulation by temperature (Smith & Armistead, 2014). The adaptability of the species with respect to spawning periods and temperatures is very likely to facilitate establishment in the RA area, where suitable temperatures for reproduction are encountered throughout much of its extent at different times of the year (see Annex VIII).

Fertilised eggs are demersal and develop into swimming and feeding larvae (termed bipinnariae) within 60h to 120h of fertilization depending on water temperature (20°C and 10°C respectively) (Lee et al., 2004). Larval duration in the plankton also varies with temperature, as well as with feeding conditions, and can range between 50 and 120 days at temperatures between 19°C and 10°C respectively (Bruce et al., 1995 and references therein). In the native range (Korea-Japan), settlement occurs during June-July, while early juveniles appear during August-September (Paik et al., 2005).

Early Tasmanian populations, sampled in 1994, showed a considerable loss of genetic diversity compared to native Russian and Japanese populations – in the order of 30-40% - indicating a small number of initial colonisers and a genetic bottleneck (Ward & Andrew, 1995). Despite the above, the species was a very successful invader in Tasmanian and later on in Victorian waters.

**Qu. 2.8. If the organism does not establish, then how likely is it that casual populations will continue to occur?**

Consider, for example, a species which cannot reproduce in the risk assessment area, because of unsuitable climatic conditions or host plants, but is present because of recurring introduction, entry and release events. This may also apply for long-living organisms.

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Considering that the most likely life stage of *A. amurensis* to enter the RA area is the planktonic larva, with the narrowest abiotic requirements, if the environmental conditions they encounter upon entry are unfavourable for survival, they are unlikely to establish or form casual populations. Casual populations may occur in the case of the arrival of adults/juveniles as hitchhikers on vessels, and this vector is unlikely to transport *A. amurensis* in large numbers or frequently (see Risk of Introduction section). Thus, the occurrence of casual populations is deemed unlikely.

**Qu. 2.9. Estimate the overall likelihood of establishment in the risk assessment area under current climatic conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under current climatic conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in current conditions: providing insight in the risk of establishment in (new areas in) the risk assessment area.

<b>RESPONSE</b>		<b>CONFIDENCE</b>	
	very unlikely		low
	unlikely		<b>medium</b>
	moderately likely		high
	<b>likely</b>		
	very likely		

Response: The response is based on combining physiological tolerances and the results from the distribution modeling (see Qu 2.1, Qu 2.9 and Annex VIII & IX for details). The reader is encouraged to consult Annex VIII in particular for a full explanation of the rationale.

Baltic Sea: unlikely, high confidence

Greater North Sea: likely, medium confidence

Celtic Seas: likely, medium confidence

Bay of Biscay and the Iberian coast: likely, medium confidence

Mediterranean Sea: moderately likely, low confidence

Black Sea: unlikely, high confidence (Sea of Marmara: moderately likely, medium confidence)

The likelihood of a successful establishment of *A. amurensis* in the RA area will be largely determined by a combination of source region, arrival time (i.e. time of the year) and abiotic conditions of the recipient region when the first larvae arrive. The survival and settlement of the first introduced larvae is likely to be of high importance for initial establishment, since, once this happens, the species has demonstrated its adaptability to local conditions by changing the seasonality of its reproductive cycle (see the Australian invasion, also spawning periods throughout its native range).

Considering spawning times in the donor regions, travel duration and arrival times (see Annex VIII), the larvae of the species are very likely to find suitable abiotic conditions for establishment during the whole year throughout most of Atlantic Europe, with the exception of the Bay of Biscay, where sea surface temperatures are generally higher than 20°C in the summer months but cooler between October and June. In the Mediterranean Sea however, there are two short time windows for larval development, in April-May and November-December, depending on the donor region of larvae being Japan/Korea or Australia. Propagules arriving to the Mediterranean from China in the winter months are still likely to find suitable temperatures for development and settlement upon release. Thus, the likelihood of establishment in the Mediterranean Sea is considered as moderate. Furthermore, if it is adults rather than larvae that first arrive, temperatures at the seabed are generally lower in the summer months due to stratification and this would favour establishment even in areas with thermally marginal surface waters, as long as there is a sufficient window for spawning and dispersal.

In the Black Sea and the Baltic Sea, establishment of *A. amurensis* will be prevented by low salinities (Black Sea range of 14-19 psu for surface salinity – Baltic Sea <15 psu). The species requires salinities above 22 psu for spawning, fertilization, and embryonic development (i.e. salinity near the seabed) and above 20 psu for complete larval development, i.e. surface salinity (Kashenko, 2005).

Biotic interactions with native species and in particular with the con-generic *A. rubens*, which is very similar ecologically and functionally, have the potential to alter the likelihood of establishment but this is very difficult to predict.

**Qu. 2.10. Estimate the overall likelihood of establishment in the risk assessment area under foreseeable climate change conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under foreseeable climate change conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of establishment (e.g. increase in average winter temperature, increase in drought periods)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely establishment within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: The response is based on the RCP4.5 scenario for the period 2050/2070. Aspects of climate change most likely to affect future distribution were considered as an increase in minimum and maximum Sea Surface Temperatures (SST). The methodology for the isotherm approach is described in Annex VIII and for the developed models in Annex IX. See also Qu. A7.

- Baltic Sea: unlikely, high confidence
- Greater North Sea: likely, medium confidence
- Celtic Seas: likely, medium confidence
- Bay of Biscay and the Iberian coast: moderately likely, medium confidence
- Mediterranean Sea: unlikely, low confidence
- Black Sea: unlikely, high confidence (Sea of Marmara: moderately likely, medium confidence)

The species distribution model predicted a very small reduction in projected suitability for *A. amurensis* for all EU marine subregions under future climate change and a small northward shift of the overall suitable area for the species. This largely agrees with previous modeling work, carried out by Townhill et al. (2017), which predicted a slight poleward shift in the projected suitability for *A. amurensis* along the continental shelf of Atlantic Europe in the order of 40-50 km. According to the isotherm approach, the warming of the Mediterranean Sea but also the Bay of Biscay and the Iberian coast, is likely to further restrict the potential for establishment of *A. amurensis* in these regions.

### 3 PROBABILITY OF SPREAD

**Important instructions:**

- Spread is defined as the expansion of the geographical distribution of an alien species within the risk assessment area.
- Repeated releases at separate locations do not represent continuous spread and should be considered in the probability of introduction and entry section (Qu. 1.7).

**Qu. 3.1. How important is the expected spread of this organism within the risk assessment area by natural means? (List and comment on each of the mechanisms for natural spread.)**

including the following elements:

- a list and description of the natural spread mechanisms of the species in relation to the environmental conditions in the risk assessment area.
- an indication of the rate of spread discussed in relation to the species biology and the environmental conditions in the risk assessment area.

The description of spread patterns here refers to the CBD pathway category “Unaided (Natural Spread)”. It should include elements of the species life history and behavioural traits able to explain its ability to spread, including: reproduction or growth strategy, dispersal capacity, longevity, dietary requirements, environmental and climatic requirements, specialist or generalist characteristics.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response:

Natural larval dispersal: *Asterias amurensis* is a highly fecund species (up to 19 million eggs per female) with pelagic larvae that can stay in the water column for up to 120 days, depending on the temperature (Bruce et al., 1995 – see also Qu. 2.7). It has the potential to develop dense populations, which increases the fertilization success, since the species is a broadcast spawner, and the ability to reproduce at different times of the year between temperatures of 5°C and 20°C. In Atlantic Europe, the thermal requirements for successful larval development are met throughout most of the year, except for the winter months in the western North Sea and the summer months in the Bay of Biscay (see Annex VIII and Qu. 2.1). This can lead to a significant potential for natural dispersal, depending of course on local/regional hydrodynamic regimes. In the Mediterranean Sea, higher sea surface temperatures will limit both the period with conditions suitable for development (November to May – See Annex VIII), as well as the duration of larval development, which can be as low as 50-60 days at 19°C (Bruce et al., 1995). Even at these temperatures, 2 months of natural dispersal with oceanic currents would be sufficient for a considerable spread.

Rafting: Drifting macroalgae are known to support entire faunal assemblages and transport them over long distances, in the range of 100s of kilometers, with starfish species having been sampled on numerous occasions from such natural rafting objects (Thiel & Gutow, 2005; Fraser et al., 2011).

Besides translocated adults or juveniles, competent larvae of *A. amurensis* could also settle on already drifting macroalgae or other natural objects (Byrne et al., 2016), enhancing the potential for spread through this mechanism. Additionally, the species has the potential for 'ballooning' (filling body cavity with air and using currents to migrate or settle on floating objects) which has led to 'swarming' in Tokyo Bay (Kurata et al., 1954, cited in Nelson et al., 2016) and may enhance the potential for spread via rafting or natural dispersal.

**Qu. 3.2a. List and describe relevant pathways of spread other than "unaided". For each pathway answer questions 4.3 to 4.9 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 4.3a, 4.4a, etc. and then 4.3b, 4.4b etc. for the next pathway.**

including the following elements:

- a list and description of pathways of spread with an indication of their importance and associated risks (e.g. the likelihood of spread in the risk assessment area, based on these pathways; likelihood of survival, or reproduction, or increase during transport and storage; ability and likelihood of transfer from the pathway to a suitable habitat or host) in relation to the environmental conditions in the risk assessment area.
- an indication of the rate of spread for each pathway discussed in relation to the species biology and the environmental conditions in the risk assessment area.
- All relevant pathways of spread (except "Unaided (Natural Spread)", which is assessed in Qu. 4.1) should be considered. The classification of pathways developed by the Convention of Biological Diversity shall be used (see Annex IV).

Pathway names:

- a) TRANSPORT-STOWAWAY (ship/boat ballast water)  
The evidence base in the Australian invaded range suggests that *Asterias amurensis* was introduced to Tasmanian waters from central Japan via ballast water discharge (Ward & Andrew, 1995). Based on a thorough evaluation of alternative pathways (Hayes et al., 2004), ballast water transfer is still considered the most plausible pathway of introduction of this species to Tasmania, as well as its subsequent spread to Victoria, mainland Australia (Dunstan & Bax, 2008). With respect to the RA area, movement of vessels between ports within its boundaries is less restricted and ballast water regulations do not apply to short journeys within states. This means that the potential of ballast waters transport of larvae to act as a vector of spread is very significant.
- b) TRANSPORT-STOWAWAY (Hitchhikers on ship/boat & ship/boat hull fouling)  
While it is unlikely that starfish would remain attached to vessels when underway for any length of time, their translocation is possible in sheltered niche areas (Dommissé & Hough, 2004; MAF, 2011). For example, *Asterias amurensis* was observed in the sea-chest of a commercial vessel operating between the Derwent Estuary, Tasmania, and Port Phillip Bay in Australia (Thresher, pers. comm in Dommissé & Hough, 2004). Additionally, *A. amurensis* DNA was found in biofouling samples collected from 3 fishing and recreational vessel hulls, both from internal and external surfaces, offering further evidence that the species can be translocated via vessel fouling (Hayes et al., 2004).
- c) TRANSPORT-CONTAMINANT Contaminant on animals (except parasites, species transported by host/vector)

*Asterias amurensis* is a notorious pest in shellfish aquaculture, both in the native and the invaded range, and is known to settle on and infest oyster trays, mussel lines and scallop spat collectors, as well as salmon cages, on-shore and offshore abalone facilities and other fish-farming equipment (e.g. Gabaev, 2018; Dommissse & Hough, 2004). Spread via this pathway is not documented for the species in the invaded range, it is considered however that infested consignments of commercial bivalve species intended for aquaculture can transport it unintentionally, as a contaminant, throughout the RA area.

d) **TRANSPORT-STOWAWAY (angling/fishing equipment)**

In both the native and invaded range, *A. amurensis* is caught, often in high quantities, as by-catch of demersal and bivalve fisheries (e.g. Hatanaka & Kosaka, 1959, Aquenal, 2008, Smith & Armistead, 2014), both by bottom towed gear as well as by longlines and hooks by professional and recreational fishermen (Parry et al., 2003). Since the species is not targeted as a commercial catch, it is discarded by the fishermen (but see potential waste disposal solutions in A13 and later in this section). Depending on discard practices and disposal of by-catch, entrainment in fishing/angling equipment poses a high risk of unintentionally translocating the species.

e) **TRANSPORT-STOWAWAY (machinery/equipment & floating debris)**

This pathway includes a diverse array of vectors of different sizes and mobility, such as mobile drilling rigs, energy extraction devices, moorings and buoys, as well as equipment dislodged by storms or damaged structures and debris lost at sea and drifting (e.g. aquaculture equipment, pontoons, pier debris, etc.). Such structures are often heavily fouled with mature fouling communities (Nall, 2015; Astudillo et al., 2009), which can provide both settlement space and abundant food resources for *A. amurensis*. Some of them enter and stay in ports for extended periods of time (e.g. tidal and wave energy devices – Loxton et al., 2017b), or are in frequent contact with offshore support vessels and can thus enhance the connectivity network for propagules of the species.

a) **TRANSPORT-STOWAWAY (ship/boat ballast water)**

**Qu. 3.3a. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional	<b>CONFIDENCE</b>	low
	<b>unintentional</b>		medium
			<b>high</b>

Response: It can be stated with high certainty that this pathway is unintentional. There is no doubt that uptake of larvae in ballast water is accidental. See categorization of pathways in Annex IV and guidance notes in the beginning of this section.

**Qu. 3.4a. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: For reproductive output and ship ballast volume & potential larval concentration, see Qu. 1.3a. With respect to spread of the organism within the EU, transshipment operations constitute the main maritime traffic that will act as the vector for spread. Important transshipment hubs are situated along the southern Mediterranean (serving the rest of the Mediterranean and the Black Sea) and the Le Havre-Hamburg range, serving the UK, the Baltic and Scandinavia (Notteboom et al., 2013). Considering that *A. amurensis* larvae are favoured by water temperatures encountered in many parts of the RA area, it is considered likely that sufficient numbers can be transferred with ballast water along this pathway. Finally, in many parts of the European Seas, ballast in passenger ferries is also a potential vector mainly due to high traffic volume potential. Due to the routes taken, measures described in the ballast water convention cannot easily be followed (exchange at depth and distance from shore) so the risk of depositing propagules at suitable locations is higher.

**Qu. 3.5a. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Short Sea shipping routes/trips within EU ports in particular are shorter than international shipping trips from Asia and Australia (where introduction events may originate from), such that survival in ballast water during passage along this pathway is much more likely. Most importantly, sea surface temperatures (which determine ballast water temperature) are generally within the optimal range

for *A. amurensis* larval survival (i.e. 5-20 °C), particularly in Atlantic Europe. In the Mediterranean favourable thermal conditions are restricted to the autumn and winter months (see Annex VIII). This is also the case for ferry routes between many European locations.

**Qu. 3.6a. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

The International Maritime Organization (IMO) Ballast Water Management Convention (BWMC) entered into force in September 2017. It requires ships in international traffic to apply ballast water management measures, in particular:

- ballast water exchange in open seas, away from coastal areas (D-1 standard for an interim period)
- fulfil a certain discharge standard (D-2 standard according to the ship specific application schedule phased in up to 8 September 2024). D-2 standard requires the installation of a certified ballast water treatment device, which enables sterilization to avoid transfers of ballast water mediated species.

Ballast Water Exchange (BWE) is currently practiced and requires ships to exchange a minimum of 95% ballast water volume whenever possible at least 200 nautical miles (nm) from the nearest land and in water depths of at least 200 metres. When this is not possible, the BWE shall be conducted at least 50 nm from the nearest land and in waters at least 200 metres in depth (David et al., 2007 and BWMC Guideline 6). Even though BWE can reduce the concentration of live organisms in ballast by 80–95% (Ruiz & Reid 2007), its application has severe limitations, primarily dependant on shipping patterns of a port (e.g., shipping routes, length of voyages) and local specifics i.e., distance from nearest shore, water depth (David et al., 2007), particularly for EU Seas where these conditions are often not met. Also, organisms may still remain in the volume of ballast not exchanged, or BWE may not be possible due to weather conditions or other safety restrictions. The survival of zooplanktonic organisms (including *A. amurensis*) is thus not unlikely when only BWE measure are implemented.

BWE for EU short sea shipping routes is usually restricted to the second criterion of at least 50 nm from the nearest land and in waters at least 200 metres in depth in the Mediterranean Sea and is often not even feasible within these limits in northern European Seas (David et al., 2007), such that ballast water exchange is not likely to be effective in preventing the spread of *A. amurensis* (and other organisms potentially transferred in ballast water) within European Seas.

As a result, ballast water treatment has been deemed necessary, such that ships shall discharge (in relation to the organism size range of interest for *A. amurensis*): less than 10 viable organisms per cubic metre greater than or equal to 50 micrometres in minimum dimension (IMO D-2 standard).

Ballast water treatment options include mechanical (filtration, separation), physical (heat treatment, ozone, UV light) and chemical methods (biocides). Efficiencies of various technologies utilised for ballast water treatment are reviewed in Tsolaki & Diamadopoulos (2010) and can vary with treatment method but the application of many combined methods (e.g. Filtration+UV or Hydroclone+chemical disinfectant) can decrease live zooplankton to undetectable levels, practically diminishing propagule pressure. As such, the survival of *A. amurensis* larvae in ballast water with full implementation of the D-2 standard (i.e. after 2024) is considered unlikely. Until then (i.e. currently), planktonic propagules of the species are likely to survive in ballast water.

It is worth noting that, even after full implementation of D2, exemptions can be granted by member states on ‘low risk’ routes (Stuer-Lauridsen et al., 2018) and it is possible that e.g. internal routes by passenger ferries etc may fall into this. If *A. amurensis* arrives undetected at a port included in this exemption it may have chance to spread to others before detection and interception is possible.

**Qu. 3.7a. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: After September 2017, with the BWMC coming into effect and gradually being implemented, detection of larval stages in ballast water during Port State Control inspections may be possible. According to Resolution MEPC.252(67), if initial inspections of ballast water samples indicate non-compliance with the D-2 standard, detailed inspections will be carried out. eDNA methodologies are rapidly becoming one of the fastest and most cost-efficient tools for the detection of NIS<sup>6</sup> in introduction water samples (Darling & Frederick, 2018; Borrell et al., 2017; Koziol et al., 2019) and have proven suitable for the detection of *A. amurensis* larvae specifically in port water samples as well as water samples from the internal spaces of small vessels (Hayes et al., 2004). However, full implementation of the BWMC is not anticipated until 2024. Until then, the likelihood that *A. amurensis* will enter the RA area undetected in ballast waters remains high. On the other hand, if the species is targeted through a national monitoring programme with molecular methods, larvae in water samples from ports/harbours can be currently detected.

**Qu. 3.8a. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely unlikely	<b>CONFIDENCE</b>	low medium
-----------------	---------------------------	-------------------	---------------

<sup>6</sup> NIS: non-indigenous species, term used in the Marine Strategy Framework Directive, synonym of “alien species” as used in the framework of Regulation (EU) 1143/2014

	moderately likely <b>likely</b> very likely		<b>high</b>
--	---	--	-------------

Response: If ballast water exchange occurs in open seas rather than in coastal areas, transfer of planktonic larvae to suitable substrate will be hampered. If, however, untreated ballast water is released in ports, estuaries or other coastal areas, then establishment will be dependent on availability of suitable habitat. Considering a) the breadth of habitat that characterizes the species; b) the wide distribution of such habitats in the RA area and c) the invasion history of the species in Australia, which is closely connected with ports and estuaries, there is a high likelihood that *A. amurensis* can transfer to a suitable habitat after release with ballast water.

**Qu. 3.9a. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area. (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly slowly moderately <b>rapidly</b> very rapidly	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: Given the amount of maritime traffic between ports and harbours of the RA area (thousands of journeys per year), the ballast volume of commercial vessels ( $10^4$ - $10^5$  tonnes) and the potentially high densities of both adult *A. amurensis* on the seabed as well as larvae in surface waters, the potential rate of spread of the species via ballast water is considerable but mainly in Atlantic Europe (see also Risk of Establishment). Due to the more limited extent and duration of favourable environmental conditions in other marine regions/subregions of the RA area, the likelihood that dense populations will develop there (and hence the corresponding larval density in the seawater in ports and harbours) is lower.

**b) TRANSPORT-STOWAWAY (ship/boat hull fouling)**

**Qu. 3.3b. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response: There is direct evidence that *A. amurensis* can travel in the sea chests of large commercial vessels and that it can settle on external and internal surfaces of small recreational (and professional) craft (Hayes et al., 2004 – see also Qu 1.3b). Moreover, it is possible that larvae may be transported in sea water systems, live wells or other deck basins of recreational craft or other small commercial craft (MPSC, 2015). In these cases, the entrainment of the species on ships/boats hulls and niche areas is accidental.

**Qu. 3.4b. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: While the maritime traffic by large commercial vessels as well as smaller professional and recreational craft is very high, only a few incidents of entrainment on hulls have been reported in the literature, and the number of individuals detected was small. For example, *Asterias amurensis* was observed in the sea-chest of a commercial vessel operating between the Derwent Estuary, Tasmania, and Port Phillip Bay in Australia (Thresher, pers. comm in Dommissie & Hough, 2004). Additionally, *A. amurensis* DNA was found in biofouling samples collected from 3 fishing and recreational vessel hulls, both from internal and external surfaces (Hayes et al., 2004). This does not necessarily mean the presence of viable propagules (as discussed in Qu. 1.3b) but is nevertheless an indication that passive or active settlement may be taking place. Considering that travel durations within the RA area are much shorter compared to journeys from the native region, particularly for small craft, it is conceivable that larvae or juveniles sheltering among protected spaces in a fouling community (e.g. barnacle or bivalve shells) can remain entrained and be translocated.

**Qu. 3.5b. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
-----------------	---------------	-------------------	-----

	unlikely moderately likely <b>likely</b> very likely		<b>medium</b> high
--	---	--	-----------------------

Response: If entrained in areas of the vessel with low food availability, *Asterias* species are capable of surviving prolonged periods of starvation, up to several weeks (St-Pierre & Gagnon, 2015) or even months (Vevers, 1949). If, on the other hand, starfish are transported in sea chests, where heavy fouling can accumulate (i.e. providing food resources, primarily in the form of bivalves), not only survival but also growth and maturation may be possible. For *A. amurensis*, this is attested by the survival and translocation of live individuals on debris from the Tohoku tsunami of 2011 from Japan to the west coast of North America almost a year later (Carlton et al., 2017; 2018). Reproduction would require the presence of at least a pair of adults and would be unlikely to happen if starvation conditions are reached (e.g. depletion of resources in sea chests), when the species would mobilise its energy reserves for survival (Aguera & Byrne, 2018). On the other hand, poorly maintained vessels (largely recreational) are a particular risk if moored for long periods of time and moved between marinas occasionally because they have the potential to harbour reproducing populations in stable, sheltered conditions for suitable periods of time to enable reproduction to occur.

**Qu. 3.6b. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Even though there are methods to prevent and minimize fouling on vessels hulls, these management measures are not mandatory in the RA area and can be expensive and time consuming, which may create a barrier to implementation. Thus, they are not carried out at a frequency and prevalence sufficient to prevent the entrainment and translocation of species like *A. amurensis* via ships hulls and niche areas (see also Qu 1.5b).

**Qu. 3.7b. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: The species is unlikely to be detected upon introduction, unless thorough inspections of hull fouling communities are carried out, which is currently not a routine practice. Even then, because the species can also settle on internal surfaces of vessels (Hayes et al., 2004), the likelihood of detection via visual inspections remains low.

In order to reach GES targets with reference to Descriptor D2, most EU states are already designing or implementing national/regional NIS-targeted monitoring programmes. Monitoring should focus on introduction hotspots (e.g. ports, marinas, aquaculture plots) and this will increase the detectability of *A. amurensis* entering the RA area through hull fouling, particularly if molecular methods are employed (Hayes et al., 2004).

**Qu. 3.8b. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Entry into the environment would require dislodgment of fouling material or active movement by the adults/juveniles. Alternatively, propagules could enter the environment in the form of gametes by at least a pair of *A. amurensis*, an event which is not considered very likely. In any case, ports and harbours provide abundant suitable habitats for colonization for *A. amurensis*, which a) is a habitat generalist and b) develops high densities on wharves and piers, due to their high food availability (Aguenal, 2008).

**Qu. 3.9b. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area. (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: Despite direct evidence that *A. amurensis* can settle on external and internal surfaces of vessels and can be transported via this pathway, the translocation risk is likely to be smaller compared to that associated with the ballast water of large commercial vessels (Hayes et al., 2004), primarily due to the smaller number of individuals potentially transported via hull fouling at one time. Additionally, the environmental limitations for establishment that apply in the different marine subregions of the RA

area (see Annex VIII) will also make entrainment and transport more likely in the North-East Atlantic (as in 3.9a).

- c) **TRANSPORT-CONTAMINANT Contaminant on animals** (except parasites, species transported by host/vector)

**Qu. 3.3c. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response: It can be stated with high certainty that this pathway is unintentional. See categorization of pathways in Annex IV and guidance notes in the beginning of this section.

Spread via this pathway is not documented for the species in the invaded range, it is considered however that infested consignments of commercial bivalve species intended for aquaculture can transport it unintentionally, as a contaminant, throughout the RA area.

**Qu. 3.4c. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: *Asterias amurensis*, like many of its congenics, is a notorious pest of shellfish aquaculture both in its native and the invaded range. It is known to infest and predate on scallops, oysters, mussels, clams and abalone (see Qu. 4.9 for details and references) and could easily spread within the RA area with routine bivalve transfer operations. All countries along the European Atlantic and the

Mediterranean coasts involved in the cultivation of bivalves are currently conducting transfer activities (Muehlbauer et al., 2014; Occhipinti-Ambrogi et al., 2016; Marchini et al., 2014; Rodrigues et al., 2015). These activities include transfers at all life stages, from field sites to wild fishery sites or from field to culture sites, from nearshore to onshore facilities or from nearshore wild bottom beds to offshore hanging cultivation devices (Muehlbauer et al., 2014).

*Asterias amurensis* can achieve very high densities when food resources are abundant, from 300 ind/m<sup>2</sup> during outbreaks in China (Li et al., 2018) to a more modest but still considerable 6 ind/m<sup>2</sup> in Japan (Nojima et al. 1986) and 7 ind/m<sup>2</sup> around shellfish beds and aquaculture facilities in Australia (MPSC, 2015). It also settles on spat collecting devices (see Qu 4.9 for details), which poses an even higher risk of spread, due to the high volume of spat transfers and the small size of the starfish at this stage.

Additionally, *A. amurensis* can reproduce asexually by regeneration of its arms, as long as part of the central disc is attached (see Qu. 2.7), thus, even a very small number of adult individuals could potentially lead to successful spread via this pathway if e.g. damaged during dredging operations to harvest the transferred material.

An additional means of transport in the invaded range was considered to be salmon cages, which can be heavily fouled with bivalves and act as settlement surfaces for starfish (Dommissé & Hough, 2004). Nevertheless, in a survey of aquaculture operators, there were no *A. amurensis* (or any native starfish species) reported from salmon cages and it was thought that application of anti-fouling on fish cages reduces the attachment of bivalves and hence settling starfish (Dommissé & Hough, 2004).

**Qu. 3.5c. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
	unlikely		medium
	moderately likely		<b>high</b>
	likely		
	<b>very likely</b>		

Response: *Asterias amurensis* is a broadcast spawner so it will not reproduce during transport, neither will it increase within the small duration of such operations (within the RA area). It is very likely to survive though, as the shellfish themselves and the methods used to contain them during transport may actually enhance the likelihood of survival of contaminant species by providing moisture and protection from harsher conditions (Minchin, 2007).

**Qu. 3.6c. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
	unlikely		<b>medium</b>
	<b>moderately likely</b>		high

	likely very likely		
--	-----------------------	--	--

Response: Management practices relevant to this pathway fall into two categories.

The first one is legislation regarding aquaculture transfers. At the EU level, COUNCIL REGULATION (EC) No 708/2007 concerning use of alien and locally absent species in aquaculture defines the procedures to be followed that minimise the risk of introducing non-target alien species accompanying commercial shellfish spat and stocks. It requires a permit procedure, involving risk assessment for the non-target species and a quarantine period for the translocated stock. Importantly, in relation to spread within the RA area, the regulation does not apply to movements of locally absent species within the Member States (i.e. in this case cultivated native species of bivalves) “except for cases where, on the basis of scientific advice, there are grounds for foreseeing environmental threats due to the translocation, Art. 2 para. 2.” Additionally, the bivalves *M. gigas* and *R. philippinarum*, listed in Annex IV, which are common prey species for *A. amurensis*, constitute exceptions and can be moved without any risk assessment or quarantine. However local/national legislation exists that can limit the translocation possibilities of species like *M. gigas*, e.g. see WG-AS & Gittenberger (2018) for the trilateral Wadden Sea area. Moreover, if the import region is a Natura2000 area, regulations can be much stricter as they aim to protect the conservation objectives of the protected area first. In general, restrictions on transfers based on the risk associated with the source areas is an effective management method, as long as extensive and up-to-date data on the distribution of the high-risk NIS are available.

The second category of measures are standard industry practices to minimize predator infestations, in this case commonly employed in the RA area to reduce predation by the native starfish *A. rubens*. There is a variety of methods, depending on the cultivated bivalve species and type of cultivation (bottom or suspended culture) that include manual removal (e.g. handpicking from suspended lines), immersion in chemical solutions or freshwater, removal by traps or specialized towed gear (see McEnnulty et al., 2001 and Barkhouse et al., 2007). The efficiency of these methods is variable but would allow opportunities for spread.

**Qu. 3.7c. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: If the species transfers at the juvenile stage, recently settled on bivalve spat, it is likely to go undetected due to its small size (<10mm ray length, Davenport & McLoughlin, 1993). Perfunctory visual inspections during bivalve aquaculture operations are likely to miss small size individuals. Moreover, juvenile/young *A. amurensis* could easily be misidentified for the native *A. rubens*, which is also a common shellfish culture pest and frequently encountered during transfer operations. See Qu. A2 for a comparison between *A. rubens* and *A. amurensis*.

**Qu. 3.8c. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: If *A. amurensis* infested bivalve seed/stock is relayed on cultivation plots without any prior management measure, the likelihood of transfer to other suitable habitats (the cultivation plots themselves are suitable habitats) is very high. These plots are often situated in coastal areas in close proximity to suitable natural habitat to which individuals may spread. The high mobility of the adults (Miyoshi et al., 2018) augments this mechanism of spread.

**Qu. 3.9c. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area. (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: Bivalve transfers are a likely mechanism of entraining and translocating *A. amurensis* in the RA area, particularly considering that suitable environmental conditions for the establishment of new populations are widespread in areas where a high volume of transfer operations takes place (i.e. throughout shallow coastal areas of Atlantic Europe, as well as the northern Adriatic, northern Aegean and the western Mediterranean).

Taking into account the degree of regulation and management in the industry and the fact that in many cases transfers are predominantly conducted within Member States, spread to distant locations through this pathway may be less important than spread through ship-mediated pathways.

**d) TRANSPORT-STOWAWAY (fishing/angling equipment)**

**Qu. 3.3d. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response: In both the native and invaded range, *A. amurensis* is caught, often in high quantities, as by-catch of demersal and bivalve fisheries (e.g. Hatanaka & Kosaka, 1959, Aquenal, 2008, Smith & Armistead, 2014), both by bottom towed gear as well as by longlines and hooks by professional and recreational fishermen (Parry et al., 2003). Since the species is not targeted as a commercial catch, it is discarded by the fishermen (but see potential waste disposal solutions in A13 and later in this section). Depending on discard practices and disposal of by-catch, entrainment in fishing/angling equipment poses a high risk of unintentionally translocating the species. Additionally, starfish may be entrained in wet wells or damp crevices on the deck (Kinloch et al., 2003).

**Qu. 3.4d. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: This will depend on the densities the species has achieved where fishing operations take place, the type of fishing gear used and the discard practices. Gear that is submerged for a long time, comes into contact with the seabed and is unselective (gill and trawl nets, dredges, traps and pots) is ranked the most likely to entrain and spread marine pests and particularly *A. amurensis* (Hayes 2002; Kinloch et al., 2003). Considering that *A. amurensis* can dominate the by-catch of demersal fisheries (see Qu 4.9 for details) and how widespread these operations are in the RA area, there is a high risk that a sufficient number of individuals to establish a new population can spread via this pathway, especially if the species is discarded at locations far away from the point of capture. Since this is a continuously active pathway of spread, reinvasion after eradication is also possible, unless preventative measures are taken.

**Qu. 3.5d. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: *Asterias* species generally display relatively high survival rates when discarded, unless heavily damaged during fishing operations (e.g. for *A. rubens* see Bergmann & Moore, 2001; Ramsay et al., 2001; Revill, 2012 for review). If it remains entangled in wet fishing equipment or damp crevices on the deck, it also has high chances of survival until the fishing gear is submerged again or the vessel returns to harbour. Furthermore, even damaged individuals can regenerate and have the capability to reproduce after translocation, even though they cannot reproduce along the pathway, being broadcast spawners. Some fishing practices fragment individuals and this will increase the number of viable propagules.

**Qu. 3.6d. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: There are currently no management practices addressing starfish by-catch during fishing operations and their discarding at sea. Handling of by-catch can be variable and depends on fishing gear and practices, such that survival of the species is generally considered likely during fishing operations. The Common Fisheries Policy (CFP) of 2013, which aims at gradually eliminating the practice of discarding through the introduction of the landing obligation by 2019, only applies to regulated commercial species.

**Qu. 3.7d. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: If *A. amurensis* is caught together with native species in high quantities, as is often the case during fishing operations, it would be easy to miss on the deck, as by-catch is not given much attention. Additionally, juveniles and even adults may be overlooked or mistaken as “unusual looking” native *A. rubens* by untrained individuals (see Qu. 3.7c).

**Qu. 3.8d. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
	unlikely		<b>medium</b>
	moderately likely		high
	<b>likely</b>		
	very likely		

Response: This will depend again on discard practices, fishing operations (e.g. if the gear is used multiple times during the same fishing trip before being cleaned and stored) and where the species has been entrained. If discarded at sea, it is very likely that individuals will survive and be released over suitable depths and substrates.

**Qu. 3.9d. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area. (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly	<b>CONFIDENCE</b>	<b>low</b>
	slowly		medium
	<b>moderately</b>		high
	rapidly		
	very rapidly		

Response: Fishing/angling equipment is considered a high risk vector for the translocation and spread of *A. amurensis*, mainly due to the high numbers of individuals that can potentially be entrained and survive transport but also due to the fact that fishing operations are so widespread throughout the RA area. Nevertheless, the geographic spread of the species via this route would be relatively limited, hence a moderately rapid rate of spread may be expected.

**e) TRANSPORT-STOWAWAY (machinery/equipment & floating debris)**

**Qu. 3.3e. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response: It can be stated with high certainty that this pathway is unintentional. See categorization of pathways in Annex IV and guidance notes in the beginning of this section.

This pathway includes a diverse array of vectors of different sizes and mobility, such as mobile drilling rigs, energy extraction devices, moorings and buoys, as well as equipment dislodged by storms or damaged structures and debris lost at sea and drifting (e.g. aquaculture equipment, pontoons, pier debris, etc.). Such structures are often heavily fouled with mature fouling communities (Nall, 2015; Astudillo et al., 2009), which provide both settlement space and abundant food resources for *A. amurensis*. Some of them enter and stay in ports for extended periods of time (e.g. tidal and wave energy devices – Loxton et al., 2017b), or are in frequent contact with offshore support vessels and can thus enhance the connectivity network for propagules of the species.

**Qu. 3.4e. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: This is difficult to predict as it will depend on the density of nearby populations, the larval density and hydrodynamic patterns in the vicinity of the different structures, the biofouling communities that develop on them and their frequency of movement between locations. As corroborating information, it is worth noting that the native starfish *A. rubens* is frequent and abundant in the subtidal zone of both fixed windmill pilings (de Mesel et al., 2015), floating, mobile wave energy devices (Nall, 2015), as well as navigational buoys (Orton & Fraser, 1930). Thus, even though

it is possible that significant numbers of *A. amurensis* may be found on mobile structures (should the species invade the RA area), particularly juveniles and young individuals, it is less likely that extensive spread will occur during the course of one year.

As far as smaller, dislodged equipment and debris are concerned, these may be the carriers of denser aggregations of *A. amurensis*. It is well documented that the starfish heavily settles and fouls e.g. aquaculture cages and piers (see previous sections for details), that are often damaged due to poor maintenance or extreme weather and lost at sea. This may increase spread sporadically and unpredictably over longer distances as this lighter material can drift for considerable distances depending on local hydrodynamic conditions.

**Qu. 3.5e. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: If *A. amurensis* find sufficient food resources on the submerged part of these structures (which is often the case, due to extensive fouling), they are very likely to survive, grow and even reproduce, if they remain undisturbed and attached for long enough (maturation in *A. amurensis* occurs at approximately 1 year – see Qu. 2.7), especially under the favourable environmental conditions of Atlantic Europe. Moreover, when such equipment/machinery is transferred between locations it is usually towed at low speeds (e.g. typically around 2 knots for a mobile drilling rig – Kinloch et al., 2003), which reduces the likelihood of dislodgement of the starfish.

Moreover, *A. amurensis* as part of fouling communities on floating debris also has high chances of survival. The most characteristic and extreme example is that of the translocation of live individuals on pier debris from the Tohoku tsunami of 2011 from Japan to the west coast of North America almost a year later (Carlton et al., 2017; 2018).

**Qu. 3.6e. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium high
-----------------	--	-------------------	-----------------------

Response: Floating/mobile marine devices have different challenges to ships/boats when it comes to fouling. Because this category covers a variety of objects with different purposes and operational characteristics, there are no overall standards for anti-fouling, like in the shipping sector. Nevertheless, anti-fouling coatings/paints can be used on moorings, buoys and sensors, and mechanical removal of

fouling communities is part of the maintenance procedure for marine renewable energy (MRE) devices (Loxton et al., 2017a; Venkatesan et al., 2017). With anti-fouling measures, the same limitations apply as for vessels, paints are effective for a period of 1.5-2 years, after which heavy fouling can start developing. As such, they would not affect the survival of *A. amurensis* on objects remaining at sea for long periods. In the case of mechanical removal (e.g. in-water cleaning), survival during spread would depend on the method employed, the disposal of the generated waste and whether cleaning takes place before a device is moved to another location.

**Qu. 3.7c. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: This will depend on the level of inspection of the fouling communities during maintenance or before transportation of the machinery/equipment. Considering that taxonomic characterization of the attached biota is not a priority in these cases and given the similarity of *A. amurensis* with the native common starfish *A. rubens*, the likelihood that the introduced species will remain undetected seems high. See also Qu. 1.6b, 1.6c, 3.7c.

With regards to floating debris, all natural sink areas can receive floating debris (Rech et al., 2016) such that rafting *A. amurensis* could potentially get stranded all along the risk assessment area, lowering the chances of detection away from monitoring hotspots.

**Qu. 3.8e. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: *Asterias amurensis* utilizes a wide range of habitats in relatively shallow coastal areas (see Qu. 2.2 for details), where machinery/equipment is most commonly deployed. Moreover, ports and harbours, where such equipment is also transferred and stored, provide additional artificial habitats, highly suitable for colonization due to the high food availability they present. For example, in the Derwent river estuary, Tasmania, *A. amurensis* near wharf structures were present in higher densities and had larger gonads compared to *Asterias* occurring on natural substrates (Ling, 2000; Aquenal, 2008). It is also important to note that many of the structures in question are anchored or connected by other means to the seabed, providing a bridge or direct physical link over which developed starfish can

move between the structure and the seabed to forage or search for suitable habitat and conspecifics. Finally, spawning of individuals living as part of these fouling communities would release planktonic propagules to the water column at locations with conditions suitable for development.

*Asterias amurensis* attached to floating debris is also likely to transfer to suitable habitats as the drifting material approaches the shore; moreover, its wide depth range and relatively high adult mobility can potentially expand the spatial scale of suitable habitats around rafting communities.

**Qu. 3.9e. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area. (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: Mobile machinery and equipment has a high likelihood to act as a settlement surface for the larvae of *A. amurensis*, as well as adult individuals if it comes in contact with the seabed or port/harbour structures that can host high densities of the species. The rate of spread however is not expected to be high, as these objects generally spend long periods at sea and are moved only infrequently.

On the other hand, a moderate rate of spread may be expected for *A. amurensis* rafting on dislodged and drifting objects, such as aquaculture gear and damaged structures/pieces, given the affinity of the species for such objects. Increased storminess resulting from climate change has the potential to increase this risk even further.

**Qu. 3.10. Within the risk assessment area, how difficult would it be to contain the organism in relation to these pathways of spread?**

<b>RESPONSE</b>	very easy easy with some difficulty difficult <b>very difficult</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: Naturally dispersing organisms are very difficult to contain, especially species such as *A. amurensis*, with high fecundity, long pelagic larval duration and the capability to develop extremely dense populations in a very short time (See Qu. 2.7 for the biological characteristics of the species and A5 for its invasion history in Australia). This was exemplified in Australia, where despite removal

efforts, the species spread from Tasmania to Port Phillip Bay in Victoria and from there to adjacent bays within a relatively short period of time (Millers, 2015; MPSC, 2015)

**Qu. 3.11. Estimate the overall potential rate of spread in relevant biogeographical regions under current conditions for this organism in the risk assessment area (indicate any key issues and provide quantitative data where possible).**

Thorough assessment of the risk of spread in relevant biogeographical regions in current conditions, providing insight in the risk of spread into (new areas in) the risk assessment area.

<b>RESPONSE</b>	very slowly slowly moderately <b>rapidly</b> very rapidly	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: Unaided dispersal and multiple pathways of human-aided spread create a considerable potential for spread of *A. amurensis* in the north-east Atlantic. Mature females are highly fecund, producing between 0.5 and 15.5 million eggs per year (see Qu. 2.7 for details). The species has long-lived planktonic larvae, whose physiological requirements are met during prolonged periods in this region; additionally, it can spread rapidly via ballast water and can also be translocated with hull fouling, bivalve consignments, and fishing equipment, although at a more moderate rate with the latter pathways. In the Mediterranean Sea, if the species is introduced and establishes, its distribution is likely to be more disjunct in the cooler, northern basins of this marine region, due to less favourable environmental conditions for larval development. Natural dispersal is expected to be more limited and human-aided spread will likely proceed at a more moderate rate due to the smaller number of potential nodes.

**Qu. 3.12. Estimate the overall potential rate of spread in relevant biogeographical regions in foreseeable climate change conditions (provide quantitative data where possible).**

Thorough assessment of the risk of spread in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk, specifically if rates of spread are likely slowed down or accelerated.

<b>RESPONSE</b>	very slowly slowly moderately <b>rapidly</b> very rapidly	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: The rate of spread is not expected to change significantly in Atlantic Europe under foreseeable climate change conditions, therefore a rapid rate of spread may still be expected.

Higher frequency and severity of storms can increase the amount of time vessels have to spend in port, increasing the likelihood of entrainment (Galil et al., 2019); it may also increase the likelihood that equipment with mature fouling communities (e.g. buoys, cages) can be detached from docks, marinas and aquaculture facilities.

In the Mediterranean Sea, an overall increase in sea surface temperatures will limit even more the potential for natural dispersal. At the same time, heat waves, can cause mass mortality of aquaculture bivalves, leading to increased shellfish transfers to replete the stocks (Rodrigues et al., 2015). More shellfish movements may be associated with a higher risk of introduction if the stocks/seed originate from areas with a high risk of contamination with *A. amurensis* and the necessary precautions are not taken.

## 4 MAGNITUDE OF IMPACT

Important instructions:

- Questions 5.1-5.5 relate to biodiversity and ecosystem impacts, 5.6-5.8 to impacts on ecosystem services, 5.9-5.13 to economic impact, 5.14-5.15 to social and human health impact, and 5.16-5.18 to other impacts. These impacts can be interlinked, for example, a disease may cause impacts on biodiversity and/or ecosystem functioning that leads to impacts on ecosystem services and finally economic impacts. In such cases the assessor should try to note the different impacts where most appropriate, cross-referencing between questions when needed.
- Each set of questions starts with the impact elsewhere in the world, then considers impacts in the risk assessment area (=EU excluding outermost regions) separating known impacts to date (i.e. past and current impacts) from potential future impacts (including foreseeable climate change).
- Only negative impacts are considered in this section (socio-economic benefits are considered in Qu. A.7)
- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”.

### Biodiversity and ecosystem impacts

**Qu. 4.1. How important is the impact of the organism on biodiversity at all levels of organisation caused by the organism in its non-native range excluding the risk assessment area?**

including the following elements:

- Biodiversity means the variability among living organisms from all sources, including terrestrial, marine and other aquatic ecosystems and the ecological complexes of which they are part; this includes diversity within species, between species and of ecosystems
- impacted chemical, physical or structural characteristics and functioning of ecosystems

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response:

NOTE: Some information is given for the functional role of the organism in its native range as a point of reference for impacts in the invaded range. It is acknowledged that these effects are not directly transferable to the invaded range and they are not taken into account when assessing the impact score for this question.

*Asterias amurensis* is an opportunistic generalist predator with a preference for bivalves (Lockhart & Ritz, 2001). It feeds on a variety of infaunal and epifaunal species including mollusks, ascidians,

bryozoans, sponges, crustaceans, polychaetes, fish and echinoderms (Hatanaka & Kosaka, 1959; Fukuyama and Oliver, 1985), as well as scavenging on carrion (Smith & Armistead, 2014 and references therein). In common with other *Asterias* species, *A. amurensis* in its native range undergoes periodic population density fluctuations (Gabaev, 2018) or “outbreak-like” population increases (Uthicke et al., 2009). Outbreak events are associated with heavy predation effects on wild and cultured bivalve populations (see Qu. 4.9)

They also compete for food with native (commercial) flatfish species (main food items are small crustaceans, lamellibranchs and small fish) Hatanaka & Kosaka (1959).

In Australia, *Asterias amurensis* reached densities up to 24 individuals/m<sup>2</sup> over a relatively short time (10 yrs) after its introduction (Byrne et al. 1997a, Grannum et al. 1996). These are densities far higher than those reported during outbreak events in its native range (e.g. 6 individuals/m<sup>2</sup> during an outbreak in Japan – Nojima et al., 1986). The starfish also has the ability to maintain high densities when food availability is high (MPSC, 2015). It has thus become the dominant benthic invertebrate predator in the two main invaded areas (Port Phillip Bay, Victoria and Derwent Estuary, Tasmania) with massive populations (See also Qu. A5, Qu. 1.3a for quantitative information).

The species was demonstrated to dramatically reduce the recruitment of native bivalves. In a manipulative experiment in Tasmania, densities of juveniles of the bivalve *Fulvia tenuicostata* were reduced by ca. 15 fold (from 580 to 35/m<sup>2</sup>) in the presence of sea stars at background densities relative to the treatment without sea stars, effectively arresting a massive settlement event (Ross et al., 2002). Predation by the starfish was also responsible for drastic population declines of adult *F. tenuicostata*, as well as another bivalve species *Katelysia rhytiphora* (Ross et al., 2004).

*Asterias amurensis* has been implicated in the dangerous decline in the 1980s of populations of the Tasmanian endemic spotted handfish, *Brachionichthys hirsutus* (Barrett et al., 1996, Ross et al., 1999), which was subsequently considered critically endangered. The mechanism was hypothesized to involve predation by *A. amurensis* on stalked ascidians, which form the primary spawning substrate of *B. hirsutus*, and subsequent reduction of key habitat availability (Bruce & Green, 1998; Green et al. 2012), although direct evidence of this is lacking (Green et al., 2012). Spotted handfish had already suffered historical habitat degradation due to scallop dredging, mooring disturbances and coastal urbanization (Wong et al., 2018). It is a species strictly restricted to the Derwent estuary, with low dispersal capability due to the lack of a planktonic larval stage, and genetic isolation between local populations. The species is vulnerable to stochastic processes that can lead to serial local extinctions such that continued conservation action (i.e. deployment of artificial spawning habitats and captive breeding program) is considered essential for its survival. (Stuart-Smith et al., 2020). In this context, the cumulative effect of *A. amurensis* on its habitat and subsequent survival can be considered a major impact.

*Asterias amurensis* has also been suggested to cause large changes to fish populations through competition for food (Parry & Hirst, 2016). During its peak abundance in Port Phillip Bay, *A. amurensis* biomass was equivalent to 56% of total fish biomass in the deep region of the bay, where sharp declines of 3 demersal fish species were observed. These species have a strong dietary overlap with *A. amurensis*, with bivalves and polychaetes being their preferred prey items (Parry & Hirst, 2016).

**Qu. 4.2. How important is the current known impact of the organism on biodiversity at all levels of organisation (e.g. decline in native species, changes in native species communities, hybridisation) in the risk assessment area (include any past impact in your response)?**

Discuss impacts that are currently occurring or are likely occurring or have occurred in the past in the risk assessment area. Where there is no direct evidence of impact in the risk assessment area (for example no studies have been conducted), evidence from outside of the risk assessment area can be used to infer impacts within the risk assessment area.

<b>RESPONSE</b>	N/A	<b>CONFIDENCE</b>	high
-----------------	-----	-------------------	------

Response: There is no evidence to confirm that the species is currently present in the RA area.

**Qu. 4.3. How important is the potential future impact of the organism on biodiversity at all levels of organisation likely to be in the risk assessment area?**

See comment above. The potential future impact shall be assessed only for the risk assessment area.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: In the risk assessment area, the functional and ecological role that *A. amurensis* plays in benthic communities is fulfilled by the native, con-specific and closely related *A. rubens*. This is the case in Atlantic Europe, where *A. amurensis* is more likely to be introduced, establish and spread. Like *A. amurensis* in the north-west Pacific, *A. rubens* is also a keystone benthic predator (Casties et al., 2015), that undergoes periodic population outbreaks (Uthicke et al., 2009), during which the species can develop extensive aggregations with high densities (“feeding fronts”) and decimate bivalve beds (Hancock, 1955; Gallagher et al., 2008). Thus, the potential biodiversity impacts of *A. amurensis* will depend to a large extent on its interaction with *A. rubens* and the density/distribution it achieves in relation to its sister species. The literature suggests that asteroid species can often co-exist, either sharing or partitioning prey resources (e.g. in terms of prey size) or by partitioning the habitat (for an extensive discussion see Qu. 2.3). *Asterias rubens* in particular has been shown to only infrequently compete with *A. forbesi* in parts of their range in the north-west Atlantic (Menge, 1979), where it is suggested that their dynamics are controlled by environmental stochasticity and prey patchiness. A higher tolerance of *A. rubens* larvae to slightly lower temperatures (down to 2 °C - Benitez Villalobos et al. 2006) and salinities (locally as low as 14-15 psu - Casties et al., 2015) may give it a competitive advantage at higher latitudes. While difficult to predict, it is hypothesised that, as long as there is sufficient prey availability and favourable conditions for successful recruitment, biotic interactions with *A. rubens* will not significantly affect the potential of *A. amurensis* to cause population declines of native species (mainly bivalves) in the RA area, such that moderate impacts may be expected, similar to elsewhere in the invaded range (Qu. 4.1). On the other hand, impacts of *A. rubens*

population outbreaks on native species may be exacerbated by simultaneous or staggered outbreaks of *A. amurensis* and this may limit system recovery from natural events.

With regards to hybridisation, within the genus *Asterias*, hybridization has been documented between *A. rubens* and *A. forbesi* in the laboratory, producing viable, fertile adults (Harper & Hart, 2005) but is limited in wild populations of the north-west Atlantic (Gulf of Maine to Nova Scotia), where the two species are sympatric (Harper & Hart, 2007). Considering the close phylogenetic relationships between all three species (Wares, 2001), hybridization between *A. rubens* and *A. amurensis* may be possible.

**Qu. 4.4. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism currently in the risk assessment area?**

including the following elements:

- native species impacted, including red list species, endemic species and species listed in the Birds and Habitats directives
- protected sites impacted, in particular Natura 2000
- habitats impacted, in particular habitats listed in the Habitats Directive, or red list habitats
- the ecological status of water bodies according to the Water Framework Directive and environmental status of the marine environment according to the Marine Strategy Framework Directive

<b>RESPONSE</b>	<b>N/A</b>	<b>CONFIDENCE</b>	<b>high</b>
-----------------	------------	-------------------	-------------

Response: There is no evidence to confirm that the species is currently present in the RA area.

**Qu. 4.5. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.4.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: A list of habitats of conservation concern that may be threatened by *A. amurensis* through predation is as follows:

Mussel beds on infralittoral rock are part of the wider Reef NATURA-1170 habitat type (Annex I of the Habitats Directive). The habitat is also part of the sublittoral rocky seabeds and kelp forests (code 11.24), listed as endangered in the Resolution no. 4 of the Council of Bern Convention (1996) (Salomidi et al., 2012). They are under severe threat from *A. amurensis* which can obliterate mussel bed populations (Gallagher et al., 2008).

Mussel beds on circalittoral rock (EUNIS A4.24).

Sublittoral mussel beds on sediment (EUNIS A5.62). Within the Habitats Directive, this biotope can be protected as Reefs (habitat type 1170).

*Modiolus modiolus* (horse mussel) beds/reefs are considered a type of Annex I biogenic reef habitat, an OSPAR listed habitat and a Habitat of Principal Importance across the UK (Morris, 2015). They significantly modify the underlying habitat and provide substratum and refuge for a wide variety of species, including commercially important bivalves (Baxter et al., 2011). Despite their sparse and patchy distribution and the somewhat intermittent recruitment, dense reefs are generally thought to be very stable in the long term (Holt et al., 1998; Rees, 2009). They are subject to predation by *A. rubens* (Tillin & Tyler-Walters, 2015) and could come under threat by *A. amurensis* as well. Predation by starfish (and crabs) is thought to be particularly important for the survival of juveniles, however it is suspected that survival is greatly enhanced by juveniles living within the mass of adult's byssus threads where predators cannot easily get them (Holt et al., 1998; Rees, 2009). Thus, irreversible impacts by *A. amurensis* are considered unlikely.

*Sabellaria* spp. reefs are listed as protected habitats under Annex I of the Habitats Directive and as a threatened and/or declining priority habitat by OSPAR (OSPAR, 2008). They provide topographically complex structures with varied microhabitats which can support high levels of biodiversity (NRW, 2019). Native starfish *A. rubens* are commonly found preying on these habitats but due to the lack of knowledge on prey-predator interactions with the reef building worms and the associated fauna, the level of risk cannot be assessed (Gibb et al., 2014). *Asterias amurensis* is known to feed on tube-building polychaetes (e.g. *Lagis koreni*, in Smith & Armistead, 2014) such that it could constitute a threat to *Sabellaria* reefs as well, however there is large uncertainty associated with this assessment. Nevertheless, the starfish has the potential to impoverish the diversity of these reef habitats by preying on the erect epifauna they support.

*Ostrea edulis* beds on shallow sublittoral muddy mixed sediment are part of the wider Reef NATURA-1170 habitat type (Annex I of the Habitats Directive). They are included in the European Red List of Habitats as Critically Endangered (EC 2016). These habitats provide important ecosystem functions, as described in Qu 4.7 and 4.9 (namely high biodiversity and productivity, nutrient cycling and benthic-pelagic coupling, increased water quality, etc.), which are under direct threat by *A. amurensis* predation. In the Mediterranean Sea, both mussel beds (*M. galloprovincialis*) and native oyster beds (*Ostrea edulis*) are included in the European Red List of Habitats as Vulnerable (EC 2016). Infralittoral mussel beds are of conservation concern (Near Threatened to Critically Endangered) across the regional seas. Nevertheless, *A. amurensis* is not expected to develop very high densities on a wide scale throughout the Mediterranean, such that habitats of conservation concern are not considered under very serious risk.

Loss of both infaunal and epifaunal bivalve populations has the potential to affect the overwintering success of protected diving seabirds such as common eider (*Somateria mollissima*) and common scoter (*Melanitta nigra*), which depend upon these prey resources for their survival (Bräger et al., 1995).

## Ecosystem Services impacts

**Qu. 4.6. How important is the impact of the organism on provisioning, regulating, and cultural services in its non-native range excluding the risk assessment area?**

- For a list of services use the CICES classification V5.1 provided in Annex V.
- Impacts on ecosystem services build on the observed impacts on biodiversity (habitat, species, genetic, functional) but focus exclusively on reflecting these changes in relation to their links with socio-economic well-being.
- Quantitative data should be provided whenever available and references duly reported.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response:

Provisioning services: Biomass – Reared aquatic animals & Wild animals: *Asterias amurensis* affects ecosystem services primarily through its negative impacts on wild and cultivated bivalve populations, as well as on commercial fisheries. Loss of food provisioning services could constitute a major impact but at the local scale, since the species heavily affects many different cultured species, including scallops, oysters and mussels, wild harvested species of clams and cockles but also interferes with trawl and long-line fisheries as by-catch (see Qu 4.1 & 4.9).

Regulation & maintenance services: Regulation of physical, chemical, biological conditions: Additionally, it is thought likely that it affects other ecological processes, such as nutrient cycling, by heavily reducing infaunal populations (Joint SCC/SCFA, 1999), and regulating and maintenance services through water quality regulation (bivalve suspension feeders remove particulate organic matter, reduce nitrogen load and improve water quality (Salomidi et al., 2012).

Cultural services: Direct, in-situ and outdoor interactions – Physical and experiential: Finally, it may be affecting the amenity and recreational value of the infested areas by reducing recreational harvests (MPSC, 2015). However, such impacts have not been quantified or assessed in the invaded range.

**Qu. 4.7. How important is the impact of the organism on provisioning, regulating, and cultural services currently in the different biogeographic regions or marine sub-regions where the species has established in the risk assessment area (include any past impact in your response)?**

- See guidance to Qu. 4.6.

<b>RESPONSE</b>	N/A	<b>CONFIDENCE</b>	
-----------------	-----	-------------------	--

Response: There is no evidence to confirm that the species is currently present in the RA area.

**Qu. 4.8. How important is the impact of the organism on provisioning, regulating, and cultural services likely to be in the different biogeographic regions or marine sub-regions where the species can establish in the risk assessment area in the future?**

- See guidance to Qu. 4.6.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: The establishment and development of dense population of *A. amurensis* in the RA area has the potential to severely impact food provisioning and regulating services through predation, as described in Qu. 4.6.

Provisioning services: Biomass – Reared aquatic animals & Wild animals: Mussel, oyster beds and reefs, cockle and clam beds are present throughout the regional seas (with similar structure and function albeit different species and community composition) and support both commercial and recreational harvests.

Regulation & maintenance services: Regulation of physical, chemical, biological conditions & lifecycle maintenance: Filter feeding bivalves and the biogenic structures they create offer valuable regulating and maintenance services in three ways. 1) Through water quality regulation (bivalve suspension feeders remove particulate organic matter, reduce nitrogen load and improve water quality (Salomidi et al., 2012), 2) through water flow regulation and coastal protection - three-dimensional structures dissipate wave energy (Boström et al., 2011; Scyphers et al., 2011) - and 3) through lifecycle maintenance processes by providing important feeding and nursery habitats (references in Scyphers et al., 2011 for oysters, for mussels see Salomidi et al., 2012; Gundersen et al., 2017).

Predation on these organisms will impact on these ecosystem services.

Cultural services: Direct, in-situ and outdoor interactions – Physical and experiential: Cultural services in the form of recreation, tourism and the degradation of important/symbolic habitats may also be impacted (Katsanevakis et al., 2014; Gundersen et al., 2017).

## Economic impacts

**Qu. 4.9. How great is the overall economic cost caused by the organism within its current area of distribution (excluding the risk assessment area), including both costs of / loss due to damage and the cost of current management.**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the world these should be reported here. The assessment of the potential costs of / loss due to damage shall describe those costs quantitatively and/or qualitatively depending on what information is available. Cost of / loss due to damage within different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage. As far as possible, it would be useful to separate costs of / loss due to the organism from costs of current management.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: Population outbreaks of *A. amurensis* in its native range are known to cause significant economic damages to fisheries and aquaculture, particularly of bivalve species, such as scallops, oysters, clams and mussels. For example, the damage on the marketable shellfishes caused by the starfish in Tokyo Bay in 1954 amounted to as much as 400 million yen (Kim, 1968), while the outbreak that occurred in the coastal waters of Qingdao, China in 2006-2007, caused economic losses up to 1.5 million US dollars in mariculture of scallop, abalone, and clams (Zhou and Wang, 2008 in Li et al., 2018). Besides predation on the seabed, the species also settles on spat collectors, where a high abundance of juvenile *A. amurensis* (with a mean value of about 10 ind./m<sup>2</sup>), can result in 95% mortality of juvenile scallops *Mizuhopecten yessoensis* (as *Patinopecten yessoensis*) (Gabaev, 1987, cited in Gabaev, 2018).

Additionally, it is a nuisance to trawl fisheries, increasing the by-catch and damaging nets (Nojima et al., 1986), while at the same time creating a waste disposal problem. In Hokkaido, Japan, the amount of starfish removed from aquaculture and fishing grounds and disposed as waste on land is estimated to be about 15,000 tons per year (Ishii et al., 2007). In the Gulf of Alaska and the Bering Sea, *A. amurensis* also constitutes a large part of the by-catch and damages trawl nets (D. Urban, pers. comm in Smith & Armistead, 2014).

In the invaded range, large numbers of *Asterias amurensis* adults and juveniles have been found on scallop spat collector bags and suspended 'grow out' cages, mussel long-lines and oyster trays (Dommissie & Hough, 2004 and references therein). It is believed that, in all cases, settlement from plankton directly onto the different gears used is the most likely origin of the sea stars (Martin and Proctor 2000). In Tasmania, losses of commercial scallop spat over a settlement season due to *A. amurensis* predation were reported to be as high as 50% (S. Crawford pers. comm. in Hutson et al., 2005) or even 100%, according to one scallop farmer (Dommissie & Hough, 2004), resulting in an overall economic loss of 1 million AUD to the industry in 2000 (Aquenal, 2008). Additionally, in 2006, 25 tonnes of *A. amurensis* were caught as by-catch by commercial scallop fishermen on the east coast of Tasmania (Aquenal, 2008). *A. amurensis* heavily reduces the densities and potential for recruitment of wild populations of commercially important clams and cockles (Ross et al., 2002; 2004). Commercial long line fishermen are also affected in Victoria, Australia, where in areas of high infestation they report significant losses of bait and the majority of their hooks catching *A. amurensis* (Parry et al., 2003).

**Qu. 4.10. How great is the economic cost of / loss due to damage (excluding costs of management) of the organism currently in the risk assessment area (include any past costs in your response)?**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the EU these should be reported here. Assessment of the potential costs of damage on human

health, safety, and the economy, including the cost of non-action. A full economic assessment at EU scale might not be possible, but qualitative data or different case studies from across the EU (or third countries if relevant) may provide useful information to inform decision making. In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. Cost of / loss due to damage within different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>	N/A	<b>CONFIDENCE</b>	<b>high</b>
-----------------	-----	-------------------	-------------

Response: There is no evidence to confirm that the species is currently present in the RA area.

**Qu. 4.11. How great is the economic cost of / loss due to damage (excluding costs of management) of the organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.10.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response:

Throughout the world, predation by starfish is considered one of the primary causes of mortality of cultivated bivalves, such that prevention/mitigation measures are standard practice for shellfish growers (e.g. see Barkhouse et al., 2007; Calderwood et al., 2016; Kamermans & Capelle, 2019). During outbreak events, *Asterias* species can eliminate entire mussel beds (e.g. Gallagher et al., 2008; Paul-Burke & Burke, 2013) and threaten local resources and industries (Magnesen & Redmond, 2012). Considering the high abundances and predation mortality rates *A. amurensis* can achieve within cultivated bivalves, both on the seabed and on suspended culture means, such as lines, trays, spat collectors (see Qu. 4.9), it has the potential to cause major economic losses to the shellfish culture industry. For reference, predation mortality by *A. amurensis* on scallop spat collectors can result in 95% mortality of juvenile scallops in northern Russia and up to 50-100% in Tasmania (Qu. 4.9). Significant resources are at risk throughout the RA area, including mussel, oyster, scallops and other cultivated molluscs, as well as harvested wild populations of cockles and clams. Considering that such bivalve resources are already under predation pressure by the native *A. rubens*, additional and/or prolonged predation impacts by *A. amurensis* can exacerbate the economic losses.

**Qu. 4.12. How great are the economic costs / losses associated with managing this organism currently in the risk assessment area (include any past costs in your response)?**

- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”.

<b>RESPONSE</b>	N/A	<b>CONFIDENCE</b>	<b>high</b>
-----------------	-----	-------------------	-------------

Response: There is no evidence to confirm that the species is currently present in the RA area.

**Qu. 4.13. How great are the economic costs / losses associated with managing this organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.12.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: Costs related to shipping (ballasts/fouling) will be borne by the shipping companies. Significant costs can be associated with the ratification of relevant legislation, e.g. the Ballast Water Management Convention, in ensuring its compliance, related to planning, monitoring, enforcement and capacity-building. These costs however are not specific to *A. amurensis* and will prevent/reduce the introduction of a wide range of species carried by ballast water.

Significant costs are anticipated if the shellfish aquaculture sector is heavily impacted but overall estimates will depend on the extent and intensity of infestation. Shellfish growers routinely employ a variety of measures to combat predation by *Asterias* species (for a review see Barkhouse et al., 2007). These range from removals with towed gear (e.g. starfish mops, dredges) or traps, manual removal by hand, chemical methods, with estimated costs in the range of  $10^3$ - $10^4$  USD per application (Barkhouse et al., 2007). These are costs that will need to be applied on a yearly basis, where the species is established and has attained high population densities. Cost estimates for the subsequent disposal of the starfish waste could not be found but need to be considered. On the other hand, potential commercial exploitation of the harvested populations (as outlined in Qu. A13) could reduce the negative costs associated with disposal. A ban of imports or restrictions in the movement of shellfish seed/stock from infected areas could have potentially significant economic implications for shellfish producers (but the alternative of allowing the risk of introduction may be even more harmful, i.e. cost of inaction – see Qu. 4.9 & 4.11).

If eradication is attempted at an early stage of invasion, estimates from a successful eradication in Australia indicate costs in the range of 500.000 AUD for a small and shallow area (<1ha and shallower than 15m) over a period of one year (Crombie et al., 2007). Population removal from artificial structures in the Derwent estuary (Australia) by divers has been estimated to incur a cost of approximately 250K AUD per year (Aquenal, 2008), while monitoring costs for this species alone were calculated in the range of  $10^4$ - $10^5$  AUD per year (Aquenal, 2008). These are examples of costs

related to different management measures, which may need to be used in combination or be repeated depending on the stage of the invasion.

For long-established and dense populations (e.g. in Port Phillip Bay, Australia), Bax et al. (2006) examined the possibility of genetic control methods and arrived at a rough cost estimate >20 million AUD for research, infrastructure and operational costs. This management option however has not materialised and was expected to be met with public concerns and legislative obstacles in Australia (Aqenal, 2008), such that the potential costs were not taken into account for the score of this question.

## Social and human health impacts

**Qu. 4.14. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism for the risk assessment area and for third countries, if relevant (e.g. with similar eco-climatic conditions).**

The description of the known impact and the assessment of potential future impact on human health, safety and the economy, shall, if relevant, include information on

- illnesses, allergies or other affections to humans that may derive directly or indirectly from a species;
- damages provoked directly or indirectly by a species with consequences for the safety of people, property or infrastructure;
- direct or indirect disruption of, or other consequences for, an economic or social activity due to the presence of a species.

Social and human health impacts can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>		<b>CONFIDENCE</b>	
	minimal		<b>low</b>
	<b>minor</b>		medium
	moderate		high
	major		
	massive		

Response: *Asterias amurensis* can accumulate paralytic shellfish toxins (Asakawa et al., 1997), and considering its (potential) uses for the production of fish meal, compost or fertiliser (McEnulty et al., 2001; Barkhouse et al., 2007) there may be concerns for indirect effects on human health. It is expected however that most of the toxin will be leached out or destroyed during the processing steps (e.g. cooking and sterilization are known to remove up to 90% of PSP toxins – EFSA, 2009 and references therein) or diluted by the other non-toxic components such that the danger to human health will be minimized. No information was found on human PSP intoxications via this indirect pathway and the metabolic routes of the toxins can vary considerably between different species (Vilariño et al., 2018) such that there is high uncertainty associated with this assessment.

On the other hand, through its effects on recreational activities (i.e. fishing, harvest of bivalves – see Qu. 4.6 & 4.9) and the aesthetic values of the marine environment, it could potentially impact tourism and the amenity value of coastal areas (Aqenal, 2008).

**Qu. 4.15. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism in the future for the risk assessment area.**

- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: As in Qu. 4.14. Minor social and health impacts may be anticipated in the RA area in the future.

## Other impacts

**Qu. 4.16. How important is the organism in facilitating other damaging organisms (e.g. diseases) as food source, a host, a symbiont or a vector etc.?**

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: Male *A. amurensis* are liable to gonad parasitisation by the ciliate parasite *Orchitophrya stellarum* (Byrne et al., 1997a), which causes complete atrophy of the testes, leading to castration. The same ciliate species infests native asteroids in the RA area, i.e. *A. rubens* in Atlantic Europe and *Sclerasterias richardi* in the Mediterranean Sea but with a lower prevalence (Jangoux, 1987). It was hypothesized that the high infestation rates in native Japan were due to the fact that *A. amurensis* was a new host for *O. stellarum* there (Byrne et al., 1997a). It is possible that the establishment of dense populations of *A. amurensis* can mediate an increase in *O. stellarum* infestations of other asteroids but high uncertainty is associated with this assessment.

Besides the risks posed for native species, *O. stellarum* is highly infectious and pathogenic to blue crabs *Callinectes sapidus* (Miller et al., 2013), another introduced species to European waters, which has already gained economic importance (Mancinelli et al., 2017).

**Qu. 4.17. How important might other impacts not already covered by previous questions be resulting from introduction of the organism?**

<b>RESPONSE</b>	minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	--	-------------------	-----------------------

Response: No other impacts were found.

**Qu. 4.18. How important are the expected impacts of the organism despite any natural control by other organisms, such as predators, parasites or pathogens that may already be present in the risk assessment area?**

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: Biotic interactions of *A. amurensis* with other species in its native and invaded range, as well as the RA area are discussed in Qu. 2.3, 2.4 & 4.3, 4.16. In Australia, the possibility for natural control has been suggested in relation to the parasite *O. stellarum* (see above) but also to the native starfish *Coscinasterias muricata* (Parry, 2015), which predate on *A. amurensis* juveniles and small adults. Possible predators of *A. amurensis* (e.g. native starfish and crab species) were also identified in Qu. 2.4, however the potential of predation by these species to limit *A. amurensis* populations is unknown. Judging from the establishment of extremely dense populations in Australia in the presence of native predators and competitors, it is thought that the impacts of the species are unlikely to be significantly moderated by natural control. On the other hand, *O. stellarum* is present and a parasite of native *A. rubens* in the RA area with the potential to infect *A. amurensis* with high prevalence rates (Byrne et al., 1997a), should it invade the RA area, hence the score of this question is accompanied by low confidence.

**Qu. 4.19. Estimate the overall impact in the risk assessment area under current climate conditions. In addition, details of overall impact in relevant biogeographical regions should be provided.**

Thorough assessment of the overall impact on biodiversity and ecosystem services, with impacts on economy as well as social and human health as aggravating factors, in current conditions.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major	<b>CONFIDENCE</b>	low medium high
-----------------	--	-------------------	-----------------------

	massive		
--	---------	--	--

Response: *Asterias amurensis*, like other asteroid species, is a benthic keystone predator with a propensity for population outbreaks that can have strong impacts on local (mainly) bivalve populations. In its invaded Australian range, it quickly developed massive populations and also maintained high densities after the first population boom. The ability to behave in a similar manner in the RA area will depend to some extent on its interaction with its sister species, the native *A. rubens*, which is very similar functionally and ecologically. Driven by examples in the literature and assuming that the two species can co-exist, *A. amurensis* has the potential to cause moderate environmental impacts in the RA area, and primarily the North East Atlantic region, through predation and, to a lesser extent, competition. Thus, population declines (locally very severe, and likely stochastic) of native species of mussels, oysters, scallops and clams may be expected, as well as declines in erect macrofauna and habitat forming polychaetes and demersal fish species that utilise the same prey resources as the starfish. Impacts on bivalve populations, although likely to be widespread, are not anticipated to be irreversible. Bivalves are broadcast spawners with high dispersal potential and relatively short generation times. Furthermore, native bivalve species are widespread and generally well connected, able to offset sudden population losses or bad recruitment years.

Mussel and oyster beds/reefs, which are listed as endangered habitats and fulfil an important ecological role are anticipated to come under threat. Of these, the most vulnerable to predation by *A. amurensis* are the *M. modiolus* reefs and the diverse fauna they support. Where infaunal bivalves are impacted, this may have implications for sediment processes and nutrient cycling, while declines in epifaunal, filtering bivalves will affect water quality regulating services but such impacts are likely to be transient. Food provisioning services through declines in commercial and recreational harvests will also be affected. The economic impacts of *A. amurensis* are likely to be even more serious (major) due to its demonstrated ability elsewhere in the invaded range to cause heavy mortalities of commercially harvested in the wild and cultivated bivalve species and, most importantly, their spat/seed. These impacts may be readily mitigated, as similar native starfish predators are routinely removed from bivalve culture plots and devices, but enhanced management practices for additional starfish populations (and possibly at different times of the year if recruitment seasons for native and alien starfish species do not exactly overlap) will entail additional significant costs. Other fisheries sectors, e.g. demersal trawling and long-lining may also suffer by increased by-catch and loss of catch.

**Qu. 4.20. Estimate the overall impact in the risk assessment area in foreseeable climate change conditions. In addition, details of overall impact in relevant biogeographical regions should be provided.**

Thorough assessment of the overall impact on biodiversity and ecosystem services, with impacts on economy as well as social and human health as aggravating factors, under future conditions.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response:

Due to the higher tolerance of *A. amurensis* for higher temperatures compared to *A. rubens*, both at the larval and the adult stage, a future warming of the seas is likely to change the dynamics of the two species in favour of the invader and push *A. rubens* northwards. In this case it may be expected that *A. amurensis* solely assumes the role of the keystone benthic predator in areas no longer suitable for *A. rubens* but the ecological and functional niche will not remain empty. The severity of the impacts is not likely to change in Atlantic Europe, the Mediterranean Sea however will present *A. amurensis* with even less favourable environmental conditions and for shorter periods of time, lowering the risk of strong recruitment, population outbreaks and associated predation impacts, such that native species, habitats and resources will be at lower risk.

<b>RISK SUMMARIES</b>			
	<b>RESPONSE</b>	<b>CONFIDENCE</b>	<b>COMMENT</b>
<b>Summarise Introduction and Entry*</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	low <b>medium</b> high	<p>The most likely pathways of introduction of <i>A. amurensis</i> in the RA area are through shipping vectors. While ballast water can potentially transport a large number of larvae, a number of conditions need to be met for the successful introduction of viable propagules from possible donor regions into the RA area, primarily uptake and transportation during thermally suitable times of the year. Moreover, the increasing implementation of the BWMC D2 standard will gradually reduce even further the survival probability of <i>A. amurensis</i> larvae entrained in ballast water.</p> <p>Entrainment in ships' sea chests and hull internal surfaces is a plausible mode of transport but less likely to be responsible for a large number of propagules entering the RA area. Based on the maritime traffic between potential source regions and EU ports, introduction and entry of <i>A. amurensis</i> larvae is considered more likely in the Greater North Sea region and less likely in the Mediterranean Sea. New Arctic Ocean shipping routes will not change the main recipient areas.</p>
<b>Summarise Establishment*</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	low <b>medium</b> high	<p>Taking into account spawning times in the donor regions, travel duration and arrival times at the different parts of the RA area, the species is very likely to find suitable abiotic conditions for establishment during most of the year throughout most of Atlantic Europe, with the exception of the Bay of Biscay. Likelihood of establishment in the Mediterranean Sea is considered as moderate. Under future climate change, a small northward shift of the overall suitable area for the species is predicted, while the Mediterranean is expected to become widely unsuitable for establishment due to high water temperatures.</p>
<b>Summarise Spread*</b>	very slowly slowly moderately <b>rapidly</b> very rapidly	low <b>medium</b> high	<p>Unaided dispersal and multiple pathways of human-aided spread create a considerable potential for spread of <i>A. amurensis</i> in the north-east Atlantic. The species has long-lived planktonic larvae,</p>

			whose physiological requirements are met during prolonged periods in this region; additionally, it can spread rapidly via ballast water and can also be translocated with hull fouling, in sea chests, bivalve consignments, and fishing equipment.
<b>Summarise Impact*</b>	minimal minor <b>moderate</b> major massive	low <b>medium</b> high	<i>Asterias amurensis</i> has the potential to cause moderate environmental impacts in the RA area, and primarily the North East Atlantic region, through predation and, to a lesser extent, competition. Population declines (locally very severe) of native species of mussels, oysters, scallops and clams may be expected, as well as declines in demersal fish species and protected bird populations that utilise the same prey resources as the starfish. Mussel and oyster beds/reefs, which are listed as endangered habitats and fulfil an important ecological role are anticipated to come under threat. Where infaunal bivalves are impacted, this may have implications for sediment processes and nutrient cycling, while declines in epifaunal, filtering bivalves will affect water quality regulating services. Food provisioning services through declines in commercial and recreational harvests will also be affected. The economic impacts of <i>A. amurensis</i> are likely to be major due to its demonstrated ability elsewhere in the invaded range to cause heavy mortalities of commercially used bivalve species.
<b>Conclusion of the risk assessment (overall risk)</b>	low <b>moderate</b> high	low <b>medium</b> high	<i>Asterias amurensis</i> is a keystone predator of benthic invertebrates, mainly bivalve molluscs, with a well-studied invasion history in Australia, where it was most likely introduced via ballast water. The North-east Atlantic is the most likely recipient region and offers highly suitable conditions for establishment and possibilities for rapid spread. The species has the propensity for massive population outbreaks, which can be very persistent in the invaded range, and can cause severe population declines of benthic bivalve and fish species. It constitutes a serious threat to bivalve fisheries and the aquaculture industry.

## Distribution Summary

Please answer as follows:

- Yes if recorded, established or invasive
- if not recorded, established or invasive
- ? Unknown; data deficient

The columns refer to the answers to Questions A5 to A12 under Section A.

For data on marine species at the Member State level, delete Member States that have no marine borders.

In all other cases, provide answers for all columns.

### Member States and the United Kingdom

	Recorded	Established (currently)	Possible establishment (under current climate)	Possible establishment (under foreseeable climate)	Invasive (currently)
Belgium	-	-	YES	YES	-
Bulgaria	-	-	-	-	-
Croatia	-	-	YES	-	-
Cyprus	-	-	-	-	-
Denmark	-	-	YES	YES	-
Estonia	-	-	-	-	-
Finland	-	-	-	-	-
France	-	-	YES	YES	-

## **ANNEX I Scoring of Likelihoods of Events**

(taken from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

<b>Score</b>	<b>Description</b>	<b>Frequency</b>
Very unlikely	This sort of event is theoretically possible, but is never known to have occurred and is not expected to occur	1 in 10,000 years
Unlikely	This sort of event has occurred somewhere at least once in the last millenium	1 in 1,000 years
Modeately likely	This sort of event has occurred somewhere at least once in the last century	1 in 100 years
Likely	This sort of event has happened on several occasions elsewhere, or on at least once in the last decade	1 in 10 years
Very likely	This sort of event happens continually and would be expected to occur	Once a year

## ANNEX II Scoring of Magnitude of Impacts

(modified from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

Score	Biodiversity and ecosystem impact	Ecosystem Services impact	Economic impact (Monetary loss and response costs per year)	Social and human health impact, and other impacts
	<i>Question 5.1-5</i>	<i>Question 5.6-8</i>	<i>Question 5.9-13</i>	<i>Question 5.14-18</i>
Minimal	Local, short-term population loss, no significant ecosystem effect	No services affected <sup>7</sup>	Up to 10,000 Euro	No social disruption. Local, mild, short-term reversible effects to individuals.
Minor	Some ecosystem impact, reversible changes, localised	Local and temporary, reversible effects to one or few services	10,000-100,000 Euro	Significant concern expressed at local level. Mild short-term reversible effects to identifiable groups, localised.
Moderate	Measureable long-term damage to populations and ecosystem, but reversible; little spread, no extinction	Measureable, temporary, local and reversible effects on one or several services	100,000-1,000,000 Euro	Temporary changes to normal activities at local level. Minor irreversible effects and/or larger numbers covered by reversible effects, localised.
Major	Long-term irreversible ecosystem change, spreading beyond local area	Local and irreversible or widespread and reversible effects on one / several services	1,000,000-10,000,000 Euro	Some permanent change of activity locally, concern expressed over wider area. Significant irreversible effects locally or reversible effects over large area.
Massive	Widespread, long-term population loss or extinction, affecting several species with serious ecosystem effects	Widespread and irreversible effects on one / several services	Above 10,000,000 Euro	Long-term social change, significant loss of employment, migration from affected area. Widespread, severe, long-term, irreversible health effects.

<sup>7</sup> Not to be confused with “no impact”.

## ANNEX III Scoring of Confidence Levels

(modified from Bacher et al. 2017)

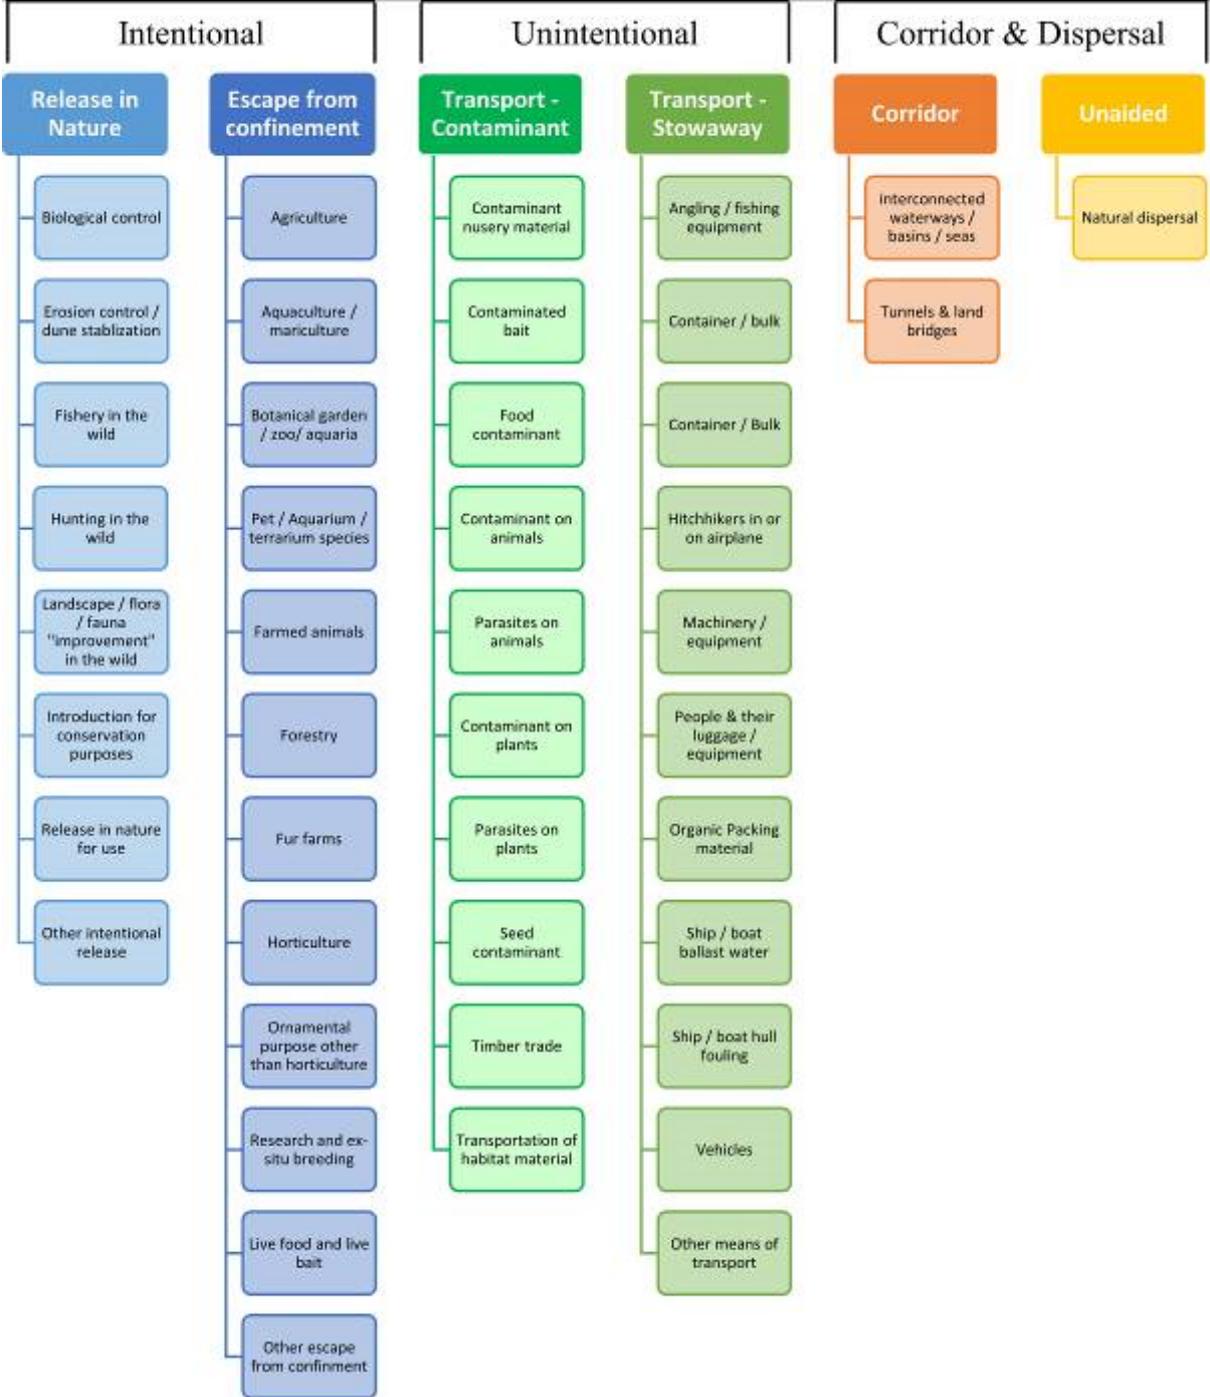

Each answer provided in the risk assessment must include an assessment of the level of confidence attached to that answer, reflecting the possibility that information needed for the answer is not available or is insufficient or available but conflicting.

The responses in the risk assessment should clearly support the choice of the confidence level.

Confidence level	Description
Low	There is no direct observational evidence to support the assessment, e.g. only inferred data have been used as supporting evidence <i>and/or</i> Impacts are recorded at a spatial scale which is unlikely to be relevant to the assessment area <i>and/or</i> Evidence is poor and difficult to interpret, e.g. because it is strongly ambiguous <i>and/or</i> The information sources are considered to be of low quality or contain information that is unreliable.
Medium	There is some direct observational evidence to support the assessment, but some information is inferred <i>and/or</i> Impacts are recorded at a small spatial scale, but rescaling of the data to relevant scales of the assessment area is considered reliable, or to embrace little uncertainty <i>and/or</i> The interpretation of the data is to some extent ambiguous or contradictory.
High	There is direct relevant observational evidence to support the assessment (including causality) <i>and</i> Impacts are recorded at a comparable scale <i>and/or</i> There are reliable/good quality data sources on impacts of the taxa <i>and</i> The interpretation of data/information is straightforward <i>and/or</i> Data/information are not controversial or contradictory.

# ANNEX IV CBD pathway categorisation scheme

Overview of CBD pathway categorisation scheme showing how the 44 pathways relate to the six main pathway categories. All of the pathways can be broadly classified into 1) those that involve intentional transport (blue), 2) those in which the taxa are unintentionally transported (green) and 3) those where taxa moved between regions without direct transportation by humans and/or via artificial corridors (orange and yellow). **Note that the pathways in the category “Escape from confinement” can be considered intentional for the introduction into the risk assessment area and unintentional for the entry into the environment.**

## ANNEX V Ecosystem services classification (CICES V5.1, simplified) and examples

For the purposes of this risk assessment, please feel free to use what seems as the most appropriate category / level / combination of impact (Section – Division – Group), reflecting information available.

Section	Division	Group	Examples (i.e. relevant CICES “classes”)
Provisioning	Biomass	<b>Cultivated <i>terrestrial</i> plants</b>	<p>Cultivated terrestrial plants (including fungi, algae) grown for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from cultivated plants, fungi, algae and bacteria for direct use or processing (excluding genetic materials);            Cultivated plants (including fungi, algae) grown as a <u>source of energy</u></p> <p><i>Example: negative impacts of non-native organisms to crops, orchards, timber etc.</i></p>
		<b>Cultivated <i>aquatic</i> plants</b>	<p>Plants cultivated by in- situ aquaculture grown for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from in-situ aquaculture for direct use or processing (excluding genetic materials);            Plants cultivated by in- situ aquaculture grown as an <u>energy source</u>.</p> <p><i>Example: negative impacts of non-native organisms to aquatic plants cultivated for nutrition, gardening etc. purposes.</i></p>
		<b>Reared animals</b>	<p>Animals reared for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from reared animals for direct use or processing (excluding genetic materials);            Animals reared to provide <u>energy</u> (including mechanical)</p> <p><i>Example: negative impacts of non-native organisms to livestock</i></p>
		<b>Reared <i>aquatic</i> animals</b>	<p>Animals reared by in-situ aquaculture for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from animals grown by in-situ aquaculture for direct use or processing (excluding genetic materials);            Animals reared by in-situ aquaculture as an <u>energy source</u></p> <p><i>Example: negative impacts of non-native organisms to fish farming</i></p>
		<b>Wild plants</b> (terrestrial and aquatic)	<p>Wild plants (terrestrial and aquatic, including fungi, algae) used for <u>nutrition</u>;  <u>Fibres and other materials</u> from wild plants for direct use or processing (excluding genetic materials);            Wild plants (terrestrial and aquatic, including fungi, algae) used as a <u>source of energy</u></p> <p><i>Example: reduction in the availability of wild plants (e.g. wild berries, ornamentals) due to non-native organisms (competition, spread of disease etc.)</i></p>
		<b>Wild animals</b> (terrestrial and aquatic)	<p>Wild animals (terrestrial and aquatic) used for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from wild animals for direct use or processing (excluding genetic materials);            Wild animals (terrestrial and aquatic) used as a <u>source of energy</u></p>

			<i>Example: reduction in the availability of wild animals (e.g. fish stocks, game) due to non-native organisms (competition, predations, spread of disease etc.)</i>
	<b>Genetic material</b> from all biota	<b>Genetic material</b> from plants, algae or fungi	<u>Seeds, spores and other plant materials</u> collected for maintaining or establishing a population; Higher and lower plants (whole organisms) used to <u>breed new strains or varieties</u> ; Individual genes extracted from higher and lower plants for the <u>design and construction of new biological entities</u>  <i>Example: negative impacts of non-native organisms due to interbreeding</i>
		<b>Genetic material</b> from animals	Animal material collected for the purposes of maintaining or establishing a population; Wild animals (whole organisms) used to breed new strains or varieties; Individual genes extracted from organisms for the design and construction of new biological entities  <i>Example: negative impacts of non-native organisms due to interbreeding</i>
	<b>Water</b> <sup>8</sup>	<b>Surface water</b> used for nutrition, materials or energy	Surface water for <u>drinking</u> ; Surface water used as a material ( <u>non-drinking purposes</u> ); Freshwater surface water, coastal and marine water used as an <u>energy source</u>  <i>Example: loss of access to surface water due to spread of non-native organisms</i>
		<b>Ground water</b> for used for nutrition, materials or energy	Ground (and subsurface) water for <u>drinking</u> ; Ground water (and subsurface) used as a material ( <u>non-drinking purposes</u> ); Ground water (and subsurface) used as an <u>energy source</u>  <i>Example: reduced availability of ground water due to spread of non-native organisms and associated increase of ground water consumption by vegetation.</i>
<b>Regulation &amp; Maintenance</b>	<b>Transformation</b> of biochemical or physical inputs to ecosystems	<b>Mediation of wastes or toxic substances</b> of anthropogenic origin by living processes	<u>Bio-remediation</u> by micro-organisms, algae, plants, and animals; <u>Filtration/sequestration/storage/accumulation</u> by micro-organisms, algae, plants, and animals  <i>Example: changes caused by non-native organisms to ecosystem functioning and ability to filtrate etc. waste or toxics</i>
		<b>Mediation of nuisances</b> of anthropogenic origin	<u>Smell reduction</u> ; <u>noise attenuation</u> ; <u>visual screening</u> (e.g. by means of green infrastructure)  <i>Example: changes caused by non-native organisms to ecosystem structure, leading to reduced ability to mediate nuisances.</i>
	<b>Regulation</b> of physical, chemical, biological conditions	<b>Baseline flows and extreme event</b> regulation	Control of <u>erosion</u> rates; Buffering and attenuation of <u>mass movement</u> ; <u>Hydrological cycle and water flow regulation</u> (Including flood control, and coastal protection); <u>Wind</u> protection; <u>Fire</u> protection

<sup>8</sup> Note: in the CICES classification provisioning of water is considered as an abiotic service whereas the rest of ecosystem services listed here are considered biotic.

			<p><i>Example: changes caused by non-native organisms to ecosystem functioning or structure leading to, for example, destabilisation of soil, increased risk or intensity of wild fires etc.</i></p>
		<p><b>Lifecycle maintenance, habitat and gene pool protection</b></p>	<p>Pollination (or 'gamete' dispersal in a marine context); <u>Seed dispersal</u>; Maintaining <u>nursery populations and habitats</u> (Including gene pool protection)</p> <p><i>Example: changes caused by non-native organisms to the abundance and/or distribution of wild pollinators; changes to the availability / quality of nursery habitats for fisheries</i></p>
		<p><b>Pest and disease control</b></p>	<p>Pest control; Disease control</p> <p><i>Example: changes caused by non-native organisms to the abundance and/or distribution of pests</i></p>
		<p><b>Soil quality regulation</b></p>	<p><u>Weathering processes</u> and their effect on soil quality; <u>Decomposition and fixing processes</u> and their effect on soil quality</p> <p><i>Example: changes caused by non-native organisms to vegetation structure and/or soil fauna leading to reduced soil quality</i></p>
		<p><b>Water conditions</b></p>	<p>Regulation of the <u>chemical condition</u> of freshwaters by living processes; Regulation of the chemical condition of salt waters by living processes</p> <p><i>Example: changes caused by non-native organisms to buffer strips along water courses that remove nutrients in runoff and/or fish communities that regulate the resilience and resistance of water bodies to eutrophication</i></p>
		<p><b>Atmospheric composition and conditions</b></p>	<p>Regulation of <u>chemical composition</u> of atmosphere and oceans; Regulation of <u>temperature and humidity</u>, including ventilation and transpiration</p> <p><i>Example: changes caused by non-native organisms to ecosystems' ability to sequester carbon and/or evaporative cooling (e.g. by urban trees)</i></p>
<b>Cultural</b>	<b>Direct, in-situ and outdoor interactions</b> with living systems that depend on presence in the environmental setting	<p><b>Physical and experiential</b> interactions with natural environment</p>	<p>Characteristics of living systems that that enable activities promoting health, recuperation or enjoyment through <u>active or immersive interactions</u>;</p> <p>Characteristics of living systems that enable activities promoting health, recuperation or enjoyment through <u>passive or observational interactions</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that make it attractive for recreation, wild life watching etc.</i></p>
		<p><b>Intellectual and representative</b> interactions with natural environment</p>	<p>Characteristics of living systems that enable <u>scientific investigation</u> or the creation of traditional ecological knowledge;</p> <p>Characteristics of living systems that enable <u>education and training</u>;</p> <p>Characteristics of living systems that are resonant in terms of <u>culture or heritage</u>;</p> <p>Characteristics of living systems that enable <u>aesthetic experiences</u></p>

			<i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have cultural importance</i>
	<b>Indirect, remote, often indoor interactions</b> with living systems that do not require presence in the environmental setting	<b>Spiritual, symbolic</b> and other interactions with natural environment	<p>Elements of living systems that have <u>symbolic meaning</u>;</p> <p>Elements of living systems that have <u>sacred or religious meaning</u>;</p> <p>Elements of living systems used for <u>entertainment or representation</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have sacred or religious meaning</i></p>
		Other biotic characteristics that have a <b>non-use value</b>	<p>Characteristics or features of living systems that have an <u>existence value</u>;</p> <p>Characteristics or features of living systems that have an <u>option or bequest value</u></p> <p><i>Example: changes caused by non-native organisms to ecosystems designated as wilderness areas, habitats of endangered species etc.</i></p>

## ANNEX VIII Larval biology/ecology of *A. amurensis* and invasion risk through ballast water

Marika Galanidi (text and analysis specifically developed for the purposes of this risk assessment)

Spawning for *A. amurensis* is reported at different times in different locations, ranging from late January/February to July (e.g. Akkeshi Bay, Hokkaido, Japan) and at temperatures ranging from 5 °C to 23 °C. In Japan and Korea, spawning takes place primarily in February-April, at temperatures between 5°C and 20°C (Paik et al., 2005; Lee et al., 2004; Yu et al., 1998; Kim, 1968; Hatanaka & Kosaka, 1959; Kashenko, 2005). In Peter the Great Bay, Russia and Alaska the species has shifted its spawning period to the summer months (June-September) and in China it is reported to reproduce between October and January (Li et al., 2018; Zhang et al., 2014). In some locations however there are two spawning events; such is the case in Yantai, China, where spawning takes place in October-November (coinciding well with the lower bottom water temperature (14.29°C) and again in March-May (Li et al., 2018) and also in Peter the Great Bay, Russia, with spawning events in June-July and in September, at temperatures of 17°C and 23°C, respectively (Novikova, 1978). This upper temperature limit to spawning comes in contrast with all other published literature derived both from field studies as well as laboratory experiments (e.g. Kashenko, 2005; Lee et al., 2004; Sutton & Bruce, 1996; Byrne et al., 2016), which indicate that normal larval development can occur at a **maximum temperature of 20°C**. This was consequently regarded as the maximum temperature threshold for establishment, with the **minimum temperature threshold set at 5°C**. In the invaded range, *A. amurensis* spawns during the austral winter from July to October, at similar degrees of latitude and a similar temperature range (i.e. 8-14°C, Byrne et al., 2016), but in the southern hemisphere, indicating photoperiodic regulation of gametogenesis, as well as modulation by temperature (Smith & Armistead, 2014). Fertilised eggs are demersal and develop into swimming and feeding larvae (termed bipinnariae) within 60h to 120h of fertilization depending on water temperature (20°C and 10°C respectively) (Lee et al., 2004). Larval duration in the plankton also varies with temperature, as well as with feeding conditions, and can range between 50 and 120 days at temperatures between 19°C and 10°C respectively (Bruce et al., 1995 and references therein).

Larvae taken up in ballast water at possible source regions are estimated to arrive at release locations in the RA area after a travel period of approximately 6 weeks. It can be seen from the following table that larvae can, theoretically, arrive at the RA area at any time of the year (this without taking into account the frequency of connections between source area ports and arrival ports).

Source region	Spawning period	Temperature	Estimated arrival	Ecoregion
Japan-Korea	February-May	5-20°C	April-July	NW Pacific
Russia-Alaska	June-September	7-??	August-November	NW/NE Pacific
Australia	July-October	8-14°C	September-December	Temperate Australasia
China	October-January	5-14.3°C	December-March	NW Pacific

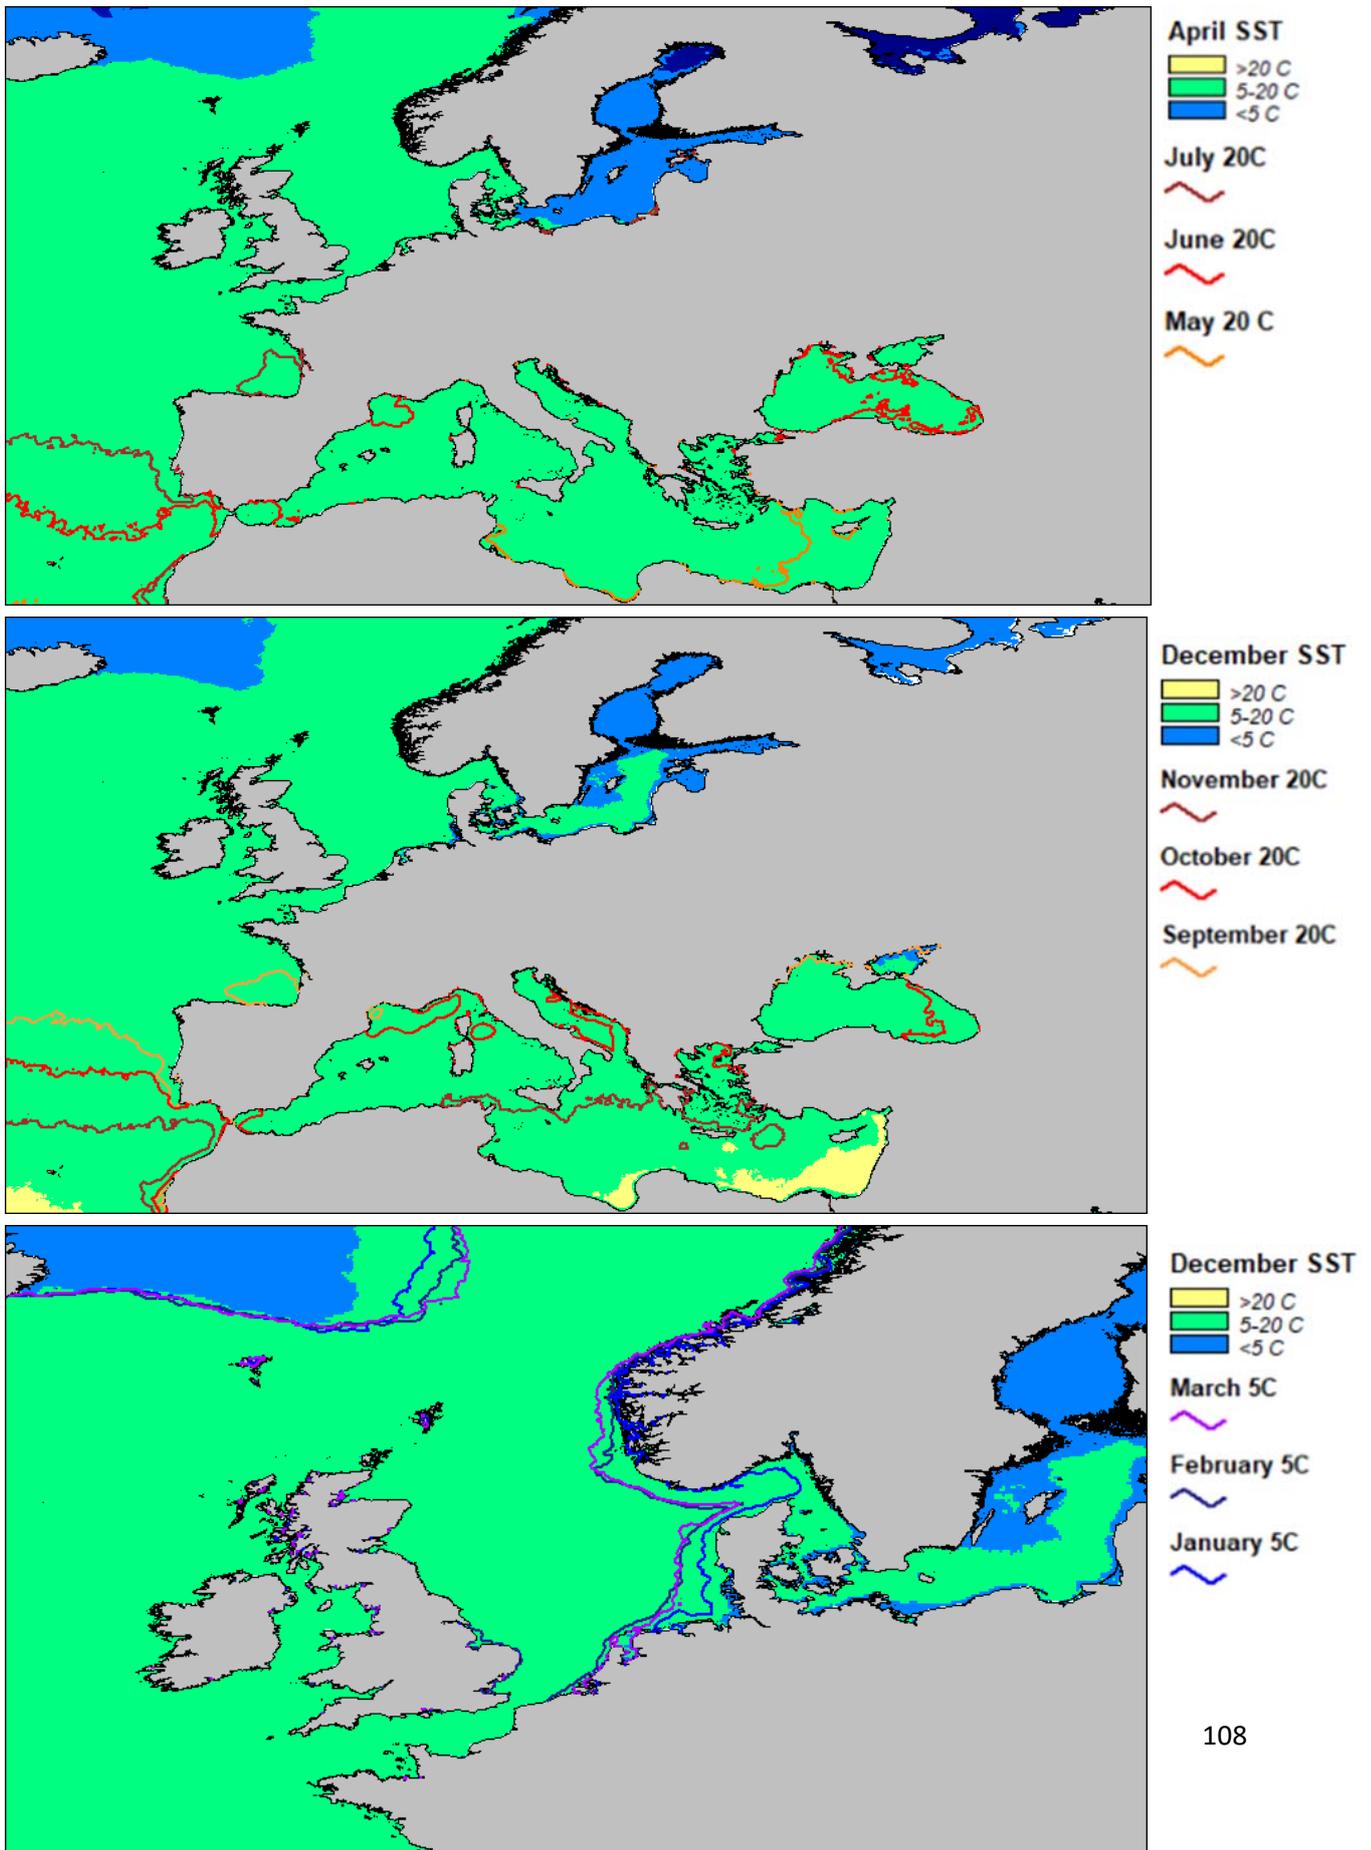

Based on the analysis of Kaluza et al. (2010), Alaska and north-eastern Russia are unlikely to act as donor regions of larvae via ballast water. Ports and coastal waters of Japan, Korea and China are well connected with Mediterranean and Eastern Atlantic ports via the Asia/Europe shipping route and receive a large amount of vessel traffic (Verny et al., 2009; Kaluza et al., 2010). Less intense maritime connections exist between Europe and temperate Australia.

In the Mediterranean Sea, propagules arriving from China in the winter months are likely to find suitable temperatures for development and settlement upon release (Temperature data layers retrieved from MARSPEC, Sbrocco et al., 2013, URL: <http://www.esapubs.org/archive/ecol/E094/086/metadata.php>). However, larvae in ballast arriving from Japan/Korea and from Australia will have a two-month window, in April-May and November-December respectively, to complete development and settle. Between June and October, sea surface temperatures will prevent normal development and survival of *A. amurensis* larvae in the Mediterranean (Figure 1). In Atlantic Europe, sea surface temperatures fall within the 5-20°C range throughout the period that *A. amurensis* larvae may be expected to arrive from Japan/Korea and for the most part from Australia, although larvae arriving from Australia later in the year will encounter increasingly colder temperatures in the Wadden Sea and around Denmark and south-eastern UK. Larvae arriving to Atlantic Europe from China in the winter months will find themselves at the lower limit of their thermal tolerance in the shallow, inshore areas of the western North Sea and along parts of the UK. The Celtic Seas, English Channel and Iberian coast/Bay of Biscay offer favourable establishment conditions throughout the year, with the exception of the Bay of Biscay (BoB), where temperatures are slightly above the 20°C threshold during the summer.

In summary, the likelihood of initial establishment of *A. amurensis* in the RA area will be determined by a combination of donor region, arrival time and abiotic conditions of the recipient region when the first larvae arrive. The survival and settlement of the first introduced larvae is likely to be of high importance for a successful invasion, since, once this happens, the species has demonstrated its adaptability to local conditions by changing the seasonality of its reproductive cycle (see the Australian invasion, also spawning periods throughout its native range). From that point on, natural dispersal and secondary spread can lead to further establishment within the RA area (see following Annex with the results of the species distribution model).

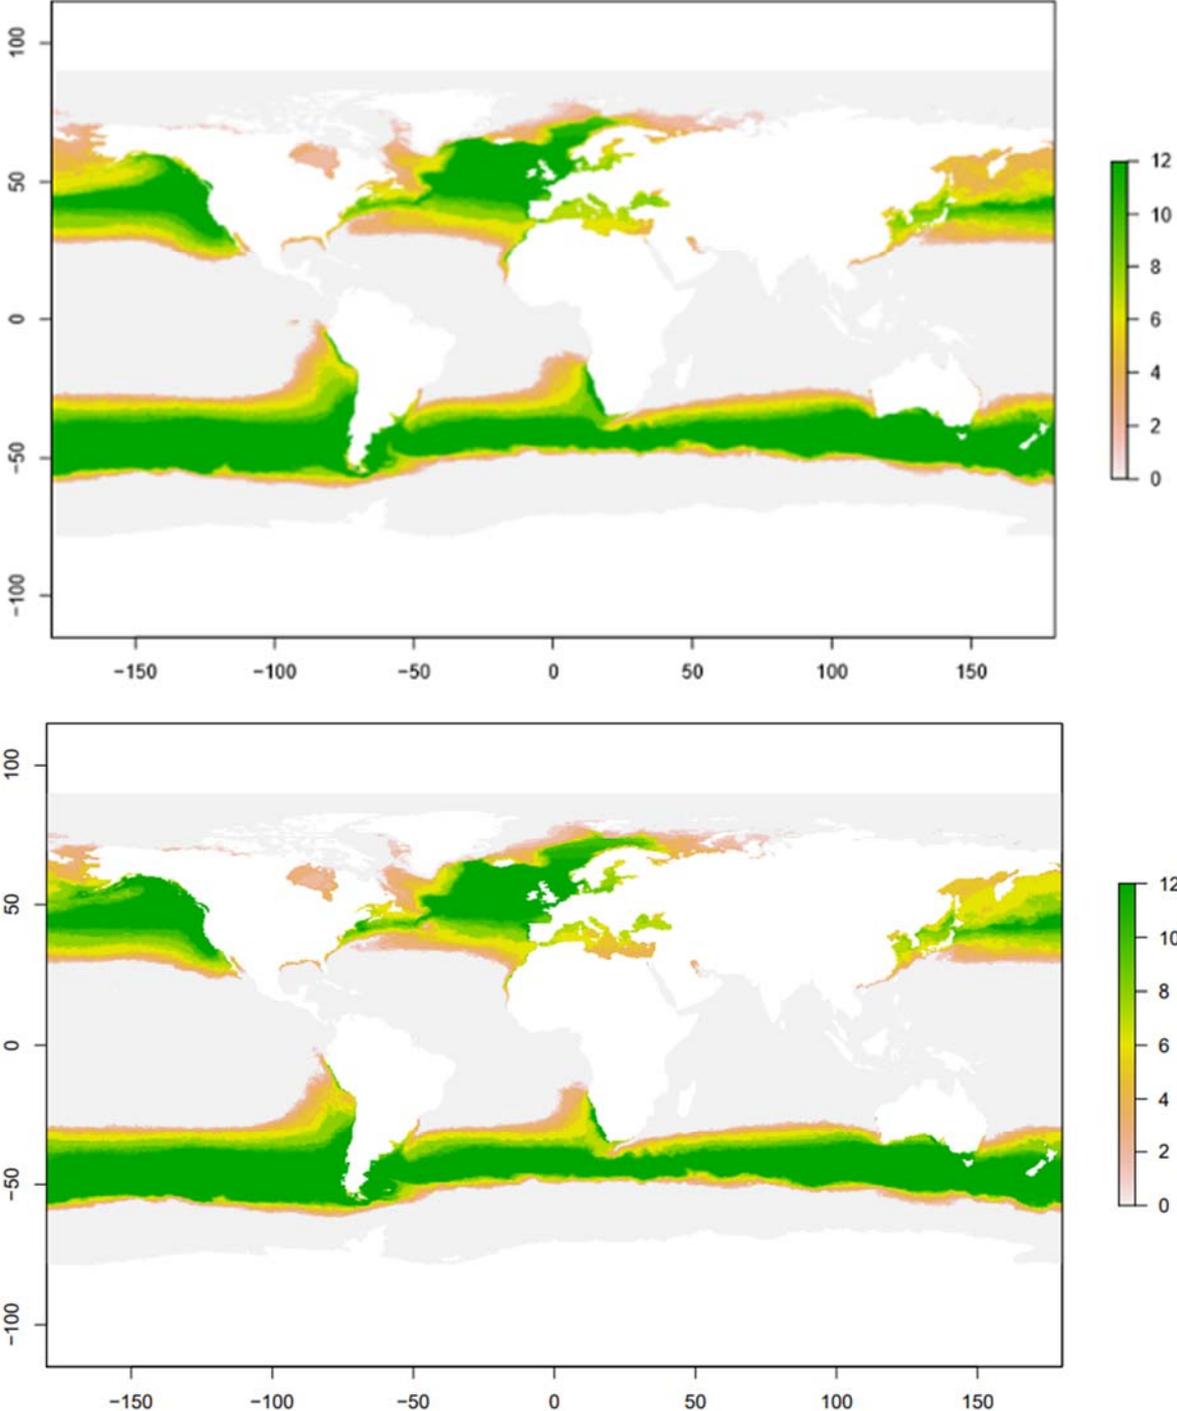

<b>Likelihood of establishment by larvae of <i>A. amurensis</i> (by primary introduction)</b>	
Mediterranean	1 main donor region – suitable in winter – high maritime connectivity only in the south – moderately likely
Iberian Coast	3 donor regions – suitable throughout the year – moderate to low maritime connectivity – moderately likely (not the Bay of Biscay)
Celtic Seas	3 donor regions – suitable throughout the year – moderate maritime connectivity – moderately likely
Greater North Sea	3 donor regions – suitable throughout the year – high maritime connectivity – likely
Black Sea	Restricted by salinity – UNLIKELY (except for the Sea of Marmara)
Baltic Sea	Restricted by salinity – UNLIKELY

Figure 2. Top: April Sea Surface Temperature (SST) and 20°C SST contours for the months of May-July. Middle: December SST and 20°C SST contours for October-November. Suitable conditions (SST<20°C) for *A. amurensis* larval development are encountered westwards and northwards of the contour lines. Bottom: December SST and 5°C SST contours for January-March.

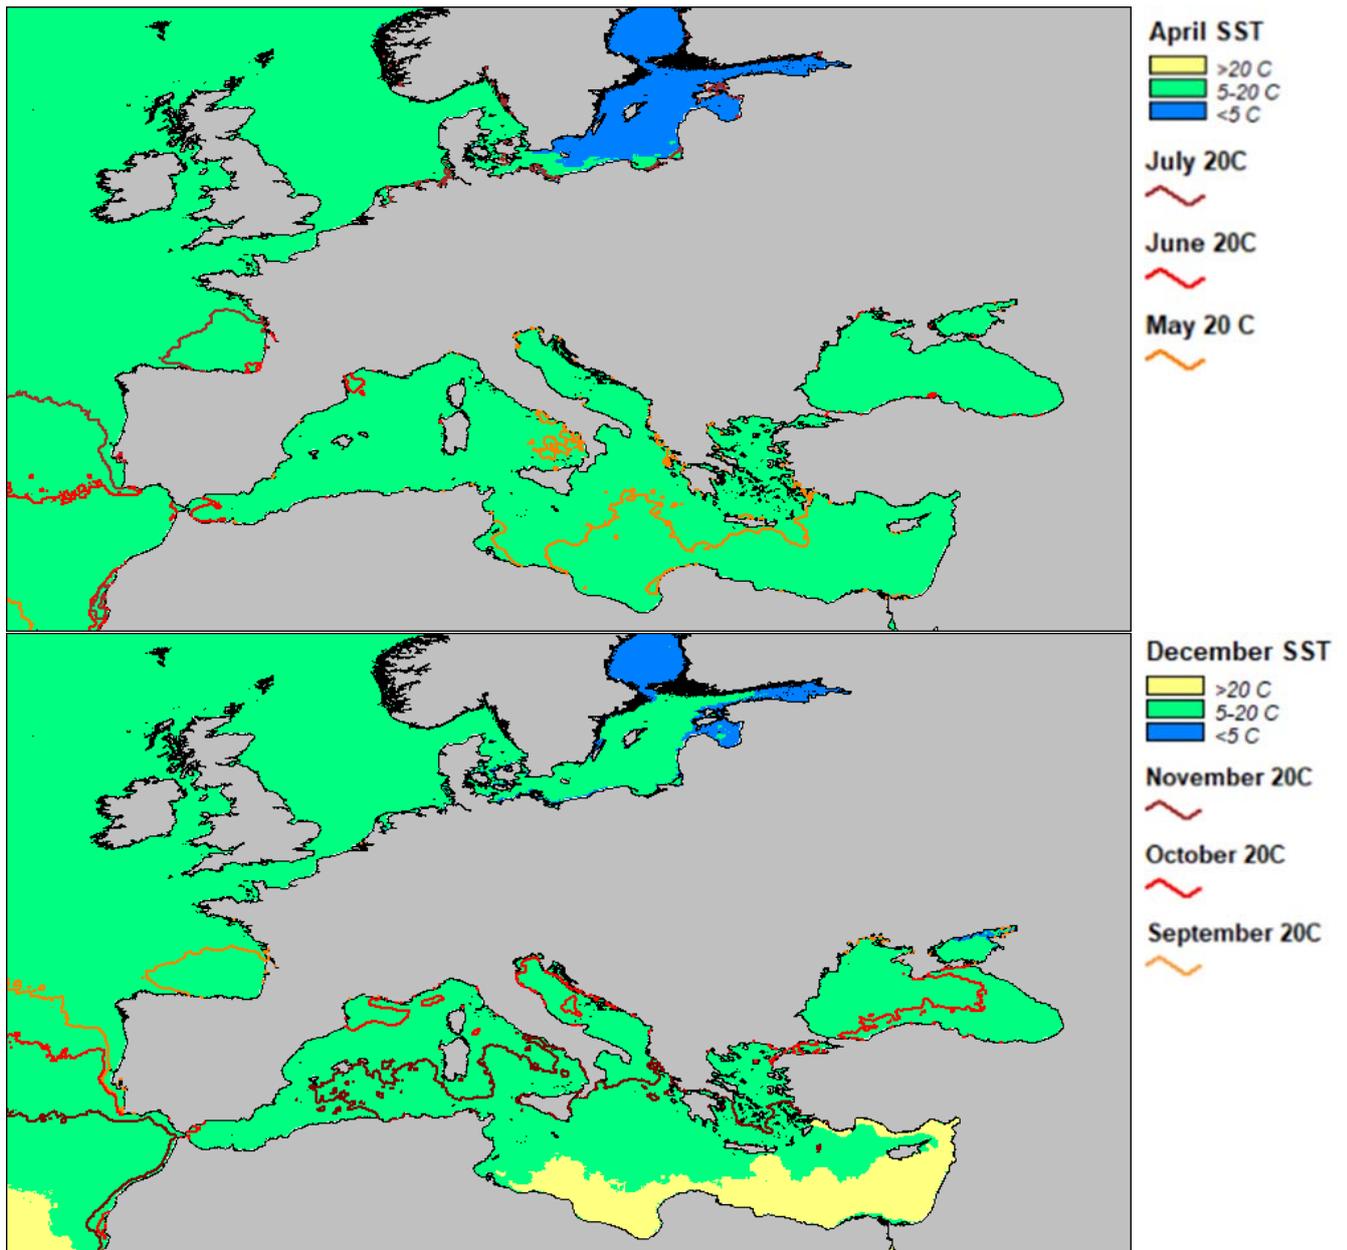

The same principles are expressed in the following map, as number of months with thermal conditions suitable for establishment (i.e. mean monthly temperatures between 5-20 °C).

Figure 3. Number of months with conditions suitable for establishment, i.e. mean monthly temperatures between 5-20 °C. Top: Under current climate conditions. Bottom: Under RCP4.5 in 2070. Maps created by Björn Beckmann.

Similar isotherm maps were produced for a future scenario of climate change (rough estimate based on a maximum increase in seawater temperatures of 0.8 °C by 2070, according to the medium timeframe RCP 4.5 scenario). It appears that, under future climate change, the conditions suitable for establishment in the Mediterranean Sea will shrink even more both in space and in time. Thus, future establishment for the Mediterranean is considered unlikely.

Figure 3: As in Figure 1 but for under RCP4.5 in 2070. Top: April Sea Surface Temperature (SST) and 20°C SST contours for the months of May-July. Bottom: December SST and 20°C SST contours for October-November. Suitable conditions (SST<20°C) for *A. amurensis* larval development are encountered westwards and northwards of the contour lines.

## **ANNEX IX Species Distribution Model**

Projection of environmental suitability for *Asterias amurensis* establishment in Europe

Björn Beckmann, Marika Galanidi and Dan Chapman

10 June 2020

### **Aim**

To project the suitability for potential establishment of *Asterias amurensis* in Europe, under current and predicted future climatic conditions.

### **Data for modelling**

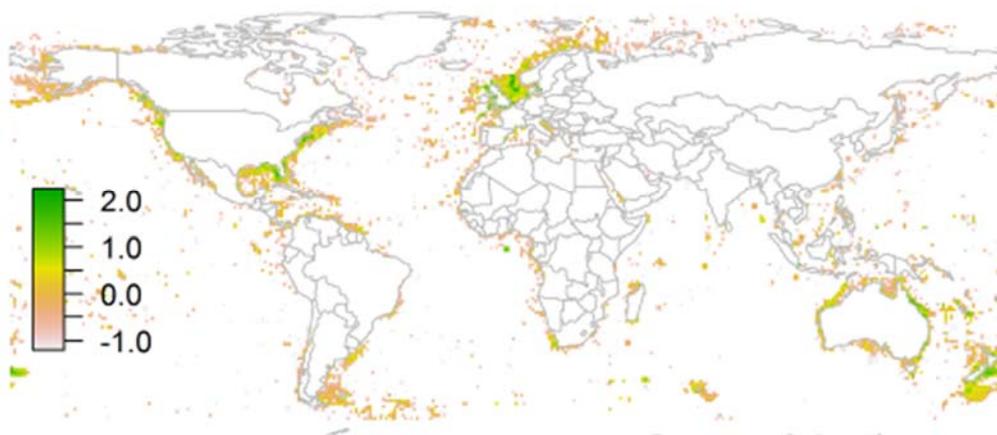

Species occurrence data were obtained from the Global Biodiversity Information Facility (GBIF) (360 records), the Ocean Biogeographic Information System (OBIS) (285 records), the Biodiversity Information Serving Our Nation database (BISON) (219 records), the Integrated Digitized Biocollections (iDigBio) (170 records), the Atlas of Living Australia (99 records), iNaturalist (65 records), and some additional records from the risk assessment team. We scrutinised occurrence records and removed any dubious ones and records where the georeferencing was too imprecise or outside of the coverage of the predictor layers. The records were gridded at a 0.25 x 0.25 degree resolution for modelling, yielding 205 grid cells with occurrences (Figure 1a). As a proxy for recording effort, the density of Asteroidea records held by GBIF was also compiled on the same grid (Figure 1b).

**Figure 1.** (a) Occurrence records obtained for *Asterias amurensis* and used in the modelling, showing native and invaded distributions. (b) The recording density of Asteroidea on GBIF, which was used as a proxy for recording effort.

(a) Species distribution used in modelling

(b) Estimated recording effort (log10-scaled)

Predictors describing the marine environment were selected from the ‘Bio-ORACLE2’ set of GIS rasters providing geophysical, biotic and environmental data for surface and benthic marine realms (Tyberghein et al., 2012, Assis et al. 2017), supplemented by variables calculated from MARSPEC monthly sea surface temperature data (Sbrocco & Barber 2013). Both were originally at 5 arcminute resolution (0.083 x 0.083 degrees of longitude/latitude) and aggregated to a 0.25 x 0.25 degree grid for use in the model.

Based on the biology of *Asterias amurensis*, the following variables were used in the modelling:

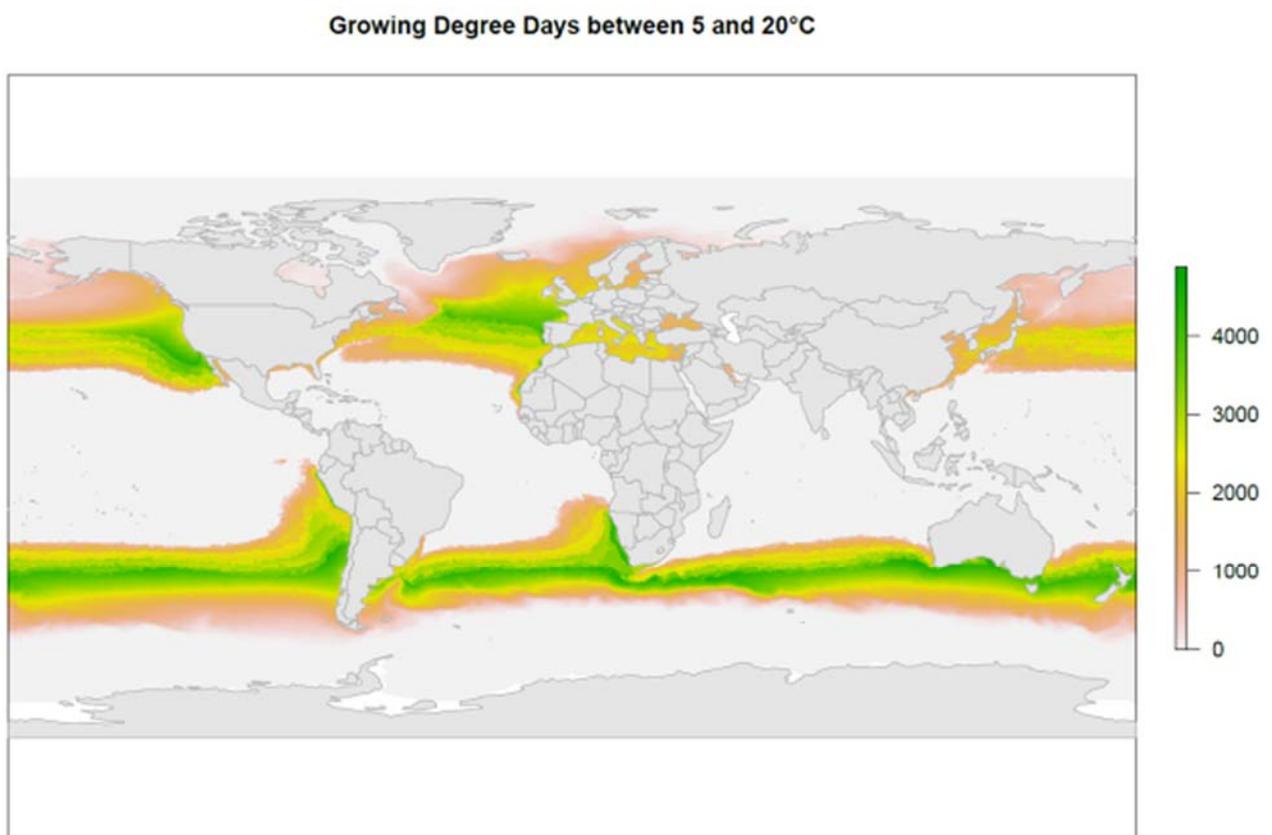

- Mean temperature (tempmean\_ss)
- Maximum long-term temperature (templtmax\_ss)
- Minimum long-term temperature (templtmin\_ss)
- Minimum salinity (salinitymin\_ss)

- Mean bathymetry (bathymean)
- Growing Degree Days between 5 and 20°C (gdd\_5\_20)

All parameters (except depth) are measured at the sea surface.

Growing Degree Days (GDD) have been widely used as a measure of the “biologically useful” sum of warmth between threshold temperatures where processes of interest occur (McMaster and Wilhelm 1997). For *Asterias amurensis*, larval development occurs between approximately 5 and 20°C (see Risk Assessment for details). GDD are usually calculated from daily temperature data, but since these are not available for the marine environment at a global scale, GDD were calculated from MARSPEC monthly mean temperature data: First, all grid cells with temperatures less than 5°C or more than 20°C were excluded for each month. Then, any positive difference from the lower temperature threshold was multiplied by the number of days in the month. For example, a grid cell with a temperature of 7°C in January had a value of 7°C - 5°C = 2°C x 31 days = 62 GDD for January. Finally, GDD values for all months were summed to produce an annual total for each grid cell (Fig. 2).

**Figure 2.** Annual Growing Degree Days (GDD) between 5 and 20°C for the current climate, calculated from MARSPEC monthly mean sea surface temperatures.

To estimate the effect of climate change on the potential distribution of *Asterias amurensis*, equivalent modelled future conditions for the 2070s under the Representative Concentration Pathways (RCP) 2.6 and 4.5 were also obtained. These represent low and medium emissions scenarios, respectively. Projections for the 2070s were calculated as averages of projections for the 2040s and 2090s (which are the time periods available on Bio-ORACLE2). Future monthly mean temperatures for calculating

Growing Degree Days were approximated by adding the temperature difference between Bio-ORACLE2 current and future scenarios to the MARSPEC monthly temperature layers, because no future layers for MARSPEC are available.

### Species distribution model

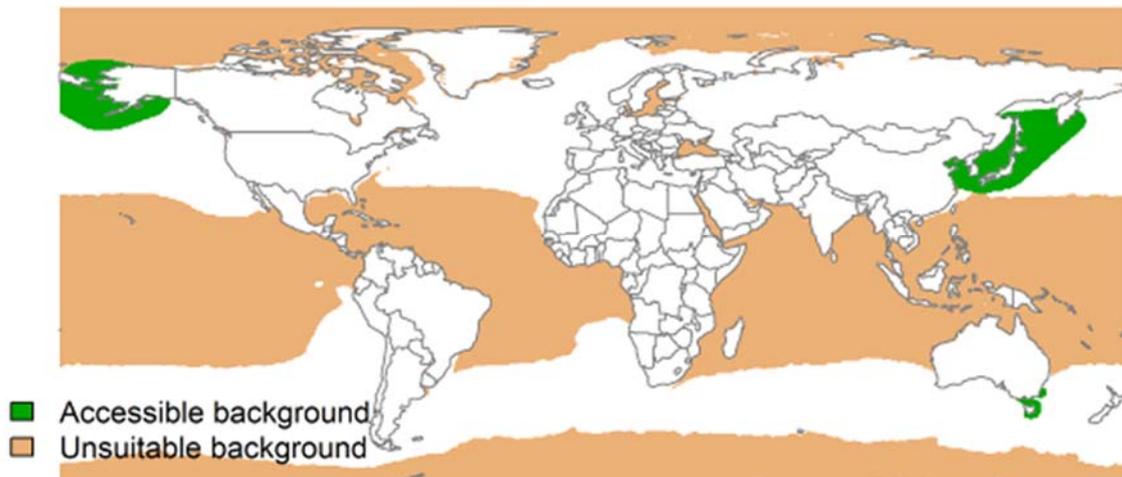

A presence-background (presence-only) ensemble modelling strategy was employed using the BIOMOD2 R package version 3.4.6 (Thuiller et al., 2020, Thuiller et al., 2009). These models contrast the environment at the species' occurrence locations against a random sample of the global background environmental conditions (often termed 'pseudo-absences') in order to characterise and project suitability for occurrence. This approach has been developed for distributions that are in equilibrium with the environment. Because invasive species' distributions are not at equilibrium and subject to dispersal constraints at a global scale, we took care to minimise the inclusion of locations suitable for the species but where it has not been able to disperse to (Chapman et al. 2019). Therefore the background sampling region included:

- The area accessible by native *Asterias amurensis* populations, in which the species is likely to have had sufficient time to disperse to all locations. Based on presumed maximum dispersal distances, the accessible region was defined as a 500km buffer around the native range occurrences; AND
- A 200km buffer around the non-native occurrences, encompassing regions likely to have had high propagule pressure for introduction by humans and/or dispersal of the species; AND
- Regions where we have an *a priori* expectation of high unsuitability for the species so that absence is assumed irrespective of dispersal constraints (see Figure 2). The following rules were applied to define a region expected to be highly unsuitable for *Asterias amurensis* at the spatial scale of the model:
  - Minimum salinity (salinitymin\_ss) < 20
  - Maximum long-term temperature (templtmax\_ss) < 5
  - Minimum long-term temperature (templtmin\_ss) > 20

Altogether, 2.4% of occurrence grid cells were located in the unsuitable background region.

Within the unsuitable background region, 10 samples of 5000 randomly sampled grid cells were obtained. In the accessible background (comprising the accessible areas around native and non-native occurrences as detailed above), the same number of pseudo-absence samples were drawn as there were presence records (205), weighting the sampling by a proxy for recording effort (Figure 3).

**Figure 3.** The background from which pseudo-absence samples were taken in the modelling of *Asterias amurensis*. Samples were taken from a 500km buffer around the native range and a 200km buffer around non-native occurrences (together forming the accessible background), and from areas expected to be highly unsuitable for the species (the unsuitable background region). Samples from the accessible background were weighted by a proxy for recording effort (Figure 1(b)).

Each dataset (i.e. combination of the presences and the individual background samples) was randomly split into 80% for model training and 20% for model evaluation. With each training dataset, five statistical algorithms were fitted with the default BIOMOD2 settings and rescaled using logistic regression, except where specified below:

- Generalised linear model (GLM)
- Generalised boosting model (GBM)
- Generalised additive model (GAM) with a maximum of four degrees of freedom per smoothing spline
- Random forest (RF)
- Maxent

Since the total background sample was larger than the number of occurrences, prevalence fitting weights were applied to give equal overall importance to the occurrences and the background. Normalised variable importance was assessed and variable response functions were produced using BIOMOD2's default procedure.

Model predictive performance was assessed by the following three measures:

- AUC, the area under the receiver operating characteristic curve (Fielding & Bell 1997). Predictions of presence-absence models can be compared with a subset of records set aside for model evaluation (here 20%) by constructing a confusion matrix with the number of true positive, false positive, false negative and true negative cases. For models generating non-dichotomous scores (as here) a threshold can be applied to transform the scores into a dichotomous set of presence-absence predictions. Two measures that can be derived from the

confusion matrix are sensitivity (the proportion of observed presences that are predicted as such, quantifying omission errors), and specificity (the proportion of observed absences that are predicted as such, quantifying commission errors). A receiver operating characteristic (ROC) curve can be constructed by using all possible thresholds to classify the scores into confusion matrices, obtaining sensitivity and specificity for each matrix, and plotting sensitivity against the corresponding proportion of false positives (equal to  $1 - \text{specificity}$ ). The use of all possible thresholds avoids the need for a selection of a single threshold, which is often arbitrary, and allows appreciation of the trade-off between sensitivity and specificity. The area under the ROC curve (AUC) is often used as a single threshold-independent measure for model performance (Manel, Williams & Ormerod 2001). AUC is the probability that a randomly selected presence has a higher model-predicted suitability than a randomly selected absence (Allouche et al. 2006).

- Cohen's Kappa (Cohen 1960). This measure corrects the overall accuracy of model predictions (ratio of the sum of true presences plus true absences to the total number of records) by the accuracy expected to occur by chance. The kappa statistic ranges from -1 to +1, where +1 indicates perfect agreement and values of zero or less indicate a performance no better than random. Advantages of kappa are its simplicity, the fact that both commission and omission errors are accounted for in one parameter, and its relative tolerance to zero values in the confusion matrix (Manel, Williams & Ormerod 2001). However, Kappa has been criticised for being sensitive to prevalence (the proportion of sites in which the species was recorded as present) and may therefore be inappropriate for comparisons of model accuracy between species or regions (McPherson, Jetz & Rogers 2004, Allouche et al. 2006).
- TSS, the true skill statistic (Allouche et al. 2006). TSS is defined as sensitivity + specificity - 1, and corrects for Kappa's dependency on prevalence. TSS compares the number of correct forecasts, minus those attributable to random guessing, to that of a hypothetical set of perfect forecasts. Like kappa, TSS takes into account both omission and commission errors, and success as a result of random guessing, and ranges from -1 to +1, where +1 indicates perfect agreement and values of zero or less indicate a performance no better than random (Allouche et al. 2006).

An ensemble model was created by first rejecting poorly performing algorithms with relatively extreme low AUC values and then averaging the predictions of the remaining algorithms, weighted by their AUC. To identify poorly performing algorithms, AUC values were converted into modified z-scores based on their difference to the median and the median absolute deviation across all algorithms (Iglewicz & Hoaglin, 1993). Algorithms with  $z < -2$  were rejected. In this way, ensemble projections were made for each dataset and then averaged to give an overall suitability, as well as its standard deviation. The projections were then classified into suitable and unsuitable regions using the 'minROCDist' method, which minimizes the distance between the ROC plot and the upper left corner of the plot (point (0,1)).

We also produced limiting factor maps for Europe following Elith et al. (2010). For this, projections were made separately with each individual variable fixed at a near-optimal value. These were chosen as the median values at the occurrence grid cells. Then, the most strongly limiting factors were identified as the one resulting in the highest increase in suitability in each grid cell.

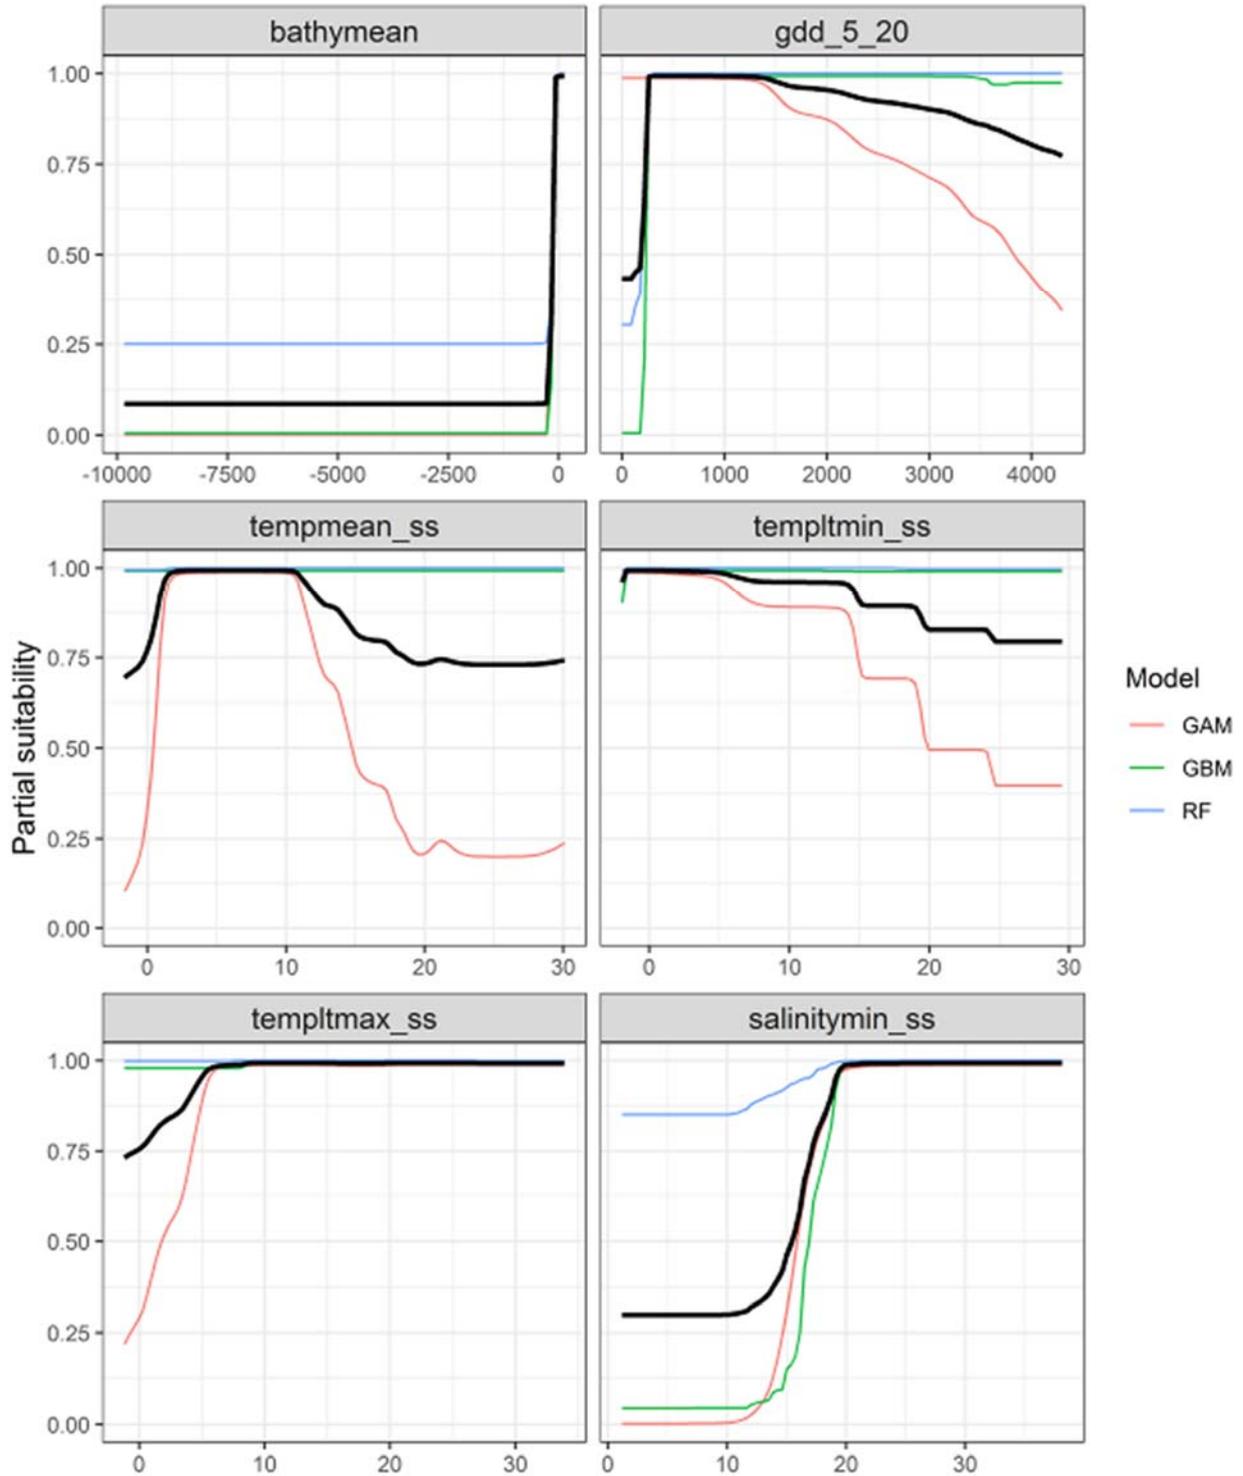

## Results

The ensemble model suggested that suitability for *Asterias amurensis* was most strongly determined by Mean bathymetry (bathymean), accounting for 42.9% of variation explained, followed by Growing Degree Days between 5 and 20°C (gdd\_5\_20) (30.8%), Mean temperature (tempmean\_ss) (9.9%), Minimum long-term temperature (tempmin\_ss) (7.3%), Maximum long-term temperature (tempmax\_ss) (6.1%) and Minimum salinity (salinitymin\_ss) (3.1%) (Table 1, Figure 4).

**Table 1.** Summary of the cross-validation predictive performance (ROC, Kappa, TSS) and variable importance of the fitted model algorithms and the ensemble (AUC-weighted average of the best performing algorithms). Results are the average from models fitted to 10 different background samples of the data.

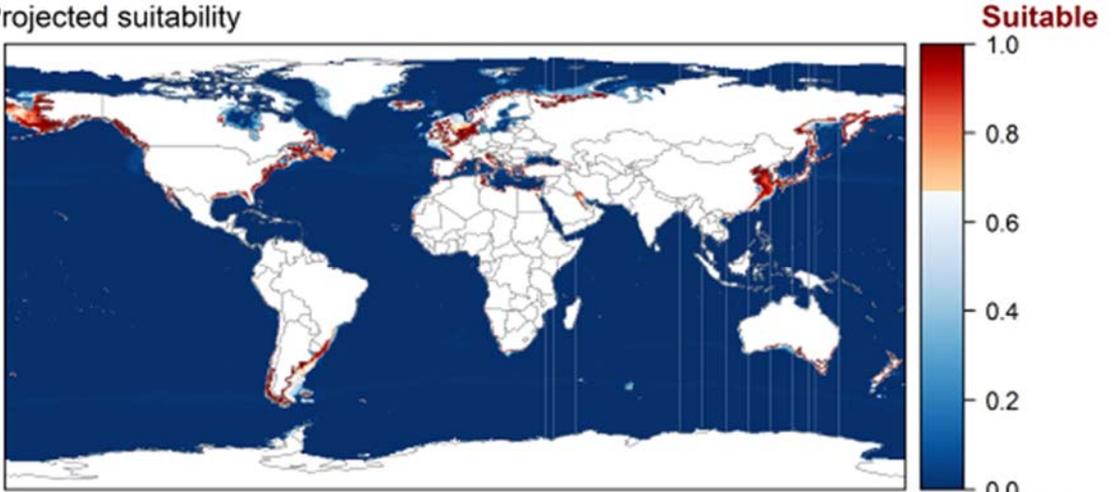

Algorithm	AUC	Kappa	TSS	Used in the ensemble	Variable importance (%)					
					Mean bathymetry (bathymeant)	Growing Degree Days between 5 and 20°C (gdd)	Mean temperature (tempmean_ss)	Minimum long-term temperature (tempmin_ss)	Maximum long-term temperature (tempmax_ss)	Minimum salinity (salinitymin_ss)
GLM	0.987	0.759	0.964	no	33	2	20	27	14	4
GAM	0.994	0.812	0.973	yes	32	1	28	18	16	4
GBM	0.992	0.818	0.966	yes	46	51	0	0	0	2
RF	0.994	0.819	0.976	yes	50	40	2	3	2	3
Maxent	0.884	0.692	0.758	no	56	22	4	6	2	10
<b>Ensemble</b>	<b>0.995</b>	<b>0.820</b>	<b>0.978</b>		<b>43</b>	<b>31</b>	<b>10</b>	<b>7</b>	<b>6</b>	<b>3</b>

**Figure 4.** Partial response plots from the fitted models. Thin coloured lines show responses from the algorithms in the ensemble, while the thick black line is their ensemble. In each plot, other model variables are held at their median value in the training data. Some of the divergence among algorithms is because of their different treatment of interactions among variables.

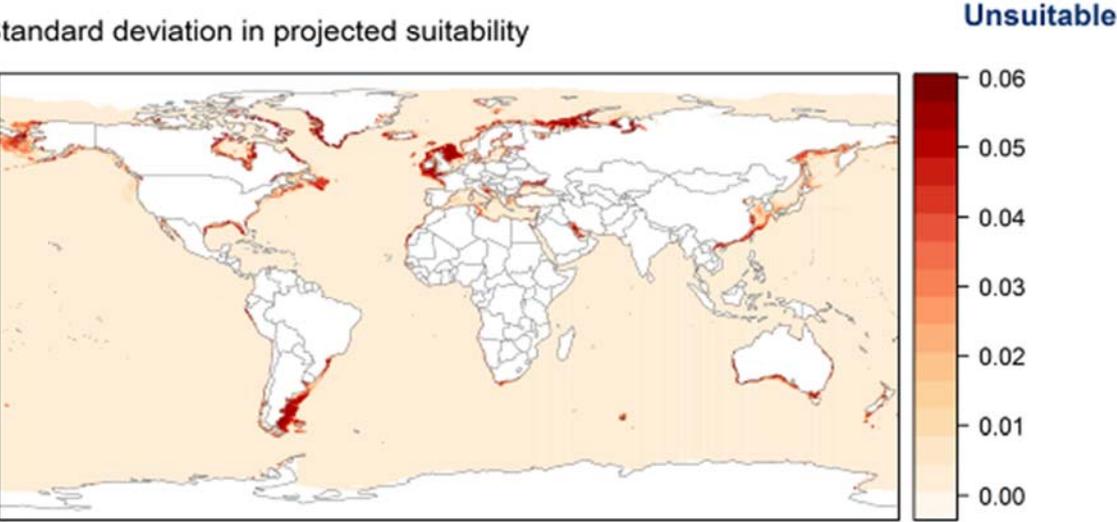

**Figure 5.** (a) Projected global suitability for *Asterias amurensis* establishment in the current climate. For visualisation, the projection has been aggregated to a 0.5 x 0.5 degree resolution, by taking the maximum suitability of constituent higher resolution grid cells. Values > 0.67 may be suitable for the species. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

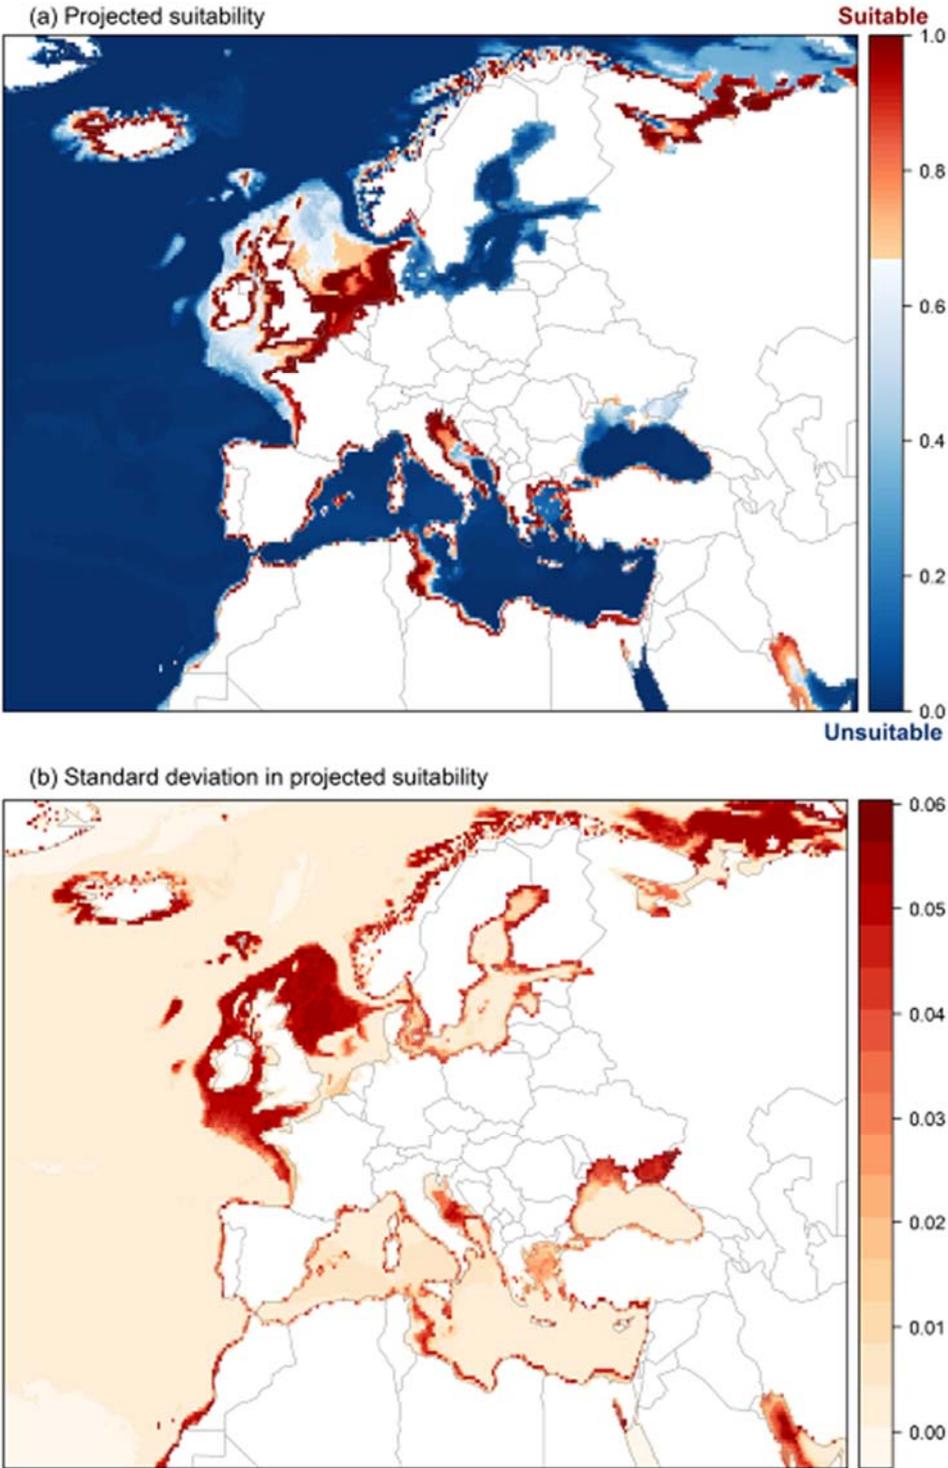

(a) Projected suitability

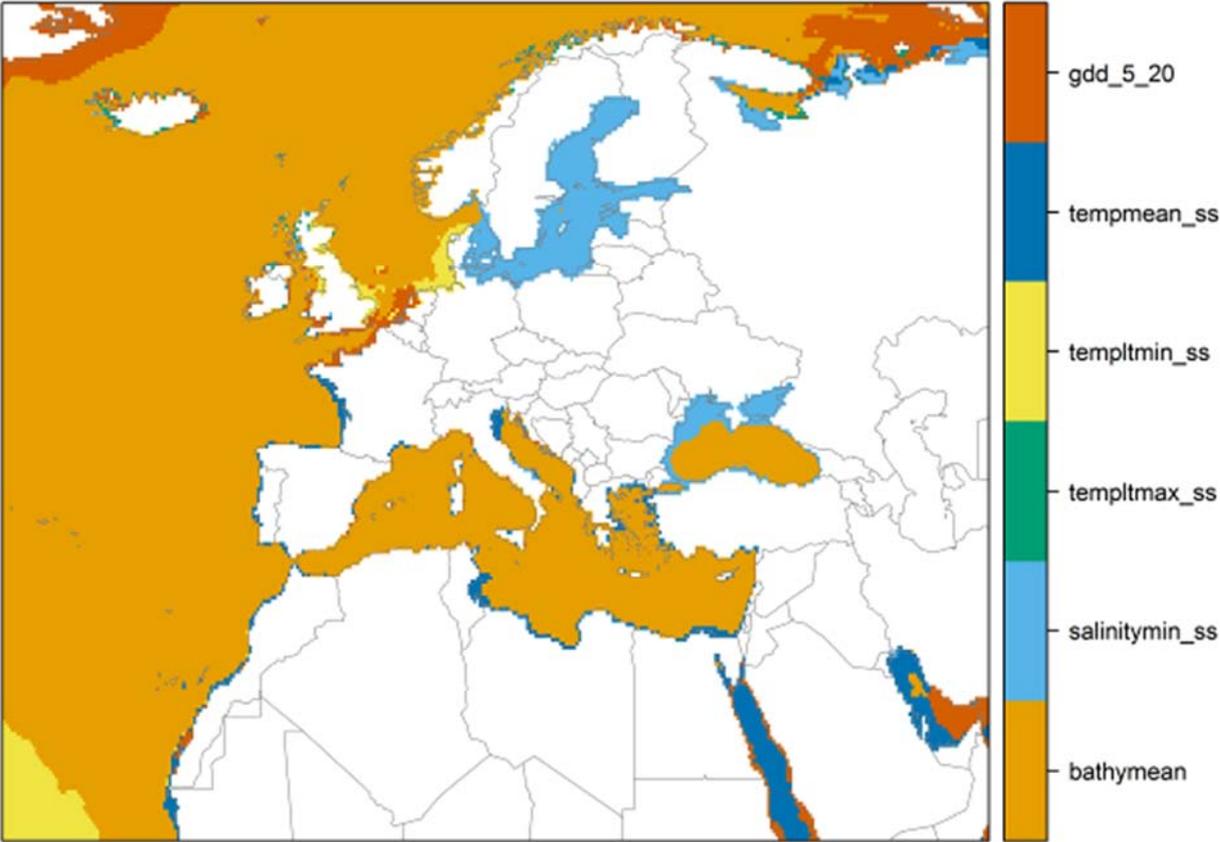

(b) Standard deviation in projected suitability

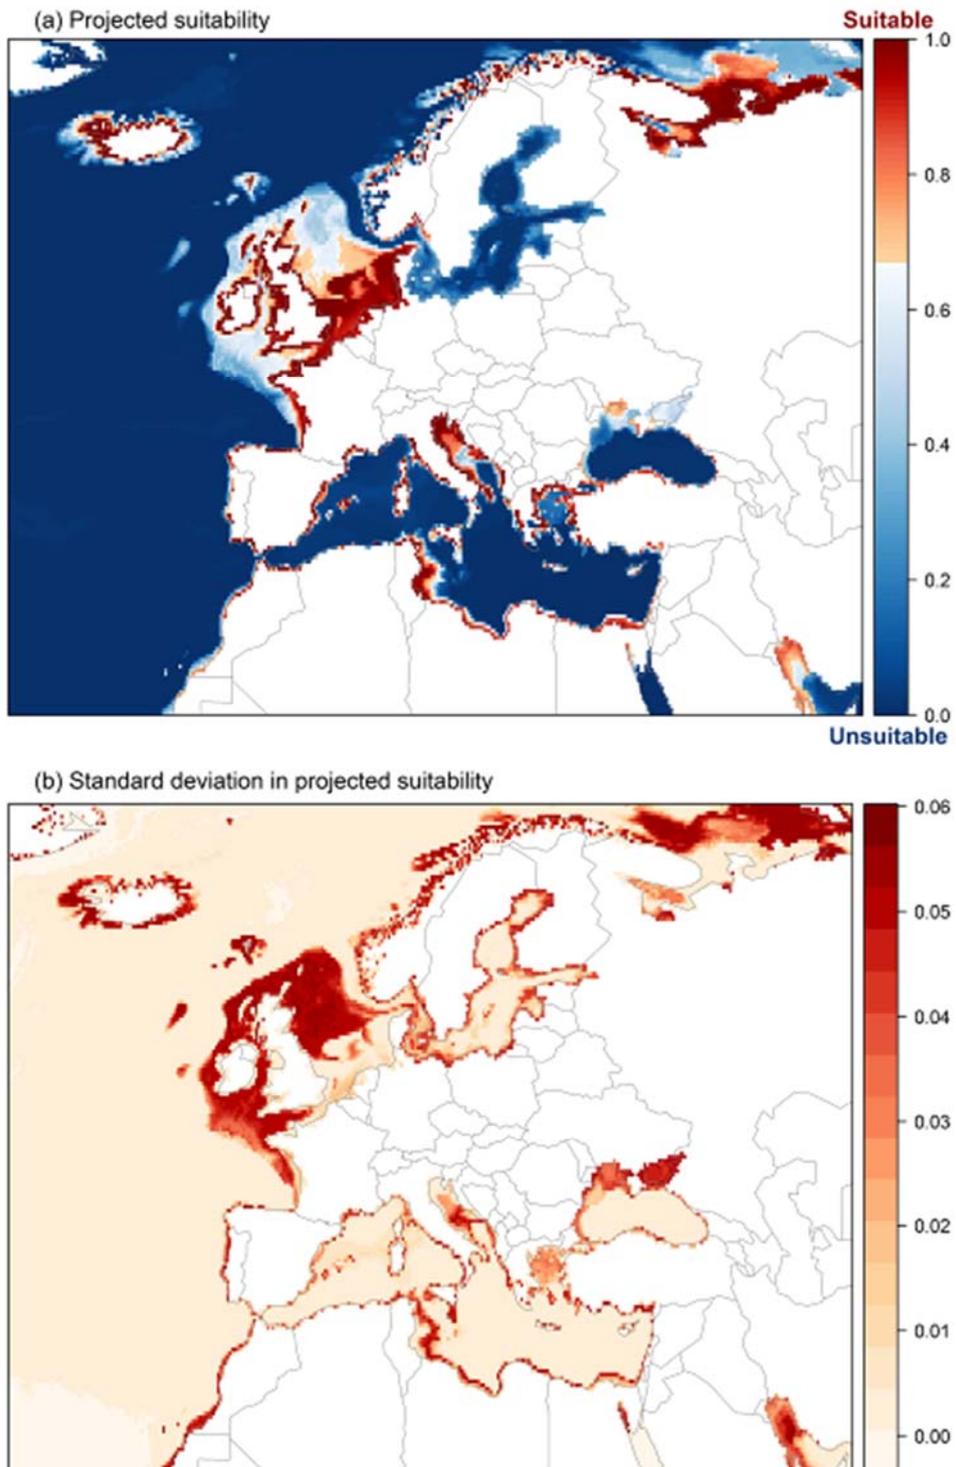

**Figure 6.** (a) Projected current suitability for *Asterias amurensis* establishment in Europe and the Mediterranean region. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

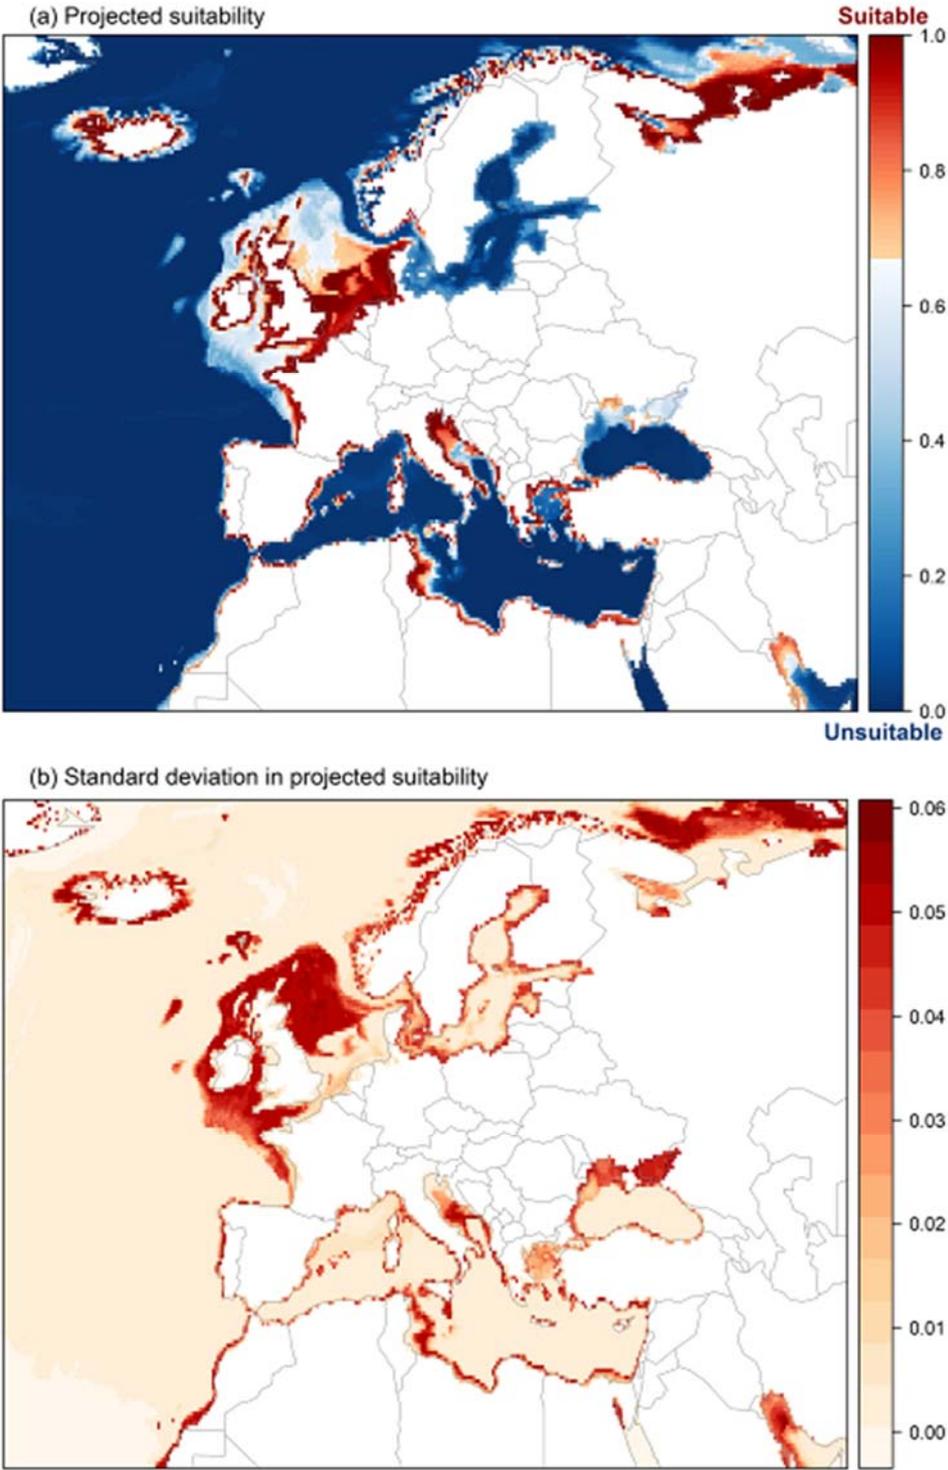

**Figure 7.** The most strongly limiting factors for *Asterias amurensis* establishment estimated by the model in Europe and the Mediterranean region in current climatic conditions.

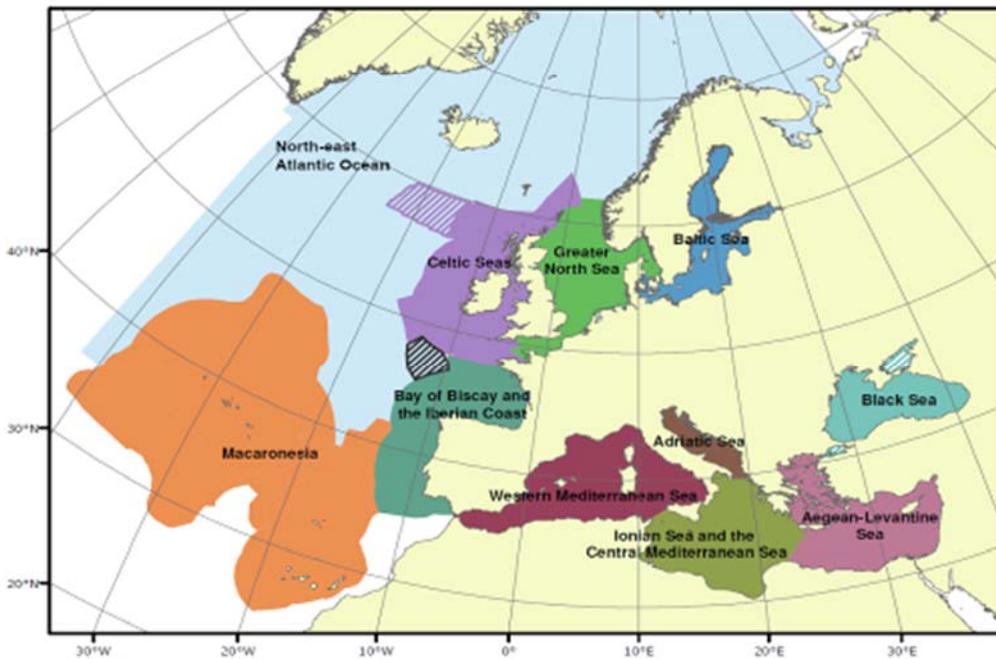

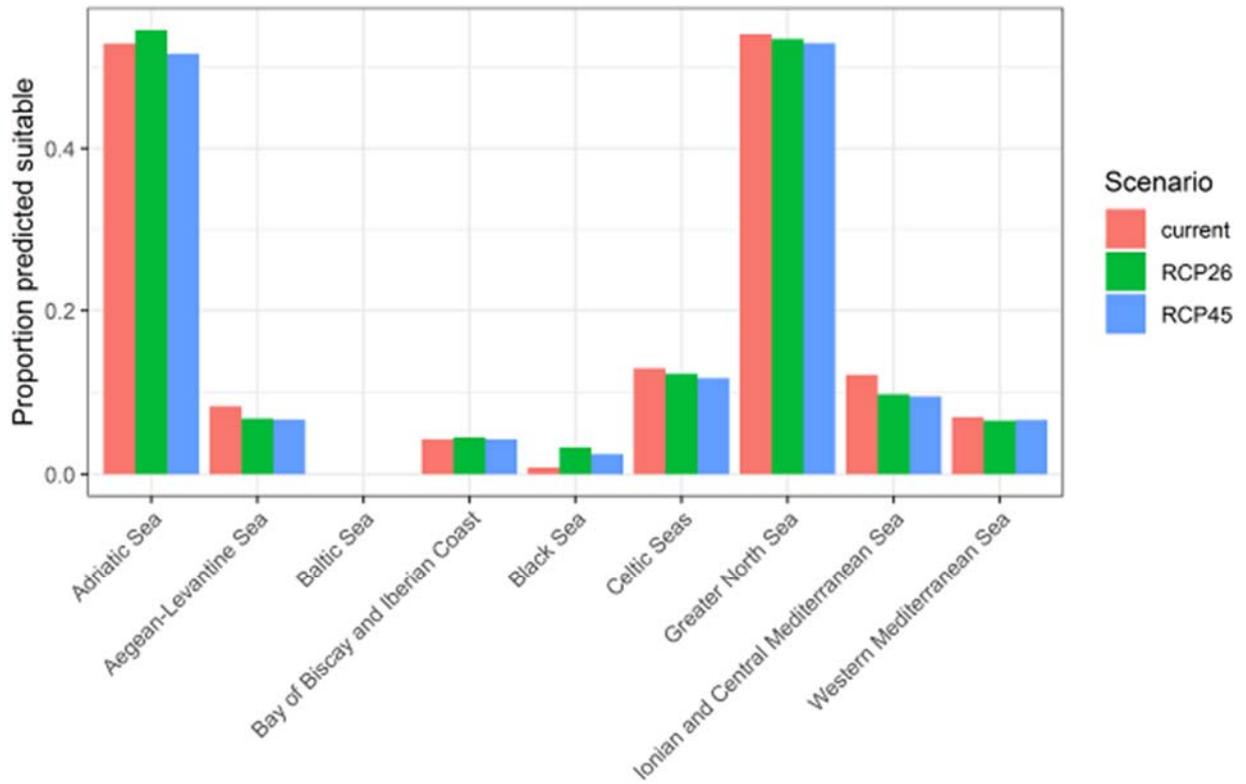

**Figure 8.** (a) Projected suitability for *Asterias amurensis* establishment in Europe and the Mediterranean region in the 2070s under climate change scenario RCP2.6, equivalent to Figure 6. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

**Figure 9.** (a) Projected suitability for *Asterias amurensis* establishment in Europe and the Mediterranean region in the 2070s under climate change scenario RCP4.5, equivalent to Figure 6. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

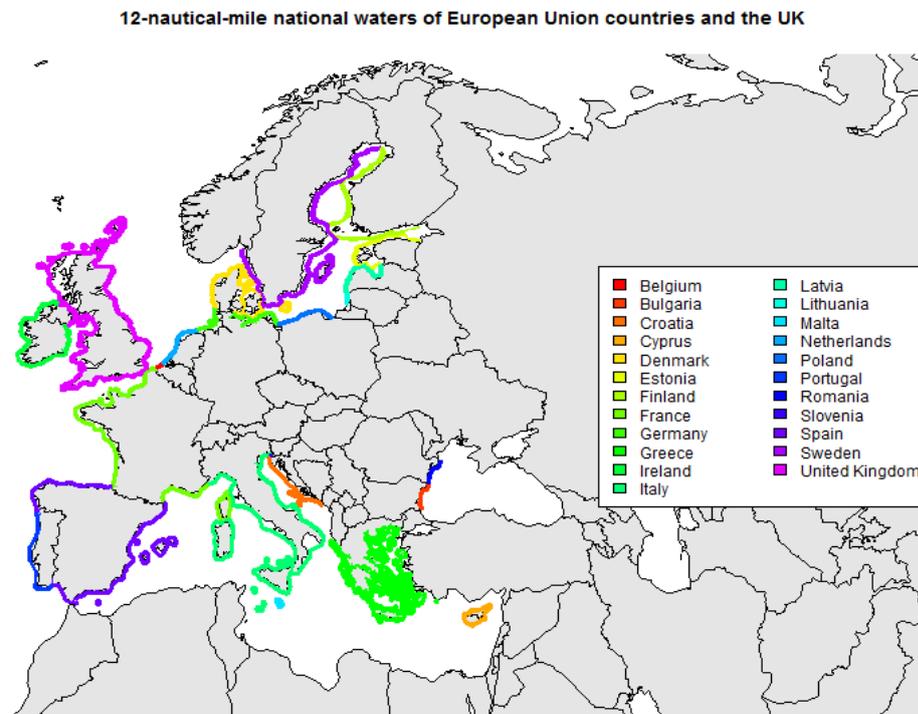

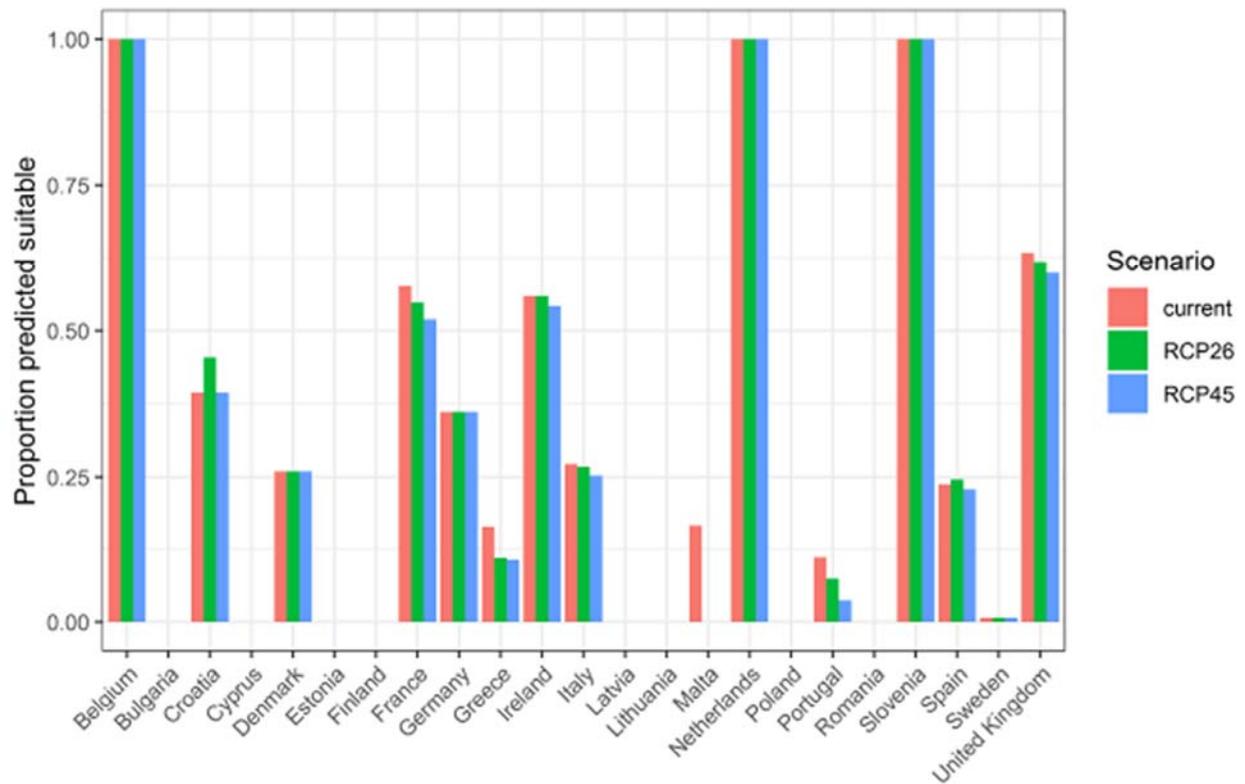

**Figure 10.** Variation in projected suitability for *Asterias amurensis* establishment among marine subregions of Europe. The bar plots show the proportion of grid cells in each region classified as suitable in the current climate and projected climate for the 2070s under two RCP emissions scenarios. The location of each region is also shown. Macaronesia is excluded as it is not part of the study area.

**Table 2.** Variation in projected suitability for *Asterias amurensis* establishment among marine subregions of Europe (numerical values of Figure 10 above). The numbers are the proportion of grid cells in each region classified as suitable in the current climate and projected climate for the 2070s under two RCP emissions scenarios.

<b>Region</b>	<b>Current climate</b>	<b>RCP26</b>	<b>RCP45</b>
Adriatic Sea	0.53	0.55	0.52
Aegean-Levantine Sea	0.08	0.07	0.07
Baltic Sea	0.00	0.00	0.00
Bay of Biscay and Iberian Coast	0.04	0.04	0.04
Black Sea	0.01	0.03	0.02
Celtic Seas	0.13	0.12	0.12
Greater North Sea	0.54	0.53	0.53
Ionian and Central Mediterranean Sea	0.12	0.10	0.10
Western Mediterranean Sea	0.07	0.07	0.07

**Figure 11.** Variation in projected suitability for *Asterias amurensis* establishment among the 12-nautical-mile national waters of European Union countries and the UK. The bar plots show the proportion of grid cells in each country's waters classified as suitable in the current climate and projected climates for the 2070s under two RCP emissions scenarios. The location of each region is also shown.

**Table 3.** Variation in projected suitability for *Asterias amurensis* establishment among 12-nautical-mile national waters of European Union countries and the UK (numerical values of Figure 11 above). The numbers are the proportion of grid cells in each country’s waters classified as suitable in the current climate and projected climate for the 2070s under two RCP emissions scenarios.

<b>Country</b>	<b>Current climate</b>	<b>RCP26</b>	<b>RCP45</b>

## Caveats to the modelling

To remove spatial recording biases, the selection of the background sample from the accessible background was weighted by the density of Asteroidea records on the Global Biodiversity Information Facility (GBIF). While this is preferable to not accounting for recording bias at all, it may not provide the perfect measure of recording bias.

There was substantial variation among modelling algorithms in the partial response plots (Figure 4). In part this will reflect their different treatment of interactions among variables. Since partial plots are made with other variables held at their median, there may be values of a particular variable at which this does not provide a realistic combination of variables to predict from.

Other variables potentially affecting the distribution of the species, such as underwater vegetation were not included in the model.

## SECTION A – Organism Information and Screening

### A1. Identify the organism. Is it clearly a single taxonomic entity and can it be adequately distinguished from other entities of the same rank?

including the following elements:

- the taxonomic family, order and class to which the species belongs;
- the scientific name and author of the species, as well as a list of the most common synonym names;
- names used in commerce (if any)
- a list of the most common subspecies, lower taxa, varieties, breeds or hybrids

As a general rule, one risk assessment should be developed for a single species. However, there may be cases where it may be justified to develop one risk assessment covering more than one species (e.g. species belonging to the same genus with comparable or identical features and impact). It shall be clearly stated if the risk assessment covers more than one species, or if it excludes or only includes certain subspecies, lower taxa, hybrids, varieties or breeds (and if so, which subspecies, lower taxa, hybrids, varieties or breeds). Any such choice must be properly justified.

This risk assessment covers one species, axis deer *Axis axis* (Erxleben, 1777), also known as chital, cheetal, spotted deer or Indian spotted deer (Class: Mammalia, Order: Artiodactyla, Family: Cervidae, Subfamily: Cervinae, Genus: *Axis*).

Synonym(s): *Cervus axis* Erxleben, 1777

According to Wilson and Reeder (2005) the genus *Axis* includes three species:

- *A. axis* in India (including Sikkim), Nepal, and Sri Lanka (plus a number of countries where the species is alien, see details in point A5 below);
- the Calamian deer *A. calamaniensis* (Heude, 1888), found in the Calamian Islands in the Philippines;
- the Indian hog deer *A. porcinus* (Zimmermann, 1780), known from Bangladesh, Burma, Cambodia, China, India, Laos, Nepal, Pakistan, Sri Lanka (perhaps introduced), and Vietnam, with introduced populations in Australia and South Africa.

Wilson and Mittermeier (2011) further include the Bawean deer *Axis kuhlii* (Temminck, 1836) in the genus, which other authors include in the genus *Hyelaphus*.

No subspecies of *A. axis* is recognised by Wilson and Reeder (2005) and Wilson and Mittermeier (2011).

There are no hybrids known to occur in the wild, however, as this cannot be completely excluded, as a precaution this risk assessment includes all *A. axis* hybrids. Attempts to cross axis deer with sika deer (*Cervus nippon*) by artificial insemination are reported (Asher et al 1999). One recorded case of hybridization arising from natural mating between sika deer and axis deer is also reported by Asher et al. (1999). In this case, the widest cross yet observed within the subfamily Cervinae, a hind exhibiting physical characteristics intermediate between the two species was born on a Tennessee deer farm sometime in 1995. Electrophoresis

analysis initially verified that hybridization had occurred, but fertility of the hybrid remained to be assessed. The potential for hybridization between axis deer and fallow deer (*Dama dama*) was explored by Willard et al. (2005), also using artificial insemination; in this case, reciprocal hybridization of the two species did not result in the establishment of hybrid pregnancies. Although anecdotal and undocumented accounts for the existence of such hybrids were reported (e.g. between sika deer and axis deer, see Bartos 2009), hybridization between these two species appears unlikely under natural conditions (Willard et al. 2005).

**A2. Provide information on the existence of other species that look very similar [that may be detected in the risk assessment area, either in the environment, in confinement or associated with a pathway of introduction]**

Include both native and non-native species that could be confused with the species being assessed, including the following elements:

- other alien species with similar invasive characteristics, to be avoided as substitute species (in this case preparing a risk assessment for more than one species together may be considered);
- other alien species without similar invasive characteristics, potential substitute species;
- native species, potential misidentification and mis-targeting

The axis deer is a moderately large deer standing 88-97cm at the shoulders. Hinds are generally smaller than stags, which may weight up to 113 kg (and even over 136 kg in farms, see Centore 2016). Antlers are about 76 cm long and take roughly five months to fully develop (they are present only on stags). The species is characterised by a reddish brown coat covered with typical small white spots (retained at all ages and all seasons), arranged on the lower flanks in longitudinal rows. Under parts are white, as well as inner hind legs and under tail. A dorsal dark stripe is present from the nape to the tip of the tail (for further details see descriptions in Wilson and Mittermeier 2011, GISD 2015, Long 2003, Prater 1965). All the features mentioned above are useful to distinguish this species from other native deer in the risk assessment area. Otherwise only the prominent white throat is absolutely distinctive, because axis deer are in other respects not easy to distinguish (from superficial observation) from fallow deer or some spotted subspecies of sika. For example, in fallow deer younger bucks and does (especially of so-called ‘common’ or ‘menil’ coloration) do not have the distinctive palmated antlers which are typical of mature bucks, therefore they might be confused with axis deer in fleeting observation. Likewise, some colour variants of sika deer and pure Japanese sika deer in summer coat could be confused. Both common-coloured fallow deer, and sika deer, also have a darker dorsal stripe and dark line extending down the tail. Albino animals are occasionally reported (Dinesan et al 2006, Leo Prabu et al. 2013).

**A3. Does a relevant earlier risk assessment exist? Give details of any previous risk assessment, including the final scores and its validity in relation to the risk assessment area.**

A risk assessment for the axis deer exists for Poland (Okarma et al. 2018a). The result shows that the risk for the country is considered “Medium” and the species is considered moderately invasive on the ground of its impact on the environment. In relation to the risk assessment area, this result may be considered valid particularly for the Continental biogeographic region.

The species was also assessed by Nentwig et al. (2018) according to whom out of 486 alien species established in Europe from a wide range of taxonomic groups, the axis deer ranked 31, among those with the highest environmental and socioeconomic impact (following the generic impact scoring system GISS, as calculated by Nentwig et al. 2010).

In Australia, a risk assessment for the species was made in Western Australia. The risk of establishing populations in the wild and the risk of becoming a pest have been assessed as “extreme” (Massam et al. 2010, Page et al. 2008). The map of Australia included in the risk assessment shows the partial suitability of the Mediterranean climate area for the species (Page et al. 2008). In Western Australia the species (either captive or released animals) was also considered as “moderately dangerous” in relation to public safety, e.g. in relation to the potential for zoonoses, deer-vehicle collisions, injuries following aggressive behaviour (Massam et al. 2010, Page et al. 2008).

#### **A4. Where is the organism native?**

including the following elements:

- an indication of the continent or part of a continent, climatic zone and habitat where the species is naturally occurring
- if applicable, indicate whether the species could naturally spread into the risk assessment area

The axis deer is a tropical or sub-tropical species, native to Asia, endemic of the Indian subcontinent, i.e. India (including Sikkim), Nepal, Bhutan, Bangladesh and Sri Lanka (Long 2003, Wilson and Reader 2005, Duckworth et al. 2015).

Axis deer is typical of the grassland-forest ecotone (Wilson and Mittermeier 2011). As summarised by Duckworth et al. (2015) the axis deer thrive in a wide range of habitats throughout its native range (see also Moe and Wegge 1994), but prefers moist and dry deciduous forest near water, interspersed with dry thorn scrublands or grasslands (Eisenberg and Seidensticker 1976). Mangrove forests (Sankar and Acharya 2004), mixed forests or plantations (with Teak *Tectona grandis* and Sal *Shorea robusta*) (Wilson and Mittermeier 2011) and agricultural crops such as coffee areas, are used too (Bali et al. 2007). This species lives mostly in flat areas and at lower elevations, usually below 1000 m, avoiding slopes, hills and mountain areas, but has also been found at high elevations (2,209 m) in India (Wilson and Mittermeier 2011, Duckworth et al. 2015, Schaller 1967, Deepan et al. 2018).

In general, this species avoids extreme habitats such as open semi-desert or desert, dense moist (evergreen) forests but introduced populations show some flexibility in this regard. For example, animals in the Andaman Islands are found in dense evergreen forests (Ali 2004, Sankar and Acharya 2004) and in Hawaii they are found in areas ranging from semi-deserts to rainforest (Moe and Wegge 1994), up to 2150 m (Waring 1996).

The native range is characterized by significant seasonal changes in temperature and, more importantly, extreme swings in precipitation (Anderson 1999), but axis deer have adapted very well to the European eco-climatic zones. For example, the typical habitat occupied in Croatia is represented by scrublands and woodlands of Euro-Mediterranean vegetation (Centore et al. 2018), while in Russia the species was successfully introduced to an area south of Moscow, characterized by deciduous and mixed forests with oak and undergrowth of spindle tree, buckthorn, dogwood, and other shrubs (Bobrov et al. 2008). In Croatia, the species could not adapt to continental climate (Kusak and Krapinec 2010).

Four key factors were identified as delineating the axis deer's distribution: (1) the need for water; (2) the need for shade; (3) an avoidance of high, rugged terrain; and (4) a preference for grass as forage (Schaller 1967, Kushwaha 2018). Habitat use varies seasonally, reflecting food availability (see also Centore 2016). The axis deer easily habituates to human presence, and herds often congregate in open areas near habitation or forest camps to spend the night, possibly due to greater safety from predators and poachers (Duckworth et al. 2015). In fact, the limiting factor seems to be winter conditions, particularly strong frosts and thick snow cover (Okarma et al. 2018b).

**A5. What is the global non-native distribution of the organism outside the risk assessment area?**

Outside the risk assessment area, the axis deer was successfully introduced in the following countries:

- Europe (Russia, and possibly Moldova and Ukraine, but see below);
- Asia (Armenia, Azerbaijan, Andaman Islands, Pakistan);
- North America (USA: California, Florida, Texas and Hawaiian Islands, México);
- South America (Argentina, Brazil, Uruguay);
- Australia

For details, see Long (2003), Lever (1985), Wilson and Reader (2005), Duckworth et al. (2015), Wilson and Mittermeier (2011), Álvarez-Romero and Medellín (2005). According to Šprem and Zachos (2020) introductions to Ukraine and Moldova (as well as to the British Isles) are sometimes mentioned, but there is no reliable information available about this or any free-living populations resulting from these alleged introductions.

The species is also present in South Africa (<https://www.invasives.org.za/legislation/item/709-axis-deer-axis-axis>, accessed on 26/07/2019).

Axis deer were considered as introduced without success in New Zealand and New Guinea by Long (2003), while Forsyth and Duncan (2001) considered the introduction of this species as “successful” in New Zealand, because the species had a self-sustaining wild population before being eradicated by hunting. This shows that axis deer could have persisted in the climatic and environmental conditions in this country.

**A6. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species been recorded and where is it established? The information needs be given separately for recorded and established occurrences.**

**A6a. Recorded: List regions**

**A6b. Established: List regions**

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

- Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea.

Comment on the sources of information on which the response is based and discuss any uncertainty in the response.

For delimitation of EU biogeographical regions please refer to <https://www.eea.europa.eu/data-and-maps/figures/biogeographical-regions-in-europe-2> (see also Annex V).

For delimitation of EU marine regions and subregions consider the Marine Strategy Framework Directive areas; please refer to <https://www.eea.europa.eu/data-and-maps/data/msfd-regions-and-subregions/technical-document/pdf> (see also Annex V).

(6a): Alpine, Continental, Mediterranean

(6b): Mediterranean

The source of information on which the response is based can be found in Qu. A8.

**A7. In which biogeographic region(s) or marine subregion(s) in the risk assessment area could the species establish in the future under current climate and under foreseeable climate change? The information needs be given separately for current climate and under foreseeable climate change conditions.**

**A7a. Current climate: List regions**

**A7b. Future climate: List regions**

With regard to EU biogeographic and marine (sub)regions, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

(7a):

Boreal, Continental, Mediterranean, Alpine, Atlantic, Black Sea, Pannonian, Steppic (see details in Annex VII).

(7b):

Boreal, Continental, Mediterranean, Alpine, Atlantic, Black Sea, Pannonian, Steppic (see details in Annex VII).

**A8. In which EU Member States has the species been recorded and in which EU Member States has it established? List them with an indication of the timeline of**

**observations. The information needs be given separately for recorded and established occurrences.**

**A8a. Recorded: List Member States**

**A8b. Established: List Member States**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden

The description of the invasion history of the species shall include information on countries invaded and an indication of the timeline of the first observations, establishment and spread.

(8a): Czech Republic, France, Ireland, Slovenia; and the United Kingdom

Attempts to introduce axis deer were made as early as 1890 in France, but they did not succeed (Dorst and Giban 1954, Lever 1985).

Axis deer was introduced to west-central Slovenia (from the Brijuni islands) in the late 1940s or in 1950, but this introduction failed (one stag, shot on 12 October 1950 is now in the Natural History Museum of Slovenia, see Duckworth et al. 2015). The species is considered as extinct in Slovenia (Mitchell-Jones et al. 1999).

According to Long (2003) axis deer were reported to be feral in Buckinghamshire, England, in 1944-45, but there is no evidence that they have been present outside a deer park and there is only one record of an escape by a single animal (hence it is dubious whether any population persisted in the wild). According to Fitter (1959) there were a number of reports of individual axis deer in England, but no evidence of breeding (one individual was shot in 1888 in West Sussex, and other animals were seen in 1944-45 in Combe at about the same time in other counties too). According to Šprem and Zachos (2020) introductions to the British Isles are sometimes mentioned, but there is no reliable information available about this or any free-living populations resulting from these alleged introductions.

Occasional records are available also for the following countries:

- Czech Republic: the species was considered as present in game reserves in the Czech Republic as early as 1850 (Mlíkovský and Stýblo 2006) but is now considered extinct (Nobanis 2019).
- Ireland (Fairley 1975).

(8b): Croatia (introduced in 1911)

The only wild populations in the EU are in Croatia, on the islands of Brijuni and Dugi Otok (Šprem and Zachos 2020, Linnell and Zachos 2011, Duckworth et al. 2015).

Axis deer are present on the Veliki Brijun island, the largest island in the Brijuni archipelago. Animals are free on the island, which has a surface of 560 ha. Despite the fact that axis deer are described as capable swimmers (Nowak 1991), Axis deer has never been seen swimming from one island to another, unlike fallow deer (*Dama dama*), so it is considered that the population is restricted in these 560 ha (Public Institution National Park Brijuni and Hunting Directorate of the Ministry of Agriculture, pers. comm. 2020). However, according to Kusak and Krapinec (2010) some animals are observed to swim sometimes from Brijuni to the mainland in the estuary of Mirna river. Also Šprem and Zachos (2020) mention that several cases had been reported of axis deer swimming from Brijuni Islands to the mainland (ca. 3 km), but establishment of new populations was unsuccessful. See also Qu. 4.1.

According to Centore (2016), the first introduction in Croatia dates back to 1911, when several individuals were introduced into Brijuni island from Germany (Šprem et al. 2008). The genetic origin of the introduced animals, however, is unknown (Kusak and Krapinec 2010). According to Long (2003) the population derived from animals which escaped from captivity in 1911 and have increased in numbers substantially. In 2008 the population in the Brijuni National Park reached about 100 individuals, was considered stable and rather numerous (Šprem et al. 2008). According to Šprem and Zachos (2020), some 150 individuals were present in the islands of Brijuni in 2017 (but the same authors also stated that up to 200 animals are removed each year for population control, which may create some confusion about the actual population size in the island). As of April 1, 2019, 76 animals were present according to the Hunting Directorate of the Ministry of Agriculture (Public Institution National Park Brijuni and Hunting Directorate of the Ministry of Agriculture, pers. comm. 2020).

In the area of Dugi Otok island, axis deer is currently present in two hunting grounds: a common open hunting ground number: XIII / 107 " DUGI OTOK – ISTOK" in which the number of axis deer is estimated at 10 individuals, and the state open hunting ground number: XIII / 4 " DUGI OTOK" in which the number is estimated at 12 individuals (as of April 1, 2019). Axis deer in these hunting grounds are not managed, but are removed from the wild in accordance to the relevant legislation (Public Institution National Park Brijuni and Hunting Directorate of the Ministry of Agriculture, pers. comm. 2020). According to Šprem and Zachos (2020) the existence of the axis deer population on the island of Dugi Otok originated in 2012 by 13 individuals escaped from a fenced area from the Brijuni Islands, and increased to about 60 individuals in 2018.

Additional introductions with animals from Brijuni were made in other parts of Croatia but did not succeed. For example, in 1953 the population introduced in the island of Cres declined gradually over the years, the last specimen being recorded in the early 1990s (Frković 2014). The species is considered well established in Brijuni, and according to Centore (2016) survived until the present day due to the favourable climate.

Lever (1985) and Long (2003) report the introduction of two dozen axis deer released in Lithuania in 1954 (which reportedly adapted well and increased to 67 by 1961). However, this information seems not correct, and may well refer to sika deer (*Cervus nippon*) (see for example relevant information on Baleišis et al. 2003), in fact no information was found that axis deer has been ever introduced in Lithuania (Viktorija Maceikaite, pers. comm. 2019). In any case, no mention is made on the species in the review for Baltic countries made by Andersone-Lilley et al. (2010).

**A9. In which EU Member States could the species establish in the future under current climate and under foreseeable climate change? The information needs be given separately for current climate and under foreseeable climate change conditions.**

**A9a. Current climate: List Member States**

**A9b. Future climate: List Member States**

With regard to EU Member States, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)

- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

(9a):

Austria, Belgium, Bulgaria, Croatia, Republic of Cyprus, Czech Republic, Denmark, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden; and the United Kingdom (see details in Annex VII).

(9b):

Austria, Belgium, Bulgaria, Croatia, Republic of Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden; and the United Kingdom (see details in Annex VII).

**A10. Is the organism known to be invasive (i.e. to threaten or adversely impact upon biodiversity and related ecosystem services) anywhere outside the risk assessment area?**

The species is known to be invasive in several countries outside the risk assessment area (see review in Okarma et al. 2018b). For example, in its alien range it is considered invasive in the Andamane Islands (Banerji 1955, Ali and Pelkey 2013, Mohanty et al 2016) and the US, i.e. in Hawaii (Anderson 1999, GISD 2015) and Texas (Long 2003), as well as in Argentina (Flueck 2009), and Russia (Bobrov et al. 2008).

**A11. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea

Mediterranean: see answer to A12.

**A12. In which EU Member States has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden

Croatia: At high population density axis deer was reported to cause significant damage in gardens, orchards and vineyards (Frković 2014). The species is mentioned as invasive in Croatia by CABI database (<https://www.cabi.org/isc/datasheet/89941>) but very little information was found on the impact on biodiversity. As reported by the Public Institution National Park Brijuni and Hunting Directorate of the Ministry of Agriculture (pers. comm. 2020), it is difficult to say how much impact the axis deer itself has on the biodiversity of Brijuni National Park, but it is certain that mouflon and deer species significantly affect the biodiversity of Veliki Brijun islands where axis deer, mouflon and fallow deer are present. In the past, axis deer dominated over the other two species, but due to one harsh winter in the past many died and fallow deer has since prevailed. As the Public Institution National Park Brijuni has been reducing the number of deer specimens in recent years, currently mouflons are predominant. All three species together have a great impact on grasslands and forests of the island Veliki Brijun. Browsing and grazing of large herbivores that live on the island without natural predators affect lower layers of forests causing a problem for the natural reforestation and affect biodiversity of grassland allowing plants that the animals avoid (for example the Spanish oyster thistle *Scolymus hispanicus*) to overly spread.

According to the few data available from literature (see Šprem et al. 2008) the axis deer forages on *Fraxinus ornus*, *Quercus ilex* leaves and acorns, and sometimes browses the areas of *Myrtus communis*, new stems of blackberry (*Rubus spp.*), moss growing on rocks and cedar (*Cedrus spp.*) seeds. However, axis deer on the Brijuni Islands regularly consume supplementary feed such as hay and corn, regardless of the quality of the grassy areas (Šprem and Zachos 2020), therefore is likely that this prevents the species from having a greater (visible) impact on the island ecosystem. The evidence of higher impact may also be hidden by the fact that the populations in Croatia are all controlled through hunting (see Šprem and Zachos 2020). Always according to Šprem and Zachos (2020) axis deer impact on forest regeneration is less than other ungulates (i.e. European mouflon), but both terminal and lateral shoots are damaged.

**A13. Describe any known socio-economic benefits of the organism.**

including the following elements:

- Description of known uses for the species, including a list and description of known uses in the Union and third countries, if relevant.
- Description of social and economic benefits deriving from those uses, including a description of the environmental, social and economic relevance of each of those uses and an indication of associated beneficiaries, quantitatively and/or qualitatively depending on what information is available.

If the information available is not sufficient to provide a description of those benefits for the entire risk assessment area, qualitative data or different case studies from across the Union or third countries shall be used, if available.

The axis deer is considered by some as amongst the most beautiful of all deer (Prater 1965) and this may explain the popularity in zoological gardens and parks around the world (Schaller 1967, Sankar and Acharya 2004). According to the European Association of Zoos and Aquaria, about 625 specimens were kept by zoos across 12 EU Member States<sup>2</sup> and the United Kingdom in October 2019 (EAZA, pers. comm. 2019). These numbers concern only zoos that are members of EAZA and can only provide an indication about the situation across the EU.

As summarised by GISD (2015) the meat of axis deer (venison) is highly regarded as it is extremely lean. It consistently ranks in the top ten of all venison in the world (Anderson 1999). As a result, there is an economic value for the meat.

The axis deer is also a prized hunting quarry, owing to its beauty, especially stags with antlers longer than 76 cm (although it was considered as an unattractive trophy animal in Croatia by Frković, 2014). Recreational deer hunting can thus provide both tangible and intangible social benefits (Jesser 2005). Many game ranches receive upwards of US\$1000 for each trophy stag taken (Anderson 1999). In South Africa the costs for a trophy fee is €2,500 (<http://www.fgsafaris.com/PriceList.htm>, accessed on 26/07/2019). Poaching and black-market sales are common wherever the species occurs (Anderson 1999), and some documented evidence of skins and antlers seized from wildlife smugglers is available for India (TRAFFIC 2017).

---

## SECTION B – Detailed assessment

### Important instructions:

- In the case of lack of information the assessors are requested to use a standardized answer: “No information has been found.”
- With regard to the scoring of the likelihood of events or the magnitude of impacts see Annexes I and II.
- With regard to the confidence levels, see Annex III.
- Highlight the selected response score and confidence level in **bold** but keep the other scores in normal text (so that the selected score is evident in the final document).

## 1 PROBABILITY OF INTRODUCTION

### Important instructions:

- **Introduction** is the movement of the species into the risk assessment area (it may be either in captive conditions and/or in the environment, depending on the relevant pathways).
- **Entry** is the release/escape/arrival in the environment, i.e. occurrence in the wild and is treated in the next section (N.B. introduction and entry may coincide for species entering through pathways such as “corridor” or “unaided”).
- The classification of pathways developed by the Convention of Biological Diversity (CBD) should be used. For detailed explanations of the CBD pathway classification scheme consult the IUCN/CEH guidance document<sup>3</sup> and the provided key to pathways<sup>4</sup>.
- For organisms which are already present in the risk assessment area, only complete this section for current active pathways and, if relevant, potential future pathways.

**Qu. 1.1. List relevant pathways through which the organism could be introduced. Where possible give details about the specific origins and end points of the pathways as well as a description of any associated commodities.**

For each pathway answer questions 1.2 to 1.7 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 1.2a, 1.3a, etc. and then 1.2b, 1.3b etc. for the next pathway.

In this context a pathway is the route or mechanism of introduction of the species.

The description of commodities with which the introduction of the species is generally associated shall include a list and description of commodities with an indication of associated risks (e.g. the volume of trade; the likelihood of a commodity being contaminated or acting as vector).

If there are no active pathways or potential future pathways this should be stated explicitly

<sup>3</sup> <https://circabc.europa.eu/sd/a/738e82a8-f0a6-47c6-8f3b-aeddb535b83b/TSSR-2016-010%20CBD%20categories%20on%20pathways%20Final.pdf>

<sup>4</sup> <https://circabc.europa.eu/sd/a/Oaeba7f1-c8c2-45a1-9ba3-bcb91a9f039d/TSSR-2016-010%20CBD%20pathways%20key%20full%20only.pdf>

here, and there is no need to answer the questions 1.2-1.9

The following active pathways of introduction have been identified in the risk assessment area:

- a) Hunting (Release in nature)
- b) Farmed animals (including animals left under limited control) (Escape from confinement)
- c) Botanical garden/zoo/aquaria (excluding domestic aquaria) (Escape from confinement)

Another pathway known for the axis deer is “Landscape / flora / fauna “improvement” in the wild (release in nature)”. However, this pathway is only known in regions other than Europe (no evidence was available for the risk assessment area). For example, in Australia, the establishment of wild deer populations began in the mid-1800s, when Acclimatisation Societies released deer for hunting or for aesthetic reasons (Moriarty 2004, Long 2003, Davis et al. 2016). The species was introduced as ornamental also in Argentina (Novillo and Ojeda 2008). As this pathway is considered not active in the risk assessment area, it is not considered further in this document.

The “natural spread” of individuals from neighbouring countries, e.g. Moldova, Russia, Ukraine (Long 2003, Duckworth et al. 2015) is another possibility. The likelihood of the species appearing in the natural environment of Poland as a result of expansion from Ukraine (near Dnipropetrovsk and in the Volga region, i.e. over 1000 km from the Polish border), however, was considered very low within the next 15 years (Okarma et al. 2018b). Moreover, the occurrence of any free-living population in Ukraine and Moldova is considered questionable by Šprem and Zachos (2020). Therefore, also this pathway, is not considered active in the risk assessment area, and not considered further in this document. Similarly, it is likely that some animals are kept as pets by private owners, for example in Croatia (according to the Public Institution National Park Brijuni and Hunting Directorate of the Ministry of Agriculture, pers. comm. 2020) and in France (where according to JF Maillard, OFB/UPADE, as pointed out in a note to the EC, it must be rarely present with private owners due to administrative constraints, hence the risk exists but it must be low). However, as no escapes are reported from this pathway, this is not considered active in the risk assessment area, and not considered further in this document.

**a) Hunting (release in nature)**

**Qu. 1.2a. Is introduction along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	<b>intentional</b>	<b>CONFIDENCE</b>	low
	unintentional		medium
			<b>high</b>

This pathway refers to animals introduced into the risk assessment area to be hunted for food and/or to provide recreational hunting opportunities (including collection of hunting trophies). This is the typical pathway of introduction also in other regions, for example in Ukraine (Page et al. 2008), USA (GISD 2015), Argentina (Carpinetti and Merino 2000, Novillo and Ojeda 2008), Andamane Islands (Long 2003, Ali and Pelkey 2013, Banerji 1955), Australia (Massam et al. 2010, Moriarty 2004) and South Africa

**Qu. 1.3a. How likely is it that large numbers of the organism will be introduced through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in introduction whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Based on evidence relevant to past events, it is possible to expect further introductions and translocations of this species motivated by hunting purposes. Introduction is not expected to take place with large quantities (e.g. hundreds) of animals at one time. It would be expected, however, to be a number large enough to establish viable wild populations (considering that a number just above 7 animals is considered sufficient, see Qu. 2.3a.).

Several introductions occurred in Croatia, despite the unsuccessful result. As summarised by Frković (2014) as part of an extensive programme of introductions to continental hunting grounds, axis deer were brought from the Brijuni islands into several sites in the Croatian Littoral in 1953. A number of factors, such as the inadequately organized capture and transport of the animals, the insufficient preparation of the introduction sites, the poor adaptation of the animals to new habitat conditions, the inability to roam, and the calf mortality in winter season, led to the failure of such introductions. The only site where the number of the introduced axis deer increased was in Punta Križa (island of Cres), where it was hunted as early as in 1955. However, due to the damage it inflicted to vineyards and households, the axis deer was hunted freely without any protection for several years (1965–1970). When the more attractive mouflon (*Ovis musimon*) and fallow deer (*Dama dama*) were introduced to the area in 1962 and 1966, the axis deer population of Punta Križa gradually declined over the years, so that the last specimen was recorded in the early 1990s. Therefore, the only wild populations still present in Croatia are those of the islands of Brijuni and Dugi Otok (Šprem and Zachos 2020).

**Qu. 1.4a. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely	<b>CONFIDENCE</b>	low medium
-----------------	---------------------------	-------------------	---------------

	moderately likely likely <b>very likely</b>		<b>high</b>
--	---	--	-------------

The species is able to survive during passage along the pathway, as demonstrated by the fact that it has been successfully introduced in the past (e.g. in Croatia) and that secondary translocations occurred too. Hence, it is very likely that the animals survive during transport and storage along the pathway (provided appropriate animal welfare standards). The species is unlikely to reproduce or increase during such transport.

**Qu. 1.5a. How likely is the organism to survive existing management practices during transport and storage along the pathway?**

<b>RESPONSE</b>	N/A very unlikely unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low medium high
-----------------	--	-------------------	-----------------------

There are no management measures applicable during the introduction of animals.

**Qu. 1.6a. How likely is the organism to be introduced into the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

The intentional introduction for hunting purposes cannot go undetected (although this is valid for authorised releases only, as any illegal introduction would likely go undetected).

**Qu. 1.7a. Estimate the overall likelihood of introduction into the risk assessment area based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

The species was already introduced to the risk assessment area in the past along this pathway, but only in a very limited number of occasions.

**b) Farmed animals (including animals left under limited control) (Escape from confinement)**

**Qu. 1.2b. Is introduction along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	intentional unintentional	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	------------------------------	-------------------	------------------------------

This pathway refers to animals that have been introduced for farming into confinements, where they were kept with the primary purpose to provide food, resources and/or as working animals (it does not include animals held in zoos, deer parks and the likes, which are treated in the points below 1.2c to 1.7c). However, the number of axis deer farms present in the EU is unknown, and no information is available about the numbers of axis deer kept in such facilities.

The only documented evidence is a small population occurring in Croatia in a fenced area in the island of Rab (Centore 2016). In Germany, the species is kept in enclosures since 1707, although no occurrences are documented in the wild (Geiter et al. 2002, Nehring et al. 2015).

In Australia, the axis deer is the most popular farmed species among deer, and the most commonly released (Moriarty 2004). According to Massam et al. (2010), the species is used as livestock, e.g. for venison production, since the early 1800s in New South Wales (Moriarty 2004). In Texas the species occurs as a confined animal on ranches in 67 counties (Davis and Schmidly 1997, Long 2003).

**Qu. 1.3b. How likely is it that large numbers of the organism will be introduced through this pathway from the point(s) of origin over the course of one year? including the following elements:**

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in introduction whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

It is possible to expect further introductions and translocations of this species motivated by farming purposes, although data on this regard are not available. It is moderately likely that large numbers of animals are introduced for farming within one year.

**Qu. 1.4b. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the**

**organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

As demonstrated by the fact that it has been frequently kept in captive facilities, the likelihood of the animals to survive during transport and storage along the pathway is high, provided that appropriate animal welfare standards are ensured. Also, the likelihood of the axis deer to survive, reproduce, or increase in a fenced area is high, provided that the species requirements are duly considered and ensured (see for example Centore 2016, Centore et al. 2018).

**Qu. 1.5b. How likely is the organism to survive existing management practices during transport and storage along the pathway?**

<b>RESPONSE</b>	N/A very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

The likelihood of the axis deer to survive existing management practices in a fenced area will vary depending on the type of deer management and extent of disturbance in the area. In principle it might be high, provided that the species requirements are duly considered and ensured (see for example Centore 2016). For example, as reported by Centore et al. (2018), the population in the fenced area in the island of Rab is actively managed through hunting. The hunting technique is stalking, distributed year round, depending on hunting season, and is characterised by an annual hunting bag of 6 animals (4 adults and 2 yearling) with a sex ratios of 0.86:1 in favour of stags. However, this is not deemed to affect the population, which in fact was specifically created and maintained for hunting purposes.

**Qu. 1.6b. How likely is the organism to be introduced into the risk assessment area undetected?**

<b>RESPONSE</b>	<b>very unlikely</b> unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

The intentional introduction for farming purposes cannot go undetected.

**Qu. 1.7b. Estimate the overall likelihood of introduction into the risk assessment area based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

The species was already introduced into the risk assessment area in the past along this pathway, but only in a very limited number of occasions.

**c) Botanical garden/zoo/aquaria (excluding domestic aquaria) (Escape from confinement)**

**Qu. 1.2c. Is introduction along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	intentional unintentional	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	------------------------------	-------------------	------------------------------

Axis deer are known to be kept in zoos and wildlife parks for ornamental reasons. In fact this species was considered for centuries a favourite with zoological gardens and parks around the world (Schaller 1967, Sankar and Acharya 2004), and managed herds still occur in parks throughout the native and introduced range (Duckworth et al. 2015).

In Europe, the species is currently known to be present in captive facilities for ornamental reasons in many countries, like in the UK (Long 2003), Italy (Boitani et al. 2003), in Poland (Okarma et al. 2018b), as well as in Denmark, Estonia, France, Croatia, Netherlands, Austria, Portugal, Sweden, Spain, Czech Republic, Cyprus and Germany (see <https://www.zootierliste.de/?klasse=1&ordnung=121&familie=12110&art=1160403>).

According to the data from the European Association of Zoos and Aquaria (EAZA, pers. comm. 2019) taken from Species360 ZIMS the axis deer population in EAZA associated facilities is represented by 96 males, 236 females and 294 animals of unknown sex across 12 EU Member States<sup>5</sup> and the United Kingdom (information correct as of 03/10/2019).

**Qu. 1.3c. How likely is it that large numbers of the organism will be introduced through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in introduction whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
-----------------	---------------	-------------------	-----

<sup>5</sup> Austria, Denmark, Czechia, Estonia, France, Germany, Hungary, Italy, Netherlands, Portugal, Spain, Sweden

	unlikely <b>moderately likely</b> likely very likely		<b>medium</b> high
--	---	--	-----------------------

It is moderately likely that large numbers of animals are introduced for keeping in zoos and deer parks within one year. So far, according to the data from the European Association of Zoos and Aquaria (EAZA, pers. comm. 2019) taken from Species360 ZIMS the axis deer population in EAZA associated facilities, there are 29 zoos hosting axis deer, with a number of animals ranging from 3 to 76 in each single facility, and about 2/3 of the facilities have at least 10 animals.

**Qu. 1.4c. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

The likelihood of the animals to survive during transport and storage along the pathway is high, as demonstrated by the fact that it has been frequently kept in captive facilities (hence provided that appropriate animal welfare standards are ensured). Also, the likelihood of the axis deer to survive, reproduce, or increase in a fenced area is high, provided that the species requirements are duly considered and ensured (see for example Centore 2016, Centore et al. 2018).

**Qu. 1.5c. How likely is the organism to survive existing management practices during transport and storage along the pathway?**

<b>RESPONSE</b>	N/A very unlikely unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low medium high
-----------------	--	-------------------	-----------------------

There are no management measures applicable during the introduction of animals.

**Qu. 1.6c. How likely is the organism to be introduced into the risk assessment area undetected?**

<b>RESPONSE</b>	<b>very unlikely</b> unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

The intentional introduction into a zoological facility cannot go undetected.

**Qu. 1.7c. Estimate the overall likelihood of introduction into the risk assessment area based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Axis deer is abundant in zoos and deer parks and the likelihood of further introductions or transport of animals between existing facilities (from outside the EU into the risk assessment area) is moderately likely.

*End of pathway assessment, repeat Qu. 1.3 to 1.7 as necessary using separate identifier.*

**Qu. 1.8. Estimate the overall likelihood of introduction into the risk assessment area based on all pathways and specify if different in relevant biogeographical regions in current conditions.**

Provide a thorough assessment of the risk of introduction in relevant biogeographical regions in current conditions: providing insight in to the risk of introduction into the Union.

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

The species is already present in the risk assessment area through the described pathways, possibly leading to a risk of introduction in all biogeographical regions (but paucity of information on animals held in farms and parks does not allow to assess which regions exactly). It is to be noted, however, that apart from the one wild population in Croatia, itself restricted to an island, all current populations (by whatever route to date) are relative to animals held in confinement.

**Qu. 1.9. Estimate the overall likelihood of introduction into the risk assessment area based on all pathways in foreseeable climate change conditions?**

Thorough assessment of the risk of introduction in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of introduction (e.g. change in trade or user preferences)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely introduction within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

There is no evidence that climate change will have any effect on the likelihood of introduction via hunting, farming or keeping animals in zoological facilities.

## 2 PROBABILITY OF ENTRY

### Important instructions:

- Entry is the release/escape/arrival in the environment, i.e. occurrence in the wild. Entry is not to be, the movement of an organism within the risk assessment area.
- The classification of pathways developed by the Convention of Biological Diversity (CBD) should be used. For detailed explanations of the CBD pathway classification scheme consult the IUCN/CEH guidance document<sup>6</sup> and the provided key to pathways<sup>7</sup>.
- For organisms which are already present in the risk assessment area, only complete this section for current active or if relevant potential future pathways. This section need not be completed for organisms which have entered in the past and have no current pathway of entry.

### Qu. 2.1. List relevant pathways through which the organism could enter into the environment.

For each pathway answer questions 2.2 to 2.7 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 2.2a, 2.3a, etc. and then 2.2b, 2.3b etc. for the next pathway. In this context a pathway is the route or mechanism of entry of the species into the environment.

If there are no active pathways or potential future pathways this should be stated explicitly here, and there is no need to answer the questions 2.2-2.8

Pathway name:

The following active pathways of entry have been identified in the risk assessment area:

- a) Hunting (Release in nature)
- b) Farmed animals (including animals left under limited control) (Escape from confinement)
- c) Botanical garden/zoo/aquaria (excluding domestic aquaria) (Escape from confinement)

The “natural spread” of individuals from neighbouring countries, e.g. Moldova, Russia, Ukraine (Long 2003, Duckworth et al. 2015) is another possibility (but the occurrence of any free-living population in Ukraine and Moldova is considered questionable by Šprem and Zachos 2020). However, as no detailed information is available on the exact location and relevant population size, or the population and expansion trends, this is not considered an active pathway for the time being and the relevant risk cannot be quantified.

#### a) Hunting (Release in nature)

### Qu. 2.2a. Is entry into the environment intentional (e.g. the organism is released for a specific purpose) or unintentional (e.g. the organism escapes from a confinement)?

<sup>6</sup> <https://circabc.europa.eu/sd/a/738e82a8-f0a6-47c6-8f3b-aeddb535b83b/TSSR-2016-010%20CBD%20categories%20on%20pathways%20Final.pdf>

<sup>7</sup> <https://circabc.europa.eu/sd/a/Oaeba7f1-c8c2-45a1-9ba3-bcb91a9f039d/TSSR-2016-010%20CBD%20pathways%20key%20full%20only.pdf>

<b>RESPONSE</b>	<b>intentional</b> unintentional	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

This pathway refers to animals released intentionally into the natural environment to be hunted for food and/or to provide recreational hunting opportunities (including collection of hunting trophies). The release for hunting purpose used to be the main pathway for the species in Europe, as documented in Croatia (Frković 2014; Centore et al. 2018), where several entries into the wild occurred, some of which with successful result (although ultimately only one population has been kept viable until present).

This has been a typical pathway of entry also in other regions, for example in Ukraine (Page et al. 2008), USA (GISD 2015), Argentina (Carpinetti and Merino 2000, Novillo and Ojeda 2008), Andamane Islands (Long 2003, Ali and Pelkey 2013, Banerji 1955), Australia (Massam et al. 2010, Moriarty 2004) and South Africa (<https://www.invasives.org.za/legislation/item/709-axis-deer-axis-axis>, accessed on 26/07/2019).

**Qu. 2.3a. How likely is it that large numbers of the organism will enter into the environment along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of entry into the environment based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in entry whereas for others high propagule pressure (many thousands of individuals) may not).

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

It seems that a very small number of hinds and a few stags is sufficient to found a new population. Despite some uncertainty regarding the outcome of the introduction of axis deer, the propagule size in deer introductions is considered a highly significant predictor of establishment success, as introduction involving four or fewer individuals failed, whereas involving seven or more individuals succeeded (Forsyth et al. 2004).

In Croatia the axis deer population is managed only in the fenced part of the state open hunting ground (number: VIII / 6 - "KALIFRONT") on the island of Rab, where a parental stock of 63 heads and an increase of 15 heads per year is defined by the game management plan (Public Institution National Park Brijuni and Hunting Directorate of the Ministry of

Agriculture, pers. comm. 2020). This population originated from seven axis deer released in 1974 and resulting in a total of 78 animals during the 2015/2016 season, according to Centore et al. (2018). Axis deer in the island of Rab are all kept in a fenced area, but there are also animals reported out of the fence (Nikica Šprem pers. comm. 2020). However, any axis deer out of the enclosure needs to be removed from the wild in accordance to the relevant regulations (Public Institution National Park Brijuni and Hunting Directorate of the Ministry of Agriculture, pers. comm. 2020).

In other introductions occurred in countries outside Europe, the animals were subject to active management (i.e. hunting) therefore the data cannot be considered representative of any specific trend. However, several other introductions occurred in Croatia, although these were unsuccessful (see Qu 1.3a).

Outside the risk assessment area, in the Hawaiian Islands, deer populations flourished on Oahu, Molokai, and Lanai following releases. For example, as reported by Waring (1996) 8 axis deer (3 stags, 4 hinds, and one male fawn) were released in 1868 on Molokai Island where the population increased to 1,000 within 20 years and reached perhaps 7,500 before specific control measures were taken (see also Anderson, 1999). Similar trends were reported in other islands (Anderson 1999). In Queensland (Australia), one herd reported as still present by Bentley (1957) was established about 1866 by the introduction of a stag and two hinds. Similarly, in Rita Island (in Queensland) a population starting in the late 1970s from 20 individuals reached 2,000 or more in 2004 (Jesser 2005). In Ukraine, the number of axis deer increased from 25 individuals to 448 in 15 years (Anderson 1999), but no specific pathways are described. Also in Russia a population of axis deer grew rapidly, from 50 head in 1973 to 109 head in 1989 (Bobrov et al. 2008) but also in this case no specific pathways are described.

**Qu. 2.4a. How likely is the organism to enter into the environment within the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

The intentional release of the species in the wild for hunting purposes cannot go undetected (although this is valid for authorised releases only, as any illegal introduction would likely go undetected).

**Qu. 2.5a. How likely is the organism to enter into the environment during the months of the year most appropriate for establishment?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

There is no documented evidence about which particular time of the year would be more appropriate for establishment. The diverse diet and habitats requirements along with the

aseasonal reproduction patterns may open the window of opportunity for the entry of the species into the environment during most (if not all) months of the year. The likelihood of the animals to enter into the environment during the period most appropriate for establishment along this pathway therefore is high. Moreover, it is likely that hunters will release the animals in the most appropriate time and place, although there is no documented evidence that this has been systematically done (hence the low confidence).

**Qu. 2.6a. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host in the environment?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Same as in 2.5a.

**Qu. 2.7a. Estimate the overall likelihood of entry into the environment within the risk assessment area based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

The species has already entered the risk assessment area through this pathway, although there is no evidence that this is going to happen regularly.

**b) Farmed animals (including animals left under limited control) (Escape from confinement)**

**Qu. 2.2b. Is entry into the environment intentional (e.g. the organism is released for a specific purpose) or unintentional (e.g. the organism escapes from a confinement)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

This pathway refers to the unintentional escape of animals from confinements where they were kept with the primary purpose to provide food, resources and/or as working animals. However, the number of deer farms present in the EU is unknown, and no information is available about the number of axis deer kept in such facilities.

Escapes from farms is a well known risk also in regions other than the EU, e.g. Ukraine (Page et al. 2008). In Australia, axis deer is the most popular farmed species among deer and the most commonly released (Moriarty 2004). According to Massam et al. (2010) escapes occurred since the early 1800s in New South Wales. Also, escapes from private captive facilities are reported in the US, particularly in Texas (Long 2003). In the USA, the origin a

population introduced in the 1930s in Volusia County in Florida was caused by the escape from a private collection (Long 2003, Page et al. 2008).

**Qu. 2.3b. How likely is it that large numbers of the organism will enter into the environment along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of entry into the environment based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in entry whereas for others high propagule pressure (many thousands of individuals) may not).

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low medium high
-----------------	--	-------------------	-----------------------

Although there are no specific data for axis deer (with the exception of some generic reference of animals escaped from fenced areas, see Šprem and Zachos 2020), escapes of other species of deer from farms are well known in Europe, as in the case of the sika deer (Bartos 2009). For example, in France an increasing number of small free-living sika deer populations have been reported to enter the wild (and establish) during the last decades, mostly as a result of escapes from deer parks (Baiwy et al. 2013) which share many analogies with deer farms. Also in Germany, according to Bartos (2009), frequent escapes of sika deer from an enclosure near Neuhaus, Mönnesee, occurred (here axis deer were present too, thus showing the inherent risk of entry associated to this pathway). Escapes of sika deer occurred also in Lithuania (Baleišis et al. 2003) and in Poland (Solarz et al. 2018).

Escapes of axis deer from farms are documented in other countries beyond Europe, e.g. in Australia (Jesser 2005). There, axis deer is known to be farmed since 1803, and already 6 years later the escape of 400 animals was recorded (Moriarty 2004).

**Qu. 2.4b. How likely is the organism to enter into the environment within the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

This is a medium sized deer heavily spotted in all seasons, and although mostly active around dawn and dusk (Wilson and Mittermeier 2011) it may be easily detected by hunters,

naturalists, farmers, etc., hence it is unlikely to be introduced in the risk assessment area undetected. Nevertheless, the occurrence of other deer species throughout much of the risk assessment area may allow the entry of axis deer into the wild to go undetected by landowners and the general public not fully familiar with deer species differences.

**Qu. 2.5b. How likely is the organism to enter into the environment during the months of the year most appropriate for establishment?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

There is no documented evidence about which particular time of the year would be more appropriate for establishment, but it can be assumed that it is not during winter months (see for example limiting factors in Qu. 1.3a and 2.3a). The diverse diet and habitats requirements along with the aseasonal reproduction patterns may open the window of opportunity for the entry of escaped animals into the environment during most (if not all) months of the year.

**Qu. 2.6b. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host in the environment?**

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

The likelihood of the animals to be able to transfer from the pathway to a suitable habitat in the environment through this pathway depends on the actual location of the deer farm. It is considered unlikely because of the lack of documented evidence on this regard, but on the basis of the experience with other deer species, it is not possible to exclude that this may happen.

**Qu. 2.7b. Estimate the overall likelihood of entry into the environment within the risk assessment area based on this pathway?**

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

The species has not yet entered the wild through this pathway, however, there is some risk for such events to happen as long as animals are kept in such facilities. For example in relation to the population on the island of Rab, as the species is known to be a good swimmer and move across islands by covering also distances of 10 km (see Qu. 4.1). However, the sound assessment of this point is affected by the lack of information about the distribution of deer farms in Europe where the species is held and their biosecurity.

c) **Botanical garden/zoo/aquaria (excluding domestic aquaria) (Escape from confinement)**

**Qu. 2.2c. Is entry into the environment intentional (e.g. the organism is released for a specific purpose) or unintentional (e.g. the organism escapes from a confinement)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

This pathway refers to the unintentional escape of animals from facilities such as zoological and deer parks where they are confined within enclosures, displayed to the public, and in which they may also breed. Nevertheless, a part from the number of zoos associated to EAZA, the total number of zoos and deer parks present in the EU is unknown, and no information is available about the number of axis deer kept in such facilities.

In Europe, there is no documented evidence on escapes of the species from captive facilities, except for some general references for the UK (Long 2003), but this possibility cannot be completely ruled out. In fact, escapes from private captive facilities is a well known risk in regions other than Europe, e.g. a release from a zoo in Armenia is reported (Long 2003), and escapes from captive facilities are reported too, e.g. for Ukraine and the US, particularly in Texas (Long 2003). Also the origin of the population introduced during early 1940s to Point Reyes Peninsula (Marin County, California) was the San Francisco Zoo (Long 2003, Page et al. 2008).

**Qu. 2.3c. How likely is it that large numbers of the organism will enter into the environment along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of entry into the environment based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in entry whereas for others high propagule pressure (many thousands of individuals) may not).

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

No specific information has been found for axis deer, but it is considered unlikely that large numbers of animals escape from zoos or deer parks within one year.

Escapes of animals from deer farms and deer parks are however well known in Europe, as in the case of the sika deer (Bartos 2009). For example, in France an increasing number of small free-living sika deer populations have been reported during the last decades, mostly as a result of escapes from deer parks (Baiwy et al. 2013). According to Bartos (2009) frequent escapes of sika deer occurred in Germany, from an enclosure near Neuhaus, Möhnensee, where axis deer were present too, thus showing the inherent risk of entry associated to this pathway. Additionally, it is known that some populations of free-ranging fallow deer in Europe derive from escapes from deer parks.

It is however unknown how many axis deer are kept in deer farms and parks in Europe (with the notable exception of the animals kept in EAZA associated facilities (see Qu. 1.2c and 1.3c), and there is no documented evidence on escapes of this species from such facilities. Also in Croatia, the Ministry of Agriculture (responsible for hunting) and the Ministry of Environment and Energy (responsible for nature protection) confirmed that they do not have any data or information on the existence of axis deer populations held in captivity (Public Institution National Park Brijuni and Hunting Directorate of the Ministry of Agriculture, pers. comm. 2020).

**Qu. 2.4c. How likely is the organism to enter into the environment within the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

This is a medium sized deer heavily spotted in all seasons, and although mostly active around dawn and dusk (Wilson and Mittermeier 2011) it may be easily detected by hunters, naturalists, farmers, etc. hence it is unlikely to enter the wild in the risk assessment area as an escape from a zoo or deer park undetected. Nevertheless, the occurrence of other deer species throughout much of the risk assessment area may allow the entry of axis deer to go undetected by landowners and the general public not fully familiar with deer species differences.

**Qu. 2.5c. How likely is the organism to enter into the environment during the months of the year most appropriate for establishment?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

There is no documented evidence about which particular time of the year would be more appropriate for establishment, but it can be assumed that it is not during winter months (see for example limiting factors in Qu. 1.3a and 2.3a). The diverse diet and habitats requirements along with the aseasonal reproduction patterns may open the window of opportunity for the entry of escaped animals into the environment during most (if not all) months of the year

**Qu. 2.6c. How likely is the organism to be able to transfer from the pathway to a**

**suitable habitat or host in the environment?**

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

The likelihood of the animals to be able to transfer from the pathway to a suitable habitat in the environment through this pathway depends on the actual location of the zoological garden or deer park. It is considered unlikely because of the lack of documented evidence on this regard, but on the basis of the experience with other deer species, it is not possible to exclude that this may happen.

**Qu. 2.7c. Estimate the overall likelihood of entry into the environment within the risk assessment area based on this pathway?**

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

The species has not yet entered the wild through this pathway (as escapee from a zoo or deer park), but some risk for such events to happen exists as long as animals are kept in such facilities. However, the sound assessment of this point is affected by the lack of information about the distribution of zoos and deer parks in Europe where the species is held and their biosecurity.

*End of pathway assessment, repeat Qu. 2.2 to 2.7. as necessary using separate identifier.*

**Qu. 2.8. Estimate the overall likelihood of entry into the environment within the risk assessment area based on all pathways in current conditions and specify if different in relevant biogeographical regions.**  
Provide a thorough assessment of the risk of entry into the environment in relevant biogeographical regions in current conditions.

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

The most likely pathway of axis deer entry into the wild within the EU is the deliberate release for hunting (as it has happened in the Mediterranean biogeographical region in the past) and, less likely, the accidental/deliberate releases of individuals from deer farms and zoological gardens or deer parks.

**Qu. 2.9. Estimate the overall likelihood of entry into the environment within the risk assessment area based on all pathways in foreseeable climate change conditions and**

**specify if different in relevant biogeographical regions.**

Thorough assessment of the risk of entry in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk, specifically if likelihood of entry is likely to increase or decrease for specific pathways.

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

There is no evidence that climate change will have any effect on the likelihood of entry via the active pathways.

### 3 PROBABILITY OF ESTABLISHMENT

#### Important instructions:

- For organisms which are already established in parts of the risk assessment area, answer the questions with regard to those areas, where the species is not yet established.

**Qu. 3.1. How likely is it that the organism will be able to establish in the risk assessment area based on the history of invasion by this organism elsewhere in the world (including similarity between other abiotic conditions within it and the organism's current distribution)?**

RESPONSE		CONFIDENCE	
	very unlikely		low
	unlikely		medium
	moderately likely		<b>high</b>
	<b>likely</b>		
	very likely		

The only population established in the wild in the EU is in Croatia, on the islands of Brijuni, off Istria (Duckworth et al. 2015). However, environmental conditions similar to those present in the native and alien range of the species are present in other areas of the EU, particularly in the Mediterranean region, therefore it is likely that suitable sites exist elsewhere in all biogeographic regions in the risk assessment area (see Annex VII).

This may be partly confirmed by the fact that before being eradicated the axis deer was considered as successfully introduced also in New Zealand (Forsyth and Duncan 2001), a country partly sharing bio-climatic conditions similar to those found in Europe, as demonstrated by the many successful introductions of alien species of European origin.

Although native to tropical and subtropical areas of the Indian subcontinent, axis deer have adapted well to other ecoclimatic zones, including those present in the EU, such as the Mediterranean, and more continental climates in Russia (and the Ukraine, although the occurrence of any free-living population in this country is considered questionable by Šprem and Zachos 2020).

**Qu. 3.2. How widespread are habitats or species necessary for the survival, development and multiplication of the organism in the risk assessment area?**

RESPONSE		CONFIDENCE	
	very isolated		low
	isolated		<b>medium</b>
	moderately widespread		high
	<b>widespread</b>		
	ubiquitous		

Axis deer seem characterised by an extreme degree of flexibility and are well adapted to a wide variety of natural and semi-natural habitats and food, according to availability. Therefore, habitats or species (food sources) necessary for the survival, development and

multiplication of axis deer are moderately widespread in the risk assessment area, particularly in the Mediterranean region.

Axis deer occupy a wide range of habitats throughout their native range, and are most commonly associated with a mixture of forest and more open grass-shrub, often avoiding rugged terrain, almost exclusively at lower elevations, below 1000 m a.s.l. (GISD 2015). Axis deer are typically associated with forest and grasslands interfaces but are highly adaptable to a wide range of habitats and changing conditions, including suburban settings (Duckworth et al. 2015). In particular, axis deer are found throughout dry and mixed deciduous forest habitat and secondary forest lands broken by glades, with a presence of understorey of grasses, forbs and tender shoots which supply adequate drinking water and shade. Axis deer consume an extremely wide variety of plants throughout their native and introduced range: about 160–190 of plant species (Duckworth et al. 2015, Sankar and Acharya 2004). Axis deer are predominantly generalist grazers that also browse leaves, flowers, fruits, and seeds, as well as bark when the preferred food items are scarce or during droughts (Anderson, 1999, Long 2003, Wilson and Mittermeier 2011 Duckworth et al. 2015, Schaller 1967), and possibly also during winter. Moreover, when natural forage is insufficient, axis deer forage in cultivated crops and cause economic damage (Anderson 1999). As summarised by Duckworth et al. (2015), axis deer is known to feed on mushrooms, crabs, rubbish and occasionally even human faeces in areas close to human habitation. Moreover, like in other deer species, antler and bone chewing is also common. The need to drink water once a day, more frequently in summer, in general restricts them to forest areas with assured presence of water, even if widely scattered.

However, the species is characterised by flexibility as shown by the significant seasonal changes in temperature and, more significantly, extreme swings in precipitation in their native range. These conditions force the species to deal regularly with long periods of drought and poor forage availability, as well as widespread flooding and lush seasonal growth during the rainy season (GISD 2015, Anderson, 1999). Outside its native range, in Hawaii, for example, axis deer is present from semi-deserts to rainforests (Moe and Wegge 1994).

**Qu. 3.3. If the organism requires another species for critical stages in its life cycle then how likely is the organism to become associated with such species in the risk assessment area?**

RESPONSE	N/A	CONFIDENCE	low medium <b>high</b>
	very unlikely unlikely moderately likely likely very likely		

No specific organism is required to be associated to axis deer for critical stages in its life cycle.

In their native range, axis deer are known to be associated with other animals, particularly monkeys, which produce alarm sounds on the presence of predators like leopard (*Panthera pardus*) or tiger (*Panthera tigris*) (Dinesan et al. 2006). However, this facilitative/mutualistic relationship is opportunistic and not obligate, and there is no evidence that this is required for critical stages in the life cycle of the species.

**Qu. 3.4. How likely is it that establishment will occur despite competition from existing species in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

There is potential for competition with the native red deer (*Cervus elaphus*) and roe deer (*Capreolus capreolus*), as well as other ungulates in the risk assessment area, but as noted for other introduced deer species such competition is unlikely to prevent establishment. However, no specific studies on axis deer exist in the EU on this regard. Studies carried out in regions outside the EU, e.g. in USA (Texas), showed aggressive and dominant behaviour in axis deer toward white-tailed deer (*Odocoileus virginianus*), demonstrating that species coexistence is unlikely, at least at the spatial scale of the study and depending on factors such as population density of the two species and habitat quality (Faas and Weckerly 2010).

Axis deer seem unable to tolerate the presence of feral pigs (Lever 1994), however explicit research on this possible relation is not available.

**Qu. 3.5. How likely is it that establishment will occur despite predators, parasites or pathogens already present in the risk assessment area?**

<b>RESPONSE</b>	N/A very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

The enemies of axis deer in its native range vary from tiger to leopard, wild dog, jackal and python (Dinesan et al. 2006). In particular, jackals may kill fawns (Moe and Wegge 1994). As summarised by Sankar and Acharya (2004) in its native range in India the main cause of death is predation, mostly from tiger (*Panthera tigris*) and leopard (*Panthera pardus*). Outside the native range, predation was thought to limit the spread of axis deer, like in Australia, as a consequence of high density of dingo populations in some areas (Moriarty 2004). Wild boar (*Sus scrofa*) may also predate on axis deer fawns or juveniles, as reported in Argentina (Gürtler et al. 2017). However, the community of predators differ in the risk assessment area and their strategies are presumably different as well (see discussion below).

Other mortality factors in its native range are diseases (e.g. foot and mouth disease). The potential impact of an exotic epidemic like foot and mouth is demonstrated by the 1924 outbreak in California (Clements 2007). Also in Azerbaijan an introduced population was reduced by foot and mouth disease (Long 2003).

The risk assessment area is certainly characterised by the presence of potential predators, parasites or pathogens of axis deer, however there are several species of native and alien deer already occurring, and this does not seem to represent a limiting factor for their populations.

Predation from large carnivores may be less effective in the risk assessment area, given the lack of tigers and leopards, and the potential impact of the large carnivores occurring in Europe is unknown. Therefore, natural enemies and diseases are unlikely to affect the likelihood of species establishment. Moreover, the role of predators in controlling ungulate populations remains uncertain, and is considered not effective, at least in some systems (Côté et al. 2004). The situation may be different in island ecosystems, where ungulates, as a consequence of their co-evolutionary history with large predators, may have very high reproductive rates, causing rapid population growth. For example in Hawaii, in the absence of predators, introduced populations of axis deer exhibit annual population growth rates of 20–30% (Hess 2008). A detailed discussion is beyond the scope of this assessment, and in any case due to the lack of specific data may be too speculative. Moreover, predicting the impact of native predators on axis deer would be a challenging task also because the impact of predators may be sensitive to the composition of the multi-prey species community (e.g. for the wolf see Sand et al. 2016)

**Qu. 3.6. How likely is the organism to establish despite existing management practices in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Deer in Europe are usually subject to hunting and culling, which are regulated by law (see Apollonio et al. 2010). Poaching and overhunting has been a factor which led to the extinction of introduced populations of axis deer, e.g. in Croatia (Frković 2014). However, controlling axis deer may be problematic because it is a charismatic species, and there may be a conflict of interest between sectors obtaining recreational or economic gains from the exploitation of exotic wildlife and sectors promoting the conservation of biodiversity, as reported for Argentina (Gürtler et al. 2017).

**Qu. 3.7. How likely are existing management practices in the risk assessment area to facilitate establishment?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> <b>high</b>
-----------------	--	-------------------	-------------------------------------

Usually axis deer populations respond positively to higher levels of protection, water availability, forage quality, flat terrain and low predation, factors that are relatively widespread in the risk assessment area, although poaching and livestock grazing may be limiting factors (Duckworth et al. 2015). The availability of food and cover, which is usually provided to deer in game management reserves or in protected areas (where hunting may be forbidden, depending on the national legislation) may certainly favour the species establishment. Axis deer may benefit from water troughs established for cattle plus water sources on golf courses and homesites, as reported in Texas (Waring 1996). Also habitat restoration measures (i.e., prescribed burns and opening of fire breakers offering permanent

pastures) may benefit axis deer (Gürtler et al. 2017). In addition, reducing competition (and perhaps predation) from wild boar due to its heavy hunting in the risk assessment area, may lead to an increase of axis deer abundance, as shown by a study assessing the result of a control program targeting both species in Argentina (Gürtler et al. 2017), which would increase the chance of successful establishment.

**Qu. 3.8. How likely is it that biological properties of the organism would allow it to survive eradication campaigns in the risk assessment area?**

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

There is no information for the risk assessment area, but overhunting has been a clear factor which led to the extinction of introduced populations (see for example Frković 2014). Nevertheless it is interesting to consider a long-term study of hunted axis deer in the introduced range in Argentina (for detail see Gürtler et al. 2017), which showed that contrary to park managers’ expectations, the control program failed to reduce the axis deer population over a 10-year period despite increasing shooting effort and increasing deer harvest. Failure to reduce deer abundance may be explained by the combined effects of several putative processes: (1) population growth of axis deer over nearly two decades; (2) deer range expansion in the region leading to increasing immigration to the park; (3) sex- and stage-biased hunting mortality which kept per capita deer recruitment rates at sub-maximal levels, and (4) release from the pressure of wild boar (which was also a target of the control program) as a competitor (and perhaps as a predator).

Overall, the success of an eradication programme may depend on several factors, including the population size and the availability of resources. For example, in Russia the axis deer population of the Prioksko-Terrasny Nature Reserve (5,000 hectares) was reduced from 109 heads in 1989 to 5 in 2006 due to a control program (Bobrov et al. 2008).

**Qu. 3.9. How likely are the biological characteristics of the organism to facilitate its establishment in the risk assessment area?**

including the following elements:

- a list and description of the reproduction mechanisms of the species in relation to the environmental conditions in the Union
- an indication of the propagule pressure of the species (e.g. number of gametes, seeds, eggs or propagules, number of reproductive cycles per year) of each of those reproduction mechanisms in relation to the environmental conditions in the Union.

If relevant, comment on the likelihood of establishment based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

	likely very likely		
--	-----------------------	--	--

Key biological characteristic which may facilitate the establishment of axis deer in the risk assessment area are the behavioural variability, opportunism and the species' extreme adaptability to changing circumstances (Anderson, 1999). As summarised by Duckworth et al. (2015) and references therein, the axis deer is a prolific breeder, which is documented by several empirical studies of the speed of increase by newly introduced subpopulations or in those where a factor restraining subpopulations was removed. For example, the population explosion in the Andaman Islands is considered a consequence of a series of factors (beside the presence of good vegetation) such as fast maturity, high annual pregnancy rate, low fawn mortality (Sivakumar 2003). In Bhadra, India, following the departure from the park of human settlements and consequent removal of anthropogenic pressures on axis deer and habitats, axis deer populations bounced back by nearly seven times in less than four years (Duckworth et al. 2015).

In the wild, axis deer are characterised by an aseasonal reproduction pattern (Centore 2016, Graf and Nichols 1966). The reproductive cycle of individual stags is not synchronised with that of other stags in the herd, hence they are found in rutting conditions throughout the year, do not retain harems and mate with hinds in more herds as they become receptive (GISD 2015). Hinds also experience non-synchronised oestrous cycles, with each cycle lasting about 3 weeks, and typically produce one fawn per pregnancy after a 210-238 days gestation period (Davis and Schmidly 1997).

**Qu. 3.10. How likely is the adaptability of the organism to facilitate its establishment?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

The diverse diet requirements and the ecological flexibility which characterise the axis deer, along with the aseasonal reproduction patterns may facilitate the establishment of the species. Several other features of the species biology may explain the invasion success of the axis deer within the many introductions which occurred worldwide. For example, it is known to be a gregarious species, found in herds ranging from a few animals to 100 or more. In its native range, population densities fall within three to 50 animals per km<sup>2</sup> in India, up to around 200 axis deer per km<sup>2</sup> in Nepal (Duckworth et al. 2015). In Hawaii a herd as large as 300 was reported (Hess 2008). Natural lifespan of the species is 9-13 years, although zoo animals may reach 18-22 years (Davis and Schmidly 1997, Page et al. 2008).

**Qu. 3.11. How likely is it that the organism could establish despite low genetic diversity in the founder population?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Apparently, a very small number of hinds and a few stags seems sufficient to fund a new population (which may show the negligible impact of genetic diversity), although no data on the impact of low genetic diversity in the founder population are available. See also **Qu. 2.3a**.

**Qu. 3.12. If the organism does not establish, then how likely is it that casual populations will continue to occur?**

Consider, for example, a species which cannot reproduce in the risk assessment area, because of unsuitable climatic conditions or host plants, but is present because of recurring introduction, entry and release events. This may also apply for long-living organisms.

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

It is likely that high number of individuals are still kept and bred in captivity in the risk assessment area, which leads to a certain risk of some being intentionally or accidentally released in the wild, building up casual occurrences. The overall likelihood of casual population to occur seems low, but no sufficient data are available to support any statement on this regard.

**Qu. 3.13. Estimate the overall likelihood of establishment in the risk assessment area based on the similarity between climatic conditions within it and the organism’s current distribution under current climatic conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under current climatic conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in current conditions: providing insight in the risk of establishment in (new areas in) the Union.

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Providing that sufficient founder individuals are encountered (see point 2.3.a), the axis deer is likely to establish self-sustaining populations in almost all EU Member States (with the exception of Estonia and Finland, see Annex VII) because appropriate climatic conditions, habitats and food are present and local natural enemies and diseases are unlikely to affect establishment.

**Qu. 3.14 Estimate the overall likelihood of establishment in the risk assessment area under foreseeable climate change conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under foreseeable climate change conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in

foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of establishment (e.g. increase in average winter temperature, increase in drought periods)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely establishment within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Providing that sufficient founder individuals are encountered (see point 2.3.a), the axis deer is likely to establish self-sustaining populations in all EU Member States (see Annex VII) because appropriate climatic conditions, habitats and food are likely to be widespread (even more than in current conditions) and local natural enemies and diseases are unlikely to affect establishment.

## 4 PROBABILITY OF SPREAD

### Important instructions:

- Spread is defined as the expansion of the geographical distribution of an alien species within the risk assessment area.
- Repeated releases at separate locations do not represent continuous spread and should be considered in the probability of entry section. In other words, intentional anthropogenic “spread” via release or escape (“jump-dispersal”), should be dealt within the entry section. However, as repeated releases contribute to the spread of the target organism in the risk assessment area, the relevant pathway(s) should be briefly discussed here too, with an explicit reference to the entry section for additional details.

### Qu. 4.1. How important is the expected spread of this organism within the risk assessment area by natural means? (List and comment on each of the mechanisms for natural spread.)

including the following elements:

- a list and description of the natural spread mechanisms of the species in relation to the environmental conditions in the risk assessment area.
- an indication of the rate of each of those spread mechanisms in relation to the environmental conditions in the Union.

The description of spread patterns should include elements of the species life history and behavioural traits able to explain its ability to spread, including: reproduction or growth strategy, dispersal capacity, longevity, dietary requirements, environmental and climatic requirements, specialist or generalist characteristics.

<b>RESPONSE</b>	<b>minimal</b> minor moderate major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

The potential of axis deer to spread within the risk assessment area by natural means is likely to be minimal, but there are no data about the rate of spread of individuals in Europe (which may vary depending on the extent of deer management and disturbance, as well as habitat availability and connectivity, appropriate food resources, presence of other species acting as competitor/predators etc.). For example, Okarma et al. (2018b) pointed out that current information based on the lack of success of previous introductions in Europe and on biological characteristics of the species (size, life history, fertility, behaviour) allow to consider the spread rate of the population rather small.

Studies on spacing behaviour and habitat use in other parts of their native and alien range, show that animals are mostly sedentary and with small home ranges, usually between 180-890 ha (Long 2003, Moe and Wegge 1994), depending on resource availability (Waring 1996). Herds travel slowly at some 0.5 km/hour (Schaller 1967), but occasionally axis deer may make long trips to reach feeding grounds and water sources, for example during the dry season, and daily movements of up to 8 km for water have been reported (Graf and Nichols

1966). In Russia, the species was introduced approx. 100 km south of Moscow, in the Serpukhovskoe Hunting Reserve, and dispersed in about 10 years spontaneously to the Prioksko-Terrasnyi Biosphere Reserve through the Oka valley, just a few kilometres from the release site (Bobrov et al. 2008). In Queensland, although much of the area appears climatically suited to the species, axis deer were mostly concentrated surrounding their original release point, although drought may lead to wider dispersals of the animals (Jesser 2005).

Isolation of the axis deer in a small island, may not prevent the species from spreading. Axis deer are capable swimmers (Nowak 1991), and have been observed to swim fairly long distances between islands, i.e. about 3 km in Croatia (Šprem and Zachos 2020) and about 10 km in the Andaman Islands (Ali 2004, Ali and Pelkey 2003). In Brazil, the species is supposed to have reached the country from Uruguay by crossing the Uruguay River at the border between the two countries (Sponchiado et al. 2011).

**Qu. 4.2. How important is the expected spread of this organism within the risk assessment area by human assistance? (List and comment on each of the mechanisms for human-assisted spread and provide a description of the associated commodities.)**

including the following elements:

- a list and description of the anthropogenic spread mechanisms of the species in relation to the environmental conditions in the Union.
- an indication of the rate of each of those spread mechanisms in relation to the environmental conditions in the Union.

<b>RESPONSE</b>	<b>minimal</b> minor moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

The main (potential) pathway of spread is the natural dispersal across borders.

Otherwise axis deer were reportedly translocated and released intentionally in the risk assessment area for hunting purposes, e.g. in Croatia (Frković 2014). Moreover, the potential for spread after escapes from deer farms and deer parks should not be underestimated. The relevant introduction and entry pathways are already discussed in the corresponding sections above.

**Qu. 4.2a. List and describe relevant pathways of spread. Where possible give detail about the specific origins and end points of the pathways. For each pathway answer questions 4.3 to 4.9 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 4.3a, 4.4a, etc. and then 4.3b, 4.4b etc. for the next pathway.**

including the following elements:

- a list and description of pathways with an indication of their importance and associated risks (e.g. the likelihood of spread in the Union, based on these pathways; likelihood of survival, or reproduction, or increase during transport and storage; ability and likelihood of transfer from the pathway to a suitable habitat or host).

Where possible details about the specific origins and end points of the pathways shall be included.

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication.
- All relevant pathways should be considered. The classification of pathways developed by the Convention of Biological Diversity shall be used.

Natural dispersal across borders of invasive alien species that have been introduced through pathways 1 to 5.

**Qu. 4.3a. Is spread along this pathway intentional or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

This pathway is unintentional, as it depends on the dispersal capacities of the species. It is facilitated by the habitat conditions which characterise the area (including, for instance, the forest management regime and the recreational hunting practices, the extent of suitable ecological corridors etc.).

**Qu. 4.4a. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

No specific information is available on this regard. However as discussed in the sections above (see for example point 1.3a), it seems that in general a very small number of hinds and a few stags are sufficient to found a new population.

**Qu. 4.5a. How likely is the organism to survive, reproduce, or increase during transport**

**and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

The likelihood of the animals to survive, reproduce, or increase during spread (there is no transport and storage as such along this pathway) will vary depending on the extent of deer management and disturbance in the area (for examples in relation to land use practices, hunting, and other pressures).

**Qu. 4.6a. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

The likelihood of the animals to survive existing management practices during spread will vary depending on the extent of deer management and disturbance in the area (for examples in relation to the hunting regime for ungulates).

**Qu. 4.7a. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

This is a medium sized deer heavily spotted in all seasons, and although mostly active around dawn and dusk (Wilson and Mittermeier 2011) it may be easily detected by hunters, naturalists, and farmers; hence it is unlikely to be spreading in the risk assessment area undetected. Nevertheless, the occurrence of other deer species throughout much of the risk assessment area may allow the spread of axis deer to go undetected by landowners and the general public not fully familiar with deer species differences.

**Qu. 4.8a. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread? (including, where possible, details about the specific origins and end points of the pathway)**

<b>RESPONSE</b>	very unlikely unlikely moderately likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

	likely <b>very likely</b>		
--	------------------------------	--	--

No information available on this regard. Based on information from similar species, animals dispersing through natural spread are highly likely to find suitable habitats for survival throughout the risk assessment area, except in areas devoid of any woodland (see GB Non-Native Species Secretariat 2011). The species would not spread by natural means along unsuitable habitats.

**Qu. 4.9a. Estimate the overall potential rate of spread within the Union based on this pathway? (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly <b>slowly</b> moderately rapidly very rapidly	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Overall, natural spread from localised population is likely to be slow, but there are no data about the rate of spread of individuals in Europe (which may vary depending on e.g. the extent of deer management and disturbance).

*End of pathway assessment, repeat Qu. 4.3 to 4.9. as necessary using separate identifiers.*

**Qu. 4.10. Within the risk assessment area, how difficult would it be to contain the organism in relation to these pathways of spread?**

<b>RESPONSE</b>	very easy easy <b>with some difficulty</b> difficult very difficult	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Effective containment measures to prevent the spread of axis deer through the pathway above are the same as those to control/eradicate the species (see for example discussion on **Qu. 3.8.**), hence their applicability is context dependent, and depends on the size of the population and the invasion stage.

**Qu. 4.11. Estimate the overall potential rate of spread in relevant biogeographical regions under current conditions for this organism in the risk assessment area (indicate any key issues and provide quantitative data where possible).**

Thorough assessment of the risk of spread in relevant biogeographical regions in current conditions, providing insight in the risk of spread into (new areas in) the Union.

<b>RESPONSE</b>	very slowly <b>slowly</b> moderately rapidly	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

	very rapidly		
--	--------------	--	--

See Qu. 4.9a.

**Qu. 4.12. Estimate the overall potential rate of spread in relevant biogeographical regions in foreseeable climate change conditions (provide quantitative data where possible).**

Thorough assessment of the risk of spread in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk, specifically if rates of spread are likely slowed down or accelerated.

<b>RESPONSE</b>	very slowly <b>slowly</b> moderately rapidly very rapidly	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

No information has been found.

## 5 MAGNITUDE OF IMPACT

Important instructions:

- Questions 5.1-5.5 relate to biodiversity and ecosystem impacts, 5.6-5.8 to impacts on ecosystem services, 5.9-5.13 to economic impact, 5.14-5.15 to social and human health impact, and 5.16-5.18 to other impacts. These impacts can be interlinked, for example a disease may cause impacts on biodiversity and/or ecosystem functioning that leads to impacts on ecosystem services and finally economic impacts. In such cases the assessor should try to note the different impacts where most appropriate, cross-referencing between questions when needed.
- Each set of questions starts with the impact elsewhere in the world, then considers impacts in the risk assessment area (=EU excluding outermost regions) separating known impacts to date (i.e. past and current impacts) from potential future impacts (including foreseeable climate change).
- Only negative impacts are considered in this section (socio-economic benefits are considered in Qu. A.7)

### Biodiversity and ecosystem impacts

**Qu. 5.1. How important is the impact of the organism on biodiversity at all levels of organisation caused by the organism in its non-native range excluding the risk assessment area?**

including the following elements:

- Biodiversity means the variability among living organisms from all sources, including terrestrial, marine and other aquatic ecosystems and the ecological complexes of which they are part; this includes diversity within species, between species and of ecosystems
- impacted chemical, physical or structural characteristics and functioning of ecosystems

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Axis deer may cause significant direct impacts on native vegetation, e.g. through browsing and bark stripping, and may have a number of indirect effects on fauna and ecosystem processes. In general their impact (as an invasive alien species) is similar to that of other native deer, however it could amplify the pressure caused by ungulates on the natural environment. The impact may be even more severe where also other alien ungulates occur.

As summarised by Page et al. (2008) axis deer can feed on many species of native plants, as documented in the Hawaiian Islands (Hess 2008). Negative impact on natural regeneration of the native forests is also reported (Novillo and Ojeda 2008). In the Andaman Islands, where axis deer feed on over 70 different plant species (Sivakumar 2003), a negative impact on

seedling and sapling survival, as well as on forest regeneration and forest structure is documented (Ali 2004; Ali and Pelkey 2013). In northern Patagonia, Argentina, introduced deer (among which axis deer) cause significant modification of the forest understory and impair the regeneration of canopy tree species (Veblen et al. 1989, Veblen et al. 1992), which seemed to negatively affect also the endemic conifer *Austrocedrus chilensis* (Relva and Veblen 1998).

Significant impact to individual trees which may limit the forests renewal is known to occur during the rut (reproductive season) when stags rub and wipe the antlers against the bark, frequently causing secondary infections, which may lead to the death of the trees, for example in Hawaii (Anderson 1999). Additionally, in extreme drought conditions (and possibly in winter) axis deer may feed on the bark of trees (Anderson 1999).

Another threat to the habitat and native vegetation may be caused by the deer trampling behaviour, which may lead to the creation of trails and increasing erosion and runoff (Hess et al. 2015, Page et al. 2008), for example in the Hawaiian Islands (Anderson 1999, Hess 2008). As summarised by GISD (2015) this results in a loss of the stability that vegetation provides, with resulting destabilisation of stream banks, subsequent changes in stream flow and increasing erosion and sedimentation of streams, ponds and rivers. When deer populations become very large, their trailing behaviour creates dirt paths even through the thickest of vegetation. These trails can lead to significant erosion and, in wet forest areas, increase runoff by decreasing the moss layer from soil that would normally retain water (Centore 2016, Anderson 1999). Soil erosion induced by the species leading to consequent siltation of offshore coral reefs is reported in Hawaii (Lever 1994).

Additionally, by opening up of habitat or by selective browsing of understory vegetation, axis deer could help in the spread and establishment of alien, and probably invasive, plants (Mohanty et al. 2016). Anecdotal observations exist that high axis deer densities lead to exposing bare ground, e.g. by removing the vegetation, which in turn may increase light levels and disrupt moisture dynamics, hence facilitating the invasion of exotic weeds (Jesser 2005, Davis et al. 2016). An example is the parthenium (*Parthenium hysterophorus*), a native to the New World accidentally introduced into several countries, including Australia, where it is flourishing in areas where axis deer are not adequately controlled (Jesser 2005).

Axis deer may also have a potential for endozoochoric dispersal of native and exotic plants, as documented in the case of the exotic hog deer (*Axis porcinus*) in south-eastern Australia (Davis et al. 2010).

Competitive displacement of native deer is another (potential) impact, as reported in Argentina (Novillo and Ojeda 2008). Axis deer is a generalist species, and scarcity of forage in the dry (or cold) season may lead to niche overlap with other cervids (Bhattarai 2019). For example, axis deer outcompeted white-tailed deer (*Odocoileus virginianus*) in experimental enclosures over an eight-year follow-up in Texas (Anonymous 2016). This study was within enclosures, where by definition competition may be enhanced because there is no opportunity to avoid competition through niche differentiation or use of species-specific refugia, therefore the results are only indicative (but may reflect situations in closed environment, e.g. small islands). Another research conducted in Texas showed aggressive and dominant behaviour in axis deer toward white-tailed deer, which subsequently modified the habitat selection and feeding patterns (Faas and Weckerly 2010). Axis deer may have a competitive advantage over white-tailed deer for being less specialized in food requirements, while the role played by the different susceptibilities to parasitic disease (Richardson and Demarais 1992). Another study

carried out in an enclosure (although about the size of a small island or a small protected area) demonstrates that coexistence of these two species is unlikely, at least at the spatial scale of the studies and in any case depending on factors such as population density of each species and habitat quality (Faas and Weckerly 2010). Ferretti and Lovari (2014) stressed the difficulty to use an experimental approach in field conditions, but pointed out that evidence on overlap in the use of resources, opposing trends in population size, and behavioural interactions support the hypothesis of competition between alien ungulates and native ones. This however needs to be evaluated on a case by case.

Indirect effects on native biodiversity by altering ecosystem processes may be more subtle and affect also animals other than ungulates. For example, a study showed that in the Andaman archipelago axis deer depressed the abundance of forest floor and semi arboreal lizards approximately five-fold, by reducing vegetative cover in the understory (Mohanty et al. 2016).

Detrimental effects of axis deer are reported from outside the risk assessment area in relation to the conservation status of threatened species at the global level. This is mostly as a consequence of the habitat degradation, as documented by the IUCN Red List, in this case with examples limited to the situation in the Hawaii (BirdLife International 2016a, 2016b, 2016c, 2016d, 2018a, 2018b, 2018c, Bruegmann and Caraway 2003, Heddle 2004). For instance, this is deemed to affect four species that are considered Critically endangered (CR): the Pacific Lacefern (*Ctenitis squamigera*), the Olomao (*Myadestes lanaiensis*), the Maui Parrotbill (*Pseudonestor xanthophrys*) and the Ou (*Psittirostra psittacea*). Two additional species, the Maui Alauahio (*Paroreomyza montana*) and the Fabulous Green Sphinx Moth (*Tinostoma smaragditi*), are considered Endangered (EN). Because of its burrows trampled by axis deer and other ungulates, the Hawaiian Petrel (*Pterodroma sandwichensis*) is considered Vulnerable (VU). Axis deer also contributed to the destruction of the habitats of two extinct Hawaiian species (EX), the Black Mamo (*Drepanis funereal*) and the Bishop's Oo (*Moho bishop*).

Overabundant deer may apparently exert cascading effects on other animals by competing directly for resources with other herbivores and omnivores and by indirectly modifying the composition and physical structure of habitats of both invertebrates and vertebrates (Côté 2005). High deer abundance resulting from the introduction of alien deer species, may have strong indirect effect on forest birds through their impact on vegetation and associated insects. For example, as documented by Allombert et al. (2005) overabundance of white-tailed deer (*Odocoileus virginianus*) populations in North America, resulted in a decrease in songbird habitat quality through decreased food resources and nest site quality and may partly explain continental-scale decreases in songbird populations. An introduced herbivore may even lead to the indirect extirpation of an abundant large carnivore, as documented in a large island in Canada, where the near eradication of shrubs producing berries by introduced white-tailed deer (*O. virginianus*) was considered as the main cause of the extirpation of black bears (*Ursus americanus*) within approximately 50–70 years (Côté 2005). As a remark, the examples above pertain to other deer species in countries other than the EU, and as such do not necessarily apply to axis deer in particular, especially if those deer are not at high densities. However, the information was deemed indicative for the purpose of this assessment, to show the diversity of impacts potentially emerging from the introduction of a new deer species in the EU.

**Qu. 5.2. How important is the current known impact of the organism on biodiversity at all levels of organisation (e.g. decline in native species, changes in native species)**

**communities, hybridisation) in the risk assessment area (include any past impact in your response)?**

Discuss impacts that are currently occurring or are likely occurring or have occurred in the past in the risk assessment area. Where there is no direct evidence of impact in the risk assessment area (for example no studies have been conducted), evidence from outside of the risk assessment area can be used to infer impacts within the risk assessment area.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

No direct evidence of impact in the risk assessment area exists other than what is reported for the presence of the species in Croatia.

As reported by the Public Institution National Park Brijuni and Hunting Directorate of the Ministry of Agriculture (pers. comm. 2020) it is difficult to say how much impact the axis deer itself has on the biodiversity of Brijuni National Park, but it is certain that mouflon and deer species significantly affect the biodiversity of Veliki Brijun islands (where axis deer, mouflon and fallow deer are present). In the past, axis deer dominated over the other two species, but due to one harsh winter in the past many died and fallow deer has since prevailed. As the Public Institution National Park Brijuni has been reducing the number of deer specimens in recent years, currently mouflons are predominant. All three species together have a great impact on grasslands and forests of the island Veliki Brijun. Browsing and grazing of large herbivores that live on the island without natural predators affect lower layers of forests causing a problem for the natural reforestation and affect biodiversity of grassland allowing plants that the animals avoid (for example the Spanish oyster thistle *Scolymus hispanicus*) to overly spread. According to the few available data from literature, in the island of Brijuni, axis deer are known to feed on grasses and ash (*Fraxinus ornus*) leaves and holm oak (*Quercus ilex*) leaves and acorns, and sometimes browse the leaves of myrtle (*Myrtus communis*), new stems of blackberry (*Rubus* spp.), mosses growing on rocks, and cedar (*Cedrus* spp.) seeds (Šprem et al. 2008). No information on the type and scale of impact is available. It must be noted that the island of Brijuni is characterised by a very intense human use, limiting the possibility of observing impacts on natural ecosystems of the axis deer.

A couple of studies were carried out in the hunting reserve in the Island of Rab (Krapinec 2002a, 2002b), but their results may be of limited applicability for the assessment of impacts in the wild, because the location was inside an actively managed forest in a fenced area.

Based on evidence from outside the risk assessment area it can be expected that overabundant deer may have a substantial impact on woodland vegetation (modifying patterns of relative abundance and vegetation dynamics), and play a significant role in woodland ecosystem function. In case axis deer would get established on islands, the impacts on the local ecosystems as well as on some bird species (e.g. petrels) could be severe. In the absence of control (either by predators or humans), deer populations can rise to very high densities. This may be further facilitated by human management of forests providing ideal habitats. Vegetation changes brought about by browsing and trampling axis deer are detrimental to other deer species as well as other vertebrate and invertebrate species (see note by Gill 2000). Cascading effects on other species may extend to insects, birds, and other vertebrates. Hence,

axis deer may tip forest ecosystems toward alternative states by acting as “ecosystem engineers” or “keystone herbivores”, as generally noted for deer (Côté et al. 2004).

According to Okarma et al. (2018b) in the worst case axis deer may locally cause hardy reversible changes in ecosystem functioning. According to Okarma et al. (2018b) it can therefore be assumed that in the event of spreading in Poland, the impact could lead to serious decreases in the population size of some native protected species. In Poland, it can be expected that axis deer may exert a certain negative impact on native deer species, as also remarked by the Council of Europe (2002) for Croatia. The potential for competition with native deer may be particularly strong because such species have not shared a common evolutionary history. Additionally, some possible competition with European bison (*Bison bonasus*) may be expected in Poland, should axis deer become established and widespread in this country (Okarma et al. 2018b).

**Qu. 5.3. How important is the potential future impact of the organism on biodiversity at all levels of organisation likely to be in the risk assessment area?**

See comment above. The potential future impact shall be assessed only for the risk assessment area.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

In the event of substantial spread and increase in numbers of axis deer to new parts of the risk assessment area, the impact may be expected to increase accordingly, even despite the possible presence of predators. However, there are no elements to foresee that the impact would lead to any irreversible change, therefore the risk is considered “moderate”. Because there is no documented evidence the confidence is low.

**Qu. 5.4. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism currently in the risk assessment area?**

including the following elements:

- native species impacted, including red list species, endemic species and species listed in the Birds and Habitats directives
- protected sites impacted, in particular Natura 2000
- habitats impacted, in particular habitats listed in the Habitats Directive, or red list habitats
- the ecological status of water bodies according to the Water Framework Directive and environmental status of the marine environment according to the Marine Strategy Framework Directive

<b>RESPONSE</b>	minimal minor <b>moderate</b> major	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

	massive		
--	---------	--	--

The axis deer may represent a potential threat for a series of species and habitats protected by the Birds and Habitats directives, as well as a number of IUCN red-listed species, as shown in countries outside the risk assessment area. The effect of axis deer on protected species of plants and relevant habitats would reflect its browsing habits and diet, as well as the ability of the plants to withstand damage (including from trampling, etc.). Therefore, several plants may be susceptible to axis deer impact, not to consider the cascading effects that overabundant axis deer populations may apparently exert on other ungulates (see for the possible competition with *Bison bonasus*, which could occur if the species were to establish in Poland, Qu. 5.2) and other groups of animals as well, including birds on islands.

**Qu. 5.5. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism likely to be in the future in the risk assessment area?**

including the following elements:

- native species impacted, including red list species and species listed in the Birds and Habitats directives
- protected sites impacted, in particular Natura 2000
- habitats impacted, in particular habitats listed in the Habitats Directive, or red list habitats
- the ecological status of water bodies according to the Water Framework Directive and environmental status of the marine environment according to the Marine Strategy Framework Directive

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

In the event of substantial spread and increase in numbers of axis deer to new parts of the risk assessment area, the impact may be expected to increase accordingly. In case of a future expansion of the species range, other native species may be affected. While there is no documented evidence of the species being able to cause the extinction of any native species, the level of risk is assessed as being “moderate” also in the future.

**Ecosystem Services impacts**

**Qu. 5.6. How important is the impact of the organism on provisioning, regulating, and cultural services in its non-native range excluding the risk assessment area?**

- For a list of relevant services use the CICES classification V5.1 provided as an annex.
- Impacts on ecosystem services build on the observed impacts on biodiversity (habitat, species, genetic, functional) but focus exclusively on reflecting these changes in relation to their links with socio-economic well-being.
- Quantitative data should be provided whenever available and references duly reported.

- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Axis deer may affect several ecosystem services, not only through the discussed impacts on biodiversity, but also due to the impacts documented on ornamental plants and agricultural crops through browsing and bark stripping, for example in the Hawaiian Islands (Hess 2008). The erosion caused by the trampling behaviour associated with the death of trees caused by the habit to wipe their antlers on the barks, may results in destabilisation of stream banks, changes in stream flow and increased erosion and sedimentation of waterways (Anderson 1999, GISD 2015). Additionally, it is known that the trailing behaviour has caused erosion and damage to a variety of culturally or archaeologically significant sites in Hawaii (Anderson 1999). The role of axis deer in the regulation of zoonosis, because of its pathogens and parasites, is another possible threat to both wildlife and livestock, and to humans (Okarma et al. 2018b).

Here follows a list of potential impacts on ecosystem services (based on the CICES classification V5.1):

#### Provisioning (Biomass)

- Cultivated terrestrial plants
- Reared animals
- Wild plants (terrestrial and aquatic)
- Wild animals (terrestrial and aquatic)

#### Regulation & Maintenance (Regulation of physical, chemical, biological conditions)

- Baseline flows and extreme event regulation
- Lifecycle maintenance, habitat and gene pool protection
- Pest and disease control
- Soil quality regulation
- Water conditions

#### Cultural (Direct, in-situ and outdoor interactions with living systems that depend on presence in the environmental setting)

- Physical and experiential interactions with natural environment
- Intellectual and representative interactions with natural environment

**Qu. 5.7. How important is the impact of the organism on provisioning, regulating, and cultural services currently in the different biogeographic regions or marine sub-regions where the species has established in the risk assessment area (include any past impact in your response)?**

- See guidance to Qu. 5.6.

<b>RESPONSE</b>	minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	--	-------------------	-----------------------

No information has been found. It is worth mentioning that the value of hunting provided by game species can be an argument for introducing, translocating and preserving populations of these species, e.g. the fallow deer (*Dama dama*) in the risk assessment area. However, only little information is available for the target species (see point A13).

**Qu. 5.8. How important is the impact of the organism on provisioning, regulating, and cultural services likely to be in the different biogeographic regions or marine sub-regions where the species can establish in the risk assessment area in the future?**

- See guidance to Qu. 5.6.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

In the event of substantial spread and increase in numbers of axis deer to new parts of the risk assessment area, the impact may be expected to increase accordingly (at the moment there is no evidence of impact, but should the population grow and spread, the impact may become evident). As there is no documented evidence of the species being able to cause other types of impact, the level of risk can be expected to be “moderate” in the future. However, because of paucity of information, confidence of this assessment is low.

## Economic impacts

**Qu. 5.9. How great is the overall economic cost caused by the organism within its current area of distribution (excluding the risk assessment area), including both costs of / loss due to damage and the cost of current management.**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the world these should be reported here. The assessment of the potential costs of / loss due to damage shall describe those costs quantitatively and/or qualitatively depending on what information is available. Cost of / loss due to damage within different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

As pointed out by Page et al. (2008), the species is capable of having an impact on sheep, cattle, cereal grain, grain legumes, and other fruit (pineapple) commodities. Crop damages by

axis deer, particularly when other available forage is scarce, have been described in both the native and the introduced range (Anderson 1999, Hess et al. 2015, GISD 2015, Page et al. 2008). For example, in Hawaii severe and extensive damage to the pineapple industry on Lānai was reported (Lever 1994, Hess et al. 2015). In Maui, more specifically, deer were blamed to be responsible of an estimated \$35,000 to \$55,000 in crop losses to Maui Pineapple Co., and one farmer claimed about 40 deer caused US \$20,000 in fence and corn crop damage in one night (Kubota 2001).

When overgrazing occurs, axis deer are known to compete with livestock and native wildlife (Long 2003). Being primarily grazers, axis deer compete for food mainly with domestic cattle and sheep (Lever 1994). In particular, direct competition for forage with cattle is reported in both California and in Texas (Anderson 1999). In California, in Point Reyes National Seashore, the cost to the park for staff, equipment, vehicles and supplies to monitor and manage non-native deer (both axis deer and fallow deer) was approximately \$140,000, or 2.5% of the park annual budget (GISD 2015, National Park Service 2004). In Argentina, although regularly hunted, axis deer populations have increased in some provinces, interfering with livestock production (Flueck 2009).

Deer may transmit infectious diseases directly to livestock (as well as to other deer and to humans), especially if deer density is high (Côté et al. 2004). In particular, axis deer have been shown to carry and transmit bovine tuberculosis (*Mycobacterium bovis*) and several other diseases in both the native range, i.e. in India (Schaller 1967) and the introduced range. For example, in Hawaii, bovine tuberculosis was found in five percent of deer from Molokai, posing an ongoing threat to cattle trade throughout the islands (Hess et al. 2015). In California, in addition to carrying several livestock and wildlife diseases, a small percentage of axis deer also harboured John's disease (*Mycobacterium paratuberculosis*), a contagious bacterial disease of the small intestines of ruminants (Hess et al. 2015). In Russia, the species was considered responsible for the introduction of the deer louse fly (*Lipoptena cervi*) (Bobrov et al. 2008), although this parasite is considered native to the region. However, some studies suggest that the indigenous parasite fauna of small founder populations of introduced exotic ungulates, such as the axis deer in Hawaii, frequently does not persist in their free-ranging progeny and that subsequent parasite communities acquired from sympatric ungulates are of limited diversity and comprised primarily of species exhibiting a broad host range (McKenzie and Davidson 1989).

Besides carrying parasites and pathogens, axis deer are responsible for a number of deer-vehicle collisions, as regularly documented on Molokai, Hawaii (Anderson 1999, Page et al. 2008), however the economic impact is not quantified.

**Qu. 5.10. How great is the economic cost of / loss due to damage (excluding costs of management) of the organism currently in the risk assessment area (include any past costs in your response)?**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the EU these should be reported here. Assessment of the potential costs of damage on human health, safety, and the economy, including the cost of non-action. A full economic assessment at EU scale might not be possible, but qualitative data or different case studies from across the EU (or third countries if relevant) may provide useful information to inform decision making. In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. Cost of / loss due to damage within

different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

No direct evidence of impact in the risk assessment area exists other than what is reported in Croatia. For example, in the island of Cres, the axis deer inflicted damage to vineyards and households (Frković 2014). No economic damage was recorded in the Island of Rab in a study aimed at the analysis of the feeding activities of axis deer and mouflon (*Ovis ammon*) in an actively managed (fenced) forest community of holm oak and manna ash (*Fraxino orn-Quercetum ilicis*) (Krapinec 2002a).

Okarma et al. (2018b) considered that in case the species established in Poland, the impact of the species on crops would be “medium”.

**Qu. 5.11. How great is the economic cost of / loss due to damage (excluding costs of management) of the organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 5.10.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

In the event of substantial spread and increase in numbers of axis deer to new parts of the risk assessment area, the impact may be expected to increase accordingly.

Overabundant deer are known to inflict major economic losses in forestry, agriculture, and transportation and contribute to the transmission of several animal and human diseases (Côté et al. 2004). See also comments in **Qu. 5.19** and **Qu. 5.10**.

**Qu. 5.12. How great are the economic costs / losses associated with managing this organism currently in the risk assessment area (include any past costs in your response)?**

- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”.

<b>RESPONSE</b>	minimal minor moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

No information has been found.

**Qu. 5.13. How great are the economic costs / losses associated with managing this organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 5.12.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

In the event of substantial spread and increase in numbers of axis deer to new parts of the risk assessment area, the costs may be expected to increase accordingly. If the species spreads and is to be managed, some costs are bound to be incurred, even if there is no info on what these costs are currently. But it is not possible to estimate the monetary value, as it depends on deer management systems and policies involved, which vary considerably across the different countries of Europe depending on species present, legislation, cultural tradition and the status of deer as *res nullius* or *res communis*.

### Social and human health impacts

**Qu. 5.14. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism for the risk assessment area and for third countries, if relevant (e.g. with similar eco-climatic conditions).**

The description of the known impact and the assessment of potential future impact on human health, safety and the economy, shall, if relevant, include information on

- illnesses, allergies or other affections to humans that may derive directly or indirectly from a species;
- damages provoked directly or indirectly by a species with consequences for the safety of people, property or infrastructure;
- direct or indirect disruption of, or other consequences for, an economic or social activity due to the presence of a species.

Social and human health impacts can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Deer may transmit infectious diseases directly to humans (as well as to other deer and to livestock), especially if deer density is high (Côté et al. 2004). The axis deer, as other ungulates (hence similar to native species), can be a carrier of a number of diseases and parasites that may be harmful to humans. For example, they carry common parasites that may

directly affect humans, i.e. if droppings enter freshwater systems (GISD 2015). Parasitic zoonoses harbored by the species include: leptospirosis, cryptosporidiosis, and strains of *Escherichia coli* (Anderson 1999). A potential role of axis deer and their associated ticks (e.g. *Ixodes pacificus*) in the ecology of the Lyme disease spirochete, *Borrelia burgdorferi*, was evidenced through a study in California, USA (Lane and Burgdorfer 1986, Page et al. 2008). However the relationship between density of deer (and other large herbivores) in the environment and environmental tick burden is controversial, with different studies coming to different conclusions, hence the information above should be considered only indicative.

Overall, as pointed out for alien mammals in general (Capizzi et al. 2018), axis deer can act as vectors of both alien and native pathogens, and as host of either native or alien parasites (which in turn can be acting as vectors of either native or alien pathogens). In this way axis deer may either introduce new pathogens, alter the epidemiology of local pathogens, become reservoir hosts, and increase disease risk for humans, along with other species (e.g. by introducing changes in the vector-host-parasite relationship). However, we could not find any evidence of the species hosting new alien species, or increasing the rate or intensity of infections of pathogens.

In addition to carrying diseases that can infect humans, axis deer may cause road collisions, e.g. as reported in the Hawaiian Islands (Hess 2008). On Maui roads, for example, at least 36 motor vehicle collisions with axis deer occurred during an 18-month period between 1999 and 2000, see <http://archives.starbulletin.com/2001/08/28/news/story8.html>).

An indirect human health issue that deer axis pose in Hawaii is the potential for stray bullets to hit people as poaching increases (Anderson 1999). In any case shooting for managing the species is considered potentially dangerous and has led to complaints as it may represent a safety risk for residents, e.g. mostly because is conducted at night, as reported in Australia (Mitchell 2015).

Axis deer is an animal that is unlikely to make an unprovoked attack but such attacks can cause serious injury (requiring hospitalisation) or fatality if animals are cornered or handled (Page et al. 2008).

**Qu. 5.15. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism in the future for the risk assessment area.**

- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

In the event of substantial spread and increase in numbers of axis deer to new parts of the risk assessment area, the impact may be expected to increase accordingly.

## Other impacts

**Qu. 5.16. How important is the impact of the organism as food, a host, a symbiont or a vector for other damaging organisms (e.g. diseases)?**

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Deer, in general, may transmit infectious diseases directly to other species of deer (as well as to livestock, and to humans), especially if their density is high (Côté et al. 2004). The axis deer, as other ungulates, can be a carrier of a number of diseases and parasites that may be harmful to native species. For example, this species is involved in the transmission of bovine tuberculosis (Anderson 1999, Schaller 1967), which is a deadly disease for native ungulates, including the European bison (*Bison bonasus*), as pointed out by Okarma et al. (2018b). Other diseases transmitted by axis deer in their native range are leptospirosis and cryptosporidiosis (Anderson 1999, Schaller 1967). The species may also act as a new host for native parasites, as in the case of the tick *Amblyomma dubitatum* found on axis deer in northern Argentina, and this interrelationship may have potential deleterious effects on the native fauna, due to acquisition and amplification of the native parasite by an introduced host (Debárbora et al. 2012).

**Qu. 5.17. How important might other impacts not already covered by previous questions be resulting from introduction of the organism?**

<b>RESPONSE</b>	minimal minor moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

No information has been found.

**Qu. 5.18. How important are the expected impacts of the organism despite any natural control by other organisms, such as predators, parasites or pathogens that may already be present in the risk assessment area?**

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

As described in Qu.3.5 the risk assessment area is certainly characterised by the presence of potential predators, parasites or pathogens of axis deer. However, there are several species of native and alien deer already occurring here, and this does not seem to represent a limiting factor for the relevant populations (predation from the large carnivores may be less effective than in the native range, given the lack of tigers and leopards). In fact, the role of predators in

controlling ungulate populations remains uncertain as pointed out by Côté et al. (2004), and is considered not effective, at least in some ecosystems.

The situation may be different in island ecosystems, where ungulates, as a consequence of their co-evolutionary history with large predators, may have very high reproductive rates, causing rapid population growth in the absence of predators. For example, in Hawaii, introduced axis deer exhibit annual population growth rates of 20–30% (Hess 2008).

**Qu. 5.19. Estimate the overall impact in the risk assessment area under current climate conditions. In addition, details of overall impact in relevant biogeographical regions should be provided.**

Thorough assessment of the overall impact on biodiversity and ecosystem services, with impacts on economy as well as social and human health as aggravating factors, in current conditions.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

The species is known to exert a multifaceted impact on both biodiversity and ecosystem services, by feeding on native vegetation and contributing to the loss of habitat structure and function (hence indirectly affecting other species, including birds, reptiles, invertebrates, etc.). Competition with other ungulates is documented. The species is known to contribute to the spread of diseases and pathogens affecting both livestock and humans. It can also damage crops and compete with livestock. It can be a threat in relation to possible deer/vehicle collisions. No documented exists to provide discuss in details the overall impact in the biogeographical regions.

**Qu. 5.20. Estimate the overall impact in the risk assessment area in foreseeable climate change conditions. In addition, details of overall impact in relevant biogeographical regions should be provided.**

Thorough assessment of the overall impact on biodiversity and ecosystem services, with impacts on economy as well as social and human health as aggravating factors, under future conditions.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

In foreseeable climate change conditions, the area suitable for the species in the risk assessment area may increase (see Annex VII), and the impact may be expected to increase accordingly. For example, in case of a future expansion of the species range, other native species may be affected. No documented evidence exists to discuss in details the overall impact in the biogeographical regions.

<b>RISK SUMMARIES</b>			
	<b>RESPONSE</b>	<b>CONFIDENCE</b>	<b>COMMENT</b>
<b>Summarise Introduction*</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	low medium <b>high</b>	The species is already present in the risk assessment area (in the wild and in confinements). Further introductions for hunting, farming or exhibitions are considered possible.
<b>Summarise Entry*</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	low medium <b>high</b>	Releases or escapes from captive facilities have been documented in the past in the risk assessment area and may take place again.
<b>Summarise Establishment*</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	low medium <b>high</b>	Axis deer, although native to tropical and subtropical areas of the Indian subcontinent, has the ability to establish in other ecoclimatic zones, including those present in the EU, such as the Mediterranean. In Croatia it is currently established. The species life-history, available habitat conditions and management practices in the EU offer the potential to support self-sustaining populations of axis deer also in other countries and biogeographical regions.
<b>Summarise Spread*</b>	very slowly <b>slowly</b> moderately rapidly very rapidly	<b>low</b> medium high	The species has a sedentary habit, but is also known to spread over some distance in specific circumstances (e.g. suitability of habitat, lack of predators), including across islands given the good swimming skills.
<b>Summarise Impact*</b>	minimal minor <b>moderate</b> major massive	<b>low</b> medium high	The species is known to exert a multifaceted impact on both biodiversity and ecosystem services, by feeding on native vegetation and contributing to the loss of habitat structure and function (hence indirectly affecting other species, including birds, reptiles, invertebrates, etc.). ## Distribution Summary

Please answer as follows:

- Yes if recorded, established or invasive
- if not recorded, established or invasive
- ? Unknown; data deficient

The columns refer to the answers to Questions A5 to A12 under Section A.

For data on marine species at the Member State level, delete Member States that have no marine borders. In all other cases, provide answers for all columns.

### Member States and the United Kingdom

	Recorded	Established (currently)	Possible establishment (under current climate)	Possible establishment (under foreseeable climate)	Invasive (currently)
Austria			Yes	Yes	
Belgium			Yes	Yes	
Bulgaria			Yes	Yes	
Croatia	Yes	Yes	Yes	Yes	Yes
Cyprus			Yes	Yes	
Czech Republic	Yes		Yes	Yes	
Denmark			Yes	Yes	
Estonia				Yes	
Finland				Yes	
France	Yes		Yes	Yes	
Germany			Yes	Yes	
Greece			Yes	Yes	
Hungary			Yes	Yes	
Ireland	Yes		Yes	Yes	
Italy			Yes	Yes	
Latvia			Yes	Yes	
Lithuania			Yes	Yes	
Luxembourg			Yes	Yes	
Malta			Yes	Yes	
Netherlands			Yes	Yes	
Poland			Yes	Yes	
Portugal			Yes	Yes	
Romania			Yes	Yes	
Slovakia			Yes	Yes	
Slovenia	Yes		Yes	Yes	
Spain			Yes	Yes	
Sweden			Yes	Yes	
United Kingdom	Yes		Yes	Yes	

Biogeographical regions of the risk assessment area

	Recorded	Established (currently)	Possible establishment (under current climate)	Possible establishment (under foreseeable climate)	Invasive (currently)
Alpine	Yes		Yes	Yes	
Atlantic			Yes	Yes	
Black Sea			Yes	Yes	
Boreal			Yes	Yes	
Continental	Yes		Yes	Yes	
Mediterranean	Yes	Yes	Yes	Yes	Yes
Pannonian			Yes	Yes	
Steppic			Yes	Yes	

## **ANNEX I Scoring of Likelihoods of Events**

(adapted from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

<b>Score</b>	<b>Description</b>	<b>Frequency</b>
Very unlikely	This sort of event is theoretically possible, but is never known to have occurred and is not expected to occur	1 in 10,000 years
Unlikely	This sort of event has not occurred anywhere in living memory	1 in 1,000 years
Moderately likely	This sort of event has occurred somewhere at least once in recent years, but not locally	1 in 100 years
Likely	This sort of event has happened on several occasions elsewhere, or on at least one occasion locally in recent years	1 in 10 years
Very likely	This sort of event happens continually and would be expected to occur	Once a year

## ANNEX II Scoring of Magnitude of Impacts

(modified from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

Score	Biodiversity and ecosystem impact	Ecosystem Services impact	Economic impact (Monetary loss and response costs per year)	Social and human health impact, and other impacts
	<i>Question 5.1-5</i>	<i>Question 5.6-8</i>	<i>Question 5.9-13</i>	<i>Question 5.14-18</i>
Minimal	Local, short-term population loss, no significant ecosystem effect	No services affected <sup>8</sup>	Up to 10,000 Euro	No social disruption. Local, mild, short-term reversible effects to individuals.
Minor	Some ecosystem impact, reversible changes, localised	Local and temporary, reversible effects to one or few services	10,000-100,000 Euro	Significant concern expressed at local level. Mild short-term reversible effects to identifiable groups, localised.
Moderate	Measureable long-term damage to populations and ecosystem, but reversible; little spread, no extinction	Measureable, temporary, local and reversible effects on one or several services	100,000-1,000,000 Euro	Temporary changes to normal activities at local level. Minor irreversible effects and/or larger numbers covered by reversible effects, localised.
Major	Long-term irreversible ecosystem change, spreading beyond local area	Local and irreversible or widespread and reversible effects on one / several services	1,000,000-10,000,000 Euro	Some permanent change of activity locally, concern expressed over wider area. Significant irreversible effects locally or reversible effects over large area.
Massive	Widespread, long-term population loss or extinction, affecting several species with serious ecosystem effects	Widespread and irreversible effects on one / several services	Above 10,000,000 Euro	Long-term social change, significant loss of employment, migration from affected area. Widespread, severe, long-term, irreversible health effects.

<sup>8</sup> Not to be confused with “no impact”.

## ANNEX III Scoring of Confidence Levels

(modified from Bacher et al. 2017)

Each answer provided in the risk assessment must include an assessment of the level of confidence attached to that answer, reflecting the possibility that information needed for the answer is not available or is insufficient or available but conflicting. The responses in the risk assessment should clearly support the choice of the confidence level.

<b>Confidence level</b>	<b>Description</b>
Low	There is no direct observational evidence to support the assessment, e.g. only inferred data have been used as supporting evidence <i>and/or</i> Impacts are recorded at a spatial scale which is unlikely to be relevant to the assessment area <i>and/or</i> Evidence is poor and difficult to interpret, e.g. because it is strongly ambiguous <i>and/or</i> The information sources are considered to be of low quality or contain information that is unreliable.
Medium	There is some direct observational evidence to support the assessment, but some information is inferred <i>and/or</i> Impacts are recorded at a small spatial scale, but rescaling of the data to relevant scales of the assessment area is considered reliable, or to embrace little uncertainty <i>and/or</i> The interpretation of the data is to some extent ambiguous or contradictory.
High	There is direct relevant observational evidence to support the assessment (including causality) <i>and</i> Impacts are recorded at a comparable scale <i>and/or</i> There are reliable/good quality data sources on impacts of the taxa <i>and</i> The interpretation of data/information is straightforward <i>and/or</i> Data/information are not controversial or contradictory.

## ANNEX IV Ecosystem services classification (CICES V5.1, simplified) and examples

For the purposes of this risk assessment, please feel free to use what seems as the most appropriate category / level / combination of impact (Section – Division – Group), reflecting information available.

Section	Division	Group	Examples (i.e. relevant CICES “classes”)
Provisioning	Biomass	Cultivated <i>terrestrial</i> plants	Cultivated terrestrial plants (including fungi, algae) grown for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from cultivated plants, fungi, algae and bacteria for direct use or processing (excluding genetic materials); Cultivated plants (including fungi, algae) grown as a <u>source of energy</u>  <i>Example: negative impacts of non-native organisms to crops, orchards, timber etc.</i>
		Cultivated <i>aquatic</i> plants	Plants cultivated by in- situ aquaculture grown for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from in-situ aquaculture for direct use or processing (excluding genetic materials); Plants cultivated by in- situ aquaculture grown as an <u>energy source</u> .  <i>Example: negative impacts of non-native organisms to aquatic plants cultivated for nutrition, gardening etc. purposes.</i>
		Reared animals	Animals reared for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from reared animals for direct use or processing (excluding genetic materials); Animals reared to provide <u>energy</u> (including mechanical)  <i>Example: negative impacts of non-native organisms to livestock</i>
		Reared <i>aquatic</i> animals	Animals reared by in-situ aquaculture for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from animals grown by in-situ aquaculture for direct use or processing (excluding genetic materials); Animals reared by in-situ aquaculture as an <u>energy source</u>  <i>Example: negative impacts of non-native organisms to fish farming</i>
		Wild plants (terrestrial and aquatic)	Wild plants (terrestrial and aquatic, including fungi, algae) used for <u>nutrition</u> ; <u>Fibres and other materials</u> from wild plants for direct use or processing (excluding genetic materials); Wild plants (terrestrial and aquatic, including fungi, algae) used as a <u>source of energy</u>  <i>Example: reduction in the availability of wild plants (e.g. wild berries, ornamentals) due to non-native organisms (competition, spread of disease etc.)</i>
		Wild animals (terrestrial and aquatic)	Wild animals (terrestrial and aquatic) used for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from wild animals for direct use or processing (excluding genetic materials); Wild animals (terrestrial and aquatic) used as a <u>source of energy</u>  <i>Example: reduction in the availability of wild animals (e.g. fish stocks, game) due to non-native organisms (competition, predations, spread of disease etc.)</i>
	Genetic material from all biota	Genetic material from plants, algae or fungi	Seeds, spores and other plant materials collected for maintaining or establishing a population; Higher and lower plants (whole organisms) used to <u>breed new</u>

			<p>strains or varieties; Individual genes extracted from higher and lower plants for the <u>design and construction of new biological entities</u></p> <p><i>Example: negative impacts of non-native organisms due to interbreeding</i></p>	
		<b>Genetic material from animals</b>	<p>Animal material collected for the purposes of maintaining or establishing a population; Wild animals (whole organisms) used to breed new strains or varieties; Individual genes extracted from organisms for the design and construction of new biological entities</p> <p><i>Example: negative impacts of non-native organisms due to interbreeding</i></p>	
		<b>Water<sup>9</sup></b>	<b>Surface water</b> used for nutrition, materials or energy	<p>Surface water for <u>drinking</u>; Surface water used as a material (<u>non-drinking purposes</u>); Freshwater surface water, coastal and marine water used as an <u>energy source</u></p> <p><i>Example: loss of access to surface water due to spread of non-native organisms</i></p>
			<b>Ground water</b> for used for nutrition, materials or energy	<p>Ground (and subsurface) water for <u>drinking</u>; Ground water (and subsurface) used as a material (<u>non-drinking purposes</u>); Ground water (and subsurface) used as an <u>energy source</u></p> <p><i>Example: reduced availability of ground water due to spread of non-native organisms and associated increase of ground water consumption by vegetation.</i></p>
<b>Regulation &amp; Maintenance</b>	<b>Transformation</b> of biochemical or physical inputs to ecosystems	<b>Mediation of wastes or toxic substances</b> of anthropogenic origin by living processes	<p><u>Bio-remediation</u> by micro-organisms, algae, plants, and animals; <u>Filtration/sequestration/storage/accumulation</u> by micro-organisms, algae, plants, and animals</p> <p><i>Example: changes caused by non-native organisms to ecosystem functioning and ability to filtrate etc. waste or toxics</i></p>	
		<b>Mediation of nuisances</b> of anthropogenic origin	<p><u>Smell reduction</u>; <u>noise attenuation</u>; <u>visual screening</u> (e.g. by means of green infrastructure)</p> <p><i>Example: changes caused by non-native organisms to ecosystem structure, leading to reduced ability to mediate nuisances.</i></p>	
	<b>Regulation</b> of physical, chemical, biological conditions	<b>Baseline flows and extreme event</b> regulation	<p>Control of <u>erosion</u> rates; Buffering and attenuation of <u>mass movement</u>; <u>Hydrological cycle and water flow regulation</u> (Including flood control, and coastal protection); <u>Wind</u> protection; <u>Fire</u> protection</p> <p><i>Example: changes caused by non-native organisms to ecosystem functioning or structure leading to, for example, destabilisation of soil, increased risk or intensity of wild fires etc.</i></p>	
		<b>Lifecycle maintenance</b> , habitat and gene pool protection	<p><u>Pollination</u> (or 'gamete' dispersal in a marine context); <u>Seed dispersal</u>; Maintaining <u>nursery populations and habitats</u> (Including gene pool protection)</p> <p><i>Example: changes caused by non-native organisms to the abundance and/or distribution of wild pollinators; changes to the availability / quality of nursery habitats for fisheries</i></p>	
		<b>Pest and disease control</b>	<p>Pest control; Disease control</p>	

<sup>9</sup> Note: in the CICES classification provisioning of water is considered as an abiotic service whereas the rest of ecosystem services listed here are considered biotic.

			<i>Example: changes caused by non-native organisms to the abundance and/or distribution of pests</i>
		<b>Soil quality regulation</b>	Weathering processes and their effect on soil quality; <u>Decomposition and fixing processes</u> and their effect on soil quality  <i>Example: changes caused by non-native organisms to vegetation structure and/or soil fauna leading to reduced soil quality</i>
		<b>Water conditions</b>	Regulation of the <u>chemical condition</u> of freshwaters by living processes; Regulation of the chemical condition of salt waters by living processes  <i>Example: changes caused by non-native organisms to buffer strips along water courses that remove nutrients in runoff and/or fish communities that regulate the resilience and resistance of water bodies to eutrophication</i>
		<b>Atmospheric composition and conditions</b>	Regulation of <u>chemical composition</u> of atmosphere and oceans; Regulation of <u>temperature and humidity</u> , including ventilation and transpiration  <i>Example: changes caused by non-native organisms to ecosystems' ability to sequester carbon and/or evaporative cooling (e.g. by urban trees)</i>
<b>Cultural</b>	<b>Direct, in-situ and outdoor interactions</b> with living systems that depend on presence in the environmental setting	<b>Physical and experiential</b> interactions with natural environment	Characteristics of living systems that enable activities promoting health, recuperation or enjoyment through <u>active or immersive interactions</u> ; Characteristics of living systems that enable activities promoting health, recuperation or enjoyment through <u>passive or observational interactions</u>  <i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that make it attractive for recreation, wild life watching etc.</i>
		<b>Intellectual and representative</b> interactions with natural environment	Characteristics of living systems that enable <u>scientific investigation</u> or the creation of traditional ecological knowledge; Characteristics of living systems that enable <u>education and training</u> ; Characteristics of living systems that are resonant in terms of <u>culture or heritage</u> ; Characteristics of living systems that enable <u>aesthetic experiences</u>  <i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have cultural importance</i>
	<b>Indirect, remote, often indoor interactions</b> with living systems that do not require presence in the environmental setting	<b>Spiritual, symbolic</b> and other interactions with natural environment	Elements of living systems that have <u>symbolic meaning</u> ; Elements of living systems that have <u>sacred or religious meaning</u> ; Elements of living systems used for <u>entertainment or representation</u>  <i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have sacred or religious meaning</i>
		Other biotic characteristics that have a <b>non-use value</b>	Characteristics or features of living systems that have an <u>existence value</u> ; Characteristics or features of living systems that have an <u>option or bequest value</u>  <i>Example: changes caused by non-native organisms to ecosystems designated as wilderness areas, habitats of endangered species etc.</i>

## **ANNEX VII Projection of climatic suitability for *Axis axis* establishment**

Björn Beckmann, Riccardo Scalera, Beth Purse and Dan Chapman

30 October 2019

### ***Aim***

To project the suitability for potential establishment of *Axis axis* in Europe, under current and predicted future climatic conditions.

### ***Data for modelling***

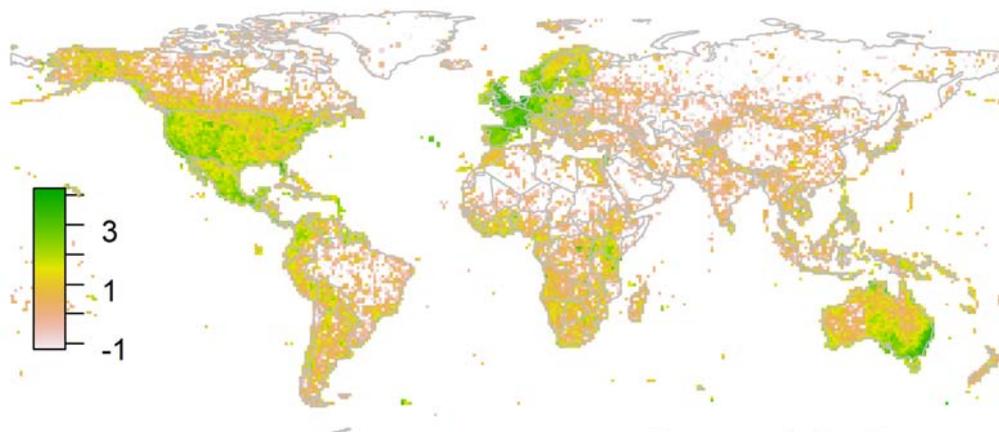

Species occurrence data were obtained from the Global Biodiversity Information Facility (GBIF) (394 records), the Biodiversity Information Serving Our Nation database (BISON) (85 records), the Atlas of Living Australia (19 records), the Integrated Digitized Biocollections (iDigBio) (8 records), and a small number of additional records from the risk assessment team. We scrutinised occurrence records from regions where the species is not known to be established and removed any dubious records (e.g. fossils, captive records) or where the georeferencing was too imprecise (e.g. records referenced to a country or island centroid) or outside of the coverage of the predictor layers (e.g. small island or coastal occurrences). The remaining records were gridded at a 0.25 x 0.25 degree resolution for modelling, yielding 156 grid cells with occurrences (Figure 1a). As a proxy for recording effort, the density of Mammalia records held by GBIF was also compiled on the same grid (Figure 1b).

**Figure 1.** (a) Occurrence records obtained for *Axis axis* and used in the modelling, showing native and invaded distributions. (b) The recording density of Mammalia on GBIF, which was used as a proxy for recording effort.

(a) Species distribution used in modelling

(b) Estimated recording effort (log10-scaled)

Climate data were selected from the ‘Bioclim’ variables contained within the WorldClim database (Hijmans et al., 2005), originally at 5 arcminute resolution (0.083 x 0.083 degrees of longitude/latitude) and aggregated to a 0.25 x 0.25 degree grid for use in the model.

Based on the biology of *Axis axis*, the following climate variables were used in the modelling:

- Minimum temperature of the coldest month (Bio6)
- Mean temperature of the warmest quarter (Bio10)
- Annual precipitation (Bio12)

To estimate the effect of climate change on the potential distribution, equivalent modelled future climate conditions for the 2070s under the Representative Concentration Pathways (RCP) 2.6 and 4.5 were also obtained. There represent low and medium emissions scenarios, respectively. The above variables were obtained as averages of outputs of eight Global Climate Models (BCC-CSM1-1, CCSM4, GISS-E2-R, HadGEM2-AO, IPSL-CM5A-LR, MIROC-ESM, MRI-CGCM3, NorESM1-M), downscaled and calibrated against the WorldClim baseline (see [http://www.worldclim.org/cmip5\\_5m](http://www.worldclim.org/cmip5_5m)).

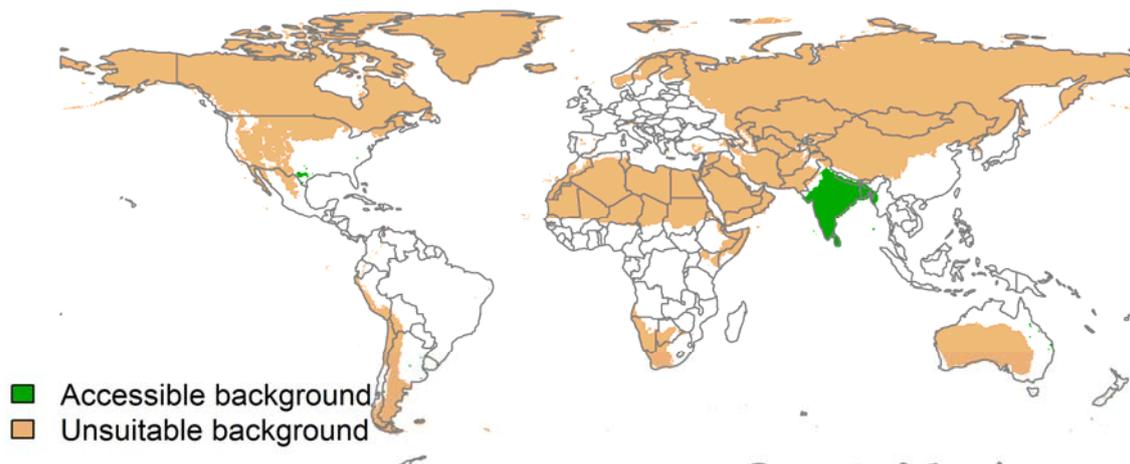

## *Species distribution model*

A presence-background (presence-only) ensemble modelling strategy was employed using the BIOMOD2 R package v3.3-7.1 (Thuiller et al., 2019, Thuiller et al., 2009). These models contrast the environment at the species' occurrence locations against a random sample of the global background environmental conditions (often termed 'pseudo-absences') in order to characterise and project suitability for occurrence. This approach has been developed for distributions that are in equilibrium with the environment. Because invasive species' distributions are not at equilibrium and subject to dispersal constraints at a global scale, we took care to minimise the inclusion of locations suitable for the species but where it has not been able to disperse to (Chapman et al. 2019). Therefore the background sampling region included:

- The area accessible by native *Axis axis* populations, in which the species is likely to have had sufficient time to disperse to all locations. Based on presumed maximum dispersal distances, the accessible region was defined as a 300km buffer around the native range occurrences; AND
- A 30km buffer around the non-native occurrences, encompassing regions likely to have had high propagule pressure for introduction by humans and/or dispersal of the species; AND
- Regions where we have an *a priori* expectation of high unsuitability for the species so that absence is assumed irrespective of dispersal constraints (see Figure 2). The following rules were applied to define a region expected to be highly unsuitable for *Axis axis* at the spatial scale of the model:
  - Minimum temperature of the coldest month (Bio6) < -12°C
  - Mean temperature of the warmest quarter (Bio10) < 11°C
  - Annual precipitation (Bio12) < 6 (i.e. < 403mm, as the Bioclim variable is on a natural log scale)

Altogether, only 0.6% of occurrence grid cells were located in the unsuitable background region. Within the background region, 10 samples of 5000 randomly sampled grid cells were obtained, weighting the sampling by recording effort (Figure 2).

**Figure 2.** The background from which pseudo-absence samples were taken in the modelling of *Axis axis*. Samples were taken from a 300km buffer around the native range and a 30km buffer around non-native occurrences (together forming the accessible background), and from areas expected to be highly unsuitable for the species (the unsuitable background region). Samples were weighted by a proxy for recording effort (Figure 1(b)).

Each dataset (i.e. combination of the presences and the individual background samples) was randomly split into 80% for model training and 20% for model evaluation. With each training dataset, seven statistical algorithms were fitted with the default BIOMOD2 settings and rescaled using logistic regression, except where specified below:

- Generalised linear model (GLM)
- Generalised boosting model (GBM)
- Generalised additive model (GAM) with a maximum of four degrees of freedom per smoothing spline
- Artificial neural network (ANN)
- Multivariate adaptive regression splines (MARS)
- Random forest (RF)
- Maxent

Since the background sample was much larger than the number of occurrences, prevalence fitting weights were applied to give equal overall importance to the occurrences and the background. Normalised variable importance was assessed and variable response functions were produced using BIOMOD2's default procedure.

Model predictive performance was assessed by the following three measures:

- AUC, the area under the receiver operating characteristic curve (Fielding & Bell 1997). Predictions of presence-absence models can be compared with a subset of records set aside for model evaluation (here 20%) by constructing a confusion matrix with the number of true positive, false positive, false negative and true negative cases. For models generating non-dichotomous scores (as here) a threshold can be applied to transform the scores into a dichotomous set of presence-absence predictions. Two measures that can be derived from the confusion matrix are sensitivity (the proportion of observed presences that are predicted as such, quantifying omission errors), and specificity (the proportion of

observed absences that are predicted as such, quantifying commission errors). A receiver operating characteristic (ROC) curve can be constructed by using all possible thresholds to classify the scores into confusion matrices, obtaining sensitivity and specificity for each matrix, and plotting sensitivity against the corresponding proportion of false positives (equal to  $1 - \text{specificity}$ ). The use of all possible thresholds avoids the need for a selection of a single threshold, which is often arbitrary, and allows appreciation of the trade-off between sensitivity and specificity. The area under the ROC curve (AUC) is often used as a single threshold-independent measure for model performance (Manel, Williams & Ormerod 2001). AUC is the probability that a randomly selected presence has a higher model-predicted suitability than a randomly selected absence (Allouche et al. 2006).

- Cohen's Kappa (Cohen 1960). This measure corrects the overall accuracy of model predictions (ratio of the sum of true presences plus true absences to the total number of records) by the accuracy expected to occur by chance. The kappa statistic ranges from -1 to +1, where +1 indicates perfect agreement and values of zero or less indicate a performance no better than random. Advantages of kappa are its simplicity, the fact that both commission and omission errors are accounted for in one parameter, and its relative tolerance to zero values in the confusion matrix (Manel, Williams & Ormerod 2001). However, Kappa has been criticised for being sensitive to prevalence (the proportion of sites in which the species was recorded as present) and may therefore be inappropriate for comparisons of model accuracy between species or regions (McPherson, Jetz & Rogers 2004, Allouche et al. 2006).
- TSS, the true skill statistic (Allouche et al. 2006). TSS is defined as sensitivity + specificity - 1, and corrects for Kappa's dependency on prevalence. TSS compares the number of correct forecasts, minus those attributable to random guessing, to that of a hypothetical set of perfect forecasts. Like kappa, TSS takes into account both omission and commission errors, and success as a result of random guessing, and ranges from -1 to +1, where +1 indicates perfect agreement and values of zero or less indicate a performance no better than random (Allouche et al. 2006).

An ensemble model was created by first rejecting poorly performing algorithms with relatively extreme low AUC values and then averaging the predictions of the remaining algorithms, weighted by their AUC. To identify poorly performing algorithms, AUC values were converted into modified z-scores based on their difference to the median and the median absolute deviation across all algorithms (Iglewicz & Hoaglin, 1993). Algorithms with  $z < -2$  were rejected. In this way, ensemble projections were made for each dataset and then averaged to give an overall suitability, as well as its standard deviation. The projections were then classified into suitable and unsuitable regions using the 'minimum ROC distance' method, which minimizes the distance between the ROC plot and the upper left corner of the plot (point (0,1)), i.e. which maximises both sensitivity (correctly classified presences) and specificity (correctly classified absences).

We also produced limiting factor maps for Europe following Elith et al. (2010). For this, projections were made separately with each individual variable fixed at a near-optimal value. These were chosen as the median values at the occurrence grid cells. Then, the most strongly limiting factors were identified as the one resulting in the highest increase in suitability in each grid cell.

## **Results**

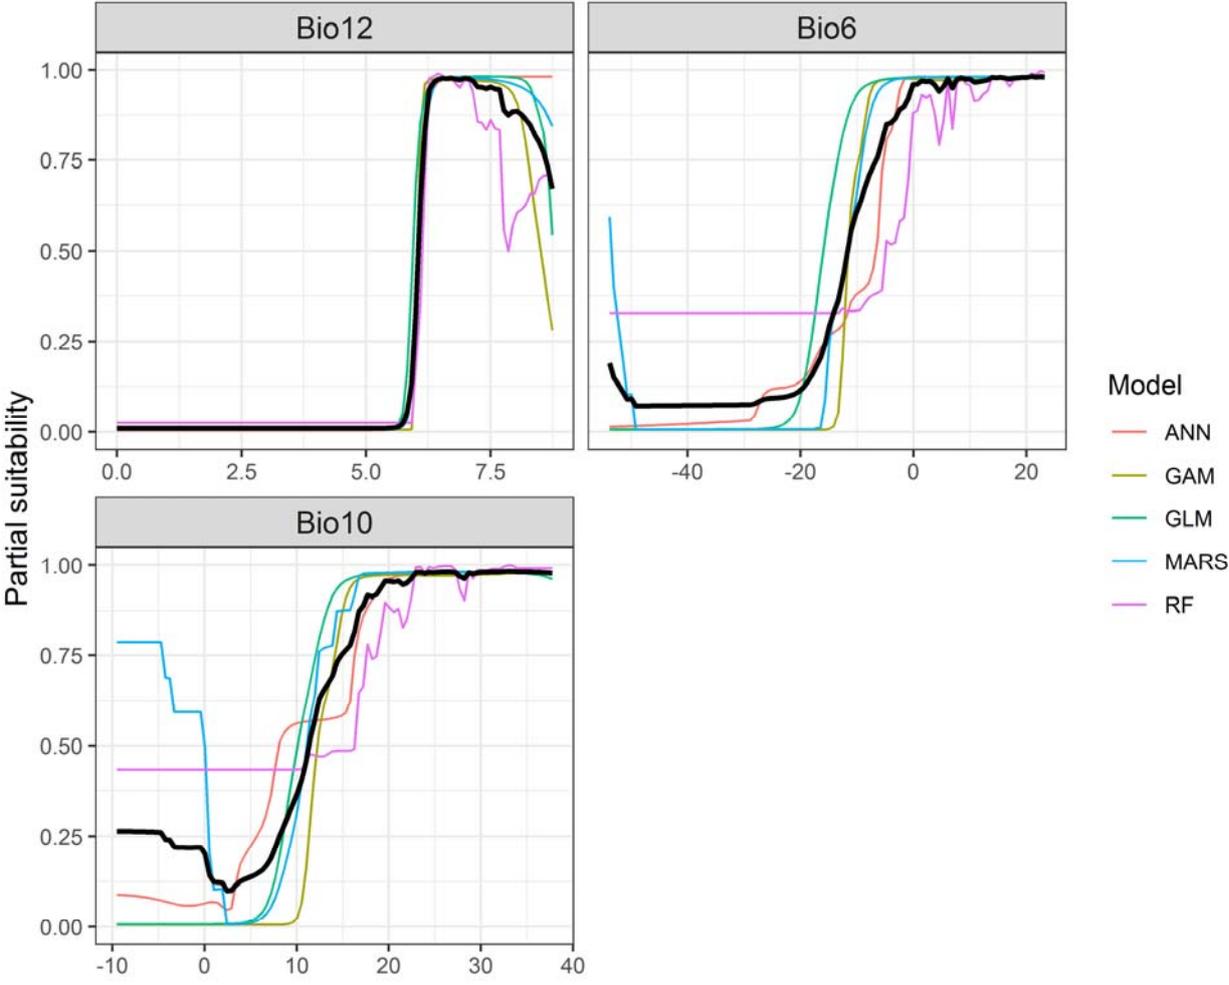

The ensemble model suggested that suitability for *Axis axis* was most strongly determined by Annual precipitation (Bio12), accounting for 45.9% of variation explained, followed by Minimum temperature

of the coldest month (Bio6) (35.1%) and Mean temperature of the warmest quarter (Bio10) (19%) (Table 1, Figure 3).

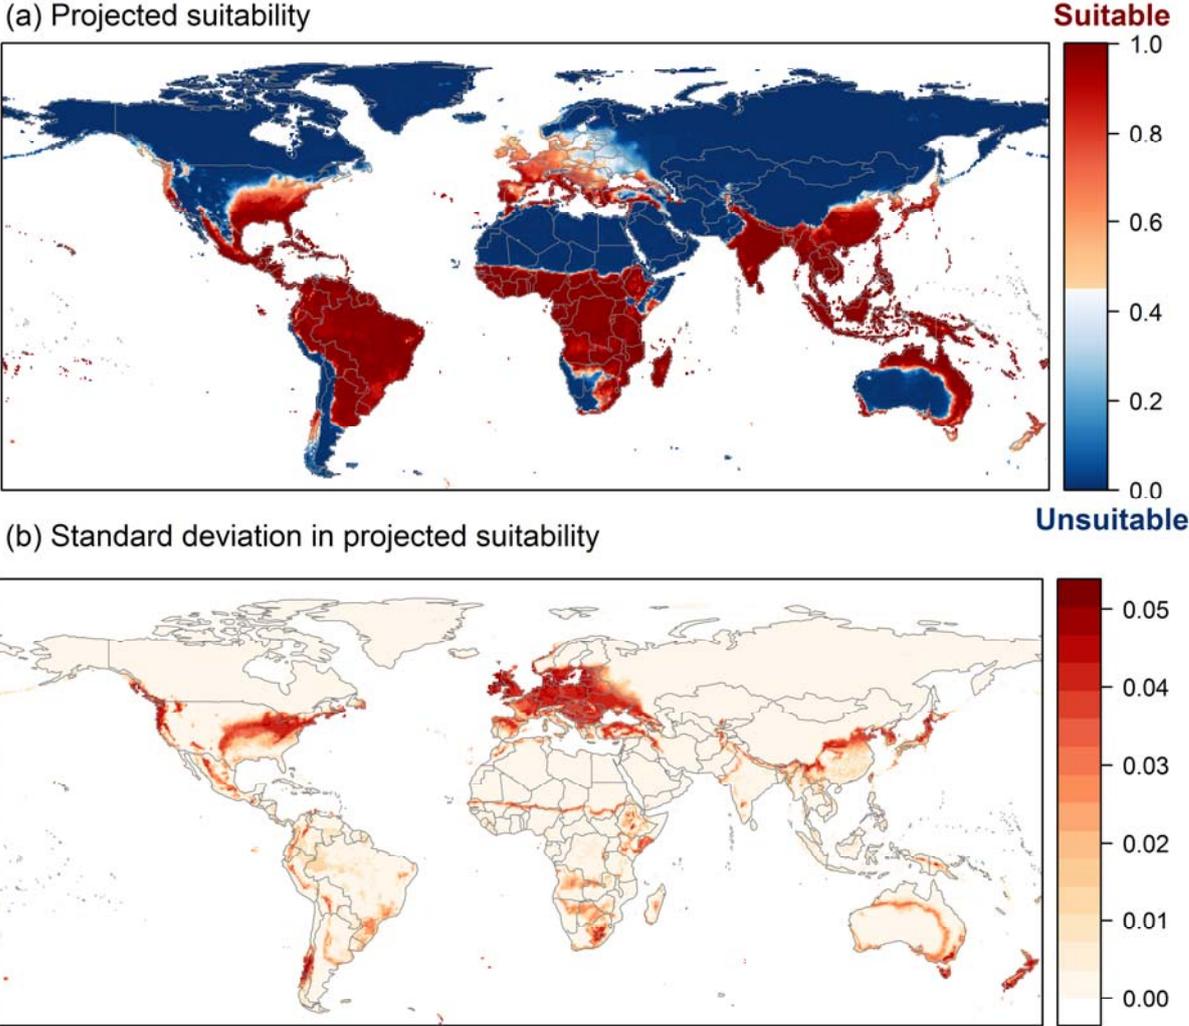

**Table 1.** Summary of the cross-validation predictive performance (AUC, Kappa, TSS) and variable importance of the fitted model algorithms and the ensemble (AUC-weighted average of the best performing algorithms). Results are the average from models fitted to 10 different background samples of the data.

Algorithm	AUC	Kappa	TSS	Used in the ensemble	variable importance (%)		
					Annual precipitation (Bio12)	Minimum temperature of the coldest month (Bio6)	Mean temperature of the warmest quarter (Bio10)
GLM	0.984	0.653	0.948	yes	47	35	18
GAM	0.982	0.668	0.949	yes	43	40	18
ANN	0.982	0.648	0.949	yes	44	37	19
GBM	0.977	0.671	0.946	no	45	33	22
MARS	0.981	0.660	0.950	yes	42	40	18
RF	0.978	0.639	0.938	yes	54	23	23
Maxent	0.976	0.675	0.943	no	46	32	22
<b>Ensemble</b>	<b>0.983</b>	<b>0.655</b>	<b>0.952</b>		<b>46</b>	<b>35</b>	<b>19</b>

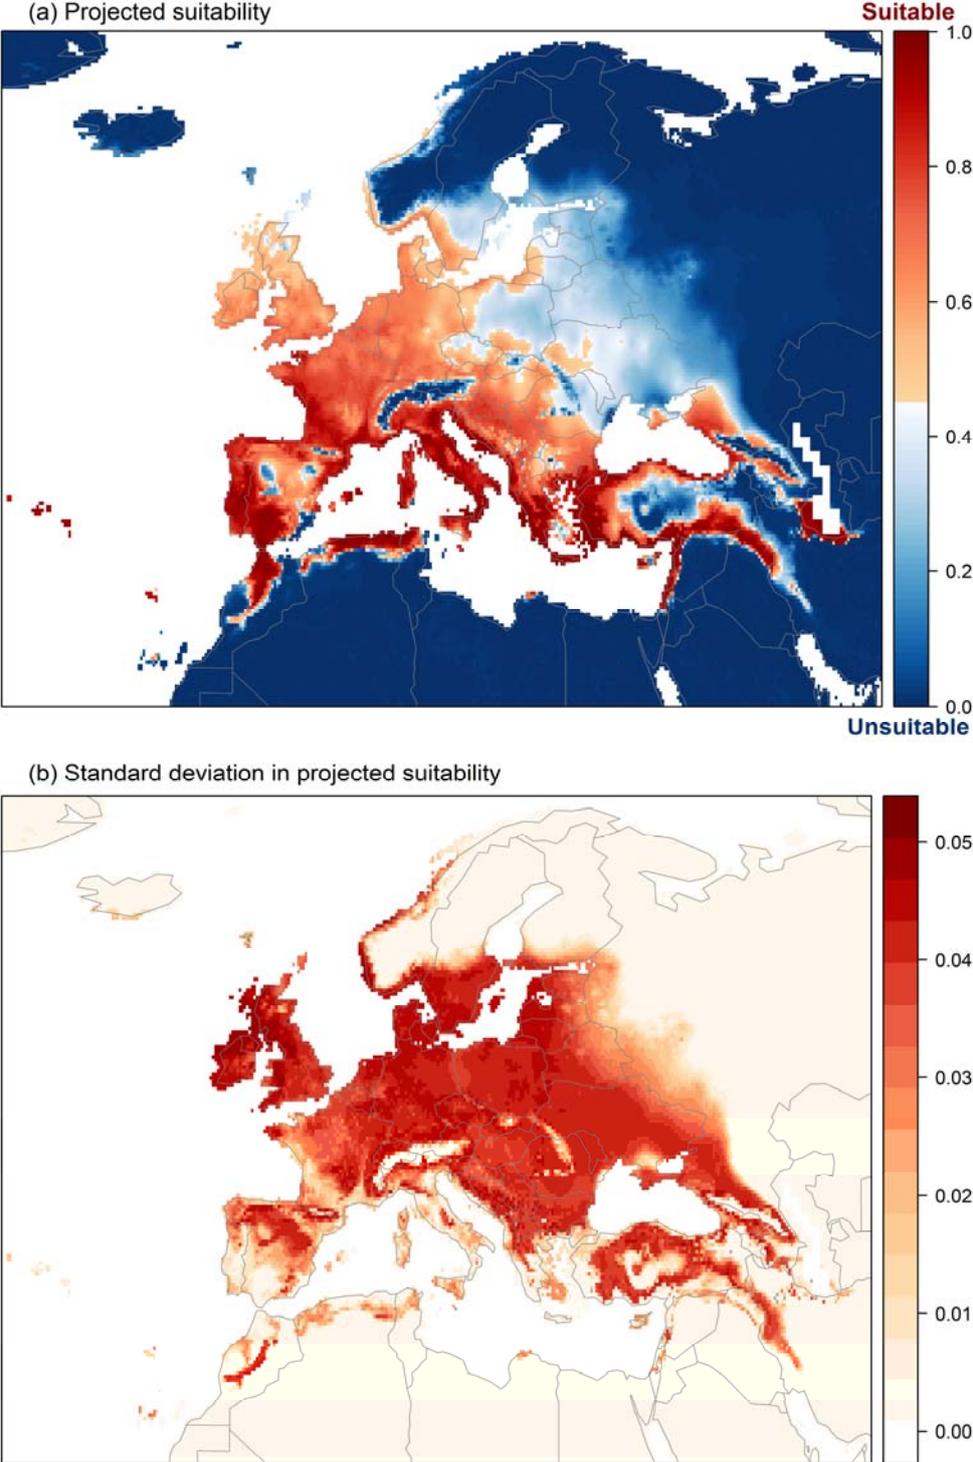

**Figure 3.** Partial response plots from the fitted models. Thin coloured lines show responses from the algorithms in the ensemble, while the thick black line is their ensemble. In each plot, other model variables are held at their median value in the training data. Some of the divergence among algorithms is because of their different treatment of interactions among variables.

**Figure 4.** (a) Projected global suitability for *Axis axis* establishment in the current climate. For visualisation, the projection has been aggregated to a 0.5 x 0.5 degree resolution, by taking the maximum suitability of constituent higher resolution grid cells. Values > 0.45 may be suitable for the species ('minimum ROC distance' threshold at which both correctly classified presences and correctly classified absences are maximised). Grey areas have climatic conditions outside the range of the training data and were excluded from the projection. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

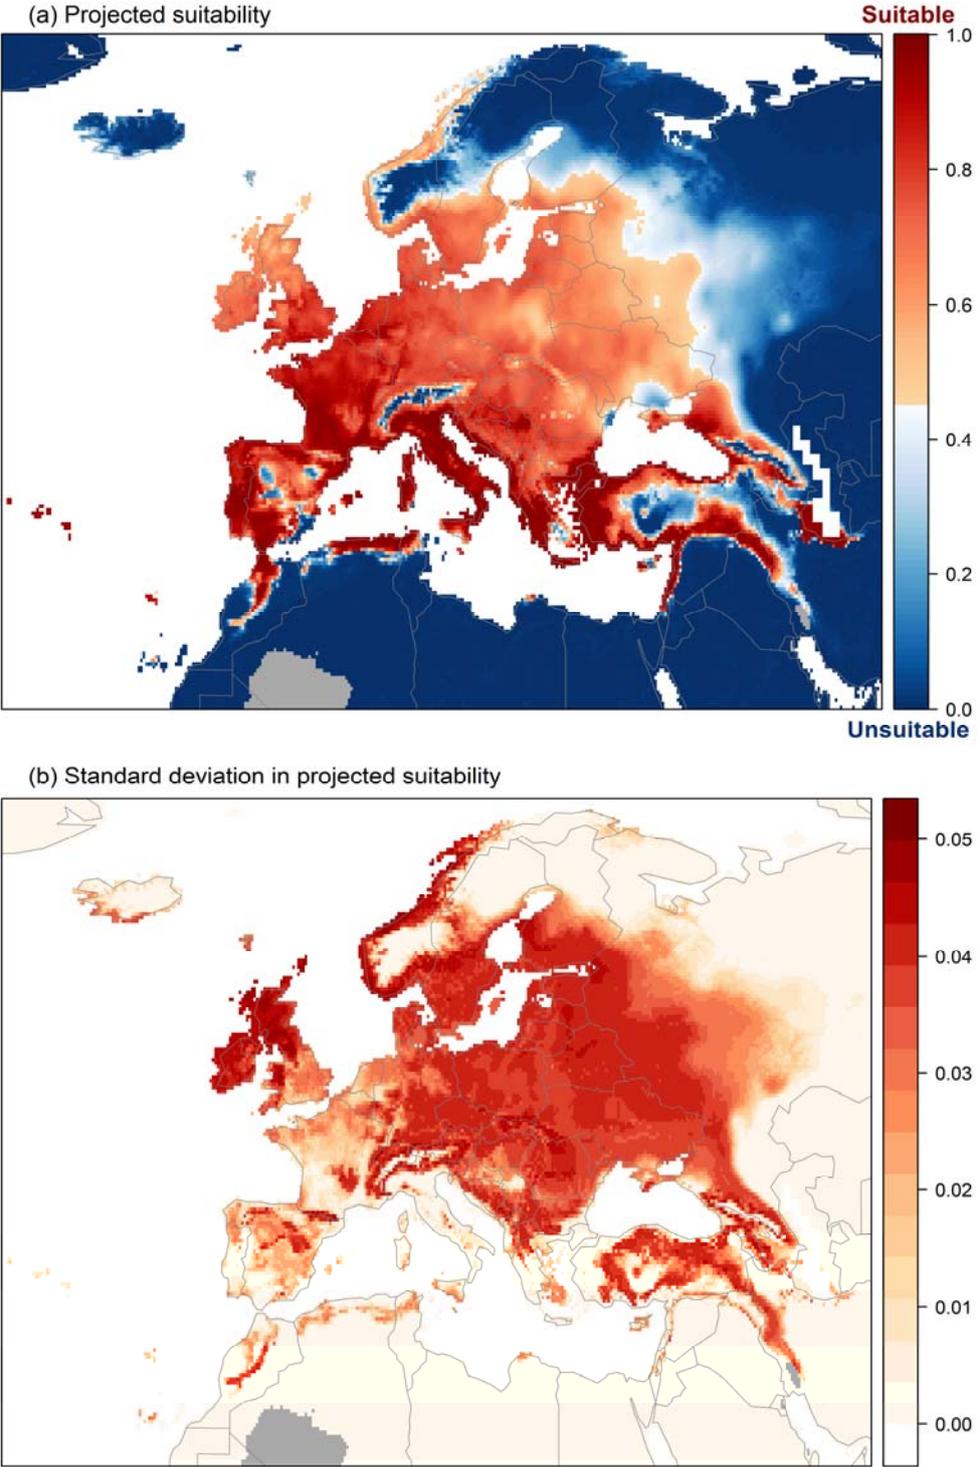

**Figure 5.** (a) Projected current suitability for *Axis axis* establishment in Europe and the Mediterranean region. Values  $> 0.45$  may be suitable for the species ('minimum ROC distance' threshold at which globally both correctly classified presences and correctly classified absences are maximised). Grey areas have climatic conditions outside the range of the training data and were excluded from the projection. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

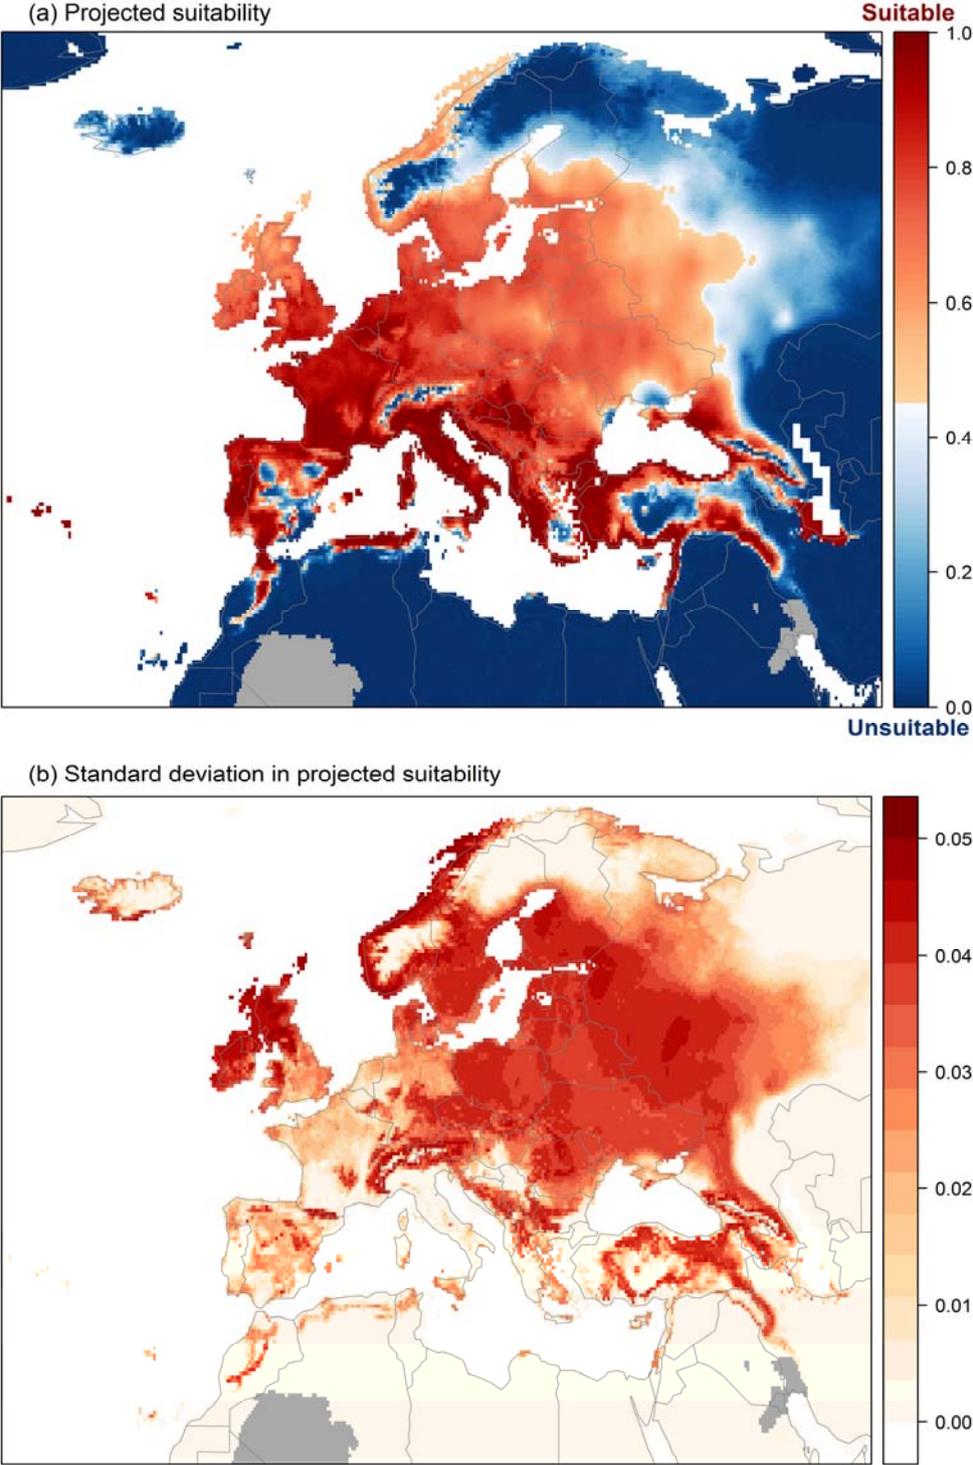

**Figure 6.** The most strongly limiting factors for *Axis axis* establishment estimated by the model in Europe and the Mediterranean region in current climatic conditions.

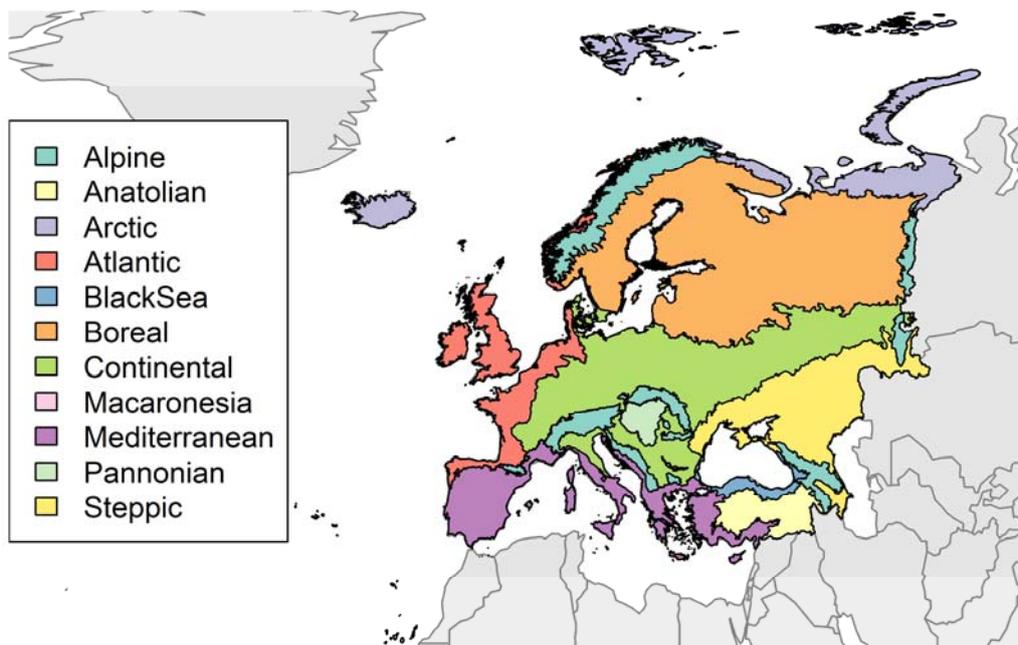

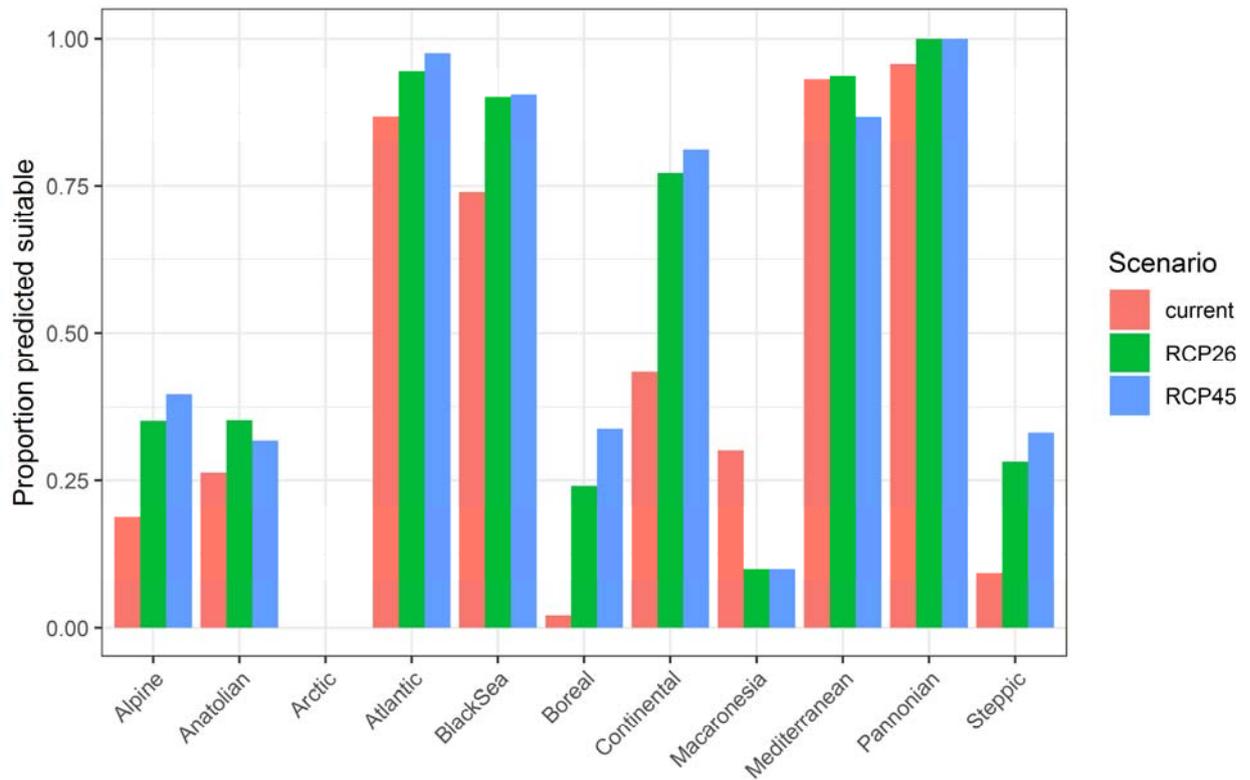

**Figure 7.** (a) Projected suitability for *Axis axis* establishment in Europe and the Mediterranean region in the 2070s under climate change scenario RCP2.6, equivalent to Figure 5. Values > 0.45 may be suitable for the species ('minimum ROC distance' threshold at which globally both correctly classified presences and correctly classified absences are maximised). Grey areas have climatic conditions outside the range of the training data and were excluded from the projection. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

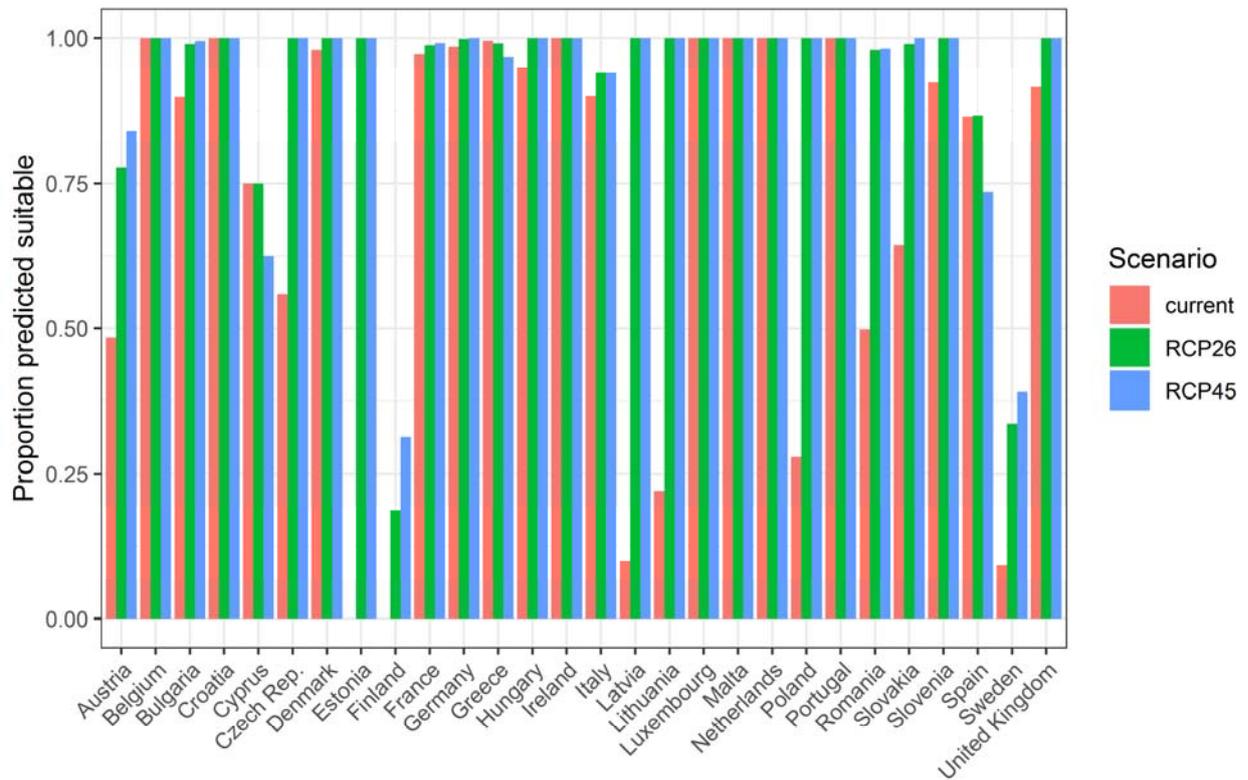

**Figure 8.** (a) Projected suitability for *Axis axis* establishment in Europe and the Mediterranean region in the 2070s under climate change scenario RCP4.5, equivalent to Figure 5. Values  $> 0.45$  may be suitable for the species ('minimum ROC distance' threshold at which globally both correctly classified presences and correctly classified absences are maximised). Grey areas have climatic conditions outside the range of the training data and were excluded from the projection. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

**Figure 9.** Variation in projected suitability for *Axis axis* establishment among Biogeographical regions of Europe (<https://www.eea.europa.eu/data-and-maps/data/biogeographical-regions-europe-3>). The bar plots show the proportion of grid cells in each region classified as suitable in the current climate and projected climate for the 2070s under two RCP emissions scenarios. The classification threshold is the same as in Figures 4, 5, 7 and 8 above (minimum ROC distance), i.e. the bars in the below diagram show the proportion of each Biogeographical region that is coloured in a shade of red in the above figures. The location of each region is also shown. The Arctic and Macaronesian biogeographical regions are not part of the study area, but are included for completeness.

**Figure 10.** Variation in projected suitability for *Axis axis* establishment among European Union countries. The bar plots show the proportion of grid cells in each country classified as suitable in the current climate and projected climate for the 2070s under two RCP emissions scenarios. The classification threshold is the same as in Figures 4, 5, 7 and 8 above (minimum ROC distance), i.e. the bars in the below diagram show the proportion of each country that is coloured in a shade of red in the above figures.

### *Caveats to the modelling*

To remove spatial recording biases, the selection of the background sample was weighted by the density of Mammalia records on the Global Biodiversity Information Facility (GBIF). While this is preferable to not accounting for recording bias at all, it may not provide the perfect measure of recording bias.

There was substantial variation among modelling algorithms in the partial response plots (Figure 3). In part this will reflect their different treatment of interactions among variables. Since partial plots are made with other variables held at their median, there may be values of a particular variable at which this does not provide a realistic combination of variables to predict from. Other variables potentially affecting the distribution of the species, such as land cover were not included in the model.

## SECTION A – Organism Information and Screening

**A1. Identify the organism. Is it clearly a single taxonomic entity and can it be adequately distinguished from other entities of the same rank?**

including the following elements:

- the taxonomic family, order and class to which the species belongs;
- the scientific name and author of the species, as well as a list of the most common synonym names;
- names used in commerce (if any)
- a list of the most common subspecies, lower taxa, varieties, breeds or hybrids

As a general rule, one risk assessment should be developed for a single species. However, there may be cases where it may be justified to develop one risk assessment covering more than one species (e.g. species belonging to the same genus with comparable or identical features and impact). It shall be clearly stated if the risk assessment covers more than one species, or if it excludes or only includes certain subspecies, lower taxa, hybrids, varieties or breeds (and if so, which subspecies, lower taxa, hybrids, varieties or breeds). Any such choice must be properly justified.

Response: This risk assessment covers one species, the paper mulberry tree *Broussonetia papyrifera* (L.) L'Hér ex Vent.

### Taxonomy

Regnum	<i>Plantae</i>
Infraregnum	<i>Streptophyta</i>
Divisio	<i>Tracheophyta</i> (Vascular plants)
Subdivisio	<i>Spermatophytina</i> (Seed plants)
Class	<i>Magnoliopsida</i>
Superordo	<i>Rosanae</i>
Ordo	<i>Rosales</i> Bercht. & J. Presl
Familia	<i>Moraceae</i> (mulberries)
Genus	<i>Broussonetia</i>

*Broussonetia papyrifera* (L.) L'Hér ex Vent. is an accepted name of a species with a temperate to subtropical East Asian origin (Chang et al. 2015) in the genus *Broussonetia* (Family *Moraceae*) (Euro+Med 2006-; The Plant List 2020). The accepted name is based on *Morus papyrifera* L. (basionym, Linnaeus 1753) (Euro+Med 2006-; IPNI 2020a). The lectotype for the name was described by Etienne Pierre Ventenat in the Tableau du Règne Végétal, Selon de Méthode de Jussieu (IPNI 2020b).

The genus name honors Pierre Auguste Marie Broussonet (1761-1807), French physician, naturalist and one-time professor of botany at Le Jardin des Plantes de Montpellier. Specific epithet comes from the Egyptian word papyrus meaning paper and the Latin word “ferre” meaning to bear in reference to the use of tree bark to make paper.

## Synonyms

According to The Plant List (2013) and Plants of the World Online (2020) synonyms for the species are:

- *Broussonetia billardii* Carruth.
- *Broussonetia cordata* Blume
- *Broussonetia dissecta* Bureau
- *Broussonetia elegans* K. Koch
- *Broussonetia kasii* Dippel
- *Broussonetia kazi* Siebold ex Blume
- *Broussonetia maculata* Steud.
- *Broussonetia nana* Bureau
- *Broussonetia navicularis* Lodd. ex Bureau
- *Broussonetia navicularis* Lodd. ex K. Koch
- *Broussonetia papyrifera* var. *integrifolia* Miq.
- *Broussonetia spathulata* Steud.
- *Broussonetia tricolor* K. Koch
- *Morus papyrifera* L.
- *Papyrius papyrifera* (L.) Kuntze
- *Smithiodendron artocarpoideum* Hu
- *Stenochasma ancolanum* Miq.
- *Streblus cordatus* Lour.
- *Trophis cordata* (Lour.) Poir.

## Common names

According to CABI (2020) and Euro+Med (2006-) common names in the European region are:

- Dutch (Belgian): papiermoerbe
- Catalan/ Valencian: morera de paper; morera de Xina; morera femella; morera paperera
- Croatian: brusonecija, dudovac
- Czech: papírovník čínský, brousonetie papíronosná
- English: paper mulberry, paper mulberry tree; tapa cloth tree
- French: mûrier à papier; mûrier de Chine; arbre à tapa
- German: Papiermaulbeerbaum; japanischer Papierbaum
- Italian: gelso papirifero del Giappone; moro della China, Brussonezia; gelso da carta; gelso della China;
- Spanish: mora de papel; moral de la China; morera del Japón; morera del papel; papelero

- Portuguese: amoreira do papel; amoreira-do-papel
- Slovak: brusonécia papierová

### **Most common subspecies, lower taxa, varieties, breeds or hybrids**

About 16 or 17 varieties (including five wild) are recognized within this species (CABI 2020; HEAR 2020; Watt 1972). Watt 1972 refers to eleven or twelve varieties in cultivated plants besides which there are five varieties of the wild species, though there are no variety names available in this reference.

These cultural varieties have their origin in the very long use of the plant by humans. Varieties can be distinguished by different leaf shapes and margins and colors of the petiole (Seelenfreund et al. 2017).

Seelenfreund et al. (2017) report three main varieties of paper mulberry (masi) for Fiji: *masi vula* (white masi); *masi damu* (red masi); *masi vutu*. *Masi vula* can be recognized by the green petiole of the leaves, while *masi damu* is recognized by the reddish or brown petiole. *Masi vutu* is recognized not by the color of the petiole, but by the round shape of leaves. On the Vatulele Island, two varieties (*bele damu*, *bele vula*) with white and red stemmed leaves independently if the leaves are rounded or lobed. In Tonga, varieties are recognized according to the shape of the leaves: *lau ma'opo'opo* (more heart-shaped leaves with occasional incuts on one side), *lau mahaehae* (deeply lobed variety), *hiapo lai mangamanga* (deeply lobed leaves) and *hiapo lau a'opo'opo* (crenate leaves). Tapa makers in Hawaii basically recognize two varieties based on leaf shape: *mana mana lima* (regularly lobed leaves) and *poa'a'aha/poa aha* (non-lobed leaves).

Hybrids are identified on a regional level, e.g. *Broussonetia* × *kazinoki* Siebold has long been utilized as a major component in the manufacturing of Korean traditional paper (hanji) and Won (2019) confirmed by a genetic analysis that *B. × kazinoki* is a hybrid between *B. monoica* and *B. papyrifera*. The hybrid is most likely formed naturally in Korea.

Payacan et al. (2017) show a genetic diversity among paper mulberry accessions from Remote Oceania. A clear separation between West and East Polynesia was found that may be indicative of pulses during its dispersal history.

Hybrids and varieties are included in this risk assessment.

**A2. Provide information on the existence of other species that look very similar [that may be detected in the risk assessment area, either in the environment, in confinement or associated with a pathway of introduction]**

Include both native and non-native species that could be confused with the species being assessed, including the following elements:

- other alien species with similar invasive characteristics, to be avoided as substitute species (in this case preparing a risk assessment for more than one species together may be considered);
- other alien species without similar invasive characteristics, potential substitute species;
- native species, potential misidentification and mis-targeting

Response: Paper mulberry is a medium to large deciduous tree with milky sap. The crown is round and spreading. It is a hardy, fast-growing tree (CABI 2020; Saito et al. 2009, Tanasombat et al. 2005; Whistler & Elevitch 2006). Its stout, grey-brown, spreading branches are brittle and susceptible to wind damage. The branches are marked with stipular scars. Young branchlets are subtomentose and shoots are pubescent when young. The bark is light-grey, smooth, with shallow fissures or ridges. The stem, branches and petioles contain a milky latex. The twigs of paper mulberry are hairy reddish brown, the bark is tan and smooth to moderately furrowed, the wood is soft and brittle, and it has conical buds.

*Broussonetia papyrifera* has variable mulberry-like papery leaves. The leaves are densely gray-pubescent, often lobed or mitten-shaped, and are alternate, opposite or whorled along the stem. Some leaves are distinctly deep lobed, while others are unlobed. Several different shapes of leaves may appear on the same shoot. The leaves are alternate/subopposite, ovate, acuminate, dentate-crenate, their bases often oblique, scabrous above, with a woolly surface on the lower side. The leaf margin is sharply toothed, the leaf base is heart-shaped to rounded with pointed tips, and the upper leaf surface is rough feeling (CABI 2020).

*Broussonetia papyrifera* is a dioecious species, with unisexual male and female flowers in inflorescences on separate plants. Trees with staminate inflorescences (hereafter male trees) produce catkins that are long clusters of flowers. Trees with pistillate inflorescences (hereafter female trees) produce ball-shaped flower clusters, which mature into red, globose aggregate fruits. The male flower is 3.5-7.5 cm long, yellowish-white, with pendulous catkin-like spikes. The perianth is campanulate, hairy, 4-fid, and its segments are valvate (CABI 2020). The female flowers are in rounded clusters in globose pedunculate heads about 1.3 cm in diameter. Persistent, hairy, clavate bracts subtend flowers. The fruit is shiny-reddish, fleshy, globose and compound with the achenes hanging on long fleshy stalks. The achenes are 1-2 cm long and wide. Globose infructescence (syncarp), 2-3 cm in diameter, orange-red when ripe, composed of drupes thinly pulpy, invested by the perianth, hanging on long fleshy stalks. Seeds ovoid, slightly compressed, papillate-asperous, crustaceous, with a keel double at the base, 1.8-2.4 mm long (Barker 2002).

#### **Existence of other native species that look very similar**

*Broussonetia papyrifera* has no known close relatives in the risk assessment area. In the Mediterranean biogeographic region there is some risk of confusion with *Ficus carica* L., in particular with the wild type.

#### **Existence of other non-native species that look very similar**

The combination of hairy twigs and leaves, variable leaves, male and female flowers appearing on separate trees, and the fleshy globular fruits helps differentiate paper mulberry from potential look-alikes. The white mulberry (*Morus alba*) has leaves with larger teeth and its fruits resemble raspberries or blackberries rather than spheres. The fruits of the red mulberry (*Morus rubra*) resemble cylindrical raspberries (Rawlins et al. 2018; Sarver et al. 2008). Some leaf forms can be confused with white mulberry; however, paper mulberry leaves have a rough, sand paper-like surface, whereas mulberry leaves are smooth (Whistler & Elevitch 2006). There is also a potential risk of confusion with *Morus kagayamae* Koidz.

Basswood (*Tilia americana*) has leaves that are very similar to leaves of species of the mulberry family, but are never lobed. Basswood also has clear sap, whereas the sap of the mulberries is milky (Sarver et al. 2008).

**A3. Does a relevant earlier risk assessment exist? Give details of any previous risk assessment, including the final scores and its validity in relation to the risk assessment area.**

Response: The paper mulberry was added to the EPPO Alert List in 2016 and was prioritized in 2019 as a species with moderate risk and added to the EPPO Observation List in 2019.

Inside of the risk assessment area

**Italy**

Crosti et al. (2010) used a modified version of the Australian Weed Risk Assessment (A-WRA) adapted for the Mediterranean region of Central Italy, to assess the risk for a number of invasive alien plants in Lazio (Italy, Mediterranean biogeographical region). *Broussonetia papyrifera* scored 7, resulting in a “reject” decision (potentially invasive) according to the A-WRA.

Outside of the risk assessment area

**Hawaii**

The Hawaiian Ecosystems at Risk project conducted a risk assessment of *B. papyrifera* for the Hawaiian Islands (HEAR 2020). The method followed the Australian/New Zealand Weed Risk Assessment adapted for Hawaii. The species is assessed as “low risk” with a score of three. A rating of “low risk” indicates that the plant has a low probability of becoming a serious pest. It is one of the principle plants introduced by early voyaging Polynesians who settled in Hawaiian region. It has become naturalized throughout Asia, from India and Pakistan to the Pacific Islands, and also in North America. *Broussonetia papyrifera* is an extremely fast growing tree highly suitable for rehabilitating eroded areas and controlling further erosion. However, a few years after introduction it often becomes invasive and is difficult to eradicate. The tree shows the characteristics of a vigorous pioneer, spreading rapidly following extreme canopy disturbance (e.g. cyclones) or farming. Following invasion of an area, it excludes other species and it is very difficult to eradicate. Its growth is extremely fast and it quickly out-competes other species. Mature fruits have not been observed in Hawaii.

As the Hawaii Islands belong to a different climatic and biogeographical region than the area of the risk assessment, basic information of e.g. biology or habitat preferences can be taken into account, though the assessment of e.g. invasiveness has to be reviewed accordingly to different climate conditions.

**Australia/Queensland**

The Department of Agriculture and Fisheries (Csurhes 2016) conducted an invasive species risk assessment of paper mulberry for the federal state Queensland of Australia. In summary, the species is currently in its early stages of population development in Queensland. It appears to be a ‘high-risk’ species and a worthy candidate for preventative control. However, an assessment of the feasibility of eradication and/or control needs to be made. Currently, *B. papyrifera* is sparingly naturalized in Queensland. Wild populations have been detected in Brisbane and coastal northern Queensland. Substantial areas of eastern Queensland appear climatically suitable. Elsewhere in Australia, *B. papyrifera* has been recorded in South Australia and New South Wales. It seems reasonable to predict that *B. papyrifera* could become widespread and problematic in suitable habitat types in coastal and subcoastal Queensland (where climate, soil and land use are favourable). Habitats most at risk are predicted to include riparian areas; semi-deciduous (closed) forests and vine thickets (especially margins and gaps); and disturbed, open sites generally, where there is relatively well-drained, moist, fertile soil. On some islands in the Pacific, only male plants are cultivated and regeneration is purely vegetative. If

male and female plants are present, long-range dispersal is via seeds. Seeds rarely germinate under dense forest canopies, but germination can be prolific in large canopy gaps, roadsides and abandoned farmland. Root suckers are produced when the main stem is cut. Over time, this can lead to the formation of dense thickets. Root suckers can be cut, dug out and replanted (the main form of reproduction when ‘male clones’ are used for agroforestry).

As Australia belongs to a different climatic and biogeographical region than the area of this risk assessment, basic information of e.g. biology or habitat preferences can be taken into account, though the assessment of e.g. invasiveness has to be reviewed accordingly to different climate conditions.

#### **Georgia – United States of America**

In 2017, the paper mulberry has been evaluated for the region of the US federal state Georgia (Bucalo 2017). The outcome is an indication of the invasive potential of Paper mulberry in Georgia, and therefore should not be considered for sale or propagation. According to Georgia Exotic Pest Plant Council (GA-EPPC), the species is ranked in the category 3: Exotic plant that is a minor problem in Georgia natural areas, or is not yet known to be a problem in Georgia but is known to be a problem in adjacent states. PRE is a 20-question plant risk assessment tool. It is also an online platform and database enabling those involved in non-native, terrestrial plant production to know before they grow if a plant poses a potential regional invasive risk. In summary, *B. papyrifera* can spread via seed and vegetative suckers, coppicing and re-sprouting, and it is a very vigorous grower. It is reported as invasive in many states that are a climate match for Georgia. Paper mulberry exhibits aggressive growth and quickly invades disturbed lands, competing with more desirable plant species. The fruits of *B. papyrifera* are consumed by many types of birds and other small animals which are thought to disseminate the seeds. Detailed species information about such animals dispersing seeds are not available. Water may also play a role of dispersal alongside water courses or irrigation channels. The seeds are spread far and wide by wildlife who feed on the fruits.

As Georgia belongs to a different climatic and biogeographical region than the area of this risk assessment, basic information of e.g. biology or habitat preferences can be taken into account, though the assessment of e.g. invasiveness has to be reviewed accordingly to different climate conditions.

#### **A4. Where is the organism native?**

including the following elements:

- an indication of the continent or part of a continent, climatic zone and habitat where the species is naturally occurring
- if applicable, indicate whether the species could naturally spread into the risk assessment area

Response: *Broussonetia papyrifera* is native to East Asia and mainland Southeast Asia (González-Lorca et al. 2015; Huston 2004; Peñailillo et al. 2016). An accurate native range distribution cannot be given as the species was introduced already prehistorically in the surroundings as a species of cultural importance (González-Lorca et al. 2015), e.g. to Polynesia as a source of bark fiber by Austronesian-speaking voyagers (Peñailillo et al. 2016).

While CABI (2020) lists China, Japan and Taiwan as countries within the native distribution (according to Ghafoor 1985), Csurhes (2016) includes parts of China (Anhui, Fujian, Gansu, Guangdong, Guangxi, Guizhou, Hainan, Hebei, Henan, Hubei, Hunan, Jiangsu, Jiangxi, Shaanxi, Shandong, Shanxi, Sichuan,

Xizang, Yunnan and Zhejiang), Japan, Korea, Taiwan, Cambodia, Laos, Myanmar, Thailand, Vietnam and Malaysia into a larger native range (compare POWO 2020). On the other hand, EPPO (2019) considers China, Japan, Korea, Taiwan and Thailand within the native range. Chung et al. (2017) give a comprehensive overview about considerable discrepancies existing in literature regarding distribution ranges of the species.

*Broussonetia papyrifera* can tolerate a wide range of climates, including humid tropical (monsoon), humid and sub-humid subtropical as well as warm temperate areas (EPPO 2019; Whistler & Elevitch 2006). It can grow in areas with an annual rainfall of 700–2 500 mm (EPPO 2019; CABI 2020), though the species can survive a 3–4 month dry season (Whistler & Elevitch 2006). The paper mulberry is considered being a pioneer species adapted to colonize disturbed sites (Csurhes 2016). The species does not grow well under full shade and is suited to disturbed habitats, in particular to riparian habitats and gaps within subtropical forest (EPPO 2019; Saito et al. 2009; Luna 1996). It exhibits a high reproductive potential, by means of both sexual and vegetative propagation (Maan et al. 2020; Morgan et al. 2019). *Broussonetia papyrifera* is insect- and wind-pollinated, and can be grown from seed, stem cuttings, coppice and root suckers (CABI 2020). The fruit, which is a compound (syncarp) of juicy, orange-red drupelets are dispersed by birds and small mammals (Seelenfreund et al. 2017). Its fecundity is high by virtue of its ability to fruit twice in a year and also achieving reproductive maturity at relatively small size. Thus sexual reproduction maybe the most important mode of reproduction that drives its invasiveness. Though trees start fruiting early, fruiting percentages increase with tree size (Kyereh et al. 2014).

Since the native distribution center in Asia and the European continent are separated by a large distance, the natural spread into the risk assessment area is very unlikely.

<b>A5. What is the global non-native distribution of the organism outside the risk assessment area?</b>
---

Response: Table 1 and Figure 1 give an overview about the global non-native distribution outside the risk assessment area. Considering the broader native range, available spatial and non-spatial data describe the non-native distribution of *B. papyrifera* covering parts of North, Middle and South America, Europe, Africa, Asia and Oceanica.

In the neighborhood of the risk assessment area, the species' status is "introduced" in Switzerland (Aeschimann & Burdet 1994; Hess 1998). In some countries of the Balkan peninsula (Bosnia and Herzegovina and Montenegro; Euro+Med 2006-, Stešević & Petrović 2010) the paper mulberry is assessed as "introduced and naturalized". Furthermore the occurrence of *B. papyrifera* is documented in Albania, Georgia, Macedonia, Moldova, Russia and Ukraine (Table 1).

**A6. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species been recorded and where is it established? The information needs be given separately for recorded (including casual or transient occurrences) and established occurrences. “Established” means the process of an alien species successfully producing viable offspring with the likelihood of continued survival<sup>2</sup>.**

**A6a. Recorded: List regions**

<sup>2</sup> Convention on Biological Diversity, Decision VI/23

**A6b. Established: List regions**

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

- Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea.

Comment on the sources of information on which the response is based and discuss any uncertainty in the response.

For delimitation of EU biogeographical regions please refer to <https://www.eea.europa.eu/data-and-maps/figures/biogeographical-regions-in-europe-2> (see also Annex VI).

For delimitation of EU marine regions and subregions consider the Marine Strategy Framework Directive areas; please refer to <https://www.eea.europa.eu/data-and-maps/data/msfd-regions-and-subregions/technical-document/pdf> (see also Annex VI).

Response: Figure 2 and Table 2 give an overview about occurrences of the species in the biogeographical regions. The Arctic, Anatolian and Macaronesian biogeographical regions are not part of the risk assessment area, but included for completeness. In the Steppic region, no occurrence information is available.

Sources of information are observation data (GBIF 2020, iDigBio 2020, iNaturalist 2020, ALA 2020), European wide overviews like Euro+Med PlantBase (providing an on-line database and information system for the vascular plants of Europe and the Mediterranean region, against an up-to-date and critically evaluated consensus taxonomic core of the species concerned) or Flora Europaea (Tutin et al. 1964-1980) as well as national floristic or invasive species references (e.g. Greuter et al. 1989, Conti et al. 2005, Nikolić 1994; Boršić et al. 2008; Strid & Tan 1997; Mifsud 2020).

Pannonian			GBIF 2020; iNaturalist 2020	
Steppic				

Response (6a):

Paper mulberry is recorded in the Alpine, Atlantic, Black Sea, Continental, Mediterranean and Pannonian biogeographical regions. No occurrence data is available for the Steppic region. In the Boreal biogeographic region, occurrence data is available only in botanical gardens.

Response (6b):

According to the available information, *B. papyrifera* can be considered as “established” in the Atlantic, Continental and Mediterranean biogeographical regions.

“Established” means the process of an alien species successfully producing viable offspring with the likelihood of continued survival. In the available references (mainly Euro+Med PlantBase and Flora Europaea), the term “naturalized” is used. In order to answer question 6b, “naturalized” is used as a synonym for “established”. The assessment of established occurrences in biogeographical regions is mainly deduced from the data available on national level (compare Table 5).

**A7. In which biogeographic region(s) or marine subregion(s) in the risk assessment area could the species establish in the future under current climate and under foreseeable climate change? The information needs to be given separately for current climate and under foreseeable climate change conditions.**

**A7a. Current climate: List regions**

**A7b. Future climate: List regions**

With regard to EU biogeographic and marine (sub)regions, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065)

and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

According to SDM results (Figure 3 and Figure 4, Table 3 and Table 4, see also Annex IX) the biogeographical regions paper mulberry could establish in are as follows:

Response (7a):

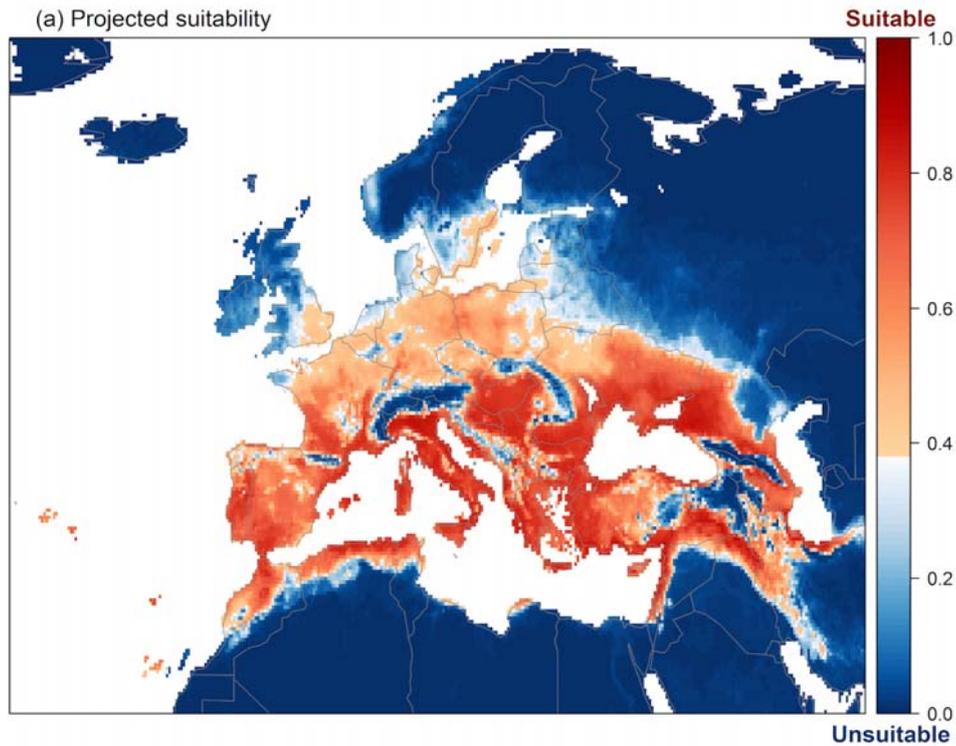

Figure 3 Projected current suitability for *Broussonetia papyrifera* establishment in Europe

Table 3 Biogeographic regions and suitability under current conditions

Biogeographic region	likeliness	confidence
Alpine	unlikely	medium
Anatolian	likely	high

**A8. In which EU Member States has the species been recorded and in which EU Member States has it established? List them with an indication of the timeline of observations. The information needs be given separately for recorded and established occurrences.**

**A8a. Recorded: List Member States**

**A8b. Established: List Member States**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden

The description of the invasion history of the species shall include information on countries invaded and an indication of the timeline of the first observations, establishment and spread.

Response: Figure 5 and Table 5 give an overview about occurrences of the species in the EU Member States. Sources of information are observation data (GBIF 2020, iDigBio 2020, iNaturalist 2020, ALA 2020), European wide overviews like Euro+Med PlantBase or Flora Europaea as well as national floristic or invasive species references (see Table 5). An indication of the first observation is not possible for every member state but given if possible. Mainly based upon Euro+Med PlantBase and CABI (2020) additional information like cultivated/planted respectively naturalized status is available in some cases. The available European wide (e.g. Euro+Med 2006-; Tutin et al. 1964-1980), national or regional (e.g. Aeschimann et al. 2004) floristic compilations are a reliable source of information.

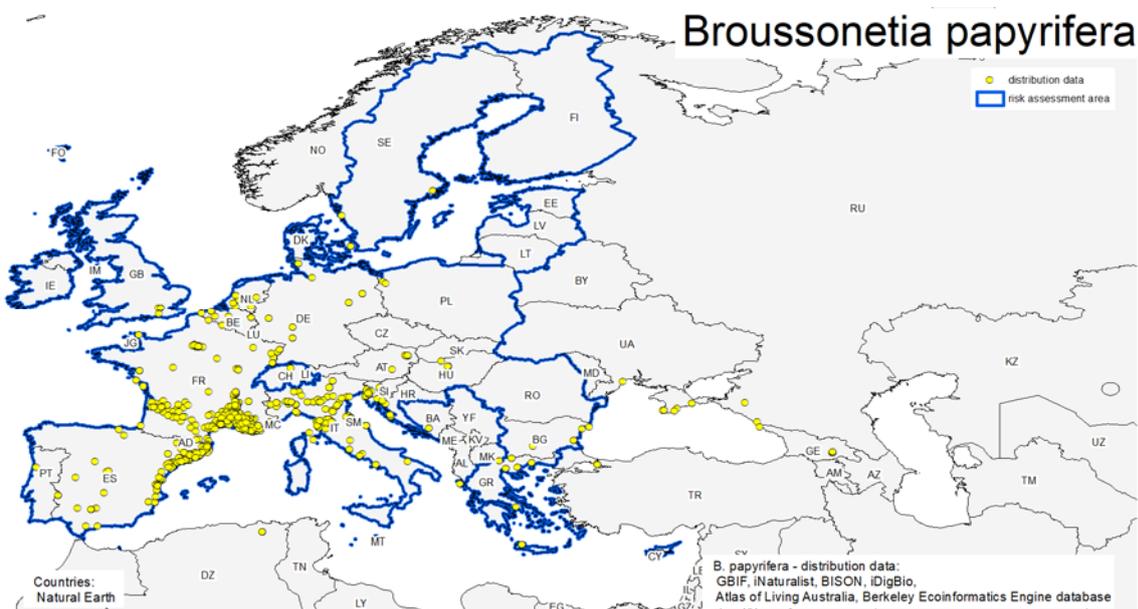

Figure 5 distribution data records of *Broussonetia papyrifera* in the EU member states (including United Kingdom) (map designed by Umweltbundesamt/Environment Agency Austria – 2020/07/01)

Table 5 EU member states and United Kingdom with recorded/established *Broussonetia papyrifera* occurrences; \* information given by Euro+Med 2006-; \*\* information by CABI 2020; N/A not available (green cell – recorded/established yes; white cell – recorded/established no; grey cell – no examined or no data available)

Response (8a): Paper mulberry is recorded in 19 (Austria, Belgium, Bulgaria, Croatia, Denmark, France, Germany, Greece, Hungary, Italy, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden) out of 27 Member States and in the United Kingdom.

Response (8b): Based upon the available data, *B. papyrifera* can be assessed as established in 8 (Bulgaria, Croatia, France, Greece, Italy, Malta, Romania, Spain) out of 27 Member States. Some of the member states with first observations about 100 or more years ago and Atlantic / Mediterranean climatic conditions (France 1890, Italy 1923, Spain 1892) exhibit a wide distribution of the species (see Figure 5).

By using a subset of GBIF records with a spatial accuracy  $\leq 100\text{m}$ , the EUNIS habitat classes at Level 2 (EEA 2019) can be spatially retrieved from the Ecosystem types of Europe 2012 raster data set (compare Table 6).

Table 6 Selected 283 *Broussonetia papyrifera* occurrences by GBIF with coordinate accuracy =< 100m and spatially related EUNIS habitat classes at Level 2 (EEA 2019)

EUNIS Label	AT	BE	BG	CH	CY	ES	FR	GR	HR	HU	IT	NL
C1: Surface standing waters											1	
C2: Surface running waters							1					
E1: Dry grasslands							2					
E2: Mesic grasslands					1		16				6	
E3: Seasonally wet and wet grasslands			1									
F3: Temperate and mediterranean-montane scrub		1										
FB: Shrub plantations							8					
G1: Broadleaved deciduous woodland						1	9				5	
G2: Broadleaved evergreen woodland											2	
G4: Mixed deciduous and coniferous woodland							4					
G5: Lines of trees, small anthropogenic woodlands, recently felled woodland, early-stage woodland and coppice							3				2	
I1: Arable land and market gardens						1	12	1			17	
I2: Cultivated areas of gardens and parks		2				2	5	1		1	9	
J1: Buildings of cities, towns and villages						10	66	1	2	1	22	1
J2: Low density buildings	1			2		2	42	1			7	
J4: Transport networks and other constructed hard-surfaced areas						1	4				5	

Most of the selected GBIF records are related to urban ecosystem types like *Buildings of cities, towns and villages* or *Low density buildings*.

Though for countries like e.g. Italy and France, the records are additionally related to *Mesic grasslands*, *Broadleaved deciduous woodland*, *Lines of trees, small anthropogenic woodlands, recently felled woodland, early-stage woodland and coppice*, *Arable land and market gardens*, *Transport networks and other constructed hard-surfaced areas*.

In summary, there is enough evidence that the used occurrence data cover several ecosystem categories from urban to more natural types.

**A9. In which EU Member States could the species establish in the future under current climate and under foreseeable climate change? The information needs be given separately for current climate and under foreseeable climate change conditions.**

**A9a. Current climate: List Member States**

**A9b. Future climate: List Member States**

With regard to EU Member States, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)

- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

The ensemble SDM model (see Annex IX) suggested that suitability for *B. papyrifera* was most strongly determined by minimum temperature of the coldest month (Bio6), accounting for 31,6 % of variation explained, followed by mean temperature of the warmest quarter (Bio10) (26.6 %), Climatic Moisture Index (CMI) (22.6 %) and Human Influence Index (HII) (19.2 %).

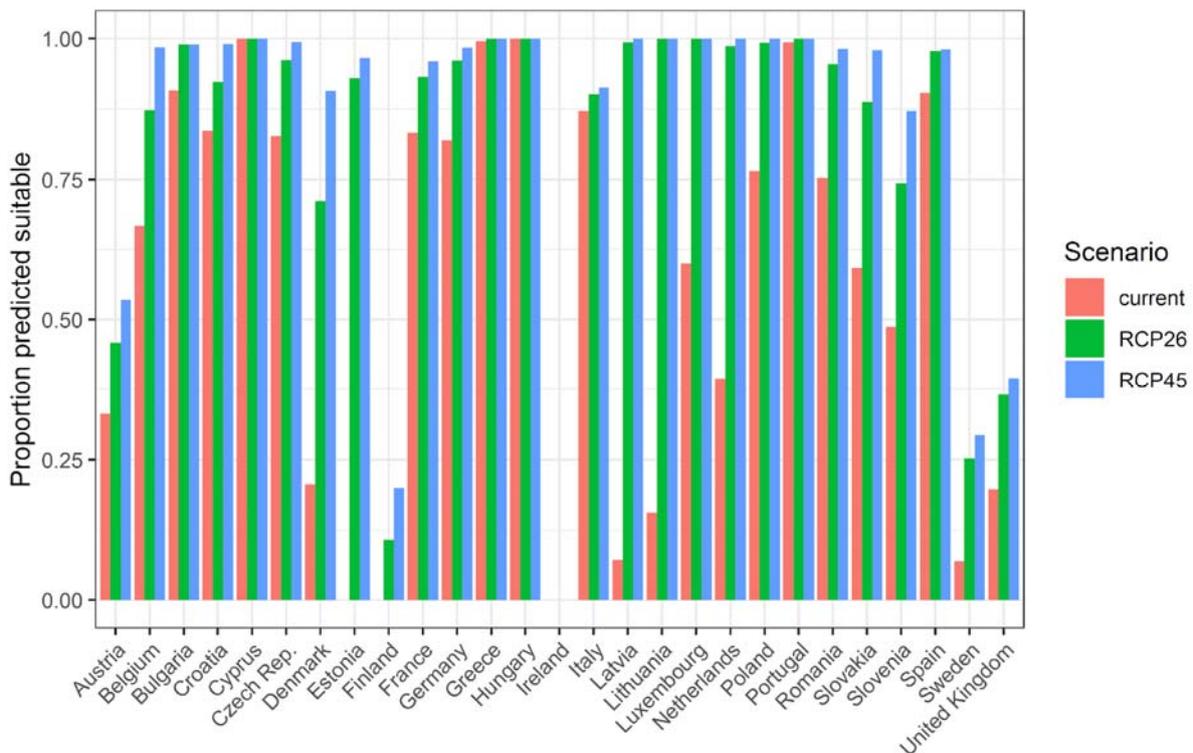

Figure 6 Variation in projected suitability for *Broussonetia papyrifera* establishment among European Union countries and the United Kingdom. The bar plots show the proportion of grid cells in each country classified as suitable in the current climate and projected climate for the 2070 using two different RCP pathways

**A10. Is the organism known to be invasive (i.e. to threaten or adversely impact upon biodiversity and related ecosystem services) anywhere outside the risk assessment area?**

Response: In Pakistan, paper mulberry was intentionally introduced to make the Islamabad (Capital) and Rawalpindi area green. In less than 30 years it not only became highly invasive in the natural vegetation but also caused health problems in the human population (Qazi et al. 2019). It is now commonly found in India and Pakistan from sea level to 1000 m altitude and has become highly invasive and a troublesome weed in many localities. In Pakistan, direct competition of *B. papyrifera* limits the growth of the native *Dalbergia sissoo*, *Morus alba* and *Ziziphus sp.*, an important source of nectar for honey bees, especially near Islamabad and Rawalpindi and Murree Hills (Ahmed et al. 2019; Khan et al. 2020). The thick monocultures at different sites have rapidly replaced the native flora and fauna, although these thickets have also become refuges for wild boar and other mammals, and enhanced the buildup of the crow population (CABI 2020; Qureshi et al. 2020a).

In Uganda, *B. papyrifera* forms dense stands which displace native plant species and prevent forest regeneration as well as reduce water availability. The plant produces vast quantities of allergenic pollen (Witt et al. 2018).

Paper mulberry was introduced into Ghana in 1969 by the Forestry Research Institute of Ghana (FORIG). The reason for its deliberate introduction was to evaluate its potential for pulp and paper production. However, the plant has now become an invasive of alarming proportion. It is perhaps the most serious non-indigenous woody invasive plant in the closed forest zone of Ghana and the second most important plant invasive after *Chromolaena odorata*. In Ghana, paper mulberry is highly concentrated in the two forest reserves, namely Pra-Anum and Afram Headwaters Forest Reserves. It is in these forest reserves that the initial experimental trial were carried out. The two reserves are located within the Moist Semi-Deciduous (MSDF) and Dry Semi-Deciduous Forest (DSDF) zones, respectively. These two forest types are types among the most floristically diverse and economically important of all the forest types in Ghana. The high concentration of paper mulberry in these two reserves and nearby reserves or forests were facilitated by extensive deforestation and bushfires. From these two centers, the

plant is spreading extensively. Dense stands of *Broussonetia* can be seen conspicuously in farms and along roads in and around Pra-Anum and Afram Headwaters forest reserves. The species is spreading to other areas up to perhaps 100 km from these point of introduction. In the Pacific Islands paper mulberry is not invasive because only male clones were introduced. Thus, no seeds are produced and propagation is by vegetative means, using root shoot suckers. In Ghana and other places where both fertile male and female plants were introduced the invasive potential of the plant increases significantly (Bosu & Apetorgor 2020).

**A11. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea

Response: Paper mulberry exhibits a widespread distribution in parts of the Atlantic and Mediterranean biogeographical regions (compare Figure 2). There are documented signs of invasiveness in the Continental biogeographical region (Northern Italy - Portale della Flora d'Italia 2020: Friuli Venezia Giulia, Lombardia (Montagnani et al. 2018), Piemonte (Gruppo di Lavoro Specie Esotiche della Regione Piemonte 2015), Veneto) and in the triangle of the Continental, Alpine and Mediterranean regions around Auvergne-Rhône-Alpes (Pôle d'information flore-habitats-fonge d'Auvergne-Rhône-Alpes 2020) and Provence Alpes-Côte d'Azur (Terrin et al. 2014). Regarding Croatia (Vuković et al. 2014, Borsic et al. 2008), no biogeographical region information is available. The endangered area includes natural and ruderal/disturbed habitats.

**A12. In which EU Member States has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden

Response: The species exhibits a widespread distribution in Spain, France and Italy (compare Figure 5). There are documented signs of invasiveness in Italy (Northern Italy - Portale della Flora d'Italia 2020: Friuli Venezia Giulia, Lombardia (Montagnani et al. 2018), Piemonte (Gruppo di Lavoro Specie Esotiche della Regione Piemonte 2015), Veneto). Paper mulberry is listed as invasive in Croatia

(Vuković et al. 2014, Borsic et al. 2008). France has some reports of local invasiveness including in the Auvergne-Rhône-Alpes (Pôle d'information flore-habitats-fonge d'Auvergne-Rhône-Alpes 2020) where it is also recorded as an emerging invasive (Debay et al. 2020) and it is listed as “one-to-watch” in the Pays de la Loire (Dortel & Le Bail 2019) and Provence Alpes-Côte d’Azur (Terrin et al. 2014). The endangered area includes natural and ruderal/disturbed habitats.

**A13. Describe any known socio-economic benefits of the organism.**

including the following elements:

- Description of known uses for the species, including a list and description of known uses in the risk assessment area and third countries, if relevant.
- Description of social and economic benefits deriving from those uses, including a description of the environmental, social and economic relevance of each of those uses and an indication of associated beneficiaries, quantitatively and/or qualitatively depending on what information is available.

If the information available is not sufficient to provide a description of those benefits for the entire risk assessment area, qualitative data or different case studies from across the risk assessment area or third countries shall be used, if available.

Response: Inside of the risk assessment area: Paper mulberry is grown as an ornamental in parks and gardens. No other kind of use is known for the risk assessment area.

Outside of the risk assessment area: Paper mulberry has been cultivated in Asia and some Pacific Islands for many centuries for food, fiber (CABI 2020; POWO 2020), medicine (Hussain et al. 2008) and other uses (Matthews 1996).

The species played a significant role in the development of paper-making (Chang et al. 2015; González-Lorca et al. 2015; POWO 2020). For centuries, the fiber from the inner bark of paper mulberry has been used to make paper in Japan and textiles throughout the Pacific. In both cases the raw material is the soft, inner bark. For paper-making, the inner bark is pounded and mixed with water, and the resulting paste then spread evenly on a mesh to make 'washi' (Japanese handmade paper). Paper-making with paper mulberry fiber was established in China by around 100 AD, and reached Japan by about 600 AD (POWO 2020).

In contrast, in the Pacific region textiles are made by beating together strips of inner bark. This tapa cloth is used for various items of clothing, such as sarongs, scarves and hats, as well as for making bags and other items such as bedding. Until relatively recently, tapa cloth was the main source of clothing worn on Pacific islands such as Fiji, Tonga and Tahiti. Tapa cloth is still worn on ceremonial occasions, during festivals and for traditional dances. The bark fiber (and indeed the roots) can also be made into rope and cord (POWO 2020).

The wood is light and easily worked, and is used for making cups, bowls and furniture (ALA 2020; POWO 2020). The timber, being soft and brittle, is used mainly in the manufacture of cheap furniture, match sticks, packing cases, boxes, plywood, building-boards, sports equipment and pencils (FAO 1980; Sheikh 1993).

The fruits of *B. papyrifera* are edible, as are the young leaves, when steamed. The leaves, fruit and bark have a variety of traditional medicinal uses. In China the leaves are fed to silk-worms (POWO 2020).

Paper mulberry is a vigorous pioneer species, which can rapidly colonise forest clearings and abandoned farmland. Its ability to colonise degraded lands may make it suitable for reforestation programs in some situations (Luna 1996), although it can become invasive when both male and female trees are present, followed by pollination and seed set. Paper mulberry is frequently planted as a shade tree. It tolerates air pollution, making it suitable for planting along roadsides and in urban settings. It is also grown as an ornamental in parks and gardens. The tree is widely coppiced for tapa and paper production, with the young trees cut every 12-18 months (POWO 2020).

Environmental pollution is an increasing global problem. In this context, *B. papyrifera* is tested for a possible use of tree planting for short-rotation coppicing and phytoremediation (Capuana 2020; Huang et al. 2019; Huimin et al. 2019; Kang et al. 2018). Soils are often polluted by different metals or organic compounds, so phytoremediation may require multiple plant species and ecotypes since most of the plants suited to this purpose show an aptitude to accumulate only one or a few pollutants. A pot experiment was carried out with the aim of determining the phytoextraction potential of the hyperaccumulator *Pteris vittata* when co-planted with a woody tree (*Morus alba* or *B. papyrifera*) in soil contaminated with Cd, Pb, Zn, or As. The uptake of As was significantly increased when co-planted with *Morus* or *Broussonetia* (by 80.0% and 64.2% respectively). However, co-plantation did not have a promoting effect on the metal accumulation of both *M. alba* and *B. papyrifera* (Capuana 2020).

Energy derived from biomass has been considered for many years, but was not pursued as a viable energy alternative to fossil fuels until recently as a result of declining fossil fuel sources and increasing oil prices. *Broussonetia papyrifera* may be considered as a 'second-generation' biofuel plant in short rotation woody crops providing lingo-cellulose, which is the woody structural material of plants that is abundant and diverse and has increasing appeal because it does not divert food away from the animal or the human food chain (Witt 2010; Dimitrou & Rutz 2015).

## SECTION B – Detailed assessment

### Important instructions:

- In the case of lack of information the assessors are requested to use a standardized answer: “No information has been found.”
- With regard to the scoring of the likelihood of events or the magnitude of impacts see Annexes I and II.
- With regard to the confidence levels, see Annex III.
- Highlight the selected response score and confidence level in **bold** but keep the other scores in normal text (so that the selected score is evident in the final document).

## 1 PROBABILITY OF INTRODUCTION AND ENTRY

### Important instructions:

- **Introduction** is the movement of the species into the risk assessment area (it may be either in captive conditions and/or in the environment, depending on the relevant pathways).
- **Entry** is the release/escape/arrival in the environment, i.e. occurrence in the wild
- Introduction and entry may coincide for species entering through pathways such as “corridor” or “unaided”, but it also may differ. If different, please consider all relevant pathways, both for the introduction into the risk assessment area and the entry in the environment.
- The classification of pathways developed by the Convention of Biological Diversity (CBD) should be used (see Annex IV). For detailed explanations of the CBD pathway classification scheme consult the IUCN/CEH guidance document<sup>3</sup> and the provided key to pathways<sup>4</sup>.
- For organisms which are already present (recorded or established) in the risk assessment area, the likelihood of introduction and entry should be scored as “very likely” by default.
- Repeated (independent) introductions and entries at separate locations in the risk assessment area should be considered here (see Qu. 1.7).

**Qu. 1.1. List relevant pathways through which the organism could be introduced into the risk assessment area and/or enter into the environment. Where possible give details about the specific origins and end points of the pathways as well as a description of any associated commodities.**

For each pathway answer questions 1.2 to 1.7 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 1.2a, 1.3a, etc. and then 1.2b, 1.3b etc. for the next pathway.

In this context a pathway is the route or mechanism of introduction and/or entry of the species.

<sup>3</sup> <https://circabc.europa.eu/sd/a/738e82a8-f0a6-47c6-8f3b-aeddb535b83b/TSSR-2016-010%20CBD%20categories%20on%20pathways%20Final.pdf>

<sup>4</sup> <https://circabc.europa.eu/sd/a/0aeba7f1-c8c2-45a1-9ba3-bcb91a9f039d/TSSR-2016-010%20CBD%20pathways%20key%20full%20only.pdf>

The description of commodities with which the introduction of the species is generally associated shall include a list and description of commodities with an indication of associated risks (e.g. the volume of trade; the likelihood of a commodity being contaminated or acting as vector).

If there are no active pathways or potential future pathways this should be stated explicitly here, and there is no need to answer the questions 1.2-1.9.

Table 8 list of pathways with relevance assessment

Category pathways	Subcategory	relevance
<b>Release in Nature</b>	Biological control	No information has been found.
	Erosion control / dune stabilization	No information has been found.
	Landscape / flora / fauna "improvement" in the wild	No information has been found.
	Introduction for conservation purposes	No information has been found.
	Release in nature for use	No information has been found.
	Other intentional release	No information has been found.
<b>Escape from confinement</b>	Agriculture	No information has been found.
	Botanical garden	relevant
	Forestry	No information has been found.
	Horticulture	relevant
	Ornamental purpose other than horticulture	relevant
	Research and ex-situ breeding	No information has been found.
	Other escape from confinement	No information has been found.
<b>Transport Containment</b>	Seed contaminant	No information has been found.
	Timber trade	No information has been found.
	Transportation of habitat material	No information has been found.
<b>Transport - Stowaway</b>	Machinery / equipment	No information has been found.
<b>Unaided</b>	Natural dispersal	No information has been found.

### Pathways considered but excluded from the risk assessment.

**Forestry:** *Broussonetia papyrifera* is mentioned in the context of biofuel plant in short rotation woody crops (Witt 2010; Dimitrou & Rutz 2015). This pathway was not considered for the risk assessment as there is no further evidence that this is an (active) pathway in the EU.

**Other escape from confinement:** *Broussonetia papyrifera* is mentioned in the context of phytoremediation (Capuana 2020; Huimin et al. 2019; Kang et al. 2018). This pathway was not considered for the risk assessment as there is no further evidence that this is an (active) pathway in the EU.

### Pathway name: Botanical garden/zoo/aquaria (excluding domestic aquaria)

**Qu. 1.2a. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	intentional	<b>CONFIDENCE</b>	low
-----------------	-------------	-------------------	-----

	unintentional		medium <b>high</b>
--	---------------	--	-----------------------

Response: Long before Linnaeus' time, paper mulberry had been cultivated widely in European gardens (Barker 2002). Currently, the species is regularly displayed in Botanical Gardens across the risk assessment area.

Selection of occurrences in botanical gardens inside the risk assessment area:

- Bochum (Germany)
- Córdoba (Spain)
- Frankenburg (Austria)
- Freiburg (Germany)
- Graz (Austria)
- Ljubljana (Slovenia)
- Meise (Belgium)
- Tübingen (Germany)
- Wrocław (Poland)
- Vienna (Austria)

**Qu. 1.3a. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: *Broussonetia papyrifera* is unisexual and dioecious. Thus, a male and female tree are needed if the ornamental and attractive fruits are to be shown to visitors. The fruits of *B. papyrifera* are consumed by birds and other small animals which are able to disseminate the seeds outside of botanical gardens. There is evidence in literature about spreading and seed dispersal by birds and small mammals (e.g. fruit bats), though no particular bird or mammal species is mentioned, neither for regions outside

of the risk assessment area nor for the risk assessment area. The seed density may be locally high. Root sprouts are produced when the main stem is cut. It can be assumed that these clonal sprouts are local and managed in botanical gardens according to the European Code of Conduct for Botanic Gardens on Invasive Alien Species (Heywood & Sharrock 2013). Nagodă et al. (2014) examined the “Dimitrie Brandza” Botanic Garden (Bucharest) as a potential centre for the dispersal of invasive plants. Paper mulberry has been assessed as: a species surviving in the climatic conditions of the Botanic Garden (Romania), it flowers, bears fruit and produces seeds and seedlings around the parent plant, without any human intervention.

**Qu. 1.4a. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
	unlikely		<b>medium</b>
	moderately likely		high
	<b>likely</b>		
	very likely		

Response: As the pathway is intentional, it is likely that the organism will survive. As the intention is showing the species itself as well as the ornamental and attractive fruits to visitors of the botanical garden, it is likely that male and female trees are planted in proximity. Then it is likely that the trees will reproduce during their life. Vegetative growth is controlled by the botanical garden management.

**Qu. 1.5a. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
	unlikely		<b>medium</b>
	moderately likely		high
	<b>likely</b>		
	very likely		

Response: As the pathway is intentional to display paper mulberry in botanical gardens, it is likely that the organism will survive.

**Qu. 1.6a. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
-----------------	---------------	-------------------	-----

	<b>unlikely</b> moderately likely likely very likely		<b>medium</b> high
--	---	--	-----------------------

Response: As the pathway is intended, it is unlikely that the organism introduction into the risk assessment area is undetected. On the other hand, an undetected dispersal of seeds by animals out of the botanical garden into the environment may be possible. A requirement for the latter is that male and female plants are present in the garden. In very rare cases, visitors may collect some fruits/seeds for planting in their garden or the wild.

**Qu. 1.7a. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	<b>isolated</b> widespread ubiquitous	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: Botanical gardens are neither ubiquitous nor widespread. Thus, the points of introduction into the environment in the risk assessment area are isolated.

**Qu. 1.8a. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: As a tree life cycle in botanical gardens normally span over several decades, planting *B. papyrifera* in such localities happens rarely. Though, if there are male and female trees in proximity, seeds may be produced over the whole life cycle. Vegetative growth is controlled by the botanical garden management. The overall likelihood of introduction is assessed as unlikely based upon the European Code of Conduct for Botanic Gardens on Invasive Alien Species (Heywood & Sharrock 2013).

**Pathway name: Horticulture**

**Qu. 1.2b. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	<b>intentional</b> unintentional	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	-------------------------------------	-------------------	------------------------------

Response: The horticulture pathway covers large scale/commercial cultivation of plants in a controlled or confined environment and is the intentional introduction of the species into the risk assessment area for commercial culturing. Paper mulberry had been cultivated widely for ornamental uses in European gardens for hundreds of years (Barker 2002).

The Horticulture pathway focuses on plants kept in commercial culturing facilities (nurseries, greenhouses) from where they may accidentally escape due to mismanagement, or during transport to/from locations as part of the nursery trade. Therefore, this pathway includes the bulk shipment of live plants for nurseries and gardens centres, and the intentional introduction of seeds (and potentially rhizomes) for planting.

An internet search reveals that the plant can be ordered (online) at local or regional tree nurseries in several EU member states (e.g. Spain, France, Ireland, Netherlands, Belgium, Germany, and Austria) as well as at online retailers like eBay or Amazon. Seeds, cuttings or trees are offered.

**Qu. 1.3b. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Seeds, cuttings or trees are offered at tree nurseries or at online retailers. *Broussonetia papyrifera* is unisexual and dioecious. Thus, it needs at least one male and well one female, tree for fruits to be produced. The fruits of paper mulberry are consumed by birds and other small animals which are able to disseminate the seeds outside of tree nurseries. There is evidence in the global literature on

spreading and seed dispersal by birds and small mammals (e.g. fruit bats), though no particular bird or mammal species is mentioned. The seed density may be locally very high, though no figures are available. Root sprouts are produced when the main stem is cut; though no information about management of root sprouts is available in the context of horticulture.

**Qu. 1.4b. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: The pathway ‘Horticulture’ is the deliberate movement of plant material into the risk assessment area and as such plant material would be maintained and moved to ensure survival. Three types of material can potentially enter the risk assessment area via this pathway (1) seed, (2) live plants and (2) rhizomes. Although seed import cannot be ruled out, it is unlikely to be part of the horticulture pathway for the commercial production of the species.

As the pathway is intentional, it is likely that the organism will survive. As the intention is to produce cuttings and, to a lesser extent, seeds for sale, it is likely that male and female trees are planted in proximity. Therefore, it is very likely that the trees will reproduce during their life.

**Qu. 1.5b. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: As the pathway is intentional, it is likely that the organism will survive existing management practices. Plant material is the commodity itself and it is deliberately moved for sale within the risk assessment area.

**Qu. 1.6b. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: As the pathway is intended, it is unlikely that the organism would be introduced into the risk assessment area undetected. On the other hand, the undetected dispersal of seeds by animals out of the tree nursery or root sprouts into the environment may be possible.

**Qu. 1.7b. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	<b>isolated</b> widespread ubiquitous	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: For live plant imports in the risk assessment area (introduction), each EU Member country has official entry points where plant material can be imported into. Tree nurseries or plant retailers are common in all EU member states; a selection of them may sell seeds, cuttings or trees of paper mulberry. Furthermore, these points are not evenly distributed over the member states area. In summary, possible points of introduction respectively the entry into the environment are assessed as isolated.

**Qu. 1.8b. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: The horticulture pathway involves the movement of plant material for planting from outside of the risk assessment area via nurseries and garden centers. As in tree nurseries or plant retailers, seeds, cuttings or trees of the paper mulberry are processed more frequently than e.g. in botanical gardens, an introduction into the risk assessment area or into the environment is assessed as moderately likely.

**Pathway name: Ornamental purpose other than horticulture**

**Qu. 1.2c. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	intentional unintentional	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	------------------------------	-------------------	------------------------------

Response: *Broussonetia papyrifera* had been cultivated widely for ornamental uses in European gardens and parks for hundreds of years (Barker 2002). The introduction into the risk assessment area is intentional for ornamental purposes in gardens and parks. A check based on a small random subset of the available spatial data (GBIF 2020) indicates that private and public gardens are the main locations recorded.

**Qu. 1.3c. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Seeds, cuttings or trees are sold at tree nurseries or at online retailers. *B. papyrifera* is unisexual and dioecious. Thus, it needs a male, as well as a female tree at least if the desired fruits are to be produced. Though, no information about sex ratio among the plant material sold in the risk assessment area is available to be able giving figures about reproduction. The fruits of *B. papyrifera* are consumed by birds and other small animals which are able to disseminate the seeds outside of gardens or parks. The seed density may be locally very high. Root sprouts are produced when the main stem is cut; though no information about management of root sprouts is available. In gardens, containment management is less common than in botanical gardens and parks.

**Qu. 1.4c. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: As the pathway is intentional (ornamental use in garden and parks), it is likely that the organism will survive. *Broussonetia papyrifera* is dioecious. Thus, it needs a male as well as a female tree to be planted in gardens or parks if fruits are to be produced. However, no information about sex ratio among the plant material sold in the risk assessment area is available to support the estimation of reproduction and the likelihood of increasing populations at such sites.

**Qu. 1.5c. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: As the pathway is intentional for ornamental purpose in gardens and parks, it is likely that the organism will survive existing management practices.

**Qu. 1.6c How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: As the pathway is intended for ornamental use in gardens and parks, it is very unlikely that the organism could be introduced into the risk assessment area undetected. On the other hand, an

undetected dispersal of seeds by animals out of the gardens or parks or root sprouts into the environment may be possible. However, no information about sex ratio among the plant material in the risk assessment area is available to be able to estimate undetected seed dispersal.

**Qu. 1.7c. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated widespread ubiquitous	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--------------------------------------	-------------------	------------------------------

Response: Occurrences in gardens and parks are neither ubiquitous nor widespread in the risk assessment area; there may be spatial clusters like in the Mediterranean or Atlantic regions. Additionally, occurrences in gardens may be more common than in botanical gardens, parks and nurseries. However in summary, possible points of introduction are assessed as isolated.

**Qu. 1.8c. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: There are no available sales figures regarding paper mulberry use in gardens. Thus, an introduction into the risk assessment area or into the environment is assessed as moderately likely with a low confidence; because the species is offered by tree nurseries, plant retailers and online in many EU member states.

**Qu. 1.9. Estimate the overall likelihood of introduction into the risk assessment area or entry into the environment based on all pathways and specify if different in relevant biogeographical regions in current conditions.**

Provide a thorough assessment of the risk of introduction in relevant biogeographical regions in current conditions: providing insight in to the risk of introduction into the risk assessment area.

<b>RESPONSE</b>	very unlikely unlikely	<b>CONFIDENCE</b>	low medium
-----------------	---------------------------	-------------------	---------------

	moderately likely likely <b>very likely</b>		<b>high</b>
--	---	--	-------------

Response: Paper mulberry is recorded in 19 EU member states (plus the United Kingdom) and already established in 8 out of 27 EU member states (see Table 5). According to the guidelines: For organisms which are already present (recorded or established) in the risk assessment area, the likelihood of introduction and entry should be scored as “very likely” by default. This has been scored with a high confidence.

However, there are differences at the biogeographical region level (see Figure 2). The species is recorded in the Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean and Pannonian biogeographical regions and can be already assessed as “established” in the Atlantic, Continental and Mediterranean biogeographical regions. The core areas of occurrences are the Atlantic, Mediterranean and Continental region parts in Western Europe.

**Qu. 1.10. Estimate the overall likelihood of introduction into the risk assessment area or entry into the environment based on all pathways in foreseeable climate change conditions?**

Thorough assessment of the risk of introduction in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of introduction (e.g. change in trade or user preferences)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely introduction within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Paper mulberry is recorded in 19 EU member states (plus the United Kingdom) and already established in 8 out of 27 (see Table 5). However, there are differences on the biogeographical region level (see Figure 3). The species is recorded in the Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean and Pannonian biogeographical regions and can be already assessed as “established” in

the Atlantic, Continental and Mediterranean biogeographical regions. The core areas are the Atlantic, Mediterranean and Continental region parts in Western Europe.

The ensemble SDM model (see Annex IX) suggested that suitability for *B. papyrifera* was most strongly determined by Minimum temperature of the coldest month (Bio6), accounting for 35% of variation explained, followed by Mean temperature of the warmest quarter (Bio10) (28%), Climatic moisture index (CMI) (25%) and Human influence index (HII) (11%).

The climate change scenarios RCP 2.6 and RCP 4.5 indicate a higher suitability in the Northern parts of Europe (compare Annex IX). Future climate change conditions may change the offer or availability of seeds, cuttings or trees by local or regional tree nurseries in the northern part of Europe as the demand from gardeners may increase with more suitable climate conditions.

## 2 PROBABILITY OF ESTABLISHMENT

### Important instructions:

- For organisms which are already established in parts of the risk assessment area or have previously been eradicated, the likelihood of establishment should be scored as “very likely” by default.
- Discuss the risk also for those parts of the risk assessment area, where the species is not yet established.

**Qu. 2.1. How likely is it that the organism will be able to establish in the risk assessment area based on similarity of climatic and abiotic conditions in its distribution elsewhere in the world?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: Paper mulberry is already established in 8 EU Member States (see Table 5) encompassing the Atlantic, Continental and Mediterranean biogeographical regions. Therefore establishment in the risk assessment area is considered very likely with a high confidence.

Paper mulberry can tolerate a wide range of climates, including humid tropical (monsoon), humid and sub-humid subtropical as well as warm temperate areas (EPPO 2019; Whistler & Elevitch 2006). The explicit Alpine, Boreal, Continental and Steppic parts of the risk assessment area are out of these climatic preferences to some extent (compare SDM in Annex IX).

*Broussonetia papyrifera* is unisexual and dioecious. Thus, it needs male as well as female trees to produce seeds. As information about sex distribution within the European occurrences is not available, it is not feasible to estimate the likelihood of species establishing from reproductive populations into new areas with suitable climatic and abiotic conditions. Root suckers are produced when the main stem is cut. Over time, this can lead to the formation of dense thickets and can be considered a means of establishment to some extent.

**Qu. 2.2. How widespread are habitats or species necessary for the survival, development and multiplication of the organism in the risk assessment area? Consider if the organism specifically requires another species to complete its life cycle.**

<b>RESPONSE</b>	very isolated isolated moderately widespread <b>widespread</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

	ubiquitous		
--	------------	--	--

Response: paper mulberry is considered a pioneer species adapted to colonize disturbed sites (Csurhes 2016). The species does not grow well under full shade and is suited to disturbed habitats, in particular to riparian habitats and gaps within subtropical forest (EPPO 2019). The fruits are dispersed by birds and small mammals (Seelenfreund et al. 2017; Wilcox 2004). The habitats are disturbed, open sites generally, where there is relatively well-drained, moist, fertile soil (e.g. along roadsides, Follak et al. 2018). There is some evidence that *B. papyrifera* also colonizes natural and semi-natural habitats such as thermophilic forests and dry grasslands (Montagnani et al. 2018). Such habitats are unevenly distributed but widespread within the European landscape.

**Qu. 2.3. How likely is it that establishment will occur despite competition from existing species in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: There is an indication of competition with other tree species as the species does not grow well under full shade. For the risk assessment area, no explicit information is available on competitive interactions with native plant species.

**Qu. 2.4. How likely is it that establishment will occur despite predators, parasites or pathogens already present in the risk assessment area?**

<b>RESPONSE</b>	N/A very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: No explicit information is available on predators, parasites or pathogens already present in the risk assessment area. Ellis (2020) gives some indication about whiteflies (*Aleyrodidae*) and scale insects (*Diaspididae*) as pests (Table 9).

Table 9 parasites on *Broussonetia papyrifera* (Ellis 2020)

organ	taxonomic group	parasite
leaf	Aleyrodidae	<i>Parabemisia myricae</i>
stem	Diaspididae	<i>Diaspidiotus ostreaeformis</i>

*Broussonetia papyrifera* can be lopped for fodder. In a study in Taiwan, the leaves were studied for digestibility. Of the various components, 67.7% of dry matter was digestible, crude protein 84.8%, crude fiber 65.5%, crude fat 35.0% and ash 50.3% (Lin et al. 1996). Paper mulberry seedlings and saplings are browsed by cattle (CABI 2020).

Pollack & Stevenson (1973) reported *Corynespora cassicola*, a fungal pathogen, causing “frog-eye” lesions on leaves of paper mulberry in Alabama (United States of America). A new disease associated with paper mulberry causing leaf yellowing and curling symptoms was observed in Nanjing, Jiangsu Province, China, in 2014 and 2015. Mei et al. (2016) identified a *Candidatus* Phytoplasma as the cause of the disease.

**Qu. 2.5. How likely is the organism to establish despite existing management practices in the risk assessment area? Explain if existing management practices could facilitate establishment.**

RESPONSE	CONFIDENCE
very unlikely	low
unlikely	medium
moderately likely	<b>high</b>
likely	
<b>very likely</b>	

Response: Paper mulberry is already established in 8 EU Member States as well as in the Atlantic, Continental and Mediterranean biogeographical regions. Thus, existing management practices related to introduction pathways/vectors could not prevent the entry into the environment of sufficient propagules for establishment. Considering the already established populations in Europe and the large EU area to be monitored, further establishment is considered very likely. The planting of paper mulberry trees in parks and gardens would serve as a new possible source of propagules (seeds). Furthermore, intensified land use facilitates establishment by disturbing semi-natural and natural habitats.

**Qu. 2.6. How likely is it that biological properties of the organism would allow it to survive eradication campaigns in the risk assessment area?**

RESPONSE	CONFIDENCE
very unlikely	low
unlikely	medium
moderately likely	<b>high</b>
likely	
<b>very likely</b>	

Response: Root shoot suckers are produced when the main stem is cut. Over time, this can lead to the formation of dense thickets (e.g. Bosu & Apetorgor 2020). The organism may survive eradication campaigns as the removal of all plant parts is difficult (CABI 2020, Csurhes 2016), though an eradication on a local level may be feasible.

**Qu. 2.7. How likely are the biological characteristics of the organism to facilitate its establishment in the risk assessment area?**

including the following elements:

- a list and description of the reproduction mechanisms of the species in relation to the environmental conditions in the risk assessment area
- an indication of the propagule pressure of the species (e.g. number of gametes, seeds, eggs or propagules, number of reproductive cycles per year) of each of those reproduction mechanisms in relation to the environmental conditions in the risk assessment area.
- If relevant, comment on the likelihood of establishment based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in establishment whereas for others high propagule pressure (many thousands of individuals) may not.
- If relevant, comment on the adaptability of the organism to facilitate its establishment and if low genetic diversity in the founder population would have an influence on establishment.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: Paper mulberry exhibits a high reproductive potential, by means of both sexual and vegetative propagation (Maan et al. 2020; Morgan et al. 2019). *Broussonetia papyrifera* is an extremely fast growing tree. Whistler & Elevitch (2006) indicate a fast growth rate with just 12-18 months required to reach a size of 3-4m. The tree shows the characteristics of a vigorous pioneer on disturbed sites. Lu et al. (1984) carried out a study on *B. papyrifera* in Taiwan to determine the variation in seed size and weight, average number of days for germination, and growth of seedlings under different nursery conditions. Seeds have a germination rate of 50 % or less in moist soils (EPPO 2019). Studies about the genetic diversity are available for the origin and their surroundings in East Asia (e.g. Liao et al. (2014), Payacan et al. (2017), Peng et al. (2019), Seelenfreund et al. (2011)), though no relevant information can be found for the risk assessment area. Furthermore, no relevant information about propagule pressure within the risk assessment can be found.

The species is dioecious. Thus, it needs male as well as female trees to produce seeds. If male and female plants are present, mid- to long-range dispersal is possible via seeds. The fruits are dispersed by birds and small mammals. Seeds rarely germinate under dense forest canopies, but germination can be prolific in large canopy gaps, roadsides and abandoned farmland.

**Qu. 2.8. If the organism does not establish, then how likely is it that casual populations will continue to occur?**

Consider, for example, a species which cannot reproduce in the risk assessment area, because of unsuitable climatic conditions or host plants, but is present because of recurring introduction, entry and release events. This may also apply for long-living organisms.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The paper mulberry is already established in 8 out of 27 EU member states as well as in the Atlantic, Continental and Mediterranean biogeographical regions. According to the above specified pathways for introduction/entry (e.g. horticulture, ornamental purpose other than horticulture), recurring introductions may occur.

*Broussonetia papyrifera* can tolerate a wide range of climates, including humid tropical (monsoon), humid and sub-humid subtropical as well as warm temperate areas (EPPO 2019; Whistler & Elevitch 2006). It can grow in areas with an annual rainfall of 700–2 500 mm (EPPO 2019; CABI 2020), though the species can survive a 3–4 month dry season (Whistler & Elevitch 2006).

It is very likely that casual populations will continue to occur, as long as habitats with disturbed site conditions are available in the neighborhood. The tree shows the characteristics of a vigorous pioneer on disturbed sites. Paper mulberry exhibits a high reproductive potential, by means of both sexual and vegetative propagation (Maan et al. 2020; Morgan et al. 2019).

**Qu. 2.9. Estimate the overall likelihood of establishment in the risk assessment area under current climatic conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under current climatic conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in current conditions: providing insight in the risk of establishment in (new areas in) the risk assessment area.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The paper mulberry is currently established in 7 EU Member States as well as in the Atlantic, Continental and Mediterranean biogeographical regions.

*Broussonetia papyrifera* can tolerate a wide range of climates, including humid tropical (monsoon), humid and sub-humid subtropical as well as warm temperate areas (EPPO 2019; Whistler & Elevitch

2006). It can grow in areas with an annual rainfall of 700–2 500 mm (EPPO 2019; CABI 2020), though the species can survive a 3–4 month dry season (Whistler & Elevitch 2006).

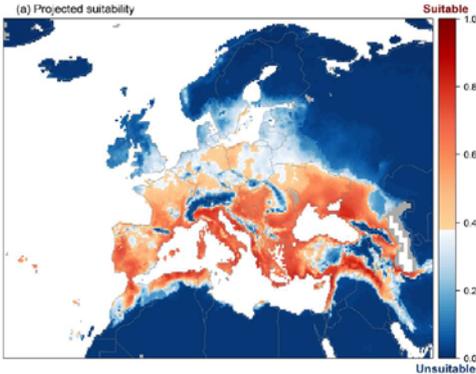

Figure 8 Projected current suitability for *Broussonetia papyrifera* establishment in Europe

According to the species distribution model (see Annex IV), large parts of the risk assessment area (compare Figure 8) are already suitable under current climatic conditions. The suitability declines in the North (Boreal biogeographical region) and Northwest regions of Europe.

**Qu. 2.10. Estimate the overall likelihood of establishment in the risk assessment area under foreseeable climate change conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under foreseeable climate change conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of establishment (e.g. increase in average winter temperature, increase in drought periods)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely establishment within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: Paper mulberry is already established in 8 EU Member States as well as in the Atlantic, Continental and Mediterranean biogeographical regions. *Broussonetia papyrifera* can tolerate a wide range of climates, including humid tropical (monsoon), humid and sub-humid subtropical as well as warm temperate areas (EPPO 2019; Whistler & Elevitch 2006). It can grow in areas with an annual rainfall of 700–2 500 mm (EPPO 2019; CABI 2020), though the species can survive a 3–4 month dry season (Whistler & Elevitch 2006). The climate change scenarios RCP 2.6 and RCP 4.5 indicate a higher suitability in the northern parts of Europe (compare Annex IX) by an increase in average winter temperature.

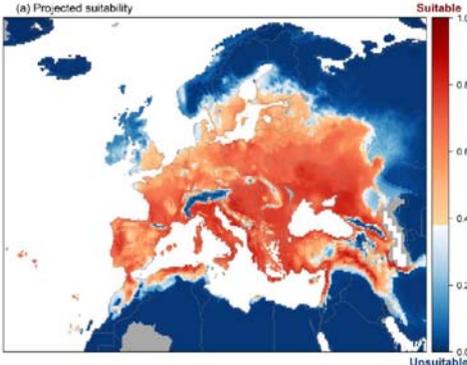

Figure 9 Projected suitability for *Broussonetia papyrifera* establishment in Europe in the 2070s under climate change scenario RCP2.6

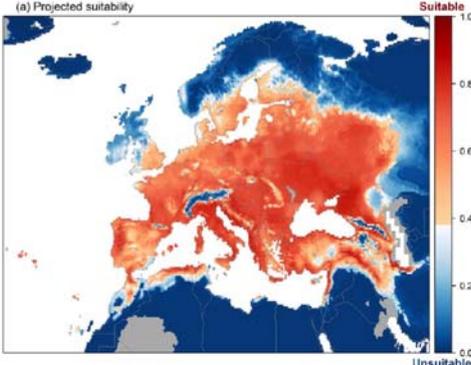

Figure 10 Projected suitability for *Broussonetia papyrifera* establishment in Europe in the 2070s under climate change scenario RCP4.5

Both climate change scenarios RCP 2.6 and RCP 4.5 indicate a higher suitability in the northern and eastern parts of Europe (compare Annex IX) by an increase in average summer temperature as well low temperature in winter (Mean temperature of the warmest quarter - Bio10, Minimum temperature of the coldest month - Bio6). Boreal and Continental regions are affected by an increased climatic suitability for *B. papyrifera*.

### 3 PROBABILITY OF SPREAD

**Important instructions:**

- Spread is defined as the expansion of the geographical distribution of an alien species within the risk assessment area.
- Repeated releases at separate locations do not represent continuous spread and should be considered in the probability of introduction and entry section (Qu. 1.7).

**Qu. 3.1. How important is the expected spread of this organism within the risk assessment area by natural means? (List and comment on each of the mechanisms for natural spread.)**

including the following elements:

- a list and description of the natural spread mechanisms of the species in relation to the environmental conditions in the risk assessment area.
- an indication of the rate of spread discussed in relation to the species biology and the environmental conditions in the risk assessment area.

The description of spread patterns here refers to the CBD pathway category “Unaided (Natural Spread)”. It should include elements of the species life history and behavioural traits able to explain its ability to spread, including: reproduction or growth strategy, dispersal capacity, longevity, dietary requirements, environmental and climatic requirements, specialist or generalist characteristics.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: The potential for natural dispersal is assessed as moderate with a medium confidence. References or figures of the spread rate of populations already established in the risk assessment area are not available.

*Broussonetia papyrifera* is dioecious. Thus, it needs male as well as female trees to produce seeds. Peñailillo et al. (2016) found that contemporary paper mulberry plants are all female in near and remote Oceania, with the exception of Hawaii, where plants of both sexes are found. Information about the sex distribution/ratio within the European occurrences is not available. If male and female plants are present, (long) to mid-range dispersal may occur via seeds as fruits are dispersed by birds and small mammals. Root suckers are produced when the main stem is cut. Over time, this can lead to the formation of dense thickets so clonal growth would allow slow spreading to some extent. Natural spread may occur as long as suitably disturbed habitats are available.

**Qu. 3.2a. List and describe relevant pathways of spread other than "unaided". For each pathway answer questions 3.3 to 3.9 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 3.3a, 3.4a, etc. and then 3.3b, 3.4b etc. for the next pathway.**

including the following elements:

- a list and description of pathways of spread with an indication of their importance and associated risks (e.g. the likelihood of spread in the risk assessment area, based on these pathways; likelihood of survival, or reproduction, or increase during transport and storage; ability and likelihood of transfer from the pathway to a suitable habitat or host) in relation to the environmental conditions in the risk assessment area.
- an indication of the rate of spread for each pathway discussed in relation to the species biology and the environmental conditions in the risk assessment area.
- All relevant pathways of spread (except “Unaided (Natural Spread)”, which is assessed in Qu. 4.1) should be considered. The classification of pathways developed by the Convention of Biological Diversity shall be used (see Annex IV).

Table 10 list of spread pathways including relevant assessment and estimated rate of spread

Category pathways	Subcategory	relevance	rate of spread
<b>Release in Nature</b>	Biological control	No information has been found.	
	Erosion control / dune stabilization	No information has been found.	
	Landscape / flora / fauna "improvement" in the wild	No information has been found.	
	Introduction for conservation purposes	No information has been found.	
	Release in nature for use	No information has been found.	
	Other intentional release	No information has been found.	
<b>Escape from confinement</b>	Agriculture	No information has been found.	
	Botanical garden	not relevant	
	Forestry	No information has been found.	
	Horticulture	relevant	slow
	Ornamental purpose other than horticulture	relevant	slow
	Research and ex-situ breeding	No information has been found.	
	Other escape from confinement	No information has been found.	
<b>Transport Containment</b>	Seed contaminant	No information has been found.	
	Timber trade	No information has been found.	
	Transportation of habitat material	No information has been found.	
<b>Transport - Stowaway</b>	Machinery / equipment	No information has been found.	

Horticulture and ornamental purpose other than horticulture are considered as relevant spread pathways. *Broussonetia papyrifera* is unisexual and dioecious. Thus, it needs male as well as female trees to produce seeds. Along both pathways, male and female individuals are not always available. There is evidence in the literature of spreading and seed dispersal by birds and small mammals (e.g. fruit bats), though no particular bird or mammal species are mentioned, neither for regions outside of the risk assessment area nor for within the risk assessment area. The rate of reproduction and rate of spread are considered to be slow.

**Pathway name: Horticulture**

**Qu. 3.3a. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	-------------------------------------	-------------------	------------------------------

Response: This spread pathway is unintentional. Nurseries and retailers are moving plants or seeds from site a to site b within the risk assessment area. Seeds may be lost while the nursery is transporting trees or seeds. Birds or mammals may disseminate seeds outside of the nurseries.

**Qu. 3.4a. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	<b>very unlikely</b> unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Although the plant can be ordered online at local or regional tree nurseries in several EU member states as well as at online retailers, information on the number male as well as female trees are kept and sold are not available. The seed density may be locally very high, though in many cases low as they are young plants. The fruits of paper mulberry are consumed by birds and other small animals which are able to disseminate the seeds outside of horticulture. Root spread is very unlikely as they will be potted beforehand. In summary it is considered as very unlikely that a number of individuals sufficient to originate a viable population over the course of a year would be spread via this pathway.

**Qu. 3.5a. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Reproduction during transport is very unlikely, though moderate likely during storage; while surviving is likely. The higher score is given.

**Qu. 3.6a. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: Existing management practices related to this spread pathway could not prevent the entry into the environment of sufficient propagules for establishment. The confidence level is low, as no references or figures are available.

**Qu. 3.7a. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Undetected dispersal of seeds by animals from a horticultural setting or of plant material during transport by nurseries into the environment may be possible.

**Qu. 3.8a. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Paper mulberry is considered to be a pioneer species adapted to colonize disturbed sites. The suitable habitats are disturbed, open sites generally, where there is relatively well-drained, moist,

fertile soil. Such suitable habitats are unevenly spatially distributed. Furthermore, the plants are grown in protected conditions and correct disposal of plant waste may be applied. The transfer from the pathway to a suitable habitat is assessed as unlikely as all conditions above have to be fulfilled.

**Qu. 3.9a. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area. (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly slowly moderately rapidly very rapidly	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: The overall potential rate of spread is assessed as very slow as all conditions mentioned in Qu. 3.8a have to be fulfilled.

**Pathway name: Ornamental purpose other than horticulture**

**Qu. 3.3b. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	-------------------------------------	-------------------	------------------------------

Response: This spread pathway is unintentional. While maintaining garden stock (bushes and trees), plant materials like seeds and cuttings may be carelessly disposed of. Birds or mammals may disseminate seeds outside of the gardens. There is evidence in literature about spreading and seed dispersal by birds and small mammals (e.g. fruit bats), though no particular bird or mammal species is mentioned, neither for regions outside of the risk assessment area nor for the risk assessment area.

**Qu. 3.4b. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway

- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: *Broussonetia papyrifera* is unisexual and dioecious. It is unlikely that both, male and female, trees are planted in e.g. gardens in most cases. The fruits of paper mulberry are consumed by birds and other small animals which are able to disseminate the seeds outside of gardens and parks. Plant material may be disposed of to a small extent. In summary it is considered as very unlikely that a number of individuals sufficient to originate a viable population over the course of a year is spread via this pathway.

**Qu. 3.5b. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: It is very unlikely that the organism will survive, reproduce or increase during transport and storage along this pathway.

**Qu. 3.6b. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Existing management practices related to this spread pathways could not prevent the entry into the environment of sufficient propagules for establishment.

**Qu. 3.7b. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Undetected dispersal of seeds by animals out of gardens or of plant material by gardeners' disposal into the environment may be possible.

**Qu. 3.8b. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	<b>very unlikely</b> unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Paper mulberry is considered to be a pioneer species adapted to colonize disturbed sites. The habitats are disturbed, open sites generally, where there is relatively well-drained, moist, fertile soil. Such suitable habitats are unevenly spatially distributed. The transfer from the pathway to a suitable habitat is assessed as unlikely as all conditions above have to be fulfilled.

**Qu. 3.9b. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area. (please provide quantitative data where possible).**

<b>RESPONSE</b>	<b>very slowly</b> slowly moderately rapidly very rapidly	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: The overall potential rate of spread is assessed as very slow as all conditions mentioned in Qu. 3.8b have to be fulfilled.

**Qu. 3.10. Within the risk assessment area, how difficult would it be to contain the organism in relation to these pathways of spread?**

<b>RESPONSE</b>	very easy easy <b>with some difficulty</b> difficult very difficult	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: Naturally dispersing organisms are difficult to contain, especially plants with pioneer character. Though, the removal of flowering trees could prevent further spread.

**Qu. 3.11. Estimate the overall potential rate of spread in relevant biogeographical regions under current conditions for this organism in the risk assessment area (indicate any key issues and provide quantitative data where possible).**

Thorough assessment of the risk of spread in relevant biogeographical regions in current conditions, providing insight in the risk of spread into (new areas in) the risk assessment area.

<b>RESPONSE</b>	very slowly <b>slowly</b> moderately rapidly very rapidly	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: *Broussonetia papyrifera* is dioecious. If male and female plants are present, mid-range dispersal may occur via seeds as birds and small mammals disperse fruits. Information on sex distribution within the European occurrences is not available. Some of the member states with early observations from about 100 or more years ago and Atlantic / Mediterranean climatic conditions (e.g. France 1890, Italy 1923, Spain 1892) exhibit a wide distribution (see Figure 3). Paper mulberry is considered to be a pioneer species adapted to colonize disturbed sites. The habitats are disturbed, open sites generally, where there is relatively well-drained, moist, fertile soil. Such suitable habitats are unevenly spatially distributed.

The overall potential rate of spread under current conditions is assessed as “slowly” because all constraint conditions (i.e. male and female plant availability, animals disseminating fruits and seeds, suitable habitats in a sufficient quantity) have to be fulfilled. Information on the rate of spread within the risk assessment area could not be found.

**Qu. 3.12. Estimate the overall potential rate of spread in relevant biogeographical regions in foreseeable climate change conditions (provide quantitative data where possible).**

Thorough assessment of the risk of spread in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk, specifically if rates of spread are likely slowed down or accelerated.

RESPONSE		CONFIDENCE	
	very slowly <b>slowly</b> moderately rapidly very rapidly		low <b>medium</b> high

Response: The overall potential rate of spread is expected to remain “slowly” as all constraint conditions (i.e. male and female plant availability, animals disseminating fruits and seeds, suitable habitats in a sufficient quantity) have to be fulfilled, but this will likely apply to an even more extensive part of the risk assessment area due to favorable climatic conditions.

## 4 MAGNITUDE OF IMPACT

Important instructions:

- Questions 4.1-4.5 relate to biodiversity and ecosystem impacts, 4.6-4.8 to impacts on ecosystem services, 4.9-4.13 to economic impact, 4.14-4.15 to social and human health impact, and 4.16-4.18 to other impacts. These impacts can be interlinked, for example, a disease may cause impacts on biodiversity and/or ecosystem functioning that leads to impacts on ecosystem services and finally economic impacts. In such cases the assessor should try to note the different impacts where most appropriate, cross-referencing between questions when needed.
- Each set of questions starts with the impact elsewhere in the world, then considers impacts in the risk assessment area (=EU+UK, excluding outermost regions) separating known impacts to date (i.e. past and current impacts) from potential future impacts (including foreseeable climate change).
- Only negative impacts are considered in this section (socio-economic benefits are considered in Qu. A.7)
- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”.

### Biodiversity and ecosystem impacts

**Qu. 4.1. How important is the impact of the organism on biodiversity at all levels of organisation caused by the organism in its non-native range excluding the risk assessment area?**

including the following elements:

- Biodiversity means the variability among living organisms from all sources, including terrestrial, marine and other aquatic ecosystems and the ecological complexes of which they are part; this includes diversity within species, between species and of ecosystems
- impacted chemical, physical or structural characteristics and functioning of ecosystems

RESPONSE		CONFIDENCE	
	minimal		low
	minor		<b>medium</b>
	moderate		high
	<b>major</b>		
	massive		

Response: *Broussonetia papyrifera* is a recognized invader in many countries around the world. Much research has been done in sensitive habitats in Pakistan where it is considered to be “one of the most unwieldy woody exotics in the Himalayas foothills due to its adverse effect on the native vegetation” (Malik & Husain 2006) and was further reported as the most critical issue confronting the managers of the Margalla Hills National Park in that country. Malik & Husein (2006) also reported that the weed “has shown vigorous growth extending over large areas excluding many other plant species, so invaded areas have considerably lower richness and biodiversity of herbaceous as well as woody species”. In a thorough biodiversity study of 77 plots in and around Islamabad, Malik & Husein (2007) described the

plant as a real threat to scrub forest floristic diversity because instead of small herbaceous vegetation, nothing else grows under the canopy of *B. papyrifera*. They observed at some plots a high density of *B. papyrifera* where vegetation is more or less undisturbed so it would seem capable of invading intact vegetation. In Pakistan, direct competition of *B. papyrifera* limits the growth of the native *Dalbergia sissoo*, *Morus alba* and *Ziziphus sp.*, an important source of nectar for honey bees, especially near Islamabad and Rawalpindi. The thick monocultures at different sites have rapidly replaced the native flora and fauna, although these thickets have also become refuges for wild boar and other mammals, and enhanced the build-up of the crow population (CABI 2020). Qureshi et al. (2020a) demonstrated that *B. papyrifera* reduced the values of diversity indices in invaded plots compared to the control plots in 5 districts in Pakistan. The authors go on to state that this trend of decreased values of ecological indices is “similar to invasion studies on *B. papyrifera* from Australia, Argentina, Carolina, Columbia, Florida, Georgia, Louisiana, Maryland, North Carolina, Oklahoma, Pennsylvania, South Tennessee, Uganda and Virginia” where it is considered invasive in natural areas (see e.g Csurhes, 2016 and Ghera et al, 2002).

In Ghana, *B papyrifera* has the ability to reduce the abundance of indigenous broadleaf forest species (Bosu et al. 2013). According to Agyeman & Kyereh (1997) and Agyeman (2000), paper mulberry is a major threat to native species regeneration and succession in Ghana’s forest ecosystems and is gradually establishing itself as one of the dominant species in the forest–savannah transition ecosystem. It is even able to displace *Chromolaena odorata*, a highly invasive species in Ghana (Bosu et al. 2013). In Uganda a recent study confirmed that areas that had been invaded by *B. papyrifera* had much lower diversity indices than the forest reserve which it is actively invading (Yamungu, 2020)

Ghera et al. (2002) consider *B. papyrifera* to be one of the worst invasive species in Pampa grasslands in Argentina.

Given the fact that many of the examples listed are at significant scale and of high impact despite being technically reversible a score of major is given with medium confidence.

**Qu. 4.2. How important is the current known impact of the organism on biodiversity at all levels of organisation (e.g. decline in native species, changes in native species communities, hybridisation) in the risk assessment area (include any past impact in your response)?**

Discuss impacts that are currently occurring or are likely occurring or have occurred in the past in the risk assessment area. Where there is no direct evidence of impact in the risk assessment area (for example no studies have been conducted), evidence from outside of the risk assessment area can be used to infer impacts within the risk assessment area.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: *Broussonetia papyrifera* is reported as invasive in the Lombardy and Piedmont and Ticino (Mangili et al. 2018) areas of Italy. The greatest environmental damage is reported to occur when it colonizes natural and semi-natural formations such as thermophilic forests and dry grasslands

(Montagnani et al. 2018). In the framework of the Italian LIFE project LIFE03 NAT/IT/000119 dense stands of *B. papyrifera* have been highlighted as a clear menace to the conservation of Habitat 6210\* (Semi-natural dry grasslands and scrubland facies on calcareous substrates - *Festuco-Brometalia* - \*important orchid sites) so that are tackled in the management plan (Lasen et al. 2008).

Further, the species is listed as invasive in Croatia (Vuković et al. 2014, Borsic et al. 2008), Montenegro (Bulatovic et al. 2016). France has several reports of invasiveness including in the Auvergne-Rhône-Alpes (Pôle d'information flore-habitats-fonge d'Auvergne-Rhône-Alpes 2020) where it is also recorded as an emerging invasive (Debay et al. 2020) and it is listed as “one-to-watch” in the Pays de la Loire (Dortel & Le Bail 2019) and Provence Alpes-Côte d’Azur (Terrin et al. 2014).

Dana et al. (2001), in their assessment of plant invaders in Spain, recorded *B. papyrifera* on a checklist of species that are considered as highly invasive in other European countries and which may represent a potential threat for Spanish ecosystems.

According to Montagnani et al. (2018) the species creates monotypic populations that exclude other species, inhibiting their renewal and changing the light conditions on the ground. It is able to absorb large quantities of water, with negative effects on water availability for other plants

The score is moderate because of the limited evidence of any impact on biodiversity in the risk assessment area.

**Qu. 4.3. How important is the potential future impact of the organism on biodiversity at all levels of organisation likely to be in the risk assessment area?**  
 See comment above. The potential future impact shall be assessed only for the risk assessment area.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: The tree is likely to continue to spread slowly and is more likely to displace native species as it has in other parts of the world, even though there is only limited evidence of impact in the risk assessment area as yet, so the score is assessed as major but confidence level is .

**Qu. 4.4. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism currently in the risk assessment area?**  
 including the following elements:

- native species impacted, including red list species, endemic species and species listed in the Birds and Habitats directives
- protected sites impacted, in particular Natura 2000
- habitats impacted, in particular habitats listed in the Habitats Directive, or red list habitats

- the ecological status of water bodies according to the Water Framework Directive and environmental status of the marine environment according to the Marine Strategy Framework Directive

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: Only limited information has been found, and the species predominantly is found in areas that are impacted by humans. However, the threats to the goals of the Habitats Directive have been highlighted by the Italian LIFE project LIFE03 NAT/IT/000119.

**Qu. 4.5. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.4.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: As there is no evidence of decline in conservation value in the risk assessment area, there is no baseline on which to extrapolate likely future impacts. It is likely that the tree will spread out from ruderal habitats especially along transport corridors and this is likely to increase the propagule pressure in natural and sensitive environments, much as it has in non-European invasions. Therefore these impacts are likely to become more significant in the future so a score of moderate with low confidence is given.

## Ecosystem Services impacts

**Qu. 4.6. How important is the impact of the organism on provisioning, regulating, and cultural services in its non-native range excluding the risk assessment area?**

- For a list of services use the CICES classification V5.1 provided in Annex V.
- Impacts on ecosystem services build on the observed impacts on biodiversity (habitat, species, genetic, functional) but focus exclusively on reflecting these changes in relation to their links with socio-economic well-being.
- Quantitative data should be provided whenever available and references duly reported.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: Qureshi et al. (2020a) refer to damaged ecosystem services due to *Broussonetia* invasion in Pakistan. It is believed to be allelopathic in the Philippines (Combalicer et al. 2019) which will have an impact on local biodiversity and succession, by affecting soil quality regulation provisioning biomass of wild plants. Further impacts on regulation services, specifically soil quality are through soil nutrient manipulation to its own benefit in Ghana (Kofi Anning et al. 2018). Additional evidence of soil quality regulation and local biodiversity comes from a recent study in India summarised that “the soil in highly invaded areas was more acidic with greater conductivity, phenolic content, and organic carbon content (Maan et al, 2021), but the authors go on to query whether *B. papyrifera* actually alters soil physico-chemical properties or prefers to inhabit soil with such characteristics.

*Broussonetia papyrifera* can affect provisioning for water as it is recorded as having the capability of massive water consumption, but also slowing the flow of water in channels and suppressing the growth of other plants. (CABI 2019). Additionally, the flow of most of the drains of Nallah Lai near Rawalpindi and Islamabad, Pakistan, are affected resulting in increased flood risks and impacting on Regulation of baseline flows and extreme events. Its shallow root system makes it susceptible to blowing over during high winds (Malik 2007), posing a hazard to people and causing slope erosion and further degradation of an area. It has a moderate impact score because the impacts are technically reversible and confidence is medium because the impact is more than minor with multiple aspects of provisioning affected but the supporting information could be better.

**Qu. 4.7. How important is the impact of the organism on provisioning, regulating, and cultural services currently in the different biogeographic regions or marine sub-regions where the species has established in the risk assessment area (include any past impact in your response)?**

- See guidance to Qu. 4.6.

<b>RESPONSE</b>	N/A minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: According to Montagnani et al. (2018) the species creates monotypic populations that exclude other species, inhibiting their renewal and changing the light conditions on the ground. It is able to absorb large quantities of water, with negative effects on water availability for other plants. Therefore, the ecosystem services impacts of *B. papyrifera* include provisioning of water with local impacts on provisioning of biomass of wild plants with associated impacts on cultural ecosystem services in the category of cultural and experiential. The score is assessed as minor given that it is reported as forming

monotypic populations that affect light and water thereby having significant ecosystem impact but since there is little direct assessment published and therefore confidence levels are low.

**Qu. 4.8. How important is the impact of the organism on provisioning, regulating, and cultural services likely to be in the different biogeographic regions or marine sub-regions where the species can establish in the risk assessment area in the future?**

- See guidance to Qu. 4.6.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: There is limited evidence of impact thus far in the risk assessment area but in future conditions, impact on ecosystem services is likely to increase along with other impacts but perhaps not enough to be scored as moderate. Confidence is low because of the lack of published evidence.

## Economic impacts

**Qu. 4.9. How great is the overall economic cost caused by the organism within its current area of distribution (excluding the risk assessment area), including both costs of / loss due to damage and the cost of current management.**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the world these should be reported here. The assessment of the potential costs of / loss due to damage shall describe those costs quantitatively and/or qualitatively depending on what information is available. Cost of / loss due to damage within different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage. As far as possible, it would be useful to separate costs of / loss due to the organism from costs of current management.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: Quereshi et al. (2020) report choking of sewerage lines in urban set-up and increased crow population acting as seed dispersal vector. The mechanical removal of paper mulberry in Islamabad alone is several million rupees per year (Rashid et al. 2014) which equates to tens of thousands of euros per year. This economic impact appears low in a European setting as it was calculated from Pakistan data, but those costs would be much higher in a European country and management costs are also being incurred in the USA, but no figures were found.

*Broussonetia papyrifera*, as other invasive tree species, are reported as “not only reducing the land value and causing economic loss to agriculture communities, but are also a source of allergy and related health problems in Islamabad and Peshawar” (Marwat et al. 2010), though no detail is given on the nature and extent of the economic impact.

**Qu. 4.10. How great is the economic cost of / loss due to damage (excluding costs of management) of the organism currently in the risk assessment area (include any past costs in your response)?**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the EU these should be reported here. Assessment of the potential costs of damage on human health, safety, and the economy, including the cost of non-action. A full economic assessment at EU scale might not be possible, but qualitative data or different case studies from across the EU (or third countries if relevant) may provide useful information to inform decision making. In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. Cost of / loss due to damage within different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>	N/A <b>minimal</b> minor moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: No information has been found on the issue but the question is applicable so a minimal score is given with low confidence.

**Qu. 4.11. How great is the economic cost of / loss due to damage (excluding costs of management) of the organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.10.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: It is assumed that increased spread and associated impact will have a greater than 10,000 euro per year cost across the many countries that would be host to the plant, especially given its allergenic impacts, but confidence is low.

**Qu. 4.12. How great are the economic costs / losses associated with managing this organism currently in the risk assessment area (include any past costs in your response)?**

- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”.

<b>RESPONSE</b>	<b>minimal</b> minor moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: There is no evidence that any management is being undertaken in the risk assessment area.

**Qu. 4.13. How great are the economic costs / losses associated with managing this organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.12.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: Due to the vigorous regrowth from cut stumps, vegetative root regeneration and seed dispersal, control using traditional methods is both labour intensive and costly with repeated applications needed to achieve a restored habitat. Manual removal (uprooting) and cutting coupled with an application of systemic herbicides have been shown to be effective in controlling shrub forms of the plant. Spread may be limited in the short term so a minor score is given with low confidence given the lack of current management figures in the area on which to build.

## Social and human health impacts

**Qu. 4.14. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism for the risk assessment area and for third countries, if relevant (e.g. with similar eco-climatic conditions).**

The description of the known impact and the assessment of potential future impact on human health, safety and the economy, shall, if relevant, include information on

- illnesses, allergies or other affections to humans that may derive directly or indirectly from a species;

- damages provoked directly or indirectly by a species with consequences for the safety of people, property or infrastructure;
- direct or indirect disruption of, or other consequences for, an economic or social activity due to the presence of a species.

Social and human health impacts can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: As far back as early 20<sup>th</sup> Century the allergenic pollen of *B. papyrifera* was recognized as a causal agent for respiratory problems like hay fever and asthma in sensitized patients (Bernton 1928; Balyeat & Rinkel 1931) particularly due to its vast pollen production (Velasco-Jiménez et al. 2014). Asthma leads to difficulty breathing whilst allergic rhinitis (hay fever) is a type of inflammation in the nose that occurs when the immune system overreacts to allergens in the air. Signs and symptoms include a runny or stuffy nose, sneezing, red, itchy, and watery eyes, and swelling around the eyes.

In Islamabad, Pakistan, *B. papyrifera* is the main source of airborne allergens (Malik & Husein 2007). Its pollen cause rhinitis and asthma in Pakistan (Qureshi et al. 2020a, 2020b) and it is a major cause of urticaria and severe respiratory symptoms (Aslam et al. 2015). Also in Taiwan (Hsu et al. 2008) it is an emerging aeroallergen associated with allergic illness (Wu et al. 2019). During 1995, the Pakistan Medical Research Council found more than 45% of the allergic patients in Islamabad and Rawalpindi showed positive sensitivity to pollen of *B. papyrifera*, and it was considered extremely important for pollen allergy tests not only because of allergenicity of its pollen, but also for the high quantity of pollen produced and pollen dispersibility (CABI 2019). A study in the same region showed a clear correlation between rate of patient admission for allergies with the flowering period of *B. papyrifera* (Ghufran et al. 2013), later supported also by a study by Qazi et al. (2019). There is a suggestion that the human reaction is triggered by two proteins of 40kDa which may lead to the development of immunological treatments (Aslam et al, 2015)

In addition, the growth and excessive root systems of *B. papyrifera* has impeded the flow of most of the drains of Nallah Lai near Rawalpindi and Islamabad, Pakistan, resulting in increased flood risks, and is considered to have assisted in the worst flood of the history in Rawalpindi where many people died or lost their homes (CABI 2019). Its shallow root system makes it susceptible to blowing over during high winds, posing a hazard to people and causing slope erosion and further degradation of an area (National Park Service 2010).

There is limited evidence of human impacts in the risk assessment areas apart from a report of pollenosis relating to *Broussonetia* in the hospital of Este (Zanforlin & Incorvaia, 2004). Despite this, the evidence from other countries shows that the human health impact is major.

**Qu. 4.15. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism in the future for the risk assessment area.**

- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”.

<b>RESPONSE</b>	N/A minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response:

There is limited evidence of current allergies caused by the pollen of *B. papyrifera* in the risk assessment area bar one case in Italy (Zanforlin & Incorvaia, 2004). *Broussonetia papyrifera* pollen is under monitoring in **Italy** at the national level since 2019 with a recent study showing the highest levels in excess of 100 parts per m<sup>3</sup> in Veneto in April 2019 (Arpa FVG report online) . The regional authority for environmental protection of the Tuscany region (ARPAT Toscana) states that so far pollen allergenicity in Italy is low, but the process needs to be monitored in consideration of what is known for other parts the world (ARPAT 2014). The few *B papyrifera* individuals recorded in a recent assessment in Brussels were not thought by the authors to play a role in pollinosis in the region (yet) (Aerts et al. 2021).

*Broussonetia* pollen could be confused with the one from *Urticaceae* species, so that there is some risk of underestimating its presence ([http://www.pollnet.it/default\\_it.asp](http://www.pollnet.it/default_it.asp)).

## Other impacts

**Qu. 4.16. How important is the organism in facilitating other damaging organisms (e.g. diseases) as food source, a host, a symbiont or a vector etc.?**

<b>RESPONSE</b>	N/A minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: Whilst there is no evidence of any facilitation of damaging organisms actually occurring in the risk assessment area, there are numerous species of plant damaging organisms present in the native range of the plant that could impact other species in the risk assessment area. Among the most serious pathogenic organisms of which *B. papyrifera* can being a carrier is the mulberry cerambicide, *Apriona germani* which can cause serious damage to several deciduous species (EPPO, 2014). In Japan the bacterial blight *Pseudomonas syringe* pv. *broussonetiae* affects paper mulberry (Whistler & Elevitch,

2006) as well as the spider mite *Tetranychus piercei* (Ohno et al. 2010). The fungi *Phytophthora boehmeriae* and *Dendryphiella broussonetiae* are also known to attack the plant (Berg 2003) but the host range of these pathogens are not fully known and may be limited.

In China the plant is known to host crown gall (*Agrobacterium tumefaciens*), which causes tumor-like growths on the plant (Whistler & Elevitch 2006; Li et al. 2015) as well as *Candidatus phytoplasma asteris* (Mei et al. 2016).

Paper Mulberry is identified as a known host of the citrus long-horned beetle *Anoplophora chinensis* (OEPP/EPPO (2013)) as well as the spotted lanternfly, *Lycorma delicatula* (EPPO, 2016). It is also a host of the cassava white peach scale *Pseudaulacaspis pentagona* in the Solomon Islands (Tsatsia & Jackson 2020). It is also on the host plant list for *Xylella fastidiosa* (EFSA 2020).

The score of minor is given with low confidence as the impacts are hypothetical assuming the arrival of the other pests.

**Qu. 4.17. How important might other impacts not already covered by previous questions be resulting from introduction of the organism?**

<b>RESPONSE</b>	N/A minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: No information has been found on the issue.

**Qu. 4.18. How important are the expected impacts of the organism despite any natural control by other organisms, such as predators, parasites or pathogens that may already be present in the risk assessment area?**

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: There are no known natural enemies that would significantly restrict its performance in the risk assessment area.

**Qu. 4.19. Estimate the overall impact in the risk assessment area under current climate conditions. In addition, details of overall impact in relevant biogeographical regions should be provided.**

Thorough assessment of the overall impact on biodiversity and ecosystem services, with impacts on economy as well as social and human health as aggravating factors, in current conditions.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: At this stage of the invasion process the impact of *B. papyrifera* could be considered relatively minor as there are very few published studies on it. It is considered established in 8 Member States, and can be locally widespread but with only limited records of impacts on biodiversity, ecosystem services and social and human health so far. However, in other relevant biogeographical regions, it has a significant impact on biodiversity by invading not only disturbed ecosystems but also intact forest. Its effects on ecosystem services range from provisioning of wild plants through competition, shading and allelopathy to regulation services through changes in soil nutrients. It can have further provisioning effects on water through its massive water consumption which can reduce availability overall and the rate of flow in specific circumstances, but it can also have a regulating impact on water causing flooding by blocking invaded drainage channels. Given that it has serious impacts outside the risk assessment area and is relatively well-established within the overall impact can be considered moderate but confidence remains low given the lack of published studies in the risk assessment area.

**Qu. 4.20. Estimate the overall impact in the risk assessment area in foreseeable climate change conditions. In addition, details of overall impact in relevant biogeographical regions should be provided.**

Thorough assessment of the overall impact on biodiversity and ecosystem services, with impacts on economy as well as social and human health as aggravating factors, under future conditions.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: Although the impact on biodiversity and ecosystem services could be assumed to be likely to increase significantly based on the experience in Pakistan, where only 30 years after a planting regime impacts were felt some *B. papyrifera* populations in Europe have been in place for a very long time without major reported problem. If populations do grow as more habitats become suitable for invasion, then direct competition for resources by this dominant tree will decrease biodiversity in invaded areas. The main impact is likely to be as an allergen impacting on human health in a similar way to *Ambrosia*

*artemisiifola*. This could become a very serious issue, as it has in Pakistan and more recently emerging in Taiwan (Wu et al. 2019).

<b>RISK SUMMARIES</b>			
	<b>RESPONSE</b>	<b>CONFIDENCE</b>	<b>COMMENT</b>
<b>Summarise Introduction and Entry*</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	low medium <b>high</b>	The main introduction and entry pathways are “escapes from confinement” (botanical garden, horticulture and ornamental purpose other than horticulture). Future climate change conditions may change the demand and availability of seeds, cuttings or trees by regional tree nurseries, especially in northern Europe.
<b>Summarise Establishment*</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	low medium <b>high</b>	The paper mulberry is recorded in 19 EU Member states (plus UK) and established in 8. The species is recorded in the Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean and Pannonian biogeographical regions and can be assessed as “established” (naturalized) in the Atlantic, Continental and Mediterranean biogeographical regions. The core areas are the Atlantic, Mediterranean and Continental region parts in Western Europe. The climate change scenarios RCP 2.6 and RCP 4.5 indicate a higher suitability to establish in the Northern and Eastern parts of Europe.
<b>Summarise Spread*</b>	very slowly <b>slowly</b> moderately rapidly very rapidly	low <b>medium</b> high	The overall potential rate of spread is expected to remain slowly as all constraint conditions (i.e. male and female plant availability, animals disseminating fruits and seeds, suitable habitats in a sufficient quantity) have to be fulfilled, but this will likely apply to an even more extensive part of the risk assessment area due to favourable climatic conditions.
<b>Summarise Impact*</b>	minimal minor <b>moderate</b> major massive	low <b>medium</b> high	Paper mulberry is considered a pioneer species adapted to colonize disturbed habitats. It exhibits a high reproductive potential, by means of both sexual and vegetative propagation. Root suckers are produced when the main stem is cut. Over time, this

			<p>can lead to the formation of dense thickets. It is believed to be allelopathic (Combalicer et al. 2019) which will have an impact on local biodiversity and succession. <i>Broussonetia papyrifera</i>, as other invasive tree species is reported as not only reducing the land value and causing economic loss to agriculture communities, but is also a source of allergens which have a direct effect on people and exacerbate other pre-existing respiratory health problems. At this stage of the invasion process the impact of <i>B. papyrifera</i> appears to be minor. Regarding future climate scenarios: although the impact on biodiversity and ecosystem services is likely to increase as more regions become suitably for invasion, the main impact is likely to be as an allergen impacting on human health.</p> <p>On the topic of biodiversity and ecosystems, the impact on biodiversity on all levels in the risk assessment area is assessed a moderate as the species is reported to invade natural and semi-natural formations such as thermophilic forests and dry grasslands (e.g. in Italy). It is likely that the tree will spread out from ruderal habitats especially along transport corridors and this is likely to increase the propagule pressure in natural and sensitive environments, much as it has in non-European invasions. If populations do grow as more habitats become suitable for invasion, then direct competition for resources by this dominant tree will decrease biodiversity in invaded areas. There is some evidence of current allergies caused by the pollen of <i>B. papyrifera</i> in the risk assessment area as one case in Italy.</p>
--	--	--	---

<p><b>Conclusion of the risk assessment (overall risk)</b></p>	<p>low <b>moderate</b> high</p>	<p>low <b>medium</b> high</p>	<p><i>Broussonetia papyrifera</i> is recorded in 19 (plus UK) and already established in 8 out of 27 EU member states. The species is recorded in the Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean and Pannonian biogeographical regions and can be assessed as established in the Atlantic, Continental and Mediterranean biogeographical regions. The core areas are the Atlantic, Mediterranean and Continental region parts in Western Europe. Under future climate conditions, further establishment may be expected, especially in the Northern parts of Europe and to the Alpine biogeographical region to some extent. The main introduction and entry pathways are manmade (botanical garden, horticulture, ornamental purpose other than horticulture). Spread may occur from the introduction and entry pathways as well as from already established occurrences. Spread rate is considered as slow because all constraint conditions (i.e. male and female plant availability, animals disseminating fruits and seeds, suitable habitats in a sufficient quantity) have to be fulfilled. Impacts on biodiversity, ecosystem services and human health are known. Considering all aspects, <i>Broussonetia papyrifera</i> is assessed as a moderately risk species for the European Union.</p>
--	---	---------------------------------------	--

\*in current climate conditions and in foreseeable future climate conditions

## Distribution Summary

Please answer as follows:

- Yes if recorded, established or invasive
- if not recorded, established or invasive
- ? Unknown; data deficient

The columns refer to the answers to Questions A5 to A12 under Section A.

For data on marine species at the Member State level, delete Member States that have no marine borders.

In all other cases, provide answers for all columns.

### Member States and the United Kingdom

	Recorded	Established (currently)	Possible establishment (under current climate)	Possible establishment (under foreseeable climate)	Invasive (currently)
Austria	Yes	-	-	Yes	-

## ANNEX I Scoring of Likelihoods of Events

(taken from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

<b>Score</b>	<b>Description</b>	<b>Frequency</b>
Very unlikely	This sort of event is theoretically possible, but is never known to have occurred and is not expected to occur	1 in 10,000 years
Unlikely	This sort of event has occurred somewhere at least once in the last millenium	1 in 1,000 years
Moderately Likely	This sort of event has occurred somewhere at least once in the last century	1 in 100 years
Likely	This sort of event has happened on several occasions elsewhere, or on at least once in the last decade	1 in 10 years
Very likely	This sort of event happens continually and would be expected to occur	Once a year

## ANNEX II Scoring of Magnitude of Impacts

(modified from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

<b>Score</b>	<b>Biodiversity and ecosystem impact</b>	<b>Ecosystem Services impact</b>	<b>Economic impact (Monetary loss and response costs per year)</b>	<b>Social and human health impact, and other impacts</b>
	<i>Question 5.1-5</i>	<i>Question 5.6-8</i>	<i>Question 5.9-13</i>	<i>Question 5.14-18</i>
Minimal	Local, short-term population loss, no significant ecosystem effect	No services affected <sup>5</sup>	Up to 10,000 Euro	No social disruption. Local, mild, short-term reversible effects to individuals.
Minor	Some ecosystem impact, reversible changes, localised	Local and temporary, reversible effects to one or few services	10,000-100,000 Euro	Significant concern expressed at local level. Mild short-term reversible effects to identifiable groups, localised.
Moderate	Measureable long-term damage to populations and ecosystem, but reversible; little spread, no extinction	Measureable, temporary, local and reversible effects on one or several services	100,000-1,000,000 Euro	Temporary changes to normal activities at local level. Minor irreversible effects and/or larger numbers covered by reversible effects, localised.
Major	Long-term irreversible ecosystem change, spreading beyond local area	Local and irreversible or widespread and reversible effects on one / several services	1,000,000-10,000,000 Euro	Some permanent change of activity locally, concern expressed over wider area. Significant irreversible effects locally or reversible effects over large area.
Massive	Widespread, long-term population loss or extinction, affecting several species with serious ecosystem effects	Widespread and irreversible effects on one / several services	Above 10,000,000 Euro	Long-term social change, significant loss of employment, migration from affected area. Widespread, severe, long-term, irreversible health effects.

<sup>5</sup> Not to be confused with “no impact”.

## ANNEX III Scoring of Confidence Levels

(modified from Bacher et al. 2017)

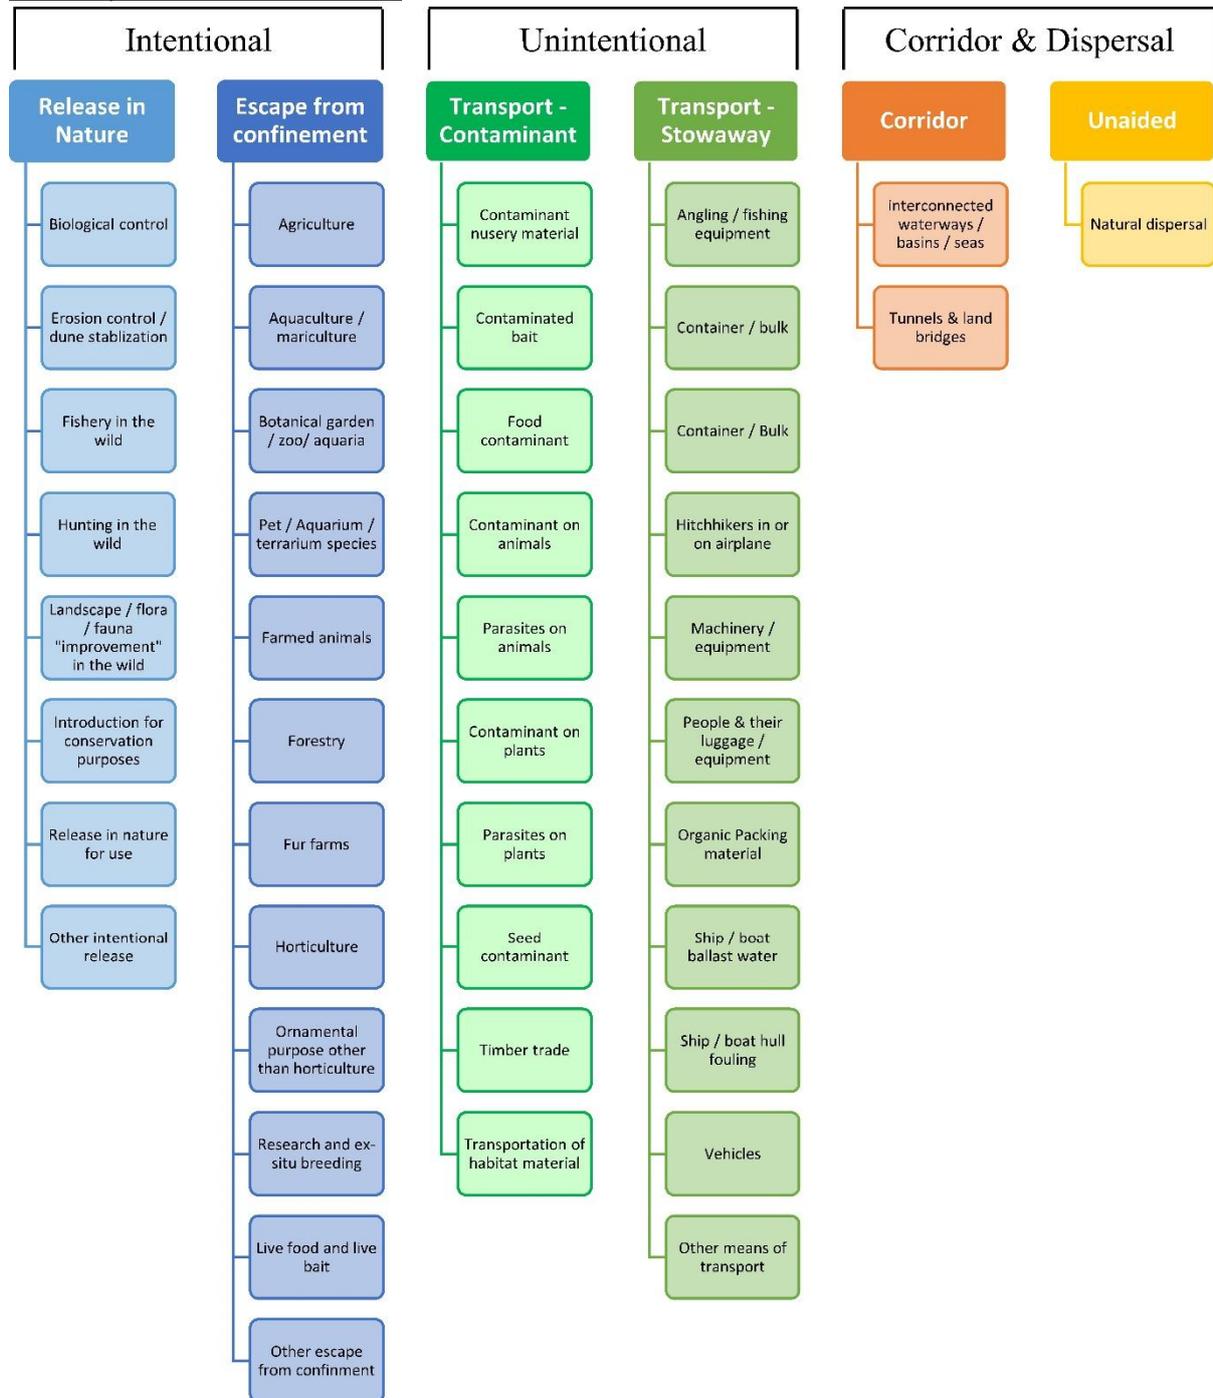

Each answer provided in the risk assessment must include an assessment of the level of confidence attached to that answer, reflecting the possibility that information needed for the answer is not available or is insufficient or available but conflicting.

The responses in the risk assessment should clearly support the choice of the confidence level.

<b>Confidence level</b>	<b>Description</b>
Low	There is no direct observational evidence to support the assessment, e.g. only inferred data have been used as supporting evidence <i>and/or</i> Impacts are recorded at a spatial scale which is unlikely to be relevant to the assessment area <i>and/or</i> Evidence is poor and difficult to interpret, e.g. because it is strongly ambiguous <i>and/or</i> The information sources are considered to be of low quality or contain information that is unreliable.
Medium	There is some direct observational evidence to support the assessment, but some information is inferred <i>and/or</i> Impacts are recorded at a small spatial scale, but rescaling of the data to relevant scales of the assessment area is considered reliable, or to embrace little uncertainty <i>and/or</i> The interpretation of the data is to some extent ambiguous or contradictory.
High	There is direct relevant observational evidence to support the assessment (including causality) <i>and</i> Impacts are recorded at a comparable scale <i>and/or</i> There are reliable/good quality data sources on impacts of the taxa <i>and</i> The interpretation of data/information is straightforward <i>and/or</i> Data/information are not controversial or contradictory.

## ANNEX IV CBD pathway categorisation scheme

Overview of CBD pathway categorisation scheme showing how the 44 pathways relate to the six main pathway categories. All of the pathways can be broadly classified into 1) those that involve intentional transport (blue), 2) those in which the taxa are unintentionally transported (green) and 3) those where taxa moved between regions without direct transportation by humans and/or via artificial corridors (orange and yellow). **Note that the pathways in the category “Escape from confinement” can be considered intentional for the introduction into the risk assessment area and unintentional for the entry into the environment.**

## ANNEX V Ecosystem services classification (CICES V5.1, simplified) and examples

For the purposes of this risk assessment, please feel free to use what seems as the most appropriate category / level / combination of impact (Section – Division – Group), reflecting information available.

Section	Division	Group	Examples (i.e. relevant CICES “classes”)
Provisioning	Biomass	<b>Cultivated <i>terrestrial</i> plants</b>	Cultivated terrestrial plants (including fungi, algae) grown for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from cultivated plants, fungi, algae and bacteria for direct use or processing (excluding genetic materials); Cultivated plants (including fungi, algae) grown as a <u>source of energy</u>  <i>Example: negative impacts of non-native organisms to crops, orchards, timber etc.</i>
		<b>Cultivated <i>aquatic</i> plants</b>	Plants cultivated by in- situ aquaculture grown for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from in-situ aquaculture for direct use or processing (excluding genetic materials); Plants cultivated by in- situ aquaculture grown as an <u>energy source</u> .  <i>Example: negative impacts of non-native organisms to aquatic plants cultivated for nutrition, gardening etc. purposes.</i>
		<b>Reared animals</b>	Animals reared for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from reared animals for direct use or processing (excluding genetic materials); Animals reared to provide <u>energy</u> (including mechanical)  <i>Example: negative impacts of non-native organisms to livestock</i>
		<b>Reared <i>aquatic</i> animals</b>	Animals reared by in-situ aquaculture for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from animals grown by in-situ aquaculture for direct use or processing (excluding genetic materials); Animals reared by in-situ aquaculture as an <u>energy source</u>  <i>Example: negative impacts of non-native organisms to fish farming</i>
		<b>Wild plants (terrestrial and aquatic)</b>	Wild plants (terrestrial and aquatic, including fungi, algae) used for <u>nutrition</u> ; <u>Fibres and other materials</u> from wild plants for direct use or processing (excluding genetic materials); Wild plants (terrestrial and aquatic, including fungi, algae) used as a <u>source of energy</u>  <i>Example: reduction in the availability of wild plants (e.g. wild berries, ornamentals) due to non-native organisms (competition, spread of disease etc.)</i>
		<b>Wild animals (terrestrial and aquatic)</b>	Wild animals (terrestrial and aquatic) used for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from wild animals for direct use or processing (excluding genetic materials); Wild animals (terrestrial and aquatic) used as a <u>source of energy</u>  <i>Example: reduction in the availability of wild animals (e.g. fish stocks, game) due to non-native organisms (competition, predations, spread of disease etc.)</i>

	<b>Genetic material</b> from all biota	<b>Genetic material</b> from plants, algae or fungi	<p><u>Seeds, spores and other plant materials</u> collected for maintaining or establishing a population; Higher and lower plants (whole organisms) used to <u>breed new strains or varieties</u>; Individual genes extracted from higher and lower plants for the <u>design and construction of new biological entities</u></p> <p><i>Example: negative impacts of non-native organisms due to interbreeding</i></p>
		<b>Genetic material</b> from animals	<p>Animal material collected for the purposes of maintaining or establishing a population; Wild animals (whole organisms) used to breed new strains or varieties; Individual genes extracted from organisms for the design and construction of new biological entities</p> <p><i>Example: negative impacts of non-native organisms due to interbreeding</i></p>
	<b>Water</b> <sup>6</sup>	<b>Surface water</b> used for nutrition, materials or energy	<p>Surface water for <u>drinking</u>; Surface water used as a material (<u>non-drinking purposes</u>); Freshwater surface water, coastal and marine water used as an <u>energy source</u></p> <p><i>Example: loss of access to surface water due to spread of non-native organisms</i></p>
		<b>Ground water</b> for used for nutrition, materials or energy	<p>Ground (and subsurface) water for <u>drinking</u>; Ground water (and subsurface) used as a material (<u>non-drinking purposes</u>); Ground water (and subsurface) used as an <u>energy source</u></p> <p><i>Example: reduced availability of ground water due to spread of non-native organisms and associated increase of ground water consumption by vegetation.</i></p>
<b>Regulation &amp; Maintenance</b>	<b>Transformation</b> of biochemical or physical inputs to ecosystems	<b>Mediation of wastes or toxic substances</b> of anthropogenic origin by living processes	<p><u>Bio-remediation</u> by micro-organisms, algae, plants, and animals; <u>Filtration/sequestration/storage/accumulation</u> by micro-organisms, algae, plants, and animals</p> <p><i>Example: changes caused by non-native organisms to ecosystem functioning and ability to filtrate etc. waste or toxics</i></p>
		<b>Mediation of nuisances</b> of anthropogenic origin	<p><u>Smell reduction; noise attenuation; visual screening</u> (e.g. by means of green infrastructure)</p> <p><i>Example: changes caused by non-native organisms to ecosystem structure, leading to reduced ability to mediate nuisances.</i></p>
	<b>Regulation</b> of physical, chemical, biological conditions	<b>Baseline flows and extreme event</b> regulation	<p>Control of <u>erosion</u> rates; Buffering and attenuation of <u>mass movement</u>; <u>Hydrological cycle and water flow regulation</u> (Including flood control, and coastal protection); <u>Wind</u> protection; <u>Fire</u> protection</p> <p><i>Example: changes caused by non-native organisms to ecosystem functioning or structure leading to, for example, destabilisation of soil, increased risk or intensity of wild fires etc.</i></p>
<b>Lifecycle maintenance</b> , habitat and gene pool protection		<p><u>Pollination</u> (or 'gamete' dispersal in a marine context); <u>Seed dispersal</u>; Maintaining <u>nursery populations and habitats</u> (Including gene pool protection)</p>	

<sup>6</sup> Note: in the CICES classification provisioning of water is considered as an abiotic service whereas the rest of ecosystem services listed here are considered biotic.

			<p><i>Example: changes caused by non-native organisms to the abundance and/or distribution of wild pollinators; changes to the availability / quality of nursery habitats for fisheries</i></p>
		<b>Pest and disease control</b>	<p>Pest control; Disease control</p> <p><i>Example: changes caused by non-native organisms to the abundance and/or distribution of pests</i></p>
		<b>Soil quality regulation</b>	<p><u>Weathering processes</u> and their effect on soil quality; <u>Decomposition and fixing processes</u> and their effect on soil quality</p> <p><i>Example: changes caused by non-native organisms to vegetation structure and/or soil fauna leading to reduced soil quality</i></p>
		<b>Water conditions</b>	<p>Regulation of the <u>chemical condition</u> of freshwaters by living processes; Regulation of the chemical condition of salt waters by living processes</p> <p><i>Example: changes caused by non-native organisms to buffer strips along water courses that remove nutrients in runoff and/or fish communities that regulate the resilience and resistance of water bodies to eutrophication</i></p>
		<b>Atmospheric composition and conditions</b>	<p>Regulation of <u>chemical composition</u> of atmosphere and oceans; Regulation of <u>temperature and humidity</u>, including ventilation and transpiration</p> <p><i>Example: changes caused by non-native organisms to ecosystems' ability to sequester carbon and/or evaporative cooling (e.g. by urban trees)</i></p>
<b>Cultural</b>	<b>Direct, in-situ and outdoor interactions</b> with living systems that depend on presence in the environmental setting	<b>Physical and experiential</b> interactions with natural environment	<p>Characteristics of living systems that that enable activities promoting health, recuperation or enjoyment through <u>active or immersive interactions</u>;</p> <p>Characteristics of living systems that enable activities promoting health, recuperation or enjoyment through <u>passive or observational interactions</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that make it attractive for recreation, wild life watching etc.</i></p>
		<b>Intellectual and representative</b> interactions with natural environment	<p>Characteristics of living systems that enable <u>scientific investigation</u> or the creation of traditional ecological knowledge;</p> <p>Characteristics of living systems that enable <u>education and training</u>;</p> <p>Characteristics of living systems that are resonant in terms of <u>culture or heritage</u>;</p> <p>Characteristics of living systems that enable <u>aesthetic experiences</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have cultural importance</i></p>
	<b>Indirect, remote, often indoor interactions</b> with living systems that do not require presence in the environmental setting	<b>Spiritual, symbolic</b> and other interactions with natural environment	<p>Elements of living systems that have <u>symbolic meaning</u>;</p> <p>Elements of living systems that have <u>sacred or religious meaning</u>;</p> <p>Elements of living systems used for <u>entertainment or representation</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have sacred or religious meaning</i></p>

		<p>Other biotic characteristics that have a <b>non-use value</b></p>	<p>Characteristics or features of living systems that have an <u>existence value</u>;  Characteristics or features of living systems that have an <u>option or bequest value</u></p> <p><i>Example: changes caused by non-native organisms to ecosystems designated as wilderness areas, habitats of endangered species etc.</i></p>

## **ANNEX VIII Species distribution model**

### **Projection of climatic suitability for *Broussonetia papyrifera* establishment in Europe**

Björn Beckmann, Helmut Kudrnovsky, Richard Shaw, David Paternoster and Dan Chapman

10 October 2020

#### **Aim**

To project the suitability for potential establishment of *Broussonetia papyrifera* in Europe, under current and predicted future climatic conditions.

#### **Data for modelling**

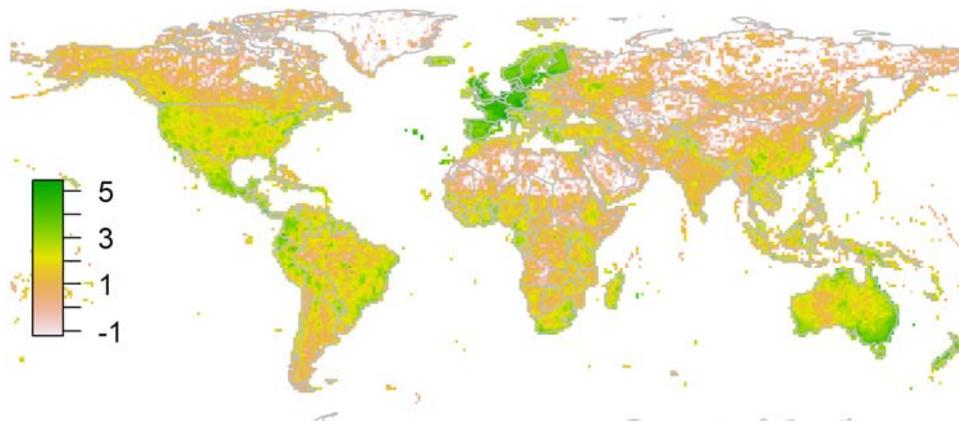

Species occurrence data were obtained from the Global Biodiversity Information Facility (GBIF) (8684 records), iNaturalist (5474 records), the Biodiversity Information Serving Our Nation database (BISON) (259 records), and additional records from the risk assessment team. We classified records as native- and invaded-range according to the CABI Invasive Species Compendium. We scrutinised occurrence records from regions where the species is not known to be established and removed any which may not refer to populations currently established in the wild (e.g. museum specimens, records from botanical gardens) or where the georeferencing was too imprecise (e.g. records referenced to a country or island centroid) or outside of the coverage of the predictor layers (e.g. small island or coastal occurrences). The remaining records were gridded at a 0.25 x 0.25 degree resolution for modelling, yielding 1773 grid cells with occurrences (Figure 1a). As a proxy for recording effort, the density of Tracheophyta records held by GBIF was also compiled on the same grid (Figure 1b).

**Figure 1.** (a) Occurrence records obtained for *Broussonetia papyrifera* and used in the modelling, showing native and invaded distributions. (b) The recording density of Tracheophyta on GBIF, which was used as a proxy for recording effort.

(a) Species distribution used in modelling

(b) Estimated recording effort (log10-scaled)

Climate data were selected from the ‘Bioclim’ variables contained within the WorldClim database (Hijmans et al. 2005), originally at 5 arcminute resolution (0.083 x 0.083 degrees of longitude/latitude) and aggregated to a 0.25 x 0.25 degree grid for use in the model.

Based on the biology of *Broussonetia papyrifera*, the following climate variables were used in the modelling:

- Minimum temperature of the coldest month (Bio6)
- Mean temperature of the warmest quarter (Bio10)
- Climatic moisture index (CMI): ratio of mean annual precipitation to potential evapotranspiration, log+1 transformed. For its calculation, monthly potential evapotranspirations were estimated from the WorldClim monthly temperature data and solar radiation using the simple method of Zomer et al. (2008) which is based on the Hargreaves evapotranspiration equation (Hargreaves, 1994).

To estimate the effect of climate change on the potential distribution, equivalent modelled future climate conditions for the 2070s under the Representative Concentration Pathways (RCP) 2.6 and 4.5 were also obtained. These represent low and medium emissions scenarios, respectively. The above variables were obtained as averages of outputs of eight Global Climate Models (BCC-CSM1-1, CCSM4, GISS-E2-R, HadGEM2-AO, IPSL-CM5A-LR, MIROC-ESM, MRI-CGCM3, NorESM1-M), downscaled and calibrated against the WorldClim baseline (see [http://www.worldclim.org/cmip5\\_5m](http://www.worldclim.org/cmip5_5m)).

The following habitat layers were also used:

- Human influence index (HII): As many non-native invasive species associate with anthropogenically disturbed habitats. We used the Global Human Influence Index Dataset of the Last of the Wild Project (Wildlife Conservation Society - WCS & Center for International Earth Science Information Network - CIESIN - Columbia University, 2005), which is developed from nine global data layers covering human population pressure (population density), human land use and infrastructure (built-up areas, nighttime lights, land use/land cover) and human access (coastlines, roads, railroads, navigable rivers). The index ranges between 0 and 1 and was  $\ln+1$  transformed for the modelling to improve normality.

### Species distribution model

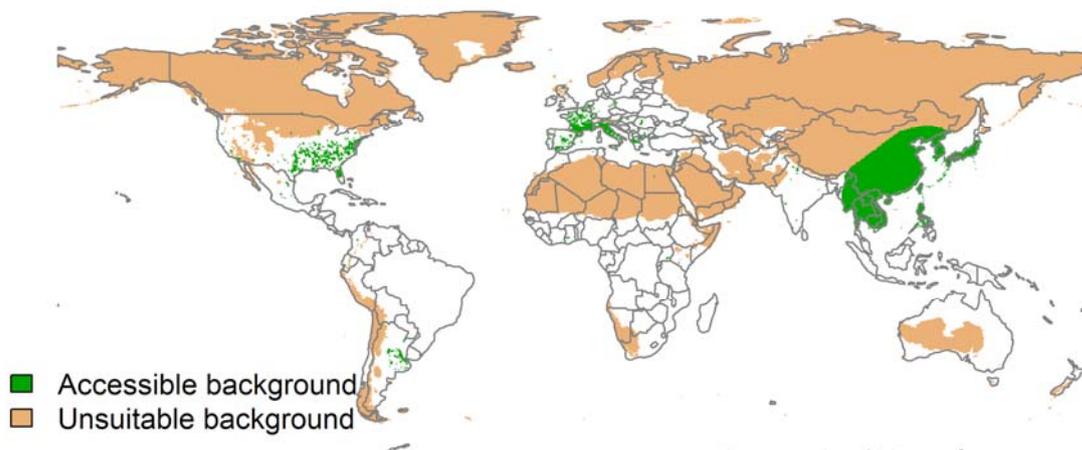

A presence-background (presence-only) ensemble modelling strategy was employed using the BIOMOD2 R package version 3.4.6 (Thuiller et al., 2020, Thuiller et al., 2009). These models contrast the environment at the species' occurrence locations against a random sample of the global background environmental conditions (often termed 'pseudo-absences') in order to characterise and project suitability for occurrence. This approach has been developed for distributions that are in equilibrium with the environment. Because invasive species' distributions are not at equilibrium and subject to dispersal constraints at a global scale, we took care to minimise the inclusion of locations suitable for the species but where it has not been able to disperse to (Chapman et al. 2019). Therefore the background sampling region included:

- The area accessible by native *Broussonetia papyrifera* populations, in which the species is likely to have had sufficient time to disperse to all locations. Based on presumed maximum dispersal distances, the accessible region was defined as a 400km buffer around the native range occurrences; AND
- A 30km buffer around the non-native occurrences, encompassing regions likely to have had high propagule pressure for introduction by humans and/or dispersal of the species; AND
- Regions where we have an *a priori* expectation of high unsuitability for the species so that absence is assumed irrespective of dispersal constraints (see Figure 2). The following rules were applied to define a region expected to be highly unsuitable for *Broussonetia papyrifera* at the spatial scale of the model:
  - Minimum temperature of the coldest month (Bio6) < -12
  - Mean temperature of the warmest quarter (Bio10) < 13
  - Climatic moisture index (CMI) < 0.15

Altogether, only 0.5% of occurrence grid cells were located in the unsuitable background region.

Within the unsuitable background region, 10 samples of 5000 randomly sampled grid cells were obtained. In the accessible background (comprising the accessible areas around native and non-native occurrences as detailed above), the same number of pseudo-absence samples were drawn as there were presence records (1773), weighting the sampling by a proxy for recording effort (Figure 2).

**Figure 2.** The background from which pseudo-absence samples were taken in the modelling of *Broussonetia papyrifera*. Samples were taken from a 400km buffer around the native range and a 30km buffer around non-native occurrences (together forming the accessible background), and from areas expected to be highly unsuitable for the species (the unsuitable background region). Samples from the accessible background were weighted by a proxy for recording effort (Figure 1(b)).

Each dataset (i.e. combination of the presences and the individual background samples) was randomly split into 80% for model training and 20% for model evaluation. With each training dataset, five statistical algorithms were fitted with the default BIOMOD2 settings and rescaled using logistic regression, except where specified below:

- Generalised linear model (GLM)
- Generalised boosting model (GBM)
- Generalised additive model (GAM) with a maximum of four degrees of freedom per smoothing spline
- Random forest (RF)
- Maxent

Since the total background sample was larger than the number of occurrences, prevalence fitting weights were applied to give equal overall importance to the occurrences and the background. Normalised

variable importance was assessed and variable response functions were produced using BIOMOD2's default procedure.

Model predictive performance was assessed by the following three measures:

- AUC, the area under the receiver operating characteristic curve (Fielding & Bell 1997). Predictions of presence-absence models can be compared with a subset of records set aside for model evaluation (here 20%) by constructing a confusion matrix with the number of true positive, false positive, false negative and true negative cases. For models generating non-dichotomous scores (as here) a threshold can be applied to transform the scores into a dichotomous set of presence-absence predictions. Two measures that can be derived from the confusion matrix are sensitivity (the proportion of observed presences that are predicted as such, quantifying omission errors), and specificity (the proportion of observed absences that are predicted as such, quantifying commission errors). A receiver operating characteristic (ROC) curve can be constructed by using all possible thresholds to classify the scores into confusion matrices, obtaining sensitivity and specificity for each matrix, and plotting sensitivity against the corresponding proportion of false positives (equal to  $1 - \text{specificity}$ ). The use of all possible thresholds avoids the need for a selection of a single threshold, which is often arbitrary, and allows appreciation of the trade-off between sensitivity and specificity. The area under the ROC curve (AUC) is often used as a single threshold-independent measure for model performance (Manel, Williams & Ormerod 2001). AUC is the probability that a randomly selected presence has a higher model-predicted suitability than a randomly selected absence (Allouche et al. 2006).
- Cohen's Kappa (Cohen 1960). This measure corrects the overall accuracy of model predictions (ratio of the sum of true presences plus true absences to the total number of records) by the accuracy expected to occur by chance. The kappa statistic ranges from -1 to +1, where +1 indicates perfect agreement and values of zero or less indicate a performance no better than random. Advantages of kappa are its simplicity, the fact that both commission and omission errors are accounted for in one parameter, and its relative tolerance to zero values in the confusion matrix (Manel, Williams & Ormerod 2001). However, Kappa has been criticised for being sensitive to prevalence (the proportion of sites in which the species was recorded as present) and may therefore be inappropriate for comparisons of model accuracy between species or regions (McPherson, Jetz & Rogers 2004, Allouche et al. 2006).
- TSS, the true skill statistic (Allouche et al. 2006). TSS is defined as sensitivity + specificity - 1, and corrects for Kappa's dependency on prevalence. TSS compares the number of correct forecasts, minus those attributable to random guessing, to that of a hypothetical set of perfect forecasts. Like kappa, TSS takes into account both omission and commission errors, and success as a result of random guessing, and ranges from -1 to +1, where +1 indicates perfect agreement and values of zero or less indicate a performance no better than random (Allouche et al. 2006).

An ensemble model was created by first rejecting poorly performing algorithms with relatively extreme low AUC values and then averaging the predictions of the remaining algorithms, weighted by their AUC. To identify poorly performing algorithms, AUC values were converted into modified z-scores based on their difference to the median and the median absolute deviation across all algorithms (Iglewicz & Hoaglin, 1993). Algorithms with  $z < -2$  were rejected. In this way, ensemble projections were made for each dataset and then averaged to give an overall suitability, as well as its standard deviation. The

projections were then classified into suitable and unsuitable regions using the ‘minROCdist’ method, which minimizes the distance between the ROC plot and the upper left corner of the plot (point (0,1)).

We also produced limiting factor maps for Europe following Elith et al. (2010). For this, projections were made separately with each individual variable fixed at a near-optimal value. These were chosen as the median values at the occurrence grid cells. Then, the most strongly limiting factors were identified as the one resulting in the highest increase in suitability in each grid cell.

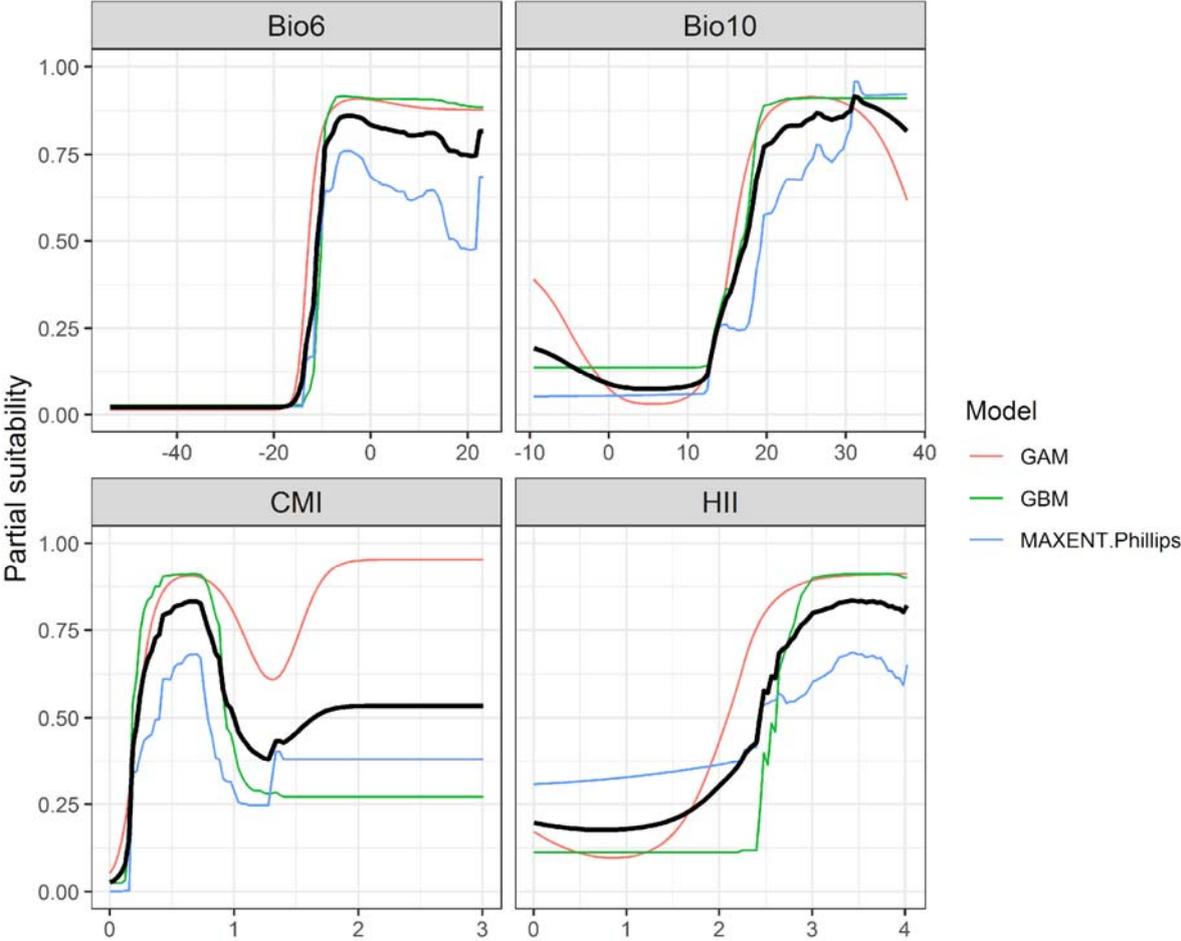

## Results

The ensemble model suggested that suitability for *Broussonetia papyrifera* was most strongly determined by Minimum temperature of the coldest month (Bio6), accounting for 31.6% of variation explained, followed by Mean temperature of the warmest quarter (Bio10) (26.6%), Climatic moisture index (CMI) (22.6%) and Human influence index (HII) (19.2%) (Table 1, Figure 3).

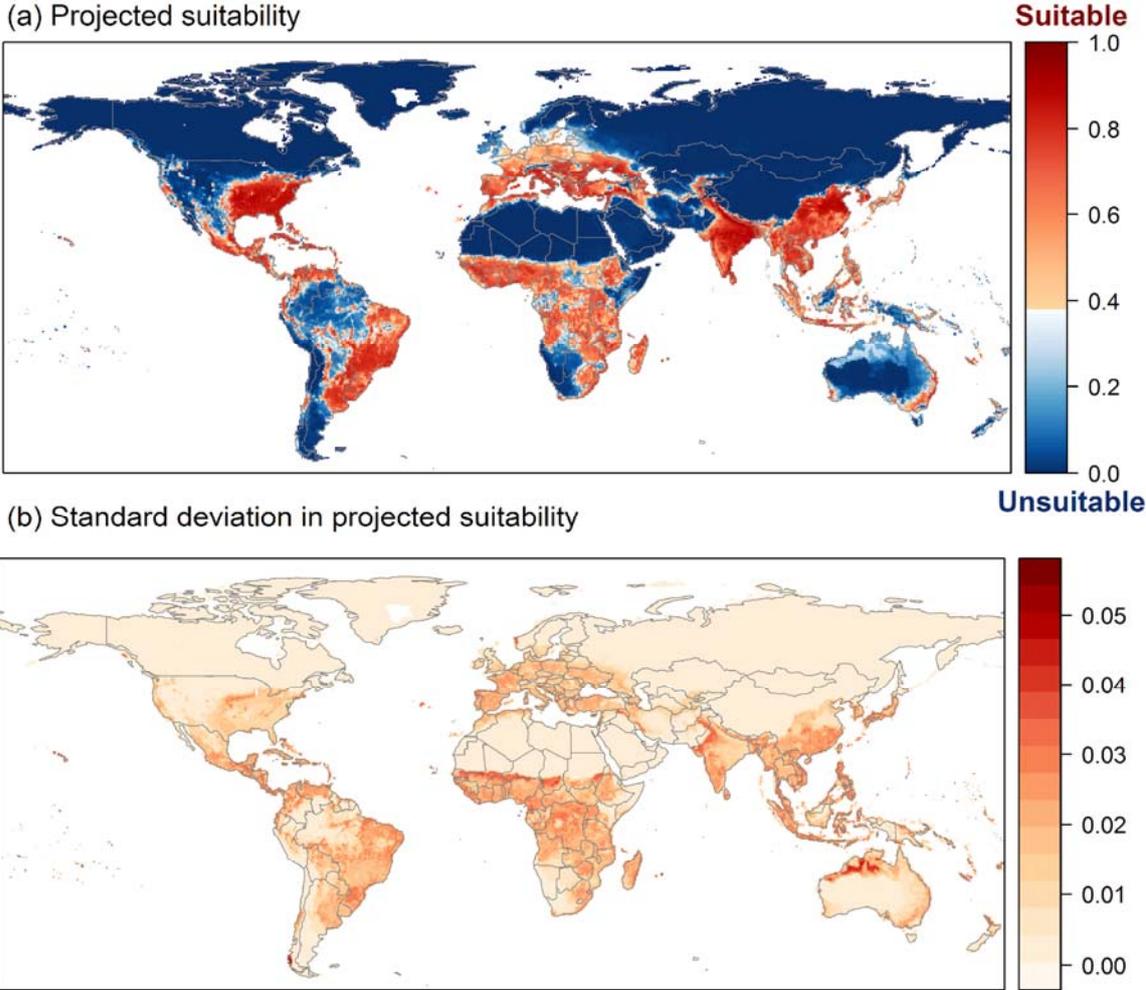

**Table 1.** Summary of the cross-validation predictive performance (AUC, Kappa, TSS) and variable importance of the fitted model algorithms and the ensemble (AUC-weighted average of the best performing algorithms). Results are the average from models fitted to 10 different background samples of the data.

Algorithm	AUC	Kappa	TSS	Used in the ensemble	Variable importance (%)			
					Minimum temperature of the coldest month (Bio6)	Mean temperature of the warmest quarter (Bio10)	Climatic moisture index (CMI)	Human influence index (HII)
GLM	0.916	0.589	0.734	no	32	27	17	24

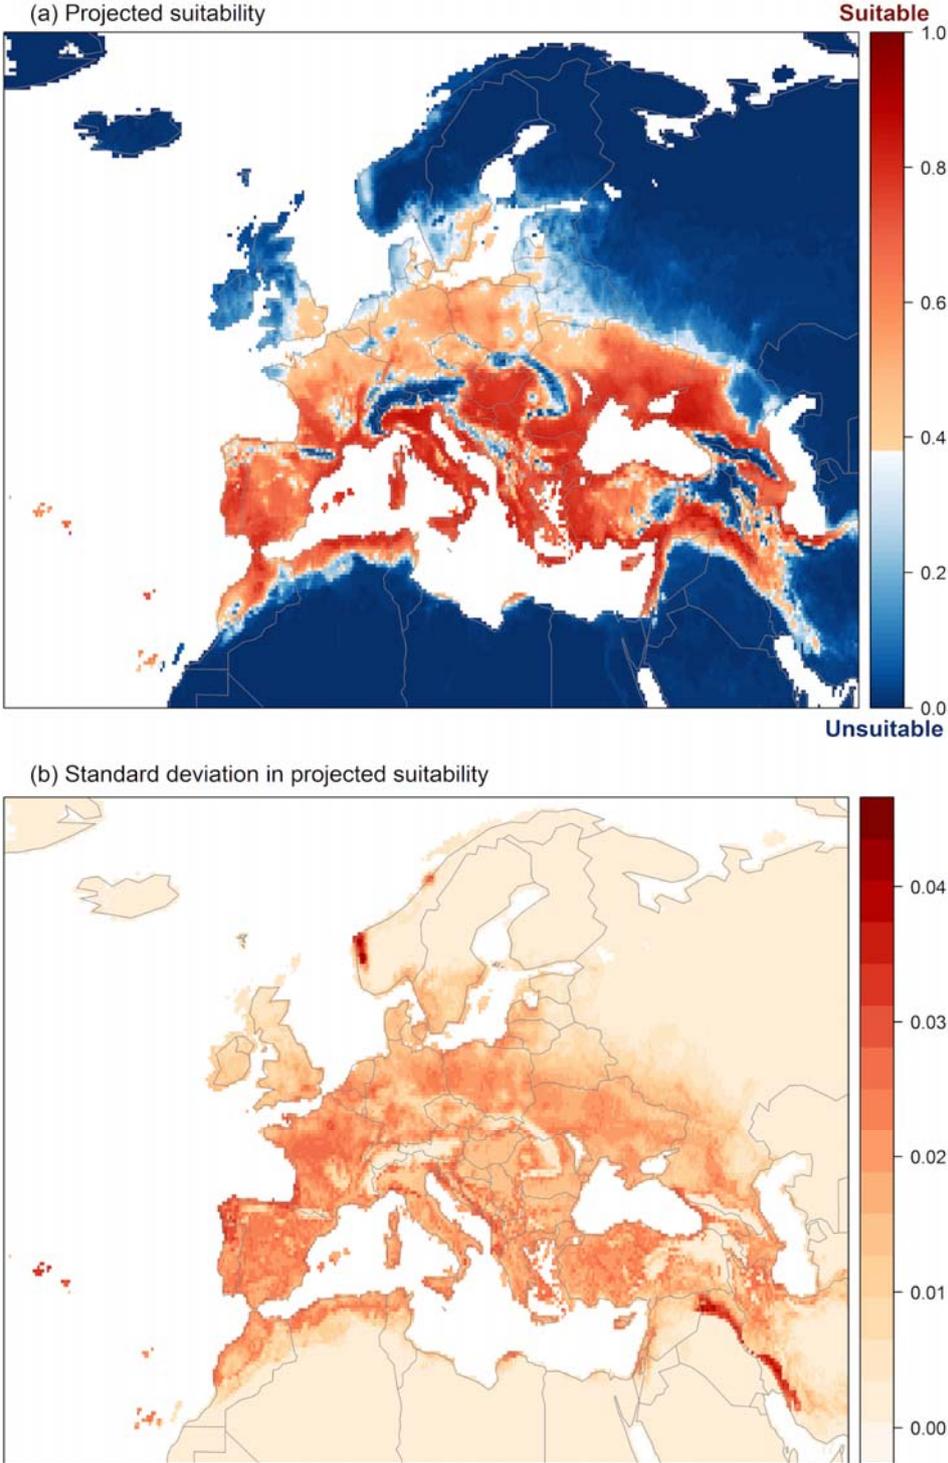

**Figure 3.** Partial response plots from the fitted models. Thin coloured lines show responses from the algorithms in the ensemble, while the thick black line is their ensemble. In each plot, other model variables are held at their median value in the training data. Some of the divergence among algorithms is because of their different treatment of interactions among variables.

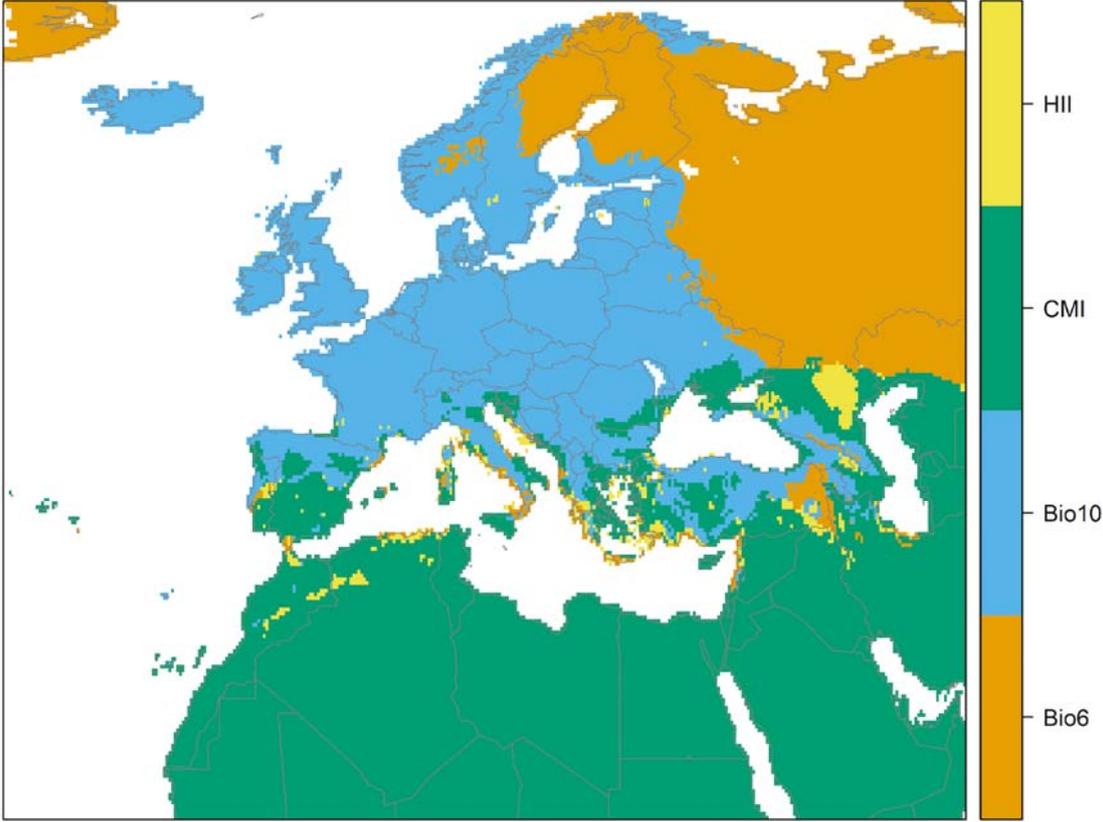

**Figure 4.** (a) Projected global suitability for *Broussonetia papyrifera* establishment in the current climate. For visualisation, the projection has been aggregated to a 0.5 x 0.5 degree resolution, by taking the maximum suitability of constituent higher resolution grid cells. Values > 0.38 may be suitable for the species. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

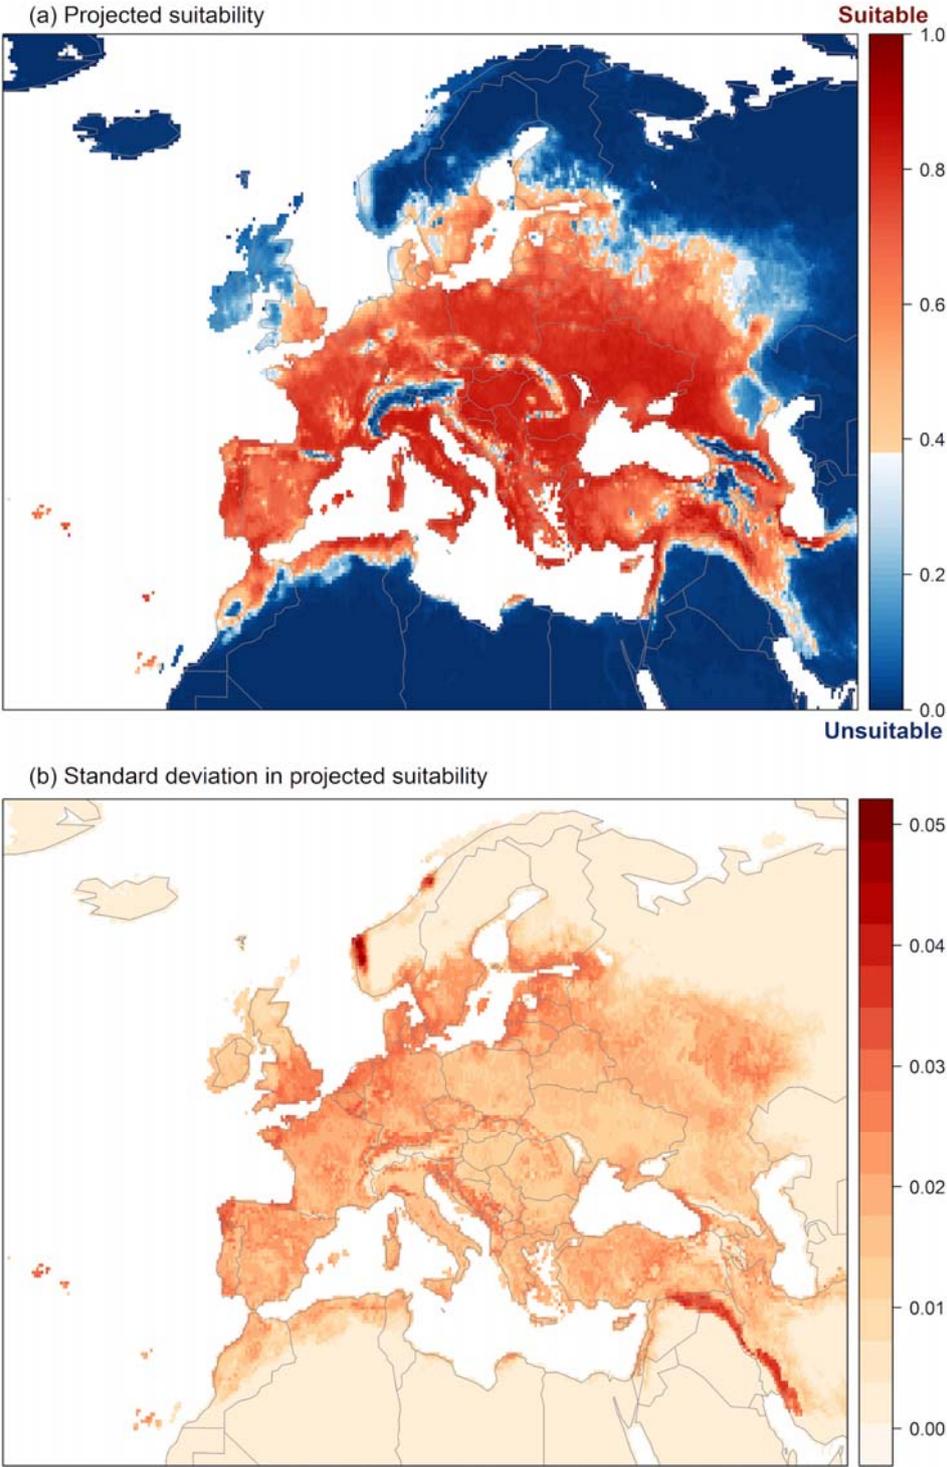

**Figure 5.** (a) Projected current suitability for *Broussonetia papyrifera* establishment in Europe and the Mediterranean region. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

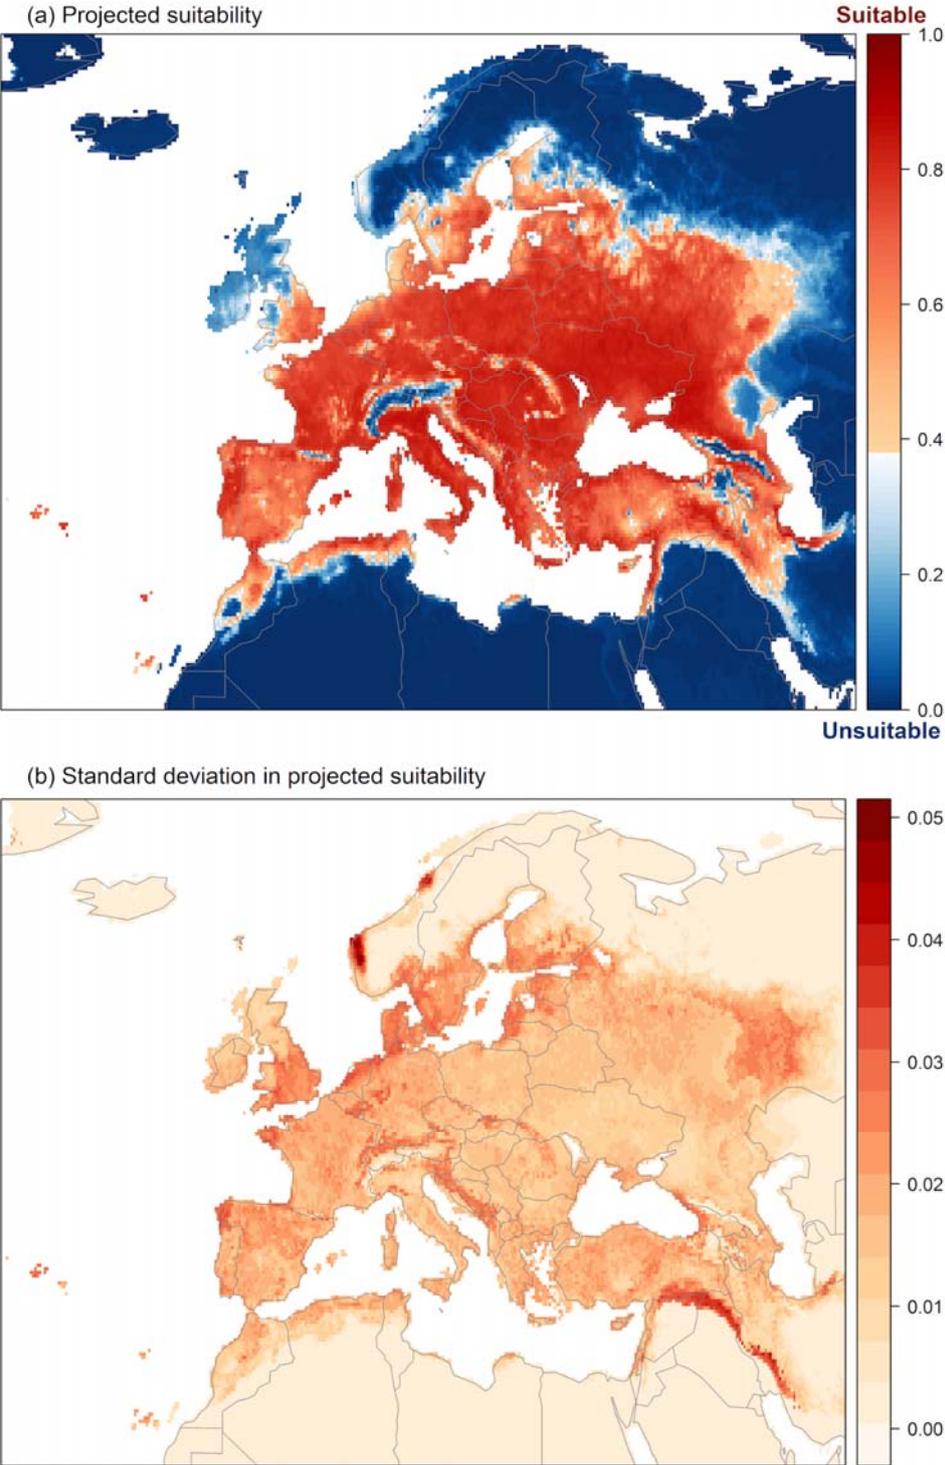

**Figure 6.** The most strongly limiting factors for *Broussonetia papyrifera* establishment estimated by the model in Europe and the Mediterranean region in current climatic conditions.

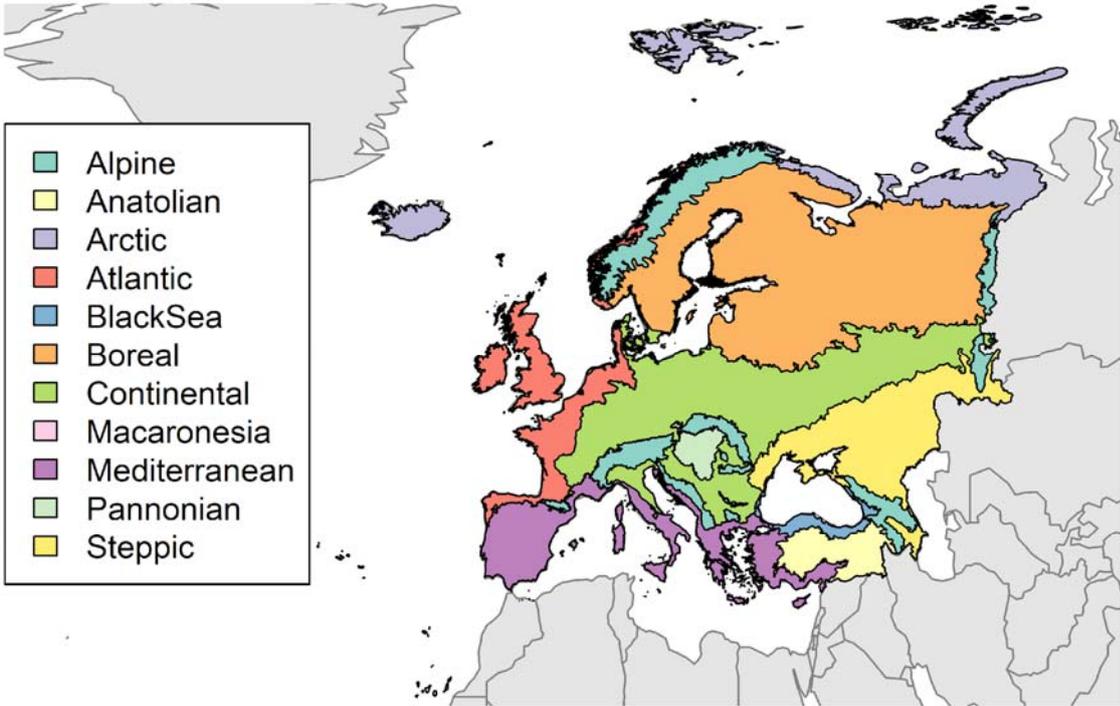

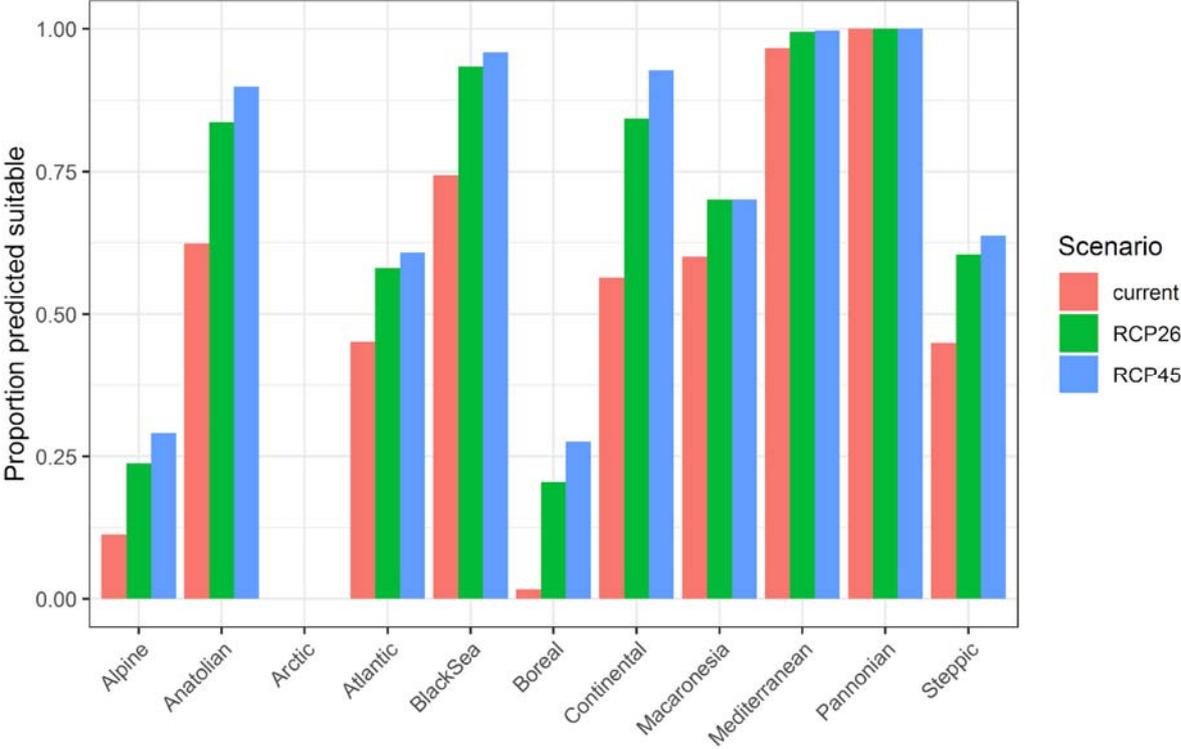

**Figure 7.** (a) Projected suitability for *Broussonetia papyrifera* establishment in Europe and the Mediterranean region in the 2070s under climate change scenario RCP2.6, equivalent to Figure 5. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

**Figure 8.** (a) Projected suitability for *Broussonetia papyrifera* establishment in Europe and the Mediterranean region in the 2070s under climate change scenario RCP4.5, equivalent to Figure 5. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

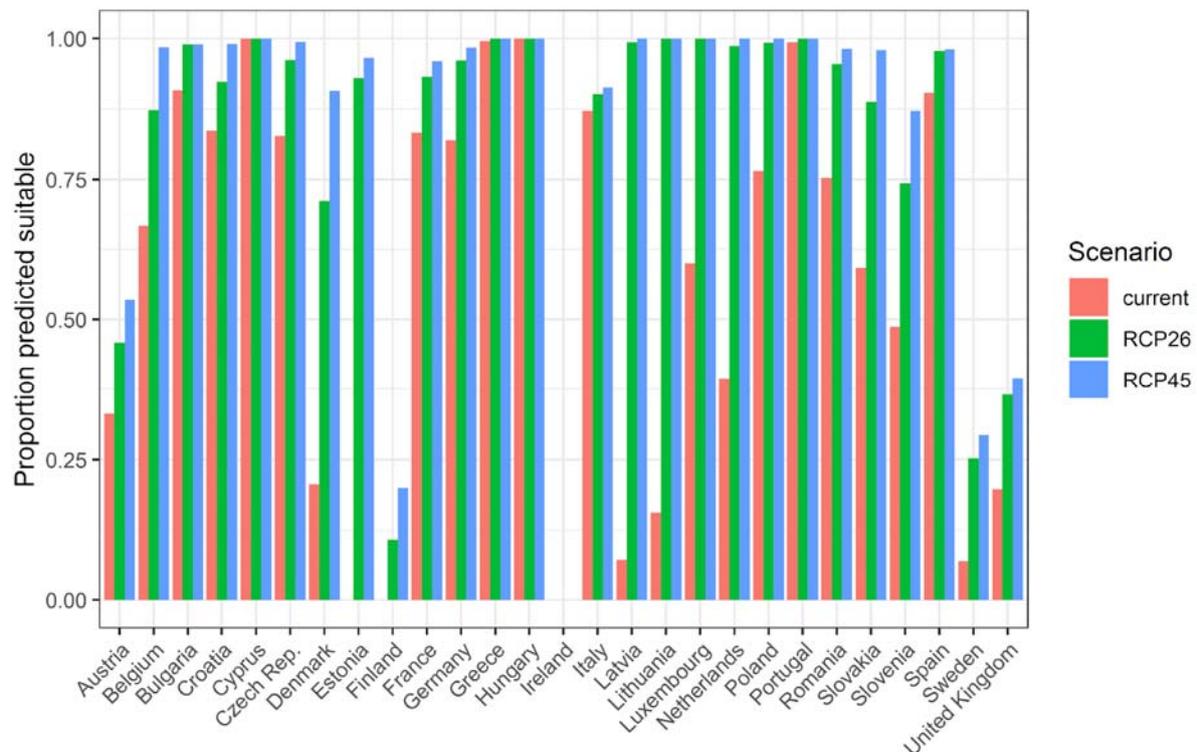

**Figure 9.** Variation in projected suitability for *Broussonetia papyrifera* establishment among Biogeographical regions of Europe (<https://www.eea.europa.eu/data-and-maps/data/biogeographical-regions-europe-3>). The bar plots show the proportion of grid cells in each region classified as suitable in the current climate and projected climate for the 2070s under two RCP emissions scenarios. The location of each region is also shown. The Arctic and Macaronesian biogeographical regions are not part of the study area, but are included for completeness.

**Table 2.** Variation in projected suitability for *Broussonetia papyrifera* establishment among Biogeographical regions of Europe (numerical values of Figure 9 above). The numbers are the proportion of grid cells in each region classified as suitable in the current climate and projected climate for the 2070s under two RCP emissions scenarios. The Arctic and Macaronesian biogeographical regions are not part of the study area, but are included for completeness.

### **Caveats to the modelling**

To remove spatial recording biases, the selection of the background sample from the accessible background was weighted by the density of Tracheophyta records on the Global Biodiversity Information Facility (GBIF). While this is preferable to not accounting for recording bias at all, it may not provide the perfect measure of recording bias.

There was substantial variation among modelling algorithms in the partial response plots (Figure 3). In part this will reflect their different treatment of interactions among variables. Since partial plots are made with other variables held at their median, there may be values of a particular variable at which this does not provide a realistic combination of variables to predict from.

Other variables potentially affecting the distribution of the species, such as types of land cover were not included in the model.

## SECTION A – Organism Information and Screening

**A1. Identify the organism. Is it clearly a single taxonomic entity and can it be adequately distinguished from other entities of the same rank?**

including the following elements:

the taxonomic family, order and class to which the species belongs;

This risk assessment covers one species, *Callinectes sapidus* Rathbun, 1896 a decapod crustacean belonging to:

- Portunidae (Family)
- Decapoda (Order)
- Malacostraca (Class)
- Arthropoda (Phylum)

Vernacular names: Blå svømmekrabbe (DK), blue crab, Atlantic blue crab (EN), Chesapeake blue crab (EN regional), crabe bleu (FR), Blaukrabbe (DE), Γαλαζοκάβουρας = galázios kávousas (GR), Cangrejo azul (ES), granchio nuotatore (IT), siri-tingasiri-azul (PT)

Mostly used name in commerce: American blue crab

*Callinectes sapidus* belongs to the family Portunidae which includes 18 genera (WoRMS Editorial board, 2020). The genus *Callinectes* alone includes 15 species, 3 distributed in the eastern Pacific Ocean (*C. arcuatus*, *C. bellicosus*, and *C. toxotes*), 5 in the eastern Atlantic (*C. amnicola*, *C. danae*, *C. gladiator*, *C. pallidus*), 7 in western Atlantic (*C. affinis*, *C. bocourti*, *C. exasperatus*, *C. ornatus*, *C. rathbunae*, *C. sapidus*, *C. similis*) and one – *C. marginatus* – occurring on both sides of the Atlantic (GBIF - , Global Biodiversity Information Facility, <https://www.gbif.org/>, accessed 29/06/2020)

Most common SYNONYMS

- *Lupa hastata* (Say 1817)
- *Portunus diacantha* (Latreille 1825) (synonym)
- *Lupa diacantha* (Milne-Edwards 1834)
- *Callinectes hastatus* (Ordway 1883)
- *Callinectes diacanthus* Latreille, 1825 (name suppressed)
- *Callinectes sapidus acutidens* Rathbun, 1896 (junior synonym)

**A2. Provide information on the existence of other species that look very similar [that may be detected in the risk assessment area, either in the environment, in confinement or associated with a pathway of introduction]**

Include both native and non-native species that could be confused with the species being assessed, including the following elements:

- other alien species with similar invasive characteristics, to be avoided as substitute species (in this case preparing a risk assessment for more than one species together may be considered);
- other alien species without similar invasive characteristics, potential substitute species;
- native species, potential misidentification and mis-targeting

Response: Worldwide, *C. sapidus* can be confused with other *Callinectes* species (*C. bocourti*, *C. maracaiboensis*, *C. rathbunae*, *C. ornatus*, *C. danae*) occurring in the same native distribution area that have the front of carapace with 4 more or less well-developed teeth (2 frontal teeth in *C. sapidus*). The inner pair of teeth are clearly smaller than the outer pair in *C. danae* and they are rudimentary in *C. ornatus*. It can be also confused with West Atlantic origin *Callinectes exasperatus* (Gerstaecker, 1856), that has been reported once from the Atlantic Spain (Cuesta et al., 2015).

In European waters it can be confused with another alien species namely the blue swimming crab *Portunus segnis*/*Neptunus pelagicus* also of economic importance in the RA area. This American blue crab was in fact often mistaken for *Portunus segnis* (Forskål, 1775) and often had been called *Neptunus pelagicus* or *Portunus pelagicus* (Linnaeus, 1758) until the *P. pelagicus* species complex was revised (Lai et al., 2010). As an example, one of the first records (Adriatic Sea: Giordani Soika, 1951) of *C. sapidus* was initially identified as *Neptunus pelagicus*. Evans & Schembri in Crocetta et al. (2015) have recently revisited the taxonomic identity of a crab recorded in Maltese waters over thirty years ago by Schembri & Lanfranco (1984), identified at the time as *C. sapidus*, and ascribed it to *Portunus segnis*.

### **Short description of *Callinectes sapidus***

*Callinectes sapidus* is a decapod crustacean of the family Portunidae. The species is characterised by a carapace wider than long (more than twice including the antero-lateral spines). Front (excluding inner orbital angles) bearing 2 obtuse to acuminate, broadly triangular teeth with sinuous inner margins longer than outer margins; 9 anterolateral, acuminate teeth, the larger one at the lateral corner long and sharp-pointed, and having a dorsal carina produced to the metagastric area; the telson is lanceolate, longer than wider. Chelipeds are strong with granular ridges; fingers have strong irregular cutting teeth; merus has 3 strong inner spines increasing in size distally; the two last segments of the fifth legs are flattened in form of paddles. The colour is greyish, bluish to brownish green dorsally. Diverse coloured tints present dorsally on the carapace ornamentation (spines or tubercles) and legs. Males with fingers on chelae blue, orange in mature females. In males, carapace widths (CW) and lengths (CL) up to 20.9 and 9.1 cm, respectively; in females, CW and CL up to 20.4 and 7.5 cm, respectively. CW range in mature females from 5.5 to 20 cm (FAO fact sheet, 2020).

*Callinectes sapidus* can be distinguished from *P. segnis*, another invasive species in the Mediterranean, by its front with two prominent triangular teeth, tips of male 1<sup>st</sup> pleopods not bent. In *Portunus* the basalantennal segment is narrow, antennal flagellum not excluded from orbit; front quadridentate. *Portunus segnis* is easily distinguished from *C. sapidus* by the prominent inner spine on cheliped carpus, triangular abdomen in males (see Figure 1). See also <http://www.bluecrab.info/identification.html>

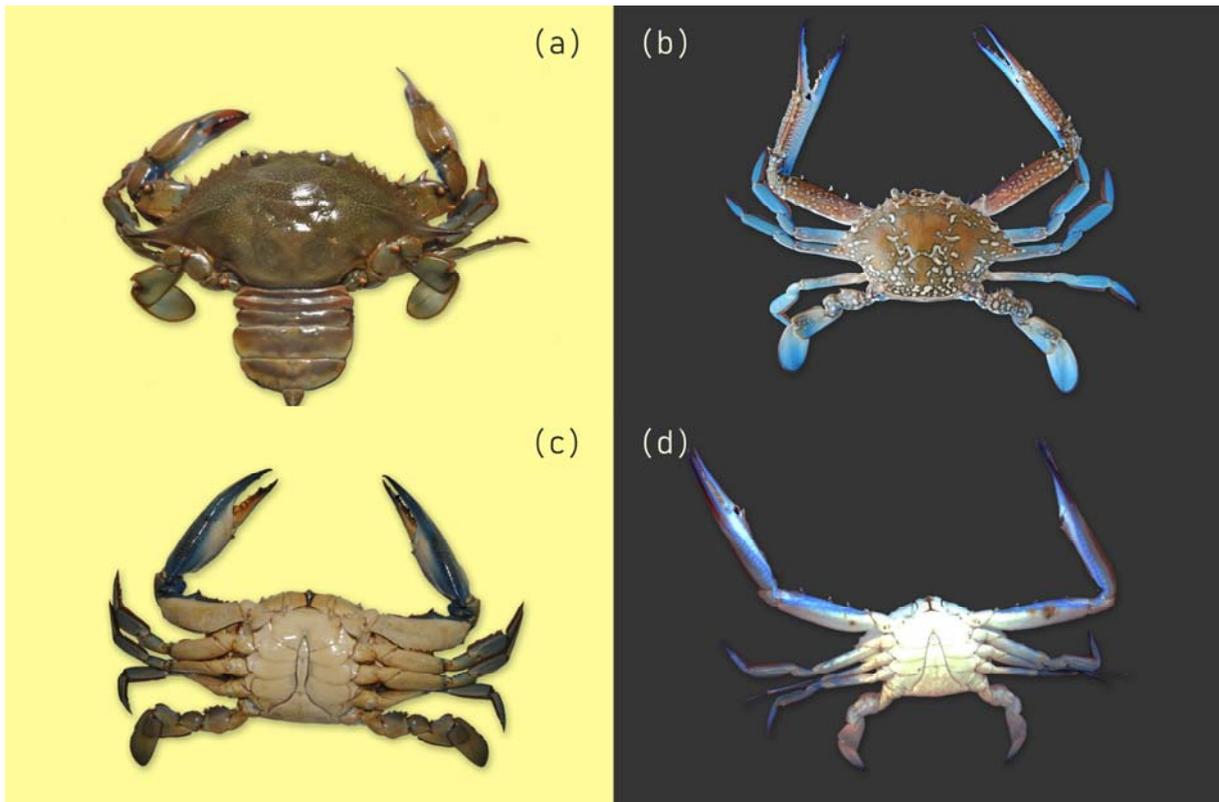

Figure 1. a) *Callinectes sapidus* dorsal side front (female); b) Upper: *Portunus segnis* dorsal side (sex not identified); c) *Callinectes sapidus* ventral side (male); d) *Portunus segnis* ventral side (male). Photo credit for *C. sapidus*: Hocein Bazairi, Morocco; photo credit for *P. segnis* Radhouan El Zrelli.

**A3. Does a relevant earlier risk assessment exist? Give details of any previous risk assessment, including the final scores and its validity in relation to the risk assessment area.**

Response: Although no formal risk assessment has been conducted for the species in the RA area, Perdikaris et al. (2016) applied the Marine Invertebrate Invasiveness Screening Kit (MIISK) risk screening tool for *C. sapidus*, concluding that this was a high-risk invasive species for western Greece. The MIISK score was based on the responses to 49 questions related to topics such as domestication/cultivation, climate and distribution, invasiveness in non-native range, undesirable traits, feeding guild, reproduction, dispersal mechanisms and persistence attributes (<http://www.cefas.defra.gov.uk/our-science/ecosystems-and-biodiversity/non-native-species/decisionsupport-tools.aspx>). A similar protocol (AS-ISK) was applied for the River Neretva Estuary (Eastern Adriatic Sea: Croatia and Bosnia– Herzegovina) by Glamuzina et al. (2021), who identified *C. sapidus* as one of the highest risk species for the region.

An initial risk assessment focusing on potential future NIS introduced by ships and taking into account the different salinity regimes in Nordic ports has included *C. sapidus* among target species that can potentially survive the conditions of the Nordic coastal waters including the outer parts of the Baltic Sea (Gollasch & Leppäkoski, 1999).

Horizon scanning to create a watch list of alien crab species that could establish along South African rocky shores under present-day and future temperature scenarios, included *C. sapidus* among potential candidates to be introduced by in all South African ecoregions (Swart & Robinson, 2019).

Roy et al. (2019) included *C. sapidus* among Invasive Non-Native Species with high likelihood of arrival, establishment and impacts within Gibraltar.

**A4. Where is the organism native?**

including the following elements:

- an indication of the continent or part of a continent, climatic zone and habitat where the species is naturally occurring
- if applicable, indicate whether the species could naturally spread into the risk assessment area

Response: The species is native to coastal habitats of the western Atlantic, apparently with a disjunct distribution encompassing temperate, subtropical, and tropical climatic zones, with a northern population from the United States and Canada (Nova Scotia, Maine, and northern Massachusetts) to Venezuela, and a southern population from Bahia, Brazil, to Argentina (Williams, 1984; Kennedy & Cronin, 2007). Estuaries and other transitional systems are the elective habitats of the species; however, during its life cycle it can be found also under fully marine conditions, as pregnant females move from brackish habitats to open sea environments for spawning (Hines, 2007). Accordingly, the species is generally found at shallow depths in the range 0 - 30/50 m, even though it has been sampled at depths comprised between 160 and 170 m (OBIS, 2020).

**A5. What is the global non-native distribution of the organism outside the risk assessment area?**

Response: Outside the risk assessment area *C. sapidus* has been reported in the Pacific Ocean and in the Mediterranean Sea. Specifically, the species has been reported from Japan since 1975 (Sakai, 1976; Milikin & Williams, 1984). Several specimens, all females, have been trapped in Kaneohe Bay, Hawaii since around 1985 (Eldredge, 1994). This crab has been transported to Hawaii since 1967 for human consumption; the majority of shipments originate from Louisiana. Speculatively, the crabs in Kaneohe Bay were purchased by an individual who released them in a personal attempt to have them available for commercial purposes. Only two records are reported (Castro, 2011, citing Stephenson, 1976 and Eldredge, 1994).

*Callinectes sapidus*, was collected occasionally in San Francisco Bay and elsewhere along the central California coast, released by private individuals (Cohen & Carlton, 1995; although listed in Jensen (1995), blue crabs are not believed to be established in San Francisco Bay). No recent records do exist of *C. sapidus* in the San Francisco Bay or in California.

The species is present in the Mediterranean Sea in a number of non EU countries. In particular there are records from Montenegro (Zenetos et al., 2010; Azzurro et al., 2019), Albania (Beqiraj & Kashta, 2010; Azzurro et al., 2019), Bosnia and Herzegovina (Dizdarević et al., 2016), Turkey (Holthuis, 1961; Kocatas, 1971), Syria (Hasan, 2018), Lebanon (George & Athanassiou, 1965), Israel (Holthuis & Gottlieb, 1955), Egypt (Banoub, 1963), Tunisia (Katsanevakis et al., 2020), Algeria (Benabdi et al.,

2019), Morocco (El-Ouamari & Bazairi in Chartosia et al., 2018; Taybi & Mabrouki, 2020). Also present and spreading in the Azov-Black Sea basin (Ukraine, Russia, Georgia, and Turkey) (Shaverdashvili & Ninua, 1975, Diripasko et al., 2009, Pashkov et al., 2012, Yağlıoğlu et al., 2014, Ceylan Y. 2020, Stefanov, 2021).

In addition, a record reported in inaturalist (<https://www.inaturalist.org>) and gbif (<https://www.gbif.org/>) from Benin, SE Atlantic is likely a misidentification of *Callinectes amnicola*. Records from the Pacific Mexico and Costa Rica are likely to be misidentifications of *C. bellicosus* or *C. arcuatus*. Records from Australia, New Zealand, Thailand, and the Philippines are deemed as misidentifications of portunids of the *Portunus segnis* complex (Mancinelli, personal observation).

**A6. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species been recorded and where is it established? The information needs to be given separately for recorded (including casual or transient occurrences) and established occurrences. “Established” means the process of an alien species successfully producing viable offspring with the likelihood of continued survival<sup>2</sup>.**

**A6a. Recorded: List regions**

Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

- Greater North Sea, incl. the Kattegat and the English Channel, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea.

**A6b. Established: List regions**

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

- Greater North Sea, incl. the Kattegat and the English Channel, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea.

Response (6a): Reported.

- Baltic Sea: in the catchment basin of the Baltic Sea (Lake Dąbie, Poland) (Czerniejewski et al., 2020);
- North-east Atlantic Ocean: a questionable record from France in 1900 (Bouvier, 1901) and since 1932 in the Netherlands (Den Hartog & Holthuis, 1951). Most recent records from the English channel (Pezy et al., 2019)
- Mediterranean Sea: since 1947 and possibly since 1935 in the Aegean Sea (Serbetis, 1959); since 1949 in the Adriatic. See Mancinelli et al. (2017a) for an exhaustive review of the distribution and ecological impacts of the species in the Mediterranean Sea, as well as of potential control strategies.

<sup>2</sup> Convention on Biological Diversity, Decision VI/23

- Black Sea: In Bulgaria – a few records from 1967 to 2005 in Varna Bay (Bulgurkov, 1968, Zaitsev 1998, Uzunova 2016), among which one female with eggs (2005, Uzunova 2016). Since 2006, the species has expended its range along the entire Bulgarian Black Sea coast (Stefanov 2021). In Romania – single records with a tendency to become common species (Petrescu et al., 2000, Papadopol & Curlișcă, 2016). There are some recent records from the southern areas and northern basin, but only from non EU countries. They refer mostly to isolated captures of adult individuals from Turkey (e.g. Yağlıoğlu et al., 2014; Ak et al., 2015; Aydin, 2017).

### **Marine subregions:**

- Greater North Sea, incl. the Kattegat and the English Channel: since 1932 in the Netherlands (Den Hartog & Holthuis, 1951). First time in the English Channel in 1973 and in 1974 in the Bay of Seine (Benerville-sur-Mer) (Vincent, 1999).
- Bay of Biscay and the Iberian Coast: observed for the first time in 1900 along the Atlantic coast of France at Rochefort (Bouvier, 1901), and then in 1960 at Le Verdon-sur-Mer (Amanieu & Le Dantec, 1961).
- Western Mediterranean Sea: first record from Livorno port in 2005 (Bisconti & Silvi, 2005).
- Adriatic Sea: since 1949 (Giordani Soika, 1951) many records ever since.
- Ionian Sea, Central Mediterranean Sea: since 2004 from Taranto Gulf (Cecere et al., 2016): common.
- Aegean-Levantine Sea: since 1947 (possibly 1935 according to fishers) (Serbetis, 1959): common.
- Black Sea: In Bulgaria – a few records from 1967 to 2005 in Varna Bay (Bulgurkov, 1968, Zaitsev 1998, Uzunova 2016), among which one female with eggs (2005, Uzunova 2016). Since 2006, the species has expended its range along the entire Bulgarian Black Sea coast (Stefanov 2021). In Romania – a few records that refer to isolated individuals (Petrescu et al., 2000, 2010).

Response (6b): Established.

- Greater North Sea: Until today blue crabs were recorded from coastal waters of several North Sea European countries (The Netherlands, Denmark, United Kingdom, Germany) but the species is considered as established in France (Pezy et al., 2019) and Belgium (OBIS, 2020)
- Bay of Biscay and the Iberian Coast: Following the first observations in 1900 along the Atlantic coast of France at Rochefort (Bouvier, 1901), and then in 1960 at Le Verdon-sur-Mer (Amanieu & Le Dantec, 1961), the blue crab was observed for the first time in 1978 in the Tagus estuary (western Portugal) (Gaudêncio & Guerra, 1979). This species is also present in the Guadalquivir estuary (southwest Spain) at least since 2002 (Castejón & Guerao, 2013); in the Gijon coast in 2004 (Cabal et al., 2006); Ría de Vigo (Bañón et al., 2016); the Sado estuary in 2009; however anecdotal reports indicate the presence of this species at least since the mid-1990's (Ribeiro & Veríssimo, 2014). Morais et al. (2019) documented its establishment in Formosa lagoon and the Guadiana estuary, while Vasconcelos et al. (2019) confirmed its establishment in the southern coast of Portugal.
- Western Mediterranean Sea: Recently, different scientific papers and communications reported its arrival in several locations in the western Mediterranean Sea such as France (Labruno et al., 2019) and Sardinia (Italy) (Piras et al., 2019; Culurgioni et al., 2020); the coastal lagoons of Ebro Delta

(Spain) (Castejón & Guerao, 2013), the estuary of the Segura river (Spain) (González-Wangüemert & Pujol, 2016), the lagoons of eastern Corsica (France) (Garrido et al., 2018; Noël, 2017) and the Balearic Islands (Spain) (Garcia et al., 2018).

- Adriatic Sea: After its first record in Venice lagoon (Giordani Soika, 1951), it has been widely reported from various locations in the north Adriatic: Florio et al. (2008), Manfrin et al. (2015; 2016); central Adriatic: Castriota et al. (2012); east Adriatic: Croatia: Dulčić et al. (2008; 2011), Mancinelli et al. (2016); Albania: Beqiraj & Kashta (2010), Milori et al. (2017). Online questionnaires administered to recreational fishers revealed that it is widely distributed in the Adriatic (Cerri et al., 2020).
- Ionian Sea, Central Mediterranean Sea: *Callinectes sapidus* has spread rapidly in the Italian Ionian (Gennaio et al., 2006) and the Greek Ionian coast (Perdikaris et al., 2016).
- Aegean-Levantine Sea: becoming naturalized on northern Greece (Kevrekidis & Antonadou, 2018)
- Black Sea: data of spreading and presence of females with eggs in the Bulgarian coast (Uzunova, 2016, Stefanov, 2021) and Turkish coast (Ceylan 2020, Gül et al., 2021).

**A7. In which biogeographic region(s) or marine subregion(s) in the risk assessment area could the species establish in the future under current climate and under foreseeable climate change? The information needs be given separately for current climate and under foreseeable climate change conditions.**

**A7a. Current climate: List regions**

**A7b. Future climate: List regions**

With regard to EU biogeographic and marine (sub)regions, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

Response (7a): Winter temperatures appear to limit the distribution of the species, reflecting the thermal tolerance of the megalopa stage, as well the sensitivity of juveniles and mature females to water temperatures < 3°C (Rome et al., 2005; Hines et al., 2010). Combining physiological tolerances and distribution modeling results, presented in Qu 2.1, Qu 2.10, the following assessments are made (See also Figure 2 and Annexes VIII and IX for details).

Baltic Sea: unlikely, high confidence (western Baltic – low winter temperatures)  
Greater North Sea: likely, medium confidence (localized establishment, southern North Sea)  
Celtic Seas: unlikely, medium confidence (localized establishment).  
Bay of Biscay and the Iberian coast: very likely , high confidence  
Mediterranean Sea: very likely, high confidence  
Black Sea: likely, medium confidence. Very likely, high Confidence in the Sea of Marmara.

Response (7b): Combining physiological tolerances and distribution modeling, aspects of climate change most likely to affect future distribution were considered as an increase in minimum and maximum Sea Surface Temperatures (SST), according to scenario RCP4.5 for 2050/2070. The methodology for the developed models is described in Annex IX.

Baltic Sea: unlikely, high confidence (except for the western Baltic - likely)  
Greater North Sea: very likely, high confidence  
Celtic Seas: moderately likely, medium confidence. However, the Severn Estuary and some coastal areas in Britany, France (included in the Celtic Sea region) look highly suitable and include several shipping ports and other potential points of introduction.  
Bay of Biscay and the Iberian coast: very likely, high confidence  
Mediterranean Sea: very likely, high confidence  
Black Sea: likely, medium confidence. However, establishment is very likely with high confidence in the Sea of Marmara due the the environmental conditions and proximity to the North -East Aegean where *C. sapidus* is already invasive.

A large body of literature from the native range strongly suggests that *C. sapidus* needs salinities above 20 psu to complete its larval development. Nevertheless, in the Black Sea with a surface salinity range of 14-19 psu, the increasing number of records and the recent findings of gravid females indicate that the species has likely developed adaptations that allow establishment of self-sustaining populations. The medium confidence score of this assessment is motivated by the fact that there is still not enough information on larval survival in the Black Sea and a lack of reports from upstream areas where one would expect to find juveniles and young males. See also Risk of Establishment section.

**A8. In which EU Member States has the species been recorded and in which EU Member States has it established? List them with an indication of the timeline of observations. The information needs be given separately for recorded and established occurrences.**

**A8a. Recorded: List Member States**

**A8b. Established: List Member States**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden

The description of the invasion history of the species shall include information on countries invaded and an indication of the timeline of the first observations, establishment and spread.

Response (8a):

**Belgium:** Besides the first record from Oostende (Adema, 1991: no collection date) several records are included in OBIS (2020)

**Bulgaria:** Single records from 1967 to 2005 in Varna Bay (Bulgurkov, 1968, Zaitsev 1998, Uzunova 2016), among which one female with eggs (2005, Uzunova 2016). Since 2006, the species has expended its range along the entire Bulgarian Black Sea coast (Stefanov 2021)

**Croatia:** several records since 2004 (Dulčić et al., 2008; 2011; Mancinelli et al., 2016; Azzurro et al., 2019; Cerri et al., 2020)

**Cyprus:** since 1964 (Demetropoulos & Neocleous, 1969)

**Denmark:** scattered records since 1951 (Wolff, 1954; Tendal & Flintegaard, 2007; Nehring et al., 2008)-casual

**France:** first observations in 1900 along the Atlantic coast of France at Rochefort (Bouvier, 1901), and then in 1960 at Le Verdon-sur-Mer (Amanieu & Le Dantec, 1961). In the Mediterranean France since 1962 (Galil et al., 2002)

**Germany:** scattered records since 1964 (Kühl, 1965; see also Nehring et al., 2008; Nehring, 2011). The first record of a fertilized female blue crab, in 2008 (Nehring & Meer, 2010)

**Greece:** since 1947 (Serbetis, 1959). Widespread in the North Aegean (Kevrekidis & Antoniadou, 2018) and in the Ionian coasts and lagoons (Perdikaris et al., 2016; Mancinelli et al., 2017a)

**Italy:** since 1949 (Giordani Soika, 1951)

**Netherlands:** scattered records since 1932 (Den Hartog & Holthuis, 1951)

**Poland:** first record in 2018 from the western part of Lake Dąbie, at the mouth of the Duńczyca Canal (Czerniejewski et al., 2020)- casual

**Portugal:** since 1978 in Tagus estuary (Gaudêncio & Guerra, 1979)

**Romania:** scattered records since 1999 (Petrescu et al., 2000; Papadopol & Curlișcă, 2016)-casual

**Spain:** first reported in the estuary of the Guadalquivir in 2002 (Cabal et al., 2006); in the Cantabrian Sea in 2004 (Cabal et al., 2006); and in the Ebro delta in 2012 (Castejón & Guerao, 2013)

**United Kingdom:** a single record in 1975 (Ingle, 1980) - The first British record of *C. sapidus* was trawled off Littlestone-on-Sea, Kent, in September 1975 (Ingle, 1980). On 24 February 2010 a live adult female crab was caught in the Fal estuary, south of Turnaware point (P.F. Clark pers. comm.).

Response (8b):

**Bulgaria:** Single records from 1967 to 2005 in Varna Bay (Bulgurkov, 1968, Zaitsev 1998, Uzunova 2016), among which one female with eggs (2005, Uzunova 2016). Since 2006, the species has expended its range along the entire Bulgarian Black Sea coast (Stefanov 2021) – considered established (Stefanov 2021)

**Greece:** since 1947 (Serbetis, 1959). Widespread in the North Aegean (Kevrekidis & Antoniadou, 2018) and in the Ionian coasts and lagoons (Perdikaris et al., 2016; Mancinelli et al., 2017a) - established

**Italy:** the species is currently distributed in northern, central, and southern Adriatic Sea, and in northern Tyrrhenian Sea (Cilenti et al., 2015; Mancinelli et al., 2017b; Manfrin et al., 2015; 2016; Suaria et al., 2017) while it has recently spread in Sardinian (Italy) (Piras et al., 2019; Culurgioni et al., 2020 and E. Sicily (Ionian Sea: Katsanevakis et al., 2020) - established

**Croatia:** several records since 2004 (Dulčić et al., 2008; 2011; Mancinelli et al., 2016; Azzurro et al., 2019; Katsanevakis et al., 2020). Online questionnaires administered to recreational fishers revealed that it is widely distributed in Croatian coastal waters (Cerri et al., 2020) - established

**France:** first observations in 1900 along the Atlantic coast of France at Rochefort (Bouvier, 1901), and then in 1960 at Le Verdon-sur-Mer (Amanieu & Le Dantec, 1961). A well established population in the English Channel was reported by Pezy et al. (2019). Zibrowius reported the occurrence of *C. sapidus* in the Mediterranean Berre lagoon (France) in 1962 (Galil et al., 2002) while Labrune et al. (2019) reported it from eleven lagoons and three sites in the Gulf of Lions (French Mediterranean) after 2016, including one ovigerous female – considered established

**Spain:** Sporadic records from the Atlantic Spain since 2002 [estuary of the Guadalquivir in 2002 (Cabal et al., 2006); Gijón in 2004 (Cabal et al., 2006); Ría de Vigo (Bañón et al., 2016)]. The first records of the blue crab on the Mediterranean coastline are from Murcia (Abelló, 2010) and the Ebro delta in 2012 (Castejón & Guerao, 2013). Currently, it is considered an established species on the Spanish Mediterranean coastline in the Ebro River, in many coastal lagoons in Valencia and in the Mar Menor lagoon in Murcia (Servicio de Vida Silvestre, 2016; Mancinelli et al., 2017a). Fuentes et al. (2019) reported its establishments in the Fluvià River and estuary and sporadic record in the Muga and Ter rivers. In addition, a rapid expansion in the coastal lagoons of the Balearic Islands was reported by Garcia et al. (2018) and Box et al. (2020).

**Portugal:** Along the Portuguese coast, previous occurrences of *C. sapidus* were reported in the western coast, namely for the Tagus estuary (Gaudêncio & Guerra, 1979) and the Sado estuary (Ribeiro & Veríssimo, 2014), followed by very recent records in the southern coast, for both the Guadiana estuary and the Ria Formosa lagoon (Morais et al., 2019), while Vasconcellos et al. (2019) confirmed its establishment in the southern coast of Portugal.

**Belgium:** Since the 1990s it seems that *C. sapidus* has become permanently established in the Belgian Scheldt estuary Reported as common in AquaNIS (Gollasch, 2015).

**Germany:** establishment success questionable. The case for accepting that *C. sapidus* is now established in German water is presented by Nehring et al. (2008) because a female mature specimen was captured but Gollasch (2015) reports it as rare.

**Netherlands:** scattered records since 1932 (Den Hartog & Holthuis, 1951)

Since the 1990s it seems that *C. sapidus* has become permanently established in the Dutch Westerschelde estuary and adjacent waters as well as in the Noordzeekanaal between Amsterdam and the North Sea (ICES, 2001; Wolff, 2005; A. Gittenberger pers. commun) but AquaNIS (Gollasch, 2015) reports it as non established.

**A9. In which EU Member States could the species establish in the future under current climate and under foreseeable climate change? The information needs be given separately for current climate and under foreseeable climate change conditions.**

**A9a. Current climate: List Member States**

**A9b. Future climate: List Member States**

With regard to EU Member States, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)?

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

Response (9a): See Annex VIII: Bulgaria, Greece, Cyprus, Malta, Italy, Croatia, Slovenia, France, Spain, Portugal, Belgium, Germany, the Netherlands.

Response (9b): In addition to Mediterranean countries (Greece, Cyprus, Malta, Italy, Croatia, Slovenia, France, Spain) and Portugal where it is already established, based on the temperature limits of the species distribution (see Qu. 2.1), and given the ongoing oceanographic variations in north Atlantic Ocean (Smeed et al., 2018), climate warming is expected to favour the spread of *C. sapidus* towards northern European waters (France, Belgium, Germany, the Netherlands and additionally Denmark, Sweden and the United Kingdom) under both RCP2.6 and RCP4.5. Despite the high habitat suitability predicted by environmental modelling procedures (see Annex VIII), low salinities may represent a limiting factor for the establishment of the species in the Baltic Sea countries (Estonia, Finland, Lithuania, Latvia).

**A10. Is the organism known to be invasive (i.e. to threaten or adversely impact upon biodiversity and related ecosystem services) anywhere outside the risk assessment area?**

Response: In its native (Atlantic USA) *C. sapidus* is the best-known predator of cultured clams and oysters, being responsible for much of their mortality in the region. It opens shellfish with its claws, by chipping the edge of a valve, or forcing the valves apart. Predation rates can be quite high (140 oysters (size 15 mm shell length) crab-/day) (Eggleston, 1990).

Outside the RA area it is established and exploited in Turkey and Egypt.

In Egypt and in particular in Bardawil lagoon where the species comprises 19% to 42% of the total lagoon production (Abdel Razek et al., 2016; Mehanna et al., 2019), there are some alleged implications that *C. sapidus* is involved in changes in the ecosystem and biological balance. For more details on impacts in Egypt and Turkey see Qu 4.2.

**A11. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea

Response:

**Mediterranean:** No specific information on the ecological impact assessment is available for the blue crab in Italy. In North Aegean (Thermaikos Gulf and Papapouli Lagoon) *C. sapidus* was found to prey on a wide variety of species including economically important molluscs, fishes, and crustaceans, indicating a substantial potential impact on fisheries and aquaculture in the region. Observation showed that over 6 years (2009–2014), the blue crabs became dominant in Papapouli Lagoon at the expense of the native commercially fished crab *Carcinus aestuarii* Nardo, 1847 according to fisheries data (Kampouris et al., 2019).

**North-east Atlantic:** Established in Portugal and France but not invasive according to Jensen (2010). However, and despite the lack of documented impacts, the rapid expansion of *C. sapidus* in Atlantic Spain, Portugal and France as indicated in recent publications and by the number of i-naturalist records, suggest a large increase in population and spread since the 2010, which implies invasiveness. In particular, recent sales at the wholesale market, reveal a rapid westward expansion of *C. sapidus* along the southern coast of Portugal. The potential impacts of this species on local ecosystems and fishing/harvesting resources in Portugal are discussed in Vasconcelos et al. (2019).

**A12. In which EU Member States has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden

Response:

**Greece:** Since its first record in Greek water (Serbetis, 1959), *C. sapidus* has expanded its distribution in most Greek Seas, becoming abundant and exploited in coastal lagoons of Northern Aegean Sea (Kevrekidis & Antoniadou, 2018), Ionian Sea (Perdikaris et al., 2016) and N. Kriti (landing reported at <https://www.okaa.gr/>). Its feeding habits and foraging behavior have been studied in the risk assessment area by Kampouris et al. (2019) who presented evidence that in northern Greece the blue

crab preys on a wide range of species, including economically important fish, molluscs and crustaceans. For more details see response to Qu. 4.2.

**Italy:** The rate of expansion is indicative of invasiveness. *Callinectes sapidus* is characterized by an almost ubiquitous distribution in the Adriatic Sea, with records occurring in the northern, central and southern sectors of the basin (Mancinelli et al., 2017a and literature cited; see also Cerri et al., 2020). In addition, established populations (including juveniles and pregnant females) have been recorded in the southern Adriatic and in the Ionian Sea (e.g., Lesina Lagoon: Florio et al., 2008 and Cilenti, personal communication; Salento Peninsula: Carrozzo et al., 2014; Mancinelli et al., 2013a; 2017a, 2017c) while in other areas of the basin occurrences refer only to adult individuals of both sexes. Fishermen from the Lesina Lagoon consider the species a nuisance, given its high abundance, null economic value, ability to tear nets and other fishing devices, coupled with the fact that once captured it eats or damages other captured fish and invertebrate species of commercial value (Cilenti, personal communication). Furthermore, for populations from the Salento Peninsula CN stable isotope analysis indicated for the species a high trophic plasticity, emphasizing a potentially high impact on multiple trophic levels of invaded food webs related with the local availability of trophic resources, ontogeny, and seasonal drivers (Carrozzo et al., 2014; Mancinelli et al., 2013a, 2017c). *Callinectes sapidus* has been recorded also in peninsular Italy in northern Tyrrhenian Sea (Mancinelli et al., 2017a; Suaria et al., 2017) while occurrences in central (e.g., Sabaudia and Fogliano lagoons) and in southern Tyrrhenian transitional habitats (e.g. Alento River mouth) are testified by unpublished records and citizen science observations (Cilenti, unpublished data; Cerri et al., 2020). The blue crab is currently expanding its range in Sicily (Giacobbe & Scaduto, 2019 and literature cited) and in the Sardinia Island, in particular in coastal lagoons of the western sector of the Island (Piras et al., 2019; Culurgioni et al., 2020).

**Spain:** After the review by Mancinelli et al. (2017a), summarizing multiple records of the species concentrated along the Valencian coasts, a number of additional occurrences has been recorded, in Atlantic waters as well as in the Mediterranean Sea, including the Balearic Island (Garcia et al., 2018; Fuentes et al., 2019 and literature cited; Vasconcelos et al., 2019; Box et al., 2020). Established populations have been indicated in the Albufera lagoon and in the Ebro River delta (Garcia et al., 2018; Mancinelli, unpublished data). Specifically, in the Ebro Delta negative impacts have been assessed for *C. sapidus* on multiple fish and invertebrate species, including some of economic interest (e.g., *Anguilla anguilla* a CITES listed with vulnerable populations throughout Europe) (Mancinelli, unpublished data). It has been documented that in Ebro Delta bays, it poses an important risk for the cultivation of Mediterranean mussel (*Mytilus galloprovincialis*) and Pacific oyster (*Crassostrea gigas*) (Prado et al., 2020).

**A13. Describe any known socio-economic benefits of the organism.**

including the following elements:

- Description of known uses for the species, including a list and description of known uses in the risk assessment area and third countries, if relevant.
- Description of social and economic benefits deriving from those uses, including a description of the environmental, social and economic relevance of each of those uses and an indication of associated beneficiaries, quantitatively and/or qualitatively depending on what information is available.

If the information available is not sufficient to provide a description of those benefits for the entire risk assessment area, qualitative data or different case studies from across the risk assessment area or third countries shall be used, if available.

Response: The species is of major interest to fisheries in temperate, tropical and subtropical waters of the Western Atlantic (Kennedy & Cronin, 2007; Mendonça et al., 2010). Specifically, it supports large valuable commercial and recreational hard- and soft-shell fisheries in the temperate areas of the Atlantic and Gulf coasts of the USA (Texas, Florida, Louisiana, New York, New Jersey); in 2013 the capture production was estimated at 74,495 tons, corresponding with a commercial and recreational asset valued at approximately US\$185 million (Mancinelli et al., 2017b).

There is no detailed information on the relative abundance of the species in the risk assessment area. The bulk of the literature reports on findings of one to few individuals. Nevertheless, locally, *C. sapidus* has established populations that support fisheries productions, a fact that is indicative of its population densities in the area. The expansion of the Atlantic blue crab into the Mediterranean basin has led to the development of fisheries focused on the species, such as in northern Greece (Kevrekidis & Antoniadou, 2018). In Spain, in 2016, the Spanish Ministry of Fisheries included *C. sapidus* in the list of commercial fishing species (BOE-A-2016-3357). In the Ebro Delta (NW Spain) total landings for the period 2016-2018 amounted to approximately 30 tones, while in 2017 *C. sapidus* sales represented 81% of the total lagoon fisheries sales (López and Rodon, 2018). The average price in 2017 was 3.94 €/kg and the profit from the species in the region of Catalonia reached 100,000 €. In Portugal, in the Olhão seafood market in April 2019, amounts of 10 kg per day are being sold (Vasconcelos et al., 2019).

In northern Greece blue crab specimens were rarely reported from fisheries and annual landings were very low until 2007. Since then, increased abundance has been reported from the northern Aegean Sea sustaining local scale fishery. In particular 84t were reported in 2010 from Thermaikos and as an average 13 t from Vistonikos (Kevrekidis & Antoniadou, 2018). In 2019 the total production was estimated to 64 t. The average wholesale price ranged from 0.58 to 4.7 euro per kg depending on the area (fisheries statistics), while the retail price reached 10 euro per kg.

## SECTION B – Detailed assessment

### Important instructions:

- In the case of lack of information the assessors are requested to use a standardized answer: “No information has been found.”
- With regard to the scoring of the likelihood of events or the magnitude of impacts see Annexes I and II.
- With regard to the confidence levels, see Annex III.
- Highlight the selected response score and confidence level in **bold** but keep the other scores in normal text (so that the selected score is evident in the final document).

## 1 PROBABILITY OF INTRODUCTION AND ENTRY

### Important instructions:

- **Introduction** is the movement of the species into the risk assessment area (it may be either in captive conditions and/or in the environment, depending on the relevant pathways).
- **Entry** is the release/escape/arrival in the environment, i.e. occurrence in the wild
- Introduction and entry may coincide for species entering through pathways such as “corridor” or “unaided”, but it also may differ. If different, please consider all relevant pathways, both for the introduction into the risk assessment area and the entry in the environment.
- The classification of pathways developed by the Convention of Biological Diversity (CBD) should be used (see Annex IV). For detailed explanations of the CBD pathway classification scheme consult the IUCN/CEH guidance document<sup>3</sup> and the provided key to pathways<sup>4</sup>.
- For organisms which are already present (recorded or established) in the risk assessment area, the likelihood of introduction and entry should be scored as “very likely” by default.
- Repeated (independent) introductions and entries at separate locations in the risk assessment area should be considered here (see Qu. 1.7).

**Qu. 1.1. List relevant pathways through which the organism could be introduced into the risk assessment area and/or enter into the environment. Where possible give details about the specific origins and end points of the pathways as well as a description of any associated commodities.**

For each pathway answer questions 1.2 to 1.7 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 1.2a, 1.3a, etc. and then 1.2b, 1.3b etc. for the next pathway.

In this context a pathway is the route or mechanism of introduction and/or entry of the species.

The description of commodities with which the introduction of the species is generally associated shall include a list and description of commodities with an indication of associated risks (e.g. the volume of trade; the likelihood of a commodity being contaminated or acting as vector).

<sup>3</sup> <https://circabc.europa.eu/sd/a/738e82a8-f0a6-47c6-8f3b-aeddb535b83b/TSSR-2016-010%20CBD%20categories%20on%20pathways%20Final.pdf>

<sup>4</sup> <https://circabc.europa.eu/sd/a/0aeba7f1-c8c2-45a1-9ba3-bcb91a9f039d/TSSR-2016-010%20CBD%20pathways%20key%20full%20only.pdf>

If there are no active pathways or potential future pathways this should be stated explicitly here, and there is no need to answer the questions 1.2-1.9.

Pathway name: A number of potential pathways/vectors have been identified in the literature, each with a different degree of support. They are here listed in order of importance:

#### **A. TRANSPORT -STOWAWAY – ship/boat ballast water/sediment**

Dispersal of larvae by ballast tanks of ships is likely with medium confidence level. Release through ballast water release is suspected as introduction vector because in its native range *C. sapidus* is found in high numbers next to well travelled shipping routes while in the RA area it is predominantly recorded in port regions where ballast water discharges do frequently occur (Galil, 2006; Nehring, 2011). Specifically, most of the early records of the species along the Atlantic coasts of Europe, including the first one in the harbour of Rochefort (France; Bouvier, 1901) and the first record in Dutch waters (Amsterdam harbour; Den Hartog & Holthuis, 1951) are concentrated in locations close to commercial ports (Nehring, 2011). Direct evidence was supplied in Gollasch (1996, cited in Nehring, 2011), reporting on three living mature specimens found in ballast tanks. Moreover, the larval development of *C. sapidus* lasts from about 37–69 days (Costlow & Bookhout, 1959), long enough to make vessel transport plausible.

#### **B. TRANSPORT -STOWAWAY -ship/boat hull fouling**

This is considered as one of the two most likely pathways/vectors of introduction in European Seas and is almost certainly responsible for records, within the confines of small marinas where only yachts and small fishing craft are berthed (Bodrum (Turkey), Porto Grande (Malta) (Ulman et al., 2017). Moreover, in Japan Otani (2004) considers that *C. sapidus* to have been introduced via hull fouling rather than via ballast water. Nehring (2011) suggested that the high affinity of adult (with the exclusion of pregnant females) and juvenile blue crabs to brackish water make them unsuitable for crossing oceanic waters on ships' hulls. No information is available on the presence of larval stages (zoeas or megalopae) of the species associated to hulls.

#### **C. TRANSPORT-STOWAWAY (other: Floating debris)**

Floating debris has been acknowledged as a raft for a number of brachyurans occurring in coastal habitats (Zaouali et al. 2007; Tutman et al., 2017a). Given the affinity of *C. sapidus* for brackish habitats, it seems unlikely that transport in marine litter is a potential pathway for transfer of *C. sapidus* into the North Sea from Mexico following the Gulf Stream. It is possible that individual crabs can cling to floating objects and drift with currents across the Atlantic, or become trapped in marine litter – e.g. several invertebrate species of NW Atlantic origin have been found washed up on European shores trapped in bait pots.

#### **D. ESCAPEE FROM CONFINEMENT- including releases (live food for such species)**

The species could have been introduced on purpose or accidentally from USA native habitats because live crustaceans (e.g. *Homarus americanus*) are imported in many European countries for human consumption. This practice is ongoing, and, at least for Germany, may include *C. sapidus* (ICES, 2006). In the USA blue crabs are regarded as a special delicacy (Williams, 1984). It is possible that still alive specimens were thrown overboard during cruises or in ports. Blue crab does appear to be available to buy live in the UK and the advert suggests possibly from the USA (see <https://readingqualityfish.co.uk/lobster-crabs/>) meaning that there may be the potential for intentional or accidental release once purchased or if unsold.

Another potential pathway (RELEASE IN NATURE- Fishery in the wild) is not discussed because it is no longer considered as an active (potential) pathway. According to Nehring (2011) unconfirmed records in Turkey dating back to 1930's are attributed to intentional introduction. This could explain the documented chronological distribution pattern (Aegean since 1947), Adriatic since 1949 (separate introduction event) but also the population establishment success (establishment first in the Aegean). However, considering the current policies regarding imported species for mariculture in the RA area, it is highly unlikely that a new introduction will occur from outside the RA area. This is a potential pathway for further spreading of the species within European Seas.

A final potential pathway (RELEASE IN NATURE -other intentional release) is also not discussed but may result in releases of large numbers of individuals at a time. We refer to intentional releases with reference to religious or other 'ethical' releases. such as of Buddhist 'fangsheng' "life release" ritual (e.g. <https://www.iflscience.com/environment/buddhists-fined-over-20000-for-releasing-invasive-species-into-sea-in-life-release-ritual/>.)

#### A. TRANSPORT-STOWAWAY (ship/boat ballast water)

**Qu. 1.2a. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	intentional	<b>CONFIDENCE</b>	low
	<b>unintentional</b>		medium
			<b>high</b>

**Qu. 1.3a. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
	unlikely		<b>medium</b>
	moderately likely		high
	<b>likely</b>		
	very likely		

Response: The lowest estimates of the volumes of ballast water taken-up, transferred and discharged into world oceans each year are around 10 billion tonnes (Interwies & Khuchua, 2017), whereas just one cubic metre of ballast water may contain from 21 up to 50,000 zooplankton specimens (Locke et al., 1991; Gollasch, 1997) and a heavy bulk carrier can carry up to more than 130,000 tonnes of ballast water (GloBallast, 2009). *Callinectes sapidus* is widespread and supports commercial fisheries along much of the east USA coast, from Rhode Island to Florida and from Louisiana to Texas (Mizerek, 2012; Sutton & Wagner, 2007). It is a very fecund species, with females releasing 1 to 2 million but up to 8 million eggs usually once in their lifetime. While data on ballasts discharges are not available from EU organizations (EMSA, ECSA, ESPO) or other international relevant organisations, it is evident from the above information that the potential for high numbers of *C. sapidus* larvae to travel along this pathway is high. In fact, mature specimens of *C. sapidus* have been found in ballast sediment of a vessel from Baltimore sampled in Bremerhaven in 1993 and also from a vessel from the east coast of north America sampled in Rotterdam (Gollasch et al., 2002 and Gollasch pers. comm). Nevertheless, and despite the frequent presence of Brachyuran larvae in ballast water (e.g. Cohen & Carlton, 1997; Gollasch, 2002), the paucity of studies directly documenting the presence of *C. sapidus* larvae in ballast water indeed lowers the confidence of this assessment.

**Qu. 1.4a. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Transfer and survival of adults in ballast tanks were documented from vessels arriving to a German and a Dutch port (Gollasch, 1996; Gollasch et al., 2002; Gollasch pers. comm). As far as larvae are concerned, direct evidence of survival is lacking. However, the larval development of *C. sapidus* lasts from about 37–69 days (Costlow & Bookhout, 1959), long enough to make survival during vessel transport plausible. Furthermore, larvae can live under a wide range of chemical-physical environmental conditions (Hill et al., 1989) and certainly under the temperatures that prevail in ballast water during a transatlantic trip from the native region, considering that ballast water temperature follows the ambient sea surface temperature (Gollasch et al., 2000). According to the analysis of Seebens et al. (2013) and based on a combination of traffic volume, distance to the most connected regions and environmental similarity, the North-West Atlantic is the major source region for invasions to Northern European Seas. Given the high propagule pressure and survival rate of larval stages (see Qu. 2.7), *C. sapidus* is characterised by a high dispersion potential, considerable probability of survival in ballast waters, and high potential of establishment.

**Qu. 1.5a. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Regulation (EU) No 1143/2014 (EU, 2014) on the prevention and management of the introduction and spread of invasive alien species recognises the International Maritime Organization (IMO) Ballast Water Management Convention (BWMC) as one of the possible management measures for species of Union concern. This entered into force in September 2017 and requires ships in international traffic to apply ballast water management measures, such as ballast water exchange (D-1 standard for an interim period) and fulfil a certain discharge standard (D-2 standard according to the ship specific application schedule). The latter generally requires the installation of a certified ballast water treatment device, which enables sterilization to avoid transfer of ballast water mediated species.

Ballast Water Exchange (BWE) can drastically reduce (by 80-95% - Ruiz & Reid, 2007) the concentration of live organisms in ballast water but has limitations to its application such that it is not always possible to practice (see David et al., 2007). Full compliance with the BWMC D2 standard on the other hand can decrease live zooplankton to undetectable levels and be highly effective against adult forms in ballast sediments as well (for a review see Tsolaki & Diamadopoulos, 2009) Its full implementation is expected by 2024 and this is expected to be sufficient to make survival of *C. sapidus* in ballast tanks unlikely. Until then, and although some of the global fleet has already installed BW treatment devices its likelihood to survive current practices is considered likely.

**Qu. 1.6a. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: The probability of observing the initial introduction event, particularly at the larval or early life stages is minimal without targeted monitoring surveys at introduction hotspots (Andersen et al., 2014) can increase the likelihood of early detection.

After September 2017, when the BWMC comes into effect and gradually starts being implemented, detection of larval stages in ballast water may be also possible. eDNA methodologies are currently being actively explored by a number of EU States (ICES, 2017) as tools for the detection of NIS in introduction

hotspot water samples and ballast water and can greatly aid the early detection even of larval stages (Darling et al., 2017).

**Qu. 1.7a. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated	<b>CONFIDENCE</b>	low
	<b>widespread</b>		<b>medium</b>
	ubiquitous		high

Response: Widespread, if the ecological requirements of the species are considered. Ports in northern and western Europe are often situated in or near estuaries that exhibit major fluctuations in diurnal, monthly, and seasonal environmental condition. Blue crabs utilize all salinity regimes of an estuary in order to complete their life cycle (Guillory et al., 2001). Repeated introductions may also occur in ports and marinas.

**Qu. 1.8a. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
	unlikely		<b>medium</b>
	moderately likely		high
	<b>likely</b>		
	very likely		

Response: If ballast water exchange occurs in open seas rather than in coastal areas, transfer of planktonic larvae to suitable substrate will be hampered. If, however ballast water is released in ports, estuaries or other coastal areas then introduction will be dependent on availability of suitable habitat.

Management measures implemented so far (i.e. BWE) have not proven adequate to prevent the introduction of this and other marine invasive species in EU marine waters. With the recent ratification of the BWMC (September 2017), compliance with the D2 standard is expected to greatly reduce the likelihood of introductions of *C. sapidus* in Europe with ballast water. Until then it is considered likely that the species can be introduced in the RA area via this pathway.

**B. TRANSPORT-STOWAWAY (ship/boat hull fouling)**

**Qu. 1.2b. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response: According to CBD (2014) and the guidelines fouling is an unintentional pathway

**Qu. 1.3b. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: *Charybdis japonica* a species belonging to the same family (Portunidae) is included among the Common Hull Fouling Invasive Species by IMO (<http://www.imo.org/en/OurWork/Environment/Biofouling/Pages/Common-Hull-Fouling-Invasive-Species.aspx>). Although living specimens of *C. sapidus* were never found on ships’ hulls, the presence of two alien crab species, *Panopeus africanus* A. Milne-Edwards, 1867 and *Pilumnopus africanus* (de Man, 1902), recently recorded in the nearby Ría de Arousa and introduced by vessel hull fouling (Cuesta et al., 2016) gives also credit to this vector of introduction (Bañon et al., 2016). In Japan hull fouling is considered the most plausible mechanism of its introduction rather than ballasts (Otani, 2004). In addition, sea-chests are recognized as an alternative mechanism for transfer of *C. sapidus* at juvenile stage (Otani, 2004). In fact, many decapod species have been found inside ships’ sea-chests (Coutts & Dodgshun, 2007; Frey et al., 2014), where they can enter as juveniles or settle as larvae and sustain themselves on the rich fouling communities that develop in these niche areas. No information is

available on the propagulate pressure e.g. estimated volume or number of individuals / propagules, or frequency of passage through this pathway.

**Qu. 1.4b. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: Crabs associated with vessel biofouling are usually restricted to heavily fouled vessels with mature fouling communities, and these are generally rare (MAF, 2011). For the reproductive biology of the species please see Qu 2.7. Considering the biological characteristics of the organism (i.e. it withstands wide temperature range and salinity range), it is considered possible that juvenile *C. sapidus* can maintain a viable population within the fouling communities on ships hulls, sufficient for a new introduction. However, no specific information on the propagule pressure of *C. sapidus* on ships hulls was found.

**Qu. 1.5b. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Mobile organisms such as the blue crab can be transported for weeks or months amongst the fouling assemblage in, for example, empty shells of barnacles, or by sheltering in densely fouled areas of the hull (Gollasch, 2002). *Callinectes sapidus* was recorded in the Mediterranean within the confines of a small marina where only yachts and small fishing craft are berthed (Ulman et al., 2017).

Implementing practices to control and manage biofouling can greatly assist in reducing the risk of the transfer of invasive aquatic species. While the International Convention on the Control of Harmful Anti-Fouling Systems on Ships, 2001 (AFS Convention) addresses anti-fouling systems on ships, its focus is on the prevention of adverse impacts from the use of anti-fouling systems and the biocides they may contain, rather than preventing the transfer of invasive aquatic species.

Given the mobile nature of the species and swimming ability, there is a good chance that individuals would ‘drop off’ the vessel as it is removed from the water, rendering dry-docking no less likely to result in release to the wild than in water cleaning. The guidelines are voluntary and apply to all ships.

Commercial ship-owners have a strong interest in having their vessels cleaned in order to decrease their fuel consumption but dry-docking frequency is determined by performance (fuel consumption below a certain threshold) and can range from 0.5-5 years (Bohn et al., 2016). With respect to small leisure craft, Gittenberger et al. (2017) found that, although the majority (64%) of boat owners in the Netherlands haul their boats out of the water and clean them at least once a year, practices vary widely from harbour to harbour, with dry-docking/cleaning prevalence varying between 6% and 95%. This level of implementation allows for plenty of opportunities for organisms such as *C. sapidus* to be transferred via hull fouling.

**Qu. 1.6b. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: The species is unlikely to be detected upon introduction, unless thorough inspections of hull fouling communities are carried out, which is currently not a routine practice. Even then, because, as part of the fouling community, it is likely to be hidden within other fouling macro-organisms, the likelihood of detection via visual inspections is medium. In order to reach GES targets with reference to Descriptor D2, most EU states are already designing or implementing national/regional NIS-targeted monitoring programmes (e.g., see ICES (2017) for national reports in France, Germany, Sweden, Denmark, Norway). Monitoring should focus on introduction hotspots (e.g. ports, marinas) and this will increase the likelihood of detection of *C. sapidus* entering the RA area through hull fouling (see ICES viewpoint by Galil et al., 2019).

**Qu. 1.7b. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: Widespread, if the ecological requirements of the species are considered. Ports in northern and western Europe are often situated in or near estuaries that exhibit major fluctuations in diurnal, monthly, and seasonal environmental condition. Blue crabs utilize all salinity regimes of an estuary in order to complete their life cycle (Guillory et al., 2001). In the Mediterranean repeated introductions may also occur in ports and marinas via shipping (ballasts and fouling).

**Qu. 1.8b. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: Brachyuran crabs have been associated with fouling communities on ships hulls and particularly with niche areas, even though usually only a small number of specimens are found. Propagule pressure (per year) is not expected to be high but need not necessarily be high for successful establishment. For example, if gravid adult females travel this way, one individual could represent very high propagule numbers (clutch size can vary between  $1-8 \times 10^6$  eggs, see Qu. 2.7 for more details). Management measures such as frequent hull cleaning have the potential to greatly reduce the risk of introduction. However, effectiveness will depend on hull cleaning frequency and the methodologies employed; and measures are not mandatory. In relation to *C. sapidus*, even though transfer on ships hulls has not been documented for the species, it was considered as a highly likely pathway for its introduction to Japan (Otani, 2004), based on shipping patterns and types of commodities transported, supported by evidence of numerous decapod species found within sea-chests. Thus, this pathway is considered moderately likely for the introduction of the species in the RA area.

### C. TRANSPORT-STOWAWAY (other: Floating debris)

**Qu. 1.2c. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

**Qu. 1.3c. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication

- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: Marine litter and floating debris have been considered a potential transport vector of non-indigenous species. It is possible that individual crabs can cling to floating objects and drift with currents across the Atlantic Ocean. Larvae, megalopae and juveniles of Portunidae, including Callinectes spp., are very abundant on floating algae in the northeast Atlantic region, as well as the east Pacific (Thiel & Gutow, 2005 and references therein). In a survey of the Atlantic, Barnes & Milner (2005) reported that mega-anthropogenic debris are particularly numerous in the North Atlantic around Europe. Holmes et al. (2015) discuss findings in trans Atlantic drift material, particularly ‘scotty pots’ used in the fishing industry in the USA and which trap otherwise mobile organisms. Most of the species described cohabit with *C. sapidus*. From these results it can be concluded that marine litter can significantly alter the biotic composition of coastal ecosystem, representing a shelter for invasive alien species and diverse natives. With reference to the Mediterranean in particular, while specific information could not be found, primary introductions of alien species in the Mediterranean Sea by rafting on floating litter through the Gibraltar strait are considered plausible, although within Brachyura the most commonly reported species are pelagic (Katsanevakis & Crocetta, 2014). Information on the propagule pressure of *C. sapidus* through this pathway was not found.

**Qu. 1.4c. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: Species that are considered likely to be transported with hull fouling over long trans-oceanic voyages are considered possible to survive on floating debris as well. Probability of survival will depend on the organism, the overall fouling community (mostly in terms of food availability) and the travelling time at sea. Transatlantic journeys of this type may be very short (e.g. in the range of a few weeks, see Holmes et al., 2015) or in some cases extremely long (months to years), depending on currents and wind (Thiel & Haye, 2006). Even though juveniles and adults of *C. sapidus* have been shown to survive periods of starvation of at least 30 and 60 days respectively (Wang & Stickle, 1986; Belgrad & Grifen,

2016), there is very high uncertainty regarding the likelihood of survival of transported propagules via this pathway which is sporadic and unpredictable.

**Qu. 1.5c. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium high
-----------------	--	-------------------	-----------------------

Response: This would primarily depend on marine debris management in the source location also (USA) as once in the water, the process is largely influenced by natural processes. The issues resulting from plastic waste in the marine environment have highlighted a general failure to control this pollutant on both land and at sea. (Raubenheimer & McIlgorm, 2018). There are no specific management practices for marine debris in EU regional seas that can affect the survival of rafting species during transport on floating debris. Relevant legislative tools regulating management practices of plastic litter in the EU are the Port Reception Facility (PRF) Directive and the Marine Strategy Framework Directive (MSFD) none taking into consideration the association of non indigenous species to it (Chen, 2005). Therefore, in the unlikely event that *C. sapidus* naturally survives the journey from the West Atlantic to the coasts of Europe on floating objects (see previous question), it is likely to remain alive and reach the shore

**Qu. 1.6c. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Considering that floating debris and marine litter are not regularly examined for fouling biota it may go undetected. However, since it is an easily recognized animal when mature it is relatively easy to detect it, if present. Post settlement and younger individuals may be less detectable. Also depends on the size and complexity (available refuge) of the particular item of debris – some larger, structurally complex items covered in goosebarnacles for example can easily hide crabs such as *Planes* spp. It is noteworthy that given the amount of coastline in Europe and random nature of strandings of litter, an effective monitoring programme covering the whole RA would be almost impossible.

**Qu. 1.7c. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	Isolated widespread <b>ubiquitous</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: All natural sink areas can receive floating debris (Rech et al., 2016) such that rafting *C. sapidus* could get stranded all along the risk assessment area.

**Qu. 1.8c. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: The species could arrive from the Gulf of Mexico on floating debris to Northern Europe e.g. Scotland assisted by the Gulf Stream. Holmes et al. (2015) discuss how and why living Western Atlantic US coastal molluscan species have been found washed up in SW England with marine debris. Moreover, paucity of information on the volume, frequency of occurrence and circulation patterns of floating debris in EU regional seas decreases the confidence level of the assessment.

**D. ESCAPEE FROM CONFINEMENT- including releases of live food for such species”**

**Qu. 1.2d. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	<b>Introduction: unintentional</b>		<b>high</b>
	<b>Entry: intentional/unintentional</b>		<b>high</b>

The species could have been introduced on purpose from USA native habitats because live crustaceans (e.g. *Homarus americanus*) are imported in many European countries for human consumption. Blue crab appears to be available to buy live in the UK and the advert suggests possibly from the USA meaning that there may be the potential for intentional or accidental release once purchased or if unsold.

Furthermore, according to Nehring (2011), records of intact but boiled specimens on the Dutch North Sea coast (Wolff 2005), seem to indicate that *C. sapidus* is consumed aboard vessels, and it is possible that leftovers (boiled or live specimens) were thrown overboard.

**Qu. 1.3d. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: The species could have been introduced on purpose or accidentally released from holding tanks because live blue crabs have been imported in many European countries for human consumption. It is believed that this practice is ongoing (ICES, 2006) although with the current presence of the species in the RA area it appears more likely that any intentional intrductions would originate in established European populations. In the USA blue crabs are regarded as a special delicacy (Williams, 1984). It is possible that still alive specimens were thrown overboard during cruises or in ports.

**Qu. 1.4d. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: Likely to survive. No reproduction is possible for blue crabs traded alive due to the low temperatures at which they are transported.

Likely to survive transport during live food trade operations (e.g. Ribeiro & Verissimo (2014) found live blue crabs, allegedly obtained from Greece, being sold at an Asian goods supermarket in Lisbon) but moderately likely to survive entry into the environment, depending on the point of entry and the local conditions. For example, recently, one of the authors (GM) witnessed an incident of accidental drop-off from a pallet of several 10-Kg packs containing live *C. sapidus* into the sea at the port of Brindisi (SE Italy), while being unloaded from a merchant ship. While such incidents could result in the survival of escaped individuals, they are expected to be rare and infrequent. Once live specimens are delivered to markets, escape into the urban environment is unlikely to lead to survival.

**Qu. 1.5d. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: There are currently Regulations (e.g. Regulation (EU) 2017/625 (EU, 2017), Commission Delegated Regulation (EU) 2019/625 (EU, 2019) and guidelines concerning live food trade (see [https://ec.europa.eu/food/safety/international\\_affairs/trade/import\\_animal\\_en](https://ec.europa.eu/food/safety/international_affairs/trade/import_animal_en)), but are oriented towards the protection of human health and not transport or translocation of species.

If *C. sapidus* is frozen before being packed for transport, the procedure determines the death of the specimens, thus survival rates equal 0. If it is live food trade then it is moderately likely. Same for Qu 1.4d as there are no dedicated management measures for accidental or deliberate releases.

**Qu. 1.6d. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	<b>very unlikely</b> unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: Only large sized animals are transferred which are easily detected if looked for. *Callinectes sapidus* is easy recognizable, and trading companies are aware of its specific characteristics (see Qu.

1.2d). Thus, the possibility that it can be misidentified and imported into the risk assessment area is very unlikely

**Qu. 1.7d. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	<b>Isolated</b> widespread ubiquitous	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: As mentioned in Qu. 1.4d, trade of live *C. sapidus* imposes a relatively low transport time. To date, the species is imported by ship, thus points of introduction and entry into the environment are primarily represented by harbors and ports. No information is available on trading of the species in the risk assessment area by flight.

**Qu. 1.8d. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: The species could have been introduced on purpose or accidentally released from holding tanks because live blue crabs are imported in many European countries for human consumption. While the practice might still be ongoing, it seems more likely that introductions for live food trade will originate in the RA area. Nevertheless, this is a plausible pathway for additional introductions which cannot be discarded, even if the survival of the escaped/released individuals is highly uncertain.

**Qu. 1.9. Estimate the overall likelihood of introduction into the risk assessment area or entry into the environment based on all pathways and specify if different in relevant biogeographical regions in current conditions.**

Provide a thorough assessment of the risk of introduction in relevant biogeographical regions in current conditions: providing insight in to the risk of introduction into the risk assessment area.

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
-----------------	---------------	-------------------	-----

	unlikely moderately likely likely <b>very likely</b>		medium <b>high</b>
--	---	--	-----------------------

Response: *C. sapidus* is already present in parts of the risk assessment area therefore the likelihood of introduction/entry is “very likely” by default (see guidelines). The spatial and temporal history of invasion indicates multiple introduction events at different locations (Mediterranean Sea, North Sea, Black Sea, Iberian Coast and the Bay of Biscay). A variety of pathways have been proposed, with existing evidence indicating that ship-mediated vectors (ballast and fouling) are the most likely means of introduction. Accidental escape and intentional release from the live food trade has also been suggested as a possible pathway and is considered still active, albeit less likely to contribute high propagule pressure. In a few cases such as of Buddhist ‘fangsheng’ animal releases may involve releases of large numbers of individuals at a time.

Introductions via rafting on floating debris, while possible, are not considered a likely event. Further introductions are very likely, given the high shipping traffic between the native area (east US coast) and EU ports and the ability of the species to survive during transport. Full implementation of the BWMC by 2024 is expected to greatly reduce the likelihood of introduction via ballast water.

Mediterranean, Iberian & Bay of Biscay, North Sea: it is already introduced and established very likely – high confidence.

Black Sea: already introduced and established. New introduction events likely with high confidence. Unaided introduction and establishment in the Sea of Marmara very likely.

Baltic Sea: unlikely – medium confidence.

Celtic Seas: likely - low confidence.

Greater North Sea: very likely – high confidence

**Qu. 1.10. Estimate the overall likelihood of introduction into the risk assessment area or entry into the environment based on all pathways in foreseeable climate change conditions?**

Thorough assessment of the risk of introduction in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of introduction (e.g. change in trade or user preferences)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely introduction within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: Future climate change conditions are not anticipated to significantly change the likelihood of introduction of *C. sapidus* through the above-mentioned pathways. Potential donor areas are not predicted to greatly expand/contract (see modelling results – global projected distribution – RCP2.6 and RCP4.5).

## 2 PROBABILITY OF ESTABLISHMENT

### Important instructions:

- For organisms which are already established in parts of the risk assessment area or have previously been eradicated, the likelihood of establishment should be scored as “very likely” by default.
- Discuss the risk also for those parts of the risk assessment area, where the species is not yet established.

### Qu. 2.1. How likely is it that the organism will be able to establish in the risk assessment area based on similarity of climatic and abiotic conditions in its distribution elsewhere in the world?

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The native range of *C. sapidus* in western Atlantic spans two continents, extending almost continuously from New England to Argentina (Millikin & Williams, 1984; Nehring, 2011), i.e., from 38.6S to 57.7N. Accordingly, the species experiences latitudinal variations in water temperature comprised between 0°C in winter at the extremes of its range and 32-33°C in transitional systems of the Caribbean area (Rodríguez, 2001; Johnson, 2015). In addition, populations in temperate areas generally experience comparable seasonal variations: in Chesapeake Bay, where one of the most abundant population in the USA is established, water temperatures range between 3 and 32°C (e.g., Shiah & Ducklow, 1994).

In its introduced range in the EU, *C. sapidus* is already established in the Mediterranean in Eastern Atlantic from Portugal to Belgium, and in the Black Sea (Bulgaria) under oceanographic and climatic conditions comprised within the abovementioned ranges (see Annex VIII). Similar climatic conditions characterize other quadrants of the RA area currently not colonized by the blue crab in the Black Sea region, and (to a lesser extent) the Celtic Seas region.

Winter temperatures appear to limit the native distribution of the species at high latitudes in both hemispheres, reflecting the thermal tolerance of the megalopa stage, as well the sensitivity of juveniles and mature females to water temperatures < 3°C (Rome et al., 2005; Hines et al., 2010). Thus, a northward expansion, as that observed in native ranges, should be expected also in European waters. Nevertheless, as with many other decapod species, the pelagic larval stages of *C. sapidus* have stricter abiotic requirements. Thus, in laboratory experiments *C. sapidus* larvae completed their development to the first zoeal stage at a minimum salinity of 20.1 psu (Costlow & Bookhout, 1959). This threshold is supported by field studies, where *C. sapidus* zoeae have been collected at salinities down to 20 psu in Chesapeake Bay (Sandifer, 1973) and the Mississippi Sound (Perry, 1975). Surface salinities in the Baltic Sea (beyond the western Baltic) and the Black Sea are lower than this threshold, most likely posing a limit for establishment in these marine regions. Temperatures suitable for spawning and larval development are reported as between 19-29°C (Hill et al., 1989). Additionally, hatching of fertilised eggs from a locally captured specimen was reported by Nehring & Meer (2010) in a German aquarium at 19°C, which is a normal ambient summer temperature for the German Wadden Sea. Such temperatures are unlikely to be encountered in most of the North Sea (east UK coast) and the Celtic

Seas, where establishment under current conditions seems unlikely and even under future climate change will probably remain localised.

However, temperature and salinity alone may not be the only limiting factors for the establishment of the species. A number of unsuccessful attempts of intentional introductions in Hawaii and California suggest that other factors such as the availability of brackish conditions during crucial stages of the biological cycle may play an important role for the establishment of *C. sapidus* populations. For further details and an extensive discussion on abiotic requirements and likelihood of establishment in the different EU marine regions see Annexes VIII and IX.

**Qu. 2.2. How widespread are habitats or species necessary for the survival, development and multiplication of the organism in the risk assessment area? Consider if the organism specifically requires another species to complete its life cycle.**

<b>RESPONSE</b>	very isolated isolated moderately widespread <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: *Callinectes sapidus* has a complex life cycle, encompassing a larval phase of 8 zoeal stages and a post-larval megalopa, followed by 16-20 juvenile instars, before molting to maturity, followed by mating and egg production (Hines, 2007). Accordingly, habitat use shifts markedly from brackish to open sea habitats as life stages disperse and migrate across the salinity gradient of the estuary or other transitional environments to offshore. Specifically, mating takes place in oligohaline and mesohaline regions of estuaries (Epifanio, 2003) where females produce a series of egg batches. They incubate them for 14-17 days, during which time they migrate to areas of higher salinity at the mouths of estuaries, where they release them (Tankersley et al., 1998). Larvae hatch and are advected onto the continental shelf. Post-larvae use tidal currents to re-enter brackish environments and then settle preferentially in seagrass beds (Forward et al., 2004), where they metamorphose and grow for approximately seven instars to 20 mm juveniles. Juveniles then disperse into lower salinity, shallow nursery habitats, where they grow to maturity and mate. Thus, transitional habitats such as estuaries and lagoons represent the primary habitats of *C. sapidus*; in addition, seagrass beds play a crucial role as nursery areas for the juvenile stages of the species. Transitional systems are widespread throughout the risk assessment area (see, for example, distribution maps of transitional systems and river mouths available at <https://www.eea.europa.eu/data-and-maps/data/wise-wfd-spatial-3>) and in the vast majority are associated with seagrass beds (see <https://data.unep-wcmc.org/datasets/7>).

**Qu. 2.3. How likely is it that establishment will occur despite competition from existing species in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: For the risk assessment area no information is available on competitive interactions with representatives of native benthic assemblages, even though possible negative effects due to competition or intra-guild predation have been suggested with other brachyurans (Gennaio et al., 2006; Mancinelli et al., 2013a; Kampouris et al., 2019). In invaded habitats, *C. sapidus* is likely to interact with a diverse group of brackish brachyurans including *Pachygrapsus marmoratus*, *Carcinus aestuarii*, and *C. maenas*. In native US habitats, where *C. maenas* is invasive, the blue crab is acknowledged to represent one of the factors controlling the southward expansion of the green crab (de Rivera et al., 2005). Thus, the blue crab may result, in particular once reached the adult stage, a competitor and even an intra-guild predator showing superior characteristics in terms of size and aggressiveness as compared with most if not all native brachyuran taxa, at least those residing in brackish habitats of the RA area. However, an important regulative role may be played by temperature: in outdoor mesocosm experiments, Rogers et al. (2018) indicated that at low temperatures, green crabs had a competitive advantage and intra-guild predation by blue crabs on green crabs was low. At high temperatures, size-matched blue and green crabs were competitively similar, while large blue crabs had a competitive advantage, and intra-guild predation on green crabs was high. Thus, depending on the specific oceanographic conditions within the RA area (e.g., Mediterranean Sea vs. Eastern Atlantic) the competitive interactions with *C. maenas* and the congeneric *C. aestuarii* in the Mediterranean basin may result in different impacts on the establishment of the blue crab.

**Qu. 2.4. How likely is it that establishment will occur despite predators, parasites or pathogens already present in the risk assessment area?**

<b>RESPONSE</b>	N/A very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: Several marine invertebrate and vertebrate predators of *C. sapidus* have been recorded in its native habitats, including conspecifics; in addition, juvenile blue crabs are included in the diet of predatory birds such as cranes and herons (Hines & Ruiz, 1995; Guillory & Elliot, 2001; Hines, 2007). However, there is no evidence that any of them exerts significant top-down controls on the abundance of blue crab populations (Seitz et al., 2003). Some of them occur also in the risk assessment area [e.g., turtles (*Lepidochelys kempii*), sharks (*Carcharhinus plumbeus*), bonyfish (e.g. *Lobotes surinamensis*, *Pomatomus saltatrix*, *Dicentrarchus labrax*), mammals (*Tursiops truncatus*)]. Their impacts on *C. sapidus* in invaded environments is still unexplored, and no information is available on whether they may exert a significant control on the species.

Parasites such as the dinoflagellate *Hematodinium perezii* have been demonstrated to represent a significant cause of mortality in blue crab populations under laboratory conditions (Shields & Overstreet, 2003; Huchin-Mian et al., 2018). With only two exceptions (Pagliara & Mancinelli, 2018; Czerniejewski et al., 2020) the pathogens associated with *C. sapidus* in the RA area have to date received no attention. Pagliara & Mancinelli, (2018) found that none of the [parasitized] crabs appeared lethargic, or showed clear signs of an on-going disease in terms of behavioral or exoskeleton anomalies. In

European invaded habitats, *H. perezii* has been detected in crustaceans from the North Sea (Small et al., 2006); thus, the possibility exists that *C. sapidus* may be infected also in invaded habitats in eastern Atlantic; however, it is unlikely that this may represent a factor limiting or reducing its establishment.

Another parasite that may represent a pathogenic risk for *C. sapidus* is the ciliate *Orchitophrya stellarum*, which was found to infect and cause high mortality to *C. sapidus* kept under laboratory conditions in Chesapeake Bay (Miller et al., 2013). *Orchitophrya stellarum* is native to the RA area but it requires a port of entry (i.e. a wound) to the crabs' body and has not been observed parasitizing wild populations, either in the species' native range (Messick & Shields, 2000; Miller et al., 2013), or in the invaded range, according to existing information. It is thus considered unlikely to prevent further establishment of *C. sapidus* in the RA area.

**Qu. 2.5. How likely is the organism to establish despite existing management practices in the risk assessment area? Explain if existing management practices could facilitate establishment.**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The organism is already established in Europe, thus existing management practices related to introduction pathways/vectors could not prevent the entry into the environment of sufficient propagules for establishment. Ballast Water Exchange and Treatment have the potential to reduce propagule pressure and, consequently, the rate of establishment due to primary introductions, these management practices however are not in full effect yet. Other management practices such as the removal of fouling species can reduce establishment potential. On the other hand, management of the natural environment (e.g. MPAs with no-take zones), is likely to limit early detection and removal by stakeholders, affording some protection to early populations.

**Qu. 2.6. How likely is it that biological properties of the organism would allow it to survive eradication campaigns in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: While eradication of marine species might be theoretically feasible if the species enters a new area and is rapidly identified when only a small number of individuals are present, in practice this does not apply to *C. sapidus*. The crabs preferentially prey during the night, when they show a high mobility. However, they can feed also during the day; in addition, during the day they do not hide, thus they can be detected and captured e.g., by hand nets. Despite the large size and easily recognizable morphology of the species, *C. sapidus* responds to low winter temperatures by burrowing in sediments, a life habit which severely hampers visual detection. If a blue crab population is already established,

complete removal would necessitate exhaustive field surveys, involvement of researchers, stakeholders (e.g., fishermen) as well as citizens, and the adoption of multiple collection strategies. However, given the high fecundity of females (see Qu. 2.7), it is very likely that even a considerable reduction in the number of pregnant females may not result in appreciable effects on the abundance of populations. Several examples from native as well as invaded habitats testify that significant negative variations in blue crab abundances but not eradication have been achieved only after prolonged overfishing (Mancinelli et al., 2017b).

**Qu. 2.7. How likely are the biological characteristics of the organism to facilitate its establishment in the risk assessment area?**

including the following elements:

- a list and description of the reproduction mechanisms of the species in relation to the environmental conditions in the risk assessment area
- an indication of the propagule pressure of the species (e.g. number of gametes, seeds, eggs or propagules, number of reproductive cycles per year) of each of those reproduction mechanisms in relation to the environmental conditions in the risk assessment area.
- If relevant, comment on the likelihood of establishment based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in establishment whereas for others high propagule pressure (many thousands of individuals) may not.
- If relevant, comment on the adaptability of the organism to facilitate its establishment and if low genetic diversity in the founder population would have an influence on establishment.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: *Callinectes sapidus* life cycle encompasses a planktonic larval phase of 8 zoeal stages and a post-larval megalopa, followed by 16-20 juvenile benthic instars, before molting to maturity, followed by mating and egg production (Jivoff et al., 2007; Hines, 2007). In native habitats, male and female crabs reach maturity in 1 to 2 years after 18-19 and 19-20 postlarval molts, respectively (Millikin & Williams, 1984). Depending on local temperature and salinity conditions, size at maturity varies considerably, with carapace widths (CW) ranging between 120 and 180 mm in males and 112 and 130 mm in females (Olm III & Bishop, 1983; Olsen et al., 2016). In invaded habitats, females are reported to reach maturity between 118 mm (Beymelek Lagoon, Turkey: Sumer et al., 2013) and 120 mm CW (Iskenderun Bay, Turkey: Türeli et al., 2018); ovigerous females captured in the Salento Peninsula (Puglia region, SE Italy) measured from 154 to 166 mm CW (Mancinelli et al., 2013a), while those captured in the English Channel had a CW between 172 and 178 mm (Pezy et al., 2019).

In native temperate habitats, the reproductive period of *C. sapidus* is seasonal (May-September) while in tropical regions reproduction occurs year-round although there can be seasonal peaks in activity (Millikin & Williams, 1984). A late spring-summer reproductive period is confirmed in invaded Italian, Greek, and Turkish habitats (Mancinelli et al., 2013a; Sumer et al., 2013; Kevrekidis & Antoniadou, 2018). Males can reproduce several times during the year, while females reproduce only once, while in the soft shell stage; in addition females are capable of storing sperm (Millikin & Williams, 1984). The reproductive output depends on the size/age of the females; clutch size generally varies between 1.7 and  $2 \times 10^6$  eggs per female, with a maximum of  $8 \times 10^6$  (Millikin & Williams, 1984; Jivoff et al., 2007). In

invaded habitats, fecundities between 0.8 and  $1 \times 10^6$  (Salento Peninsula, SE Italy: Mancinelli et al., 2013a) and between 0.7 and  $4.7 \times 10^6$  eggs per female have been reported (Turkey: Türeli et al., 2018). Zoeal stages can survive and complete development in 32-43 days under optimal temperature and salinity conditions (25°C and 30 PSU); under the same conditions, the megalopa gains competency and undergoes metamorphosis in 6 - 12 days (Millikin & Williams, 1984; Jivoff et al., 2007). Mortality from hatching to the megalopa stage under field conditions in native habitats has been estimated between -0.07 and -0.32 per day (McConaugha, 1992). Given the high propagule pressure and survival rate of larval stages, *C. sapidus* is characterized by high potential of establishment. The availability of habitats with appropriate characteristics of salinity and submerged vegetation is likely to regulate and reduce the actual establishment of populations in invaded habitats.

No information is to date available, either from native or invaded areas, as to whether low genetic diversity in a blue crab founder population may influence its establishment success.

**Qu. 2.8. If the organism does not establish, then how likely is it that casual populations will continue to occur?**

Consider, for example, a species which cannot reproduce in the risk assessment area, because of unsuitable climatic conditions or host plants, but is present because of recurring introduction, entry and release events. This may also apply for long-living organisms.

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: Adult *C. sapidus* can tolerate a wide range of abiotic conditions, both climatic- and habitat related, even though the availability of transitional environments with appropriate salinity gradients is a crucial prerequisite for the completion of the species' life cycle (Hines, 2007). However, survival at high latitudes in temperate zones is limited, as combinations of cold water temperatures (< 3°C) and low salinity (< 8 PSU) can cause markedly increased mortality, especially for small juveniles and mature females (Hines et al., 2010 and literature cited). Thus, if adult individuals are recurrently released in habitats unsuitable only for reproduction and larval survival, occasional populations will likely occur for some time periods, given also the life span of the species (up to 6 years: McMillen-Jackson & Bert, 2004 and literature cited). This is also testified by some intentional releases attempted in Hawaii and California: even though they were unsuccessful, they determined repeated records that were temporarily included in local lists of non-indigenous species.

**Qu. 2.9. Estimate the overall likelihood of establishment in the risk assessment area under current climatic conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under current climatic conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in current conditions: providing insight in the risk of establishment in (new areas in) the risk assessment area.

<b>RESPONSE</b>	very unlikely unlikely moderately likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

	likely <b>very likely</b>		
--	------------------------------	--	--

Response: *Callinectes sapidus* is already established in parts of the risk assessment area therefore the likelihood of establishment is “very likely” by default. Based on recent records (e.g., Ribeiro & Verissimo, 2014; Bañón et al., 2016; Morais et al., 2019; Pezy et al., 2019; Vasconcelos et al., 2019; Czerniejewski et al., 2020) and the occurrence of suitable environmental conditions and habitats, the establishment of *C. sapidus* is very likely but localised in the Greater North Sea (i.e. Normandy coast and southern North Sea) and in the Bay of Biscay and the Iberian Coast, primarily its southern parts. Furthermore, based on the increasing frequency of records in the Black Sea and the findings of gravid females in the past decade (Uzunova 2016; Stefanov 2021; Gül et al., 2021), establishment has already occurred in this region. Similarly, a burgeoning number of records published in the last decade indicates that a further increase in the establishment of blue crab populations in the whole Mediterranean Sea and in particular in the northwestern, southwestern (e.g., Balearic Sea) and central (e.g., Tyrrhenian Sea) sectors of the basin is very likely (e.g., Garcia et al., 2018; Suaria et al., 2017; Piras et al., 2019; Box et al., 2020).

**Qu. 2.10. Estimate the overall likelihood of establishment in the risk assessment area under foreseeable climate change conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under foreseeable climate change conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of establishment (e.g. increase in average winter temperature, increase in drought periods)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely establishment within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Based on the temperature limits of the species distribution (see Qu. 2.1), and given the ongoing oceanographic variations in north Atlantic Ocean (Smeed et al., 2018), climate warming is expected to favour the spread of *C. sapidus* towards northern European waters. The spread is also expected to occur since the blue crab demography (in terms of length of the seasons for reproduction, settlement, and growth, growth rates, maturation/generation times, reproductive output) is markedly

affected by the seasonal cycle of temperature (Hines et al., 2010). In this context, for native areas Johnson (2015) highlighted in the last decades a northward expansion of *C. sapidus* to the Gulf of Maine and Nova Scotia, 500 km north of its historic range. Conversely, there are no published predictions for invaded European habitats besides the output of the modelling efforts presented in Annex VIII, clearly showing an increase in suitability of northern European waters under both RCP2.6 and RCP4.5 (fig. 9). However, as already mentioned (Qu. 2.1), temperature alone may result an inadequate predictor of the blue crab future distribution. The articulated - and to date hard to be delineated - effects of climate change on i) sea level, and in turn on the extent and biological characteristics (e.g., seagrass beds) of transitional environments crucial for the completion of early life stages ii) salinity ranges in these environments, as affected by changes in continental freshwater discharges iii) stratification and related effects on the occurrence and extent of hypoxic zones are to be necessarily taken into consideration (Elliott et al., 2019).

### 3 PROBABILITY OF SPREAD

**Important instructions:**

- Spread is defined as the expansion of the geographical distribution of an alien species within the risk assessment area.
- Repeated releases at separate locations do not represent continuous spread and should be considered in the probability of introduction and entry section (Qu. 1.7).

**Qu. 3.1. How important is the expected spread of this organism within the risk assessment area by natural means? (List and comment on each of the mechanisms for natural spread.)**

including the following elements:

- a list and description of the natural spread mechanisms of the species in relation to the environmental conditions in the risk assessment area.
- an indication of the rate of spread discussed in relation to the species biology and the environmental conditions in the risk assessment area.

The description of spread patterns here refers to the CBD pathway category “Unaided (Natural Spread)”. It should include elements of the species life history and behavioural traits able to explain its ability to spread, including: reproduction or growth strategy, dispersal capacity, longevity, dietary requirements, environmental and climatic requirements, specialist or generalist characteristics.

<b>RESPONSE</b>	minimal	<b>CONFIDENCE</b>	low
	minor		<b>medium</b>
	moderate		high
	<b>major</b>		
	massive		

Natural dispersal across borders from neighbouring countries, where the species has been established (for example Spain, France, Belgium) by planktotrophic larvae dispersed with oceanic currents, as well as by swimming adults. Considering the high fecundity, the long pelagic life of its larvae and the swimming ability of *C. sapidus*, which can travel from 10s to 100s of kilometers according to tagging experiments (e.g. west coast of Florida - Guillory et al., 2001 and references therein), the potential for natural dispersal is very high, particularly in the Mediterranean, the Black Sea and the south/south-western Iberian peninsula (Vasconcelos et al., 2019), where climatic conditions are more favourable for longer periods. Nevertheless, it is expected that natural dispersal will likely be much more limited along the Atlantic coast of W. Europe due to the lower temperatures prevailing there. For example, a new study currently in review indicates that despite the multiple records along the west and north of the Iberian Peninsula the species does not seem to have achieved wide-spread establishment yet and doubts the possibility of migrant individuals (Izquierdo Gomez, 2021). On the other hand, in the English Channel, two ovigerous females were captured in offshore locations, off the Normandy coast at depths of 10 and 12m (Pezy et al., 2019). Thus, under future climate conditions, considerable natural dispersal cannot be discarded even for western European locations, as indicated by the isotherm maps in Annex VIII.

**Qu. 3.2a. List and describe relevant pathways of spread other than "unaided". For each pathway answer questions 4.3 to 4.9 (copy and paste additional rows at the end of this section**

**as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 4.3a, 4.4a, etc. and then 4.3b, 4.4b etc. for the next pathway.**

including the following elements:

- a list and description of pathways of spread with an indication of their importance and associated risks (e.g. the likelihood of spread in the risk assessment area, based on these pathways; likelihood of survival, or reproduction, or increase during transport and storage; ability and likelihood of transfer from the pathway to a suitable habitat or host) in relation to the environmental conditions in the risk assessment area.
- an indication of the rate of spread for each pathway discussed in relation to the species biology and the environmental conditions in the risk assessment area.
- All relevant pathways of spread (except “Unaided (Natural Spread)”, which is assessed in Qu. 4.1) should be considered. The classification of pathways developed by the Convention of Biological Diversity shall be used (see Annex IV).

#### **A. TRANSPORT - STOWAWAY – ship/boat ballast water**

Dispersal of larvae by ballast tanks of ships is likely with medium confidence level (see Qu. 3.4a, 3.5a). Ballast water release is suspected as introduction and spread vector because blue crabs were predominantly found in port regions where ballast water discharges do frequently occur (Galil, 2006). Due to the sheer volume of ballast water in global shipping and the large amount of *C. sapidus* larvae potentially taken up, the rate of spread via this pathway is likely to be rapid (Qu. 3.9a)

#### **B. TRANSPORT - STOWAWAY -ship/boat hull fouling**

This is considered as one of the two most likely pathways of spread and is almost certainly responsible for records, within the confines of a small marinas where only yachts and small fishing craft are berthed (Bodrum (Turkey), Porto Grande (Malta) (Ulman et al., 2017). Even though the number of propagules per vessel is not expected to be high, the amount of maritime traffic between the harbours and marinas of the RA area is such that a moderate rate of spread, at least, may be expected through this pathway (Qu 3.4b, 3.5b, 3.9b).

**C. ESCAPEE FROM CONFINEMENT-** Pet / aquarium / terrarium species (including live food for such species). The species could be accidentally released from holding tanks because live blue crabs have been imported in many European countries for human consumption. Blue crab does appear to be available to buy live in the UK (see <https://readingqualityfish.co.uk/lobster-crabs/>) and other EU countries (e.g. Portugal, see Ribeiro & Verissimo (2014)), meaning that there may be the potential for intentional or accidental release once purchased or if unsold., particularly with reference to religious or other ‘ethical’ releases. (see Qu 3.4c, 3.5c)

#### **D. RELEASE IN NATURE- Fishery in the wild**

Intentional introduction by **commercial enterprises** is likely but with a low confidence level. Aquaculture transfers has been attempted in California (Cohen & Carlton, 1995), and Hawai (Eldredge, 1994) which however were not successful. According to Nehring et al. (2008) unconfirmed records in Turkey dating back to 1930’s are attributed to intentional introduction. This could explain the documented chronological distribution pattern (Aegean since 1947), Adriatic since 1949 (separate introduction event) but also the population establishment success (establishment first in the Aegean). In fact, deliberate introductions for harvesting purposes are increasingly hypothesised, as the species continues spreading in the western Mediterranean and gains commercial importance, e.g. the possibility was raised by Fuentes et

al. (2019) and by Box et al. (2020) for two different Spanish locations, but such hypotheses are very difficult to verify (see also Qu 3.4d, 3,9d).

**E. TRANSPORT-STOWAWAY (other: Floating debris)**

Although it seems unlikely, transport in marine litter is a potential pathway for transfers of *C. sapidus*. It is possible that individual crabs can cling to floating objects and drift with currents within the RA area. (see Qu. 3.4e, 3.5e). Due to the stochastic nature of these events and the patchy distribution of potentially suitable recipient habitats, spread via this pathway is likely to proceed at a slow rate.

**F. TRANSPORT-CONTAMINANT**

Shellfish, such as oysters, mussels, scallops, cockles and clams are grown in open systems and *Callinectes sapidus* that feed on them could be transported between sites throughout the RAA. However, the risk of importation of contaminated bivalve is low since a) transportations are now carefully regulated to minimize introduction to member states via movements of shellfish between sites; and b) only big animals feed on these species (Prado et al., 2020) and they could not go unnoticed during inspection. Therefore this pathway is not analysed further.

**A. TRANSPORT -STOWAWAY – ship/boat ballast water**

**Qu. 3.3a. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional	<b>CONFIDENCE</b>	low
	<b>unintentional</b>		medium
			<b>high</b>

Regional vessel movements are more likely than those from outside the RAA to pass over suitable habitat where any larvae released in transit may be able to survive. Particularly small vessels which may take routes close to the coast and shelter in estuaries or bays overnight or in bad weather.

**Qu. 3.4a. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
	unlikely		<b>medium</b>

	moderately likely <b>likely</b> very likely		high
--	---	--	------

Response: For reproductive output and ship ballast volume and potential larval concentration, see Qu. 1.3a. With respect to spread of the organism within the EU, transshipment operations constitute the main maritime traffic that will act as the vector for spread. Important transshipment hubs are situated along the southern Mediterranean (serving the rest of the Mediterranean and the Black Sea) and the Le Havre-Hamburg range, serving the UK, the Baltic and Scandinavia (Notteboom & de Langen, 2015). Moreover, recreational boats operating across European ports may transfer *C. sapidus* from one regional sea to another, from a country to another. Noteworthy are also larger passenger/ car ferries which operate in most regions and use ballast water tanks – currently often unchecked, untreated and unregulated with member states permitted under ballast water convention to allow exemptions to apparently low risk inter-regional shipping routes. Considering *C. sapidus* larvae are favoured by water temperatures encountered throughout the Mediterranean and the south Iberian Peninsula, it is considered likely that sufficient numbers can be transferred with ballast water along this pathway, although direct evidence of this is lacking. Nevertheless, mature specimens of *C. sapidus* have been found in ballast sediment of a vessel from Baltimore sampled in Bremerhaven in 1993 and also from a vessel from the east coast of north America sampled in Rotterdam (Gollasch et al., 2002 and Gollasch pers. comm) and Brachyuran larvae are found frequently in ballast water (e.g. Cohen & Carlton, 1997; Gollasch, 2002),

**Qu. 3.5a. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: See Qu. 1.4a. If larvae can survive trans-oceanic trips, they are likely to survive transfer within EU marine areas which are shorter trips.

**Qu. 3.6a. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: As in Qu.1.5a. Worth noting is that some of the regulations and requirements under the Ballast Water Convention may be relaxed for shorter, low-risk shipping routes under regional exemption options.

**Qu. 3.7a. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: As in Qu. 1.6a

**Qu. 3.8a. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: If ballast water exchange occurs in open seas rather than in coastal areas, transfer of planktonic larvae to suitable substrate will be hampered. If, however, untreated ballast water is released in ports, estuaries or other coastal areas, then establishment will be dependent on availability of suitable habitat. Considering (a) the breadth of habitat that characterizes the species; (b) the wide distribution of such habitats in the RA; and (c) the documented records inside/near harbours (e.g. Bouvier, 1901; Tortonese, 1965; Cabal et al., 2006; Nehring, 2011), there is a high likelihood that *C. sapidus* can transfer to a suitable habitat after release with ballast water.

**Qu. 3.9a. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area. (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly slowly moderately <b>rapidly</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

	very rapidly		
--	--------------	--	--

Response: The overall potential rate is the product of the interaction of several factors, such as the intensity of shipping transport, the frequency of ballast water discharge, the origin of ships - together with many other biotic and abiotic factors related with the conditions of ballast waters as well as those characterizing the location where ballast waters are discharged. Based on the existing populations, their distribution and the intensity of maritime traffic within the RA area, *Callinectes sapidus* has the potential to spread rapidly via ballast water transfers, particularly in the Mediterranean Sea, the Iberian coast/Bay of Biscay and to a lesser extent the Greater North Sea.

### B. TRANSPORT-STOWAWAY (ship/boat hull fouling)

**Qu. 3.3b. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional	<b>CONFIDENCE</b>	low
	<b>unintentional</b>		medium <b>high</b>

Regional vessel movements are more likely than those from outside the RAA to pass over suitable habitat where any larger individuals detached in transit may be able to survive. Particularly small vessels which may take routes close to the coast and shelter in estuaries or bays overnight or in bad weather.

**Qu. 3.4b. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
	unlikely		<b>medium</b>
	moderately likely		high
	<b>likely</b>		
	very likely		

Response: Although not reported from a ship hull its presence in marinas (Ulman et al., 2017) gives credit to this vector of introduction. For the reproductive biology of the species please see Qu 2.7. Considering the biological characteristics of the organism (withstand wide temperature range and

salinity range), it is considered possible that *C. sapidus* can settle as a competent larva or a juvenile and maintain a viable population within the fouling communities on ships hulls and especially niche areas, sufficient for a new introduction.

In addition to merchant vessels travelling all year round, with thousands of trips per year between the ports of the RA area (Seebens et al., 2013), recreational boats (mostly cruise boats) can also transport the species on their hulls and niche areas. The world cruise tourism represented as Equivalent Fulltime Navigation Vessel (EFNV) index, allocated hot spots of activity of the world cruise fleet. According to EFNV, in 2015 the Mediterranean Sea was the second visited areas (EFNV=36.71) after the North Atlantic (EFNV=45.53), while the Norwegian Sea (11.76) and North Sea (6.47) played an important role (Vicente-Cera et al., 2020).

**Qu. 3.5b. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: As in Qu 1.4.b. The likelihood of survival is higher due to shorter distances and reduced likelihood of passing through unfavourable conditions

**Qu. 3.6b. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Consider answer in 1.5b, but also consider that management practices are likely to be reduced for 'local' travel with potential stepping stone effects resulting from short, unregulated and unmonitored journeys.

**Qu. 3.7b. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely	<b>CONFIDENCE</b>	Low <b>Medium</b>
-----------------	---------------------------	-------------------	----------------------

	moderately likely <b>likely</b> very likely		high
--	---	--	------

Response: Shorter journey may mean smaller size on arrival and increased number of surviving young and even less likelihood of detection than 1.6b

**Qu. 3.8b. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: Early benthic life stages of *C. sapidus* can be detached and inhabit soft and hard bottom communities or seagrass/eelgrass beds in the recipient area. Considering (a) the breadth of habitat that characterizes the species; (b) the wide distribution of such habitats in the RA; and (c) the documented records inside/near harbours (e.g. Bouvier, 1901; Tortonese, 1965; Cabal et al., 2006; Nehring, 2011), there is a high likelihood that *C. sapidus* can transfer to a suitable habitat.

**Qu. 3.9b. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: Hull fouling is a plausible, albeit not documented, mechanism of spread of *C. sapidus* in the RA area. It can be mediated by large merchant vessels, passenger ships, recreational and fishing boats as well as other small vessels. Even though the number of propagules per vessel is not expected to be high, the amount of maritime traffic between the harbours and marinas of the RA area is such that a moderate rate of spread, at least, may be expected through this pathway.

**C. ESCAPEE FROM CONFINEMENT- Pet / aquarium / terrarium species (including live food for such species)**

**Qu. 3.3c. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	<b>intentional and unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--------------------------------------	-------------------	------------------------------

Response: The import of species to be kept as live food is an intentional pathway. Its escape in the marine environment however is unintentional. On the other hand, its release such as ethical release or disposal of leftover stock is deliberate.

The economic interest in *C. sapidus* has progressively increased in Mediterranean countries in the last decade. *Callinectes sapidus* captured in Greek waters is exported to Italy at least since 2016 (Mancinelli, personal observation); no information is available on traded quantities. According with Sea-Ex Trade Seafood Directory (<http://www.trade-seafood.com/>) live *C. sapidus* is actually exported from Turkey by North Aegean Seafood Ltd ([www.northaegeanseafood.com](http://www.northaegeanseafood.com)) and from Greece by Blue Crab P.C. (<http://www.bluecrab.gr/>), Mediterranean Crabs (<http://www.mediterraneancrabs.com>), and Dimoudis Bros. S.A. (<http://www.dimoudis.gr>). No information is available on exports from Italy or Spain.

Crabs that are not being sold/consumed locally end up discarded in the environment (an incident has been recently documented in Lake Kastoria, North-West Greece, <https://www.facebook.com/eppkast/posts/2840062492781951>). In addition, trading of live specimens may also be related with unintentional release episodes: recently, one of the authors (GM) witnessed an incident of accidental drop-off from a pallet of several 10-Kg packs containing live *C. sapidus* into the sea at the port of Brindisi (SE Italy), while being unloaded from a merchant ship. Blue crabs originated from Greece and were transferred to refrigerated trucks for delivery to local distributors for the live seafood market.

**Qu. 3.4c. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely	<b>CONFIDENCE</b>	<b>Low</b> medium high
-----------------	---	-------------------	------------------------------

	very likely		
--	-------------	--	--

Response: It depends on the accidental or deliberate events. *Callinectes sapidus* is traded alive for alimentary purposes; accordingly, in principle even though exported in relatively high quantities, it should be expected that all specimens are killed soon after the arrival in the recipient country and not released alive.

Even though blue crabs of both sexes are traded, females carrying egg sponges are generally discarded. Accordingly, direct propagules release is a remote possibility. On the other hand, if specimens of both sexes survive after accidental release until mating, even at low abundances it is likely that this may set the basis for the establishment of a population, also given the high fecundity of female blue crabs (see section establishment).

**Qu. 3.5c. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
	<b>unlikely</b>		<b>medium</b>
	moderately likely		high
	likely		
	very likely		

Response: As mentioned in Qu. 1.3d, live *C. sapidus* are traded at low temperatures. Under natural conditions, the species can survive to temperature close to 0°C entering a state of quiescence (Millikin & Williams, 1984) even though for prolonged periods this can cause an increase in populations' mortality (Hines, 2007). Thus, survival during transport is likely, given that the duration of the journey is limited to 24-48 h (Mancinelli, personal observation). Obviously, longer transport times would imply that the species is traded frozen.

No reproduction is possible for blue crabs traded alive.

**Qu. 3.6c. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
	unlikely		<b>medium</b>
	<b>moderately likely</b>		high
	likely		
	very likely		

Response: There are currently Regulations (e.g. Regulation (EU) 2017/625, Commission Delegated Regulation (EU) 2019/625) and guidelines concerning live food trade (see [https://ec.europa.eu/food/safety/international\\_affairs/trade/import\\_animal\\_en](https://ec.europa.eu/food/safety/international_affairs/trade/import_animal_en)), but are oriented towards

the protection of human health and not transport or translocation of species. If *C. sapidus* is frozen before being packed for transport, the procedure determines the death of the specimens, thus survival rates equal 0.

Existing laws in member states prohibiting the release of non-native species have been used to prosecute those undertaking large-scale, intentional releases of non-native crabs and lobster for religious reasons (see previous article link). However, these are not preventative and there is great scope for avoidance of prosecution and illegal but un-regulated actions. The incident noted in the previous section by the authors illustrates also that management practices are insufficient to prevent release during transit.

**Qu. 3.7c. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Only large sized animals are traded and they are likely to easily detected if looked for. However, if large numbers are released in estuarine areas not regularly surveyed nor frequented by divers etc and where soft sediment is available in which crabs could hide, then they can be undetected. *C. sapidus* is easy recognisable and trading companies as well as fishermen in most parts of the world and consumers are aware of its specific characteristics (see Qu. 1.2d). Thus, the possibility that it can be misidentified and imported into the risk assessment area is unlikely.

**Qu. 3.8c. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Accidental release may occur during e.g., landing operations (as described in Qu. 3.3c) thus there is a moderately likely possibility of release through this pathway. For example, one of the authors (GM) witnessed an incident of accidental drop-off from a pallet of several 10-Kg packs containing live *C. sapidus* into the sea at the port of Brindisi (SE Italy), while being unloaded from a merchant ship. Blue crabs originated from Greece and were transferred to refrigerated trucks for delivery to local distributors for the live sea-food market.

As live blue crabs are transported at low temperatures in mesh bags or similar containers, once in seawater at ambient temperature specimens may become active, tear the mesh and spread in the

environment. It is also possible that unwanted or leftover specimens from the live food trade are disposed of inappropriately in the environment, e.g. thrown overboard from vessels (Nehring et al., 2008). This is most likely to take place in shallow coastal waters e.g. ports often sheltered in estuarine sites where habitat is most suitable.

**Qu. 3.9c. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area. (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: Given the increasing commercial interest in *C. sapidus*, it is moderately likely that the trade of the species, especially if not regulated, will progressively increase in the next few years. This will determine an increase of exporting countries offering the blue crab as a shellfish product, as well as in the traded volumes, and in the points of introduction. This will in turn increase the probability that the species is introduced in the risk assessment area by this pathway.

#### **D. RELEASE IN NATURE- Fishery in the wild**

**Qu. 3.3d. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	<b>intentional</b> unintentional	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response: Considering the high commercial value of the species, it has been postulated that intentional introductions aiming to create a population for fisheries purposes were/are a possibility (Nehring, 2011). These hypotheses mainly referred to the early presence of the species in the Aegean Sea, which according to some authors, is suspected since as early as 1935 (Enzenroß et al., 1997). This narrative could not be verified but similar incidents remain a possibility.

**Qu. 3.4d. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely moderately <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: Since this is only speculation, no actual information was found for introductions in the RA area. The disjunct distribution of the species in areas where it is already commercially exploited could point to intentional releases for harvesting purposes. For example, an intentional human introduction is suspected in inland waters of Catalonia, in a waterbody without fluvial connectivity with the sea (Fuentes et al., 2019), however it is unclear if this incident is associated with an intent to start a breeding population. In fact, deliberate introductions for harvesting are increasingly speculated on, as the species continues spreading in the western Mediterranean and gains commercial importance, e.g. the possibility was raised by Box et al. (2020) following the appearance of *C. sapidus* in Ibiza and Formentera, Balearic Islands, however this is very difficult to verify. A hypothesis about the frequency of such events cannot be made but if/when such incidents occur, they will definitely involve a large number of individuals at various lifestages, including gravid females to be released over a long period of time to ensure a viable population. Overall though this is unlikely to be done legally due to restrictions on the introduction, in reality, any 'black market' introductions would be very unpredictable.

**Qu. 3.5d. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: It is assumed that if organisms are transported for the sole purpose of starting a population for fishery purposes, then it will be ensured that they are kept alive.

**Qu. 3.6d. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The management practice most relevant in this case is Council Regulation (EC) No 708/2007 concerning use of alien and locally absent species in aquaculture. According to the regulation, all aquaculture operators who intend to introduce an alien species or translocate a locally absent species must first apply for a permit from the competent authority of the Member State where the transfer will take place. The Regulation specifies the information to be provided by the applicant and the type of assessment that the competent authority must perform before granting the permit.

*Callinectes sapidus* is not included in the list of Annex IV of Council Regulation 708/2007 which defines the species that are exempted and can be moved without any risk assessment or quarantine; as such, it would have to be risk assessed if transferred between Member States but it is still likely that it could be transported after a positive decision regarding its commercial harvesting. However, the regulation does not apply to movements of locally absent species within the Member States “except for cases where, on the basis of scientific advice, there are grounds for foreseeing environmental threats due to the translocation, Art. 2 para. 2.“, which means that the species could easily spread within Member States without any additional procedures/restrictions.

**Qu. 3.7d. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	<b>very unlikely</b> unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: *Callinectes sapidus* is easy recognisable and trading companies as well as fishermen and consumers in most parts of the world are aware of its specific characteristics. Thus, the possibility that it can be misidentified and transferred within the risk assessment area undetected is very unlikely, especially the large, mature individuals that would be transferred intentionally in order to establish a new fishery in the wild.

**Qu. 3.8d. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

	likely <b>very likely</b>		
--	------------------------------	--	--

Response: In the case of an intentional release for harvesting purposes, it is expected that the species will be transferred to a suitable habitat.

**Qu. 3.9d. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area. (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: Not enough concrete information is available to assess the rate of spread via this pathway with any confidence. However, the increasing number of new locations for *C. sapidus* in the risk assessment area and neighbouring countries may be partly attributed to intentional releases for harvesting, especially considering the increasing commercial exploitation of the already established populations. A moderately rapid rate of spread is possible.

#### **E. TRANSPORT-STOWAWAY (other: Floating debris)**

**Qu. 3.3e. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

**Qu. 3.4e. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Marine litter and floating debris have been considered a potential transport vector of non-indigenous species. In coastal waters the identification of sources, trajectories and deposition sites of marine litter is often hampered by the complex oceanography of shallow shelf seas. Oceanographic modelling revealed that the distribution of floating litter in the North Sea is largely determined by the site of origin of floating objects whereas the trajectories are strongly influenced by wind drag. (Gutow et al., 2018). In the Mediterranean, transport of fouling as rafting material has been demonstrated in the Tyrrhenian and Ligurian Seas (Aliani & Molcard, 2003). In a recent study of fouling organisms on litter discharge in the Gulf of Naples, it was found that Arthropoda colonized 7-10% of the total colonized items. They were mostly found on cotton ( $13.33 \pm 13.33\%$ ) and on plastic ( $8.32 \pm 4.22\%$ ), litter (Crocetta et al., 2020). In a study developed in Tjärnö (Sweden), at the entry of the Baltic Sea, the communities inhabiting coastal litter and natural substrates were monitored from eight sites. The results showed that more diverse communities were found on litter. In fact, 10 Arthropoda species were identified fouling on litter vs 2 species fouling on natural substrata. Non-indigenous species were attached mainly to non-plastic artificial materials (Garcia-Vazquez et al., 2018). Although relevant information was not found in the literature specifically for *C. sapidus*, larvae, megalopae and juveniles of Portunidae, including *Callinectes* spp., have been repeatedly reported rafting on floating algae in the northeast Atlantic region, as well as the east Pacific (Thiel & Gutow, 2005 and references therein). Furthermore, its documented history of attacking fishing nets makes it also a likely candidate to be transported by drifting fishing gear, particularly at the adult stage.

From these results it can be concluded that marine litter can significantly alter the biotic composition of coastal ecosystem, representing a shelter for invasive species and diverse natives.

**Qu. 3.5e. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Species that are considered likely to be transported with hull fouling over long trans-oceanic voyages can, very likely, survive on floating debris as well. Probability of survival will depend on the fouling community and the travelling time at sea. As an example, Aliani & Molcard (2003) developed a numerical model showing that 45% of floating objects could reach the Ligurian coast from Corsica

(about 75 km) in 50 days. Gutow et al. (2018) estimated the average residence time of floating items in the German Bight that was largely independent of the wind drag coefficient to vary between 16 and 23 days. In contrast, in both the Skagerrak and the wider North Sea the average residence time of floating items declined continuously with increasing wind drag factor from about 33 to 2 days and from 79 to 48 days, respectively. According to CIESM (2014) more than 80% of alien species in the Mediterranean might have arrived on floating debris or used this vector for further dispersal.

**Qu. 3.6e. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: There are no relevant management practices for marine debris in EU regional seas. EU is trying to tackle marine litter issues through the descriptor D-10 of Marine Strategy Framework Directive. The need to comply with MSFD regulations may require member states to begin managing litter more effectively through removal, trapping and avoiding incidents of lost gear and equipment to keep the D-10 indicator down, which might in turn reduce likelihood of surviving.

**Qu. 3.7e. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Considering that floating debris and marine litter are not regularly examined for fouling biota it may go undetected. However, since it is an easily recognized animal when mature it is relatively easy to detect it, if present. Post settlement and younger individuals may be less detectable. Short journey time may mean less growth and smaller size at arrival which may decrease likelihood of detection more than transAtlantic drift.

**Qu. 3.8e. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	<b>low</b>
-----------------	---------------	-------------------	------------

	unlikely <b>moderately likely</b> likely very likely		medium <b>high</b>
--	---	--	-----------------------

Response: Marine litter is often washed up in areas with low flow and lagoons and estuaries can funnel debris, particularly travelling in coastal currents. Considering the disjunct distribution of suitable habitats with the necessary conditions for the species to complete its life cycle (i.e. estuaries, lagoons), it is considered moderately likely that it will find its way, via stranded floating debris, to these habitats.

**Qu. 3.9e. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area. (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly <b>slowly</b> moderately rapidly very rapidly	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: The trajectory and the destination of a floating object strongly depend on its buoyancy and persistence at the sea surface (Thiel & Gutow, 2005). Loss of buoyancy and sinking of floating litter can be accelerated by biofouling when colonizing organisms enhance the specific gravity of an object (Ye & Andrady, 1991) especially in objects with a high surface:volume ratio (Chubarenko et al., 2016).

It is certainly possible for *C. sapidus* to spread throughout the regional seas hitchhiking on natural and man-made floating objects, with drifting fishing gear being a very likely candidate as its substrate. On the other hand, arrival at a suitable habitat is considered a less likely event due to the patchy distribution of lagoons and estuaries.

Key factors that would cause rate of spread to be very slow is the irregular and stochastic nature of the environmental conditions and events that would be needed for spread by this pathway to be successful. It is thus concluded that spread via this pathway will proceed at a slow rate. Paucity of information on the volume, frequency of occurrence and circulation patterns of floating debris in EU regional seas decreases the confidence level of the assessment.

**Qu. 3.10. Within the risk assessment area, how difficult would it be to contain the organism in relation to these pathways of spread?**

<b>RESPONSE</b>	very easy easy with some difficulty difficult	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

	<b>very difficult</b>		
--	-----------------------	--	--

Response: Naturally dispersing organisms are very difficult to contain, especially species such as *C. sapidus*, with high fecundity, long pelagic larval duration and a strong swimming ability ((Millikin & Williams, 1984), which enhances their dispersal potential (See Qu. 2.7 for the biological characteristics of the species). In the case of *C. sapidus* in particular, the increasing commercial value of the already established populations adds to the potential for spread through intentional releases.

**Qu. 3.11. Estimate the overall potential rate of spread in relevant biogeographical regions under current conditions for this organism in the risk assessment area (indicate any key issues and provide quantitative data where possible).**

Thorough assessment of the risk of spread in relevant biogeographical regions in current conditions, providing insight in the risk of spread into (new areas in) the risk assessment area.

<b>RESPONSE</b>	very slowly slowly moderately <b>rapidly</b> very rapidly	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: The increasing rate of appearance of new records, especially in the Mediterranean Sea, indicates a rapid rate of spread (see figure 3), which is most likely attributable to natural dispersal, although the contribution of other pathways of spread cannot be overlooked. In the Black Sea, human-assisted mechanisms of spread, particularly through shipping vectors and/or the live food trade and intentional releases for commercial exploitation are likely to maintain a moderately rapid rate of spread. In the Greater North Sea, due to the limited availability of suitable climatic conditions, anthropogenic pathways of spread are expected to be primarily responsible for the spreading of the species. Due to the high shipping traffic volume and the precedence of live food trade escape, a rapid rate of spread may be expected.

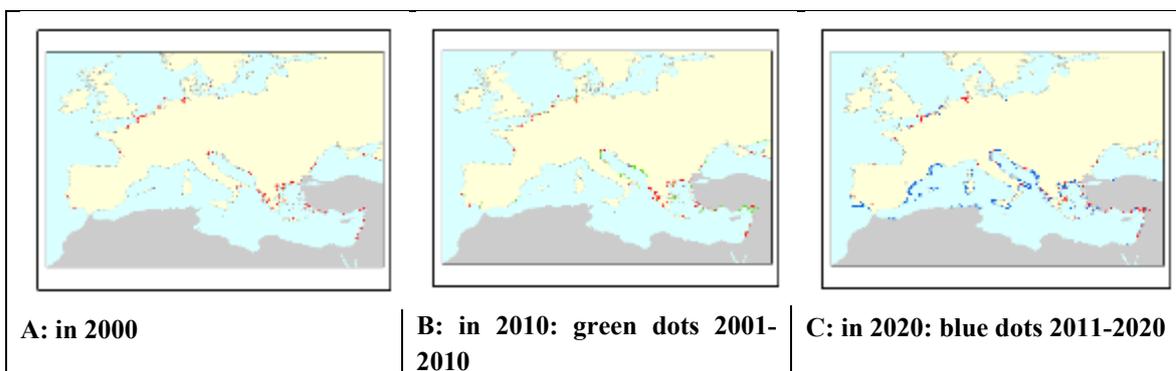

Figure 3. Distribution of *Callinectes sapidus* in the European Seas. (source Mancinelli et al. 2021)

Mediterranean Sea: rapidly, high confidence, all pathways involved

Bay of Biscay and the Iberian coast: rapidly, medium confidence, all pathways involved

Greater North Sea: rapidly, mostly due to shipping traffic and live food trade.

Black Sea: moderately rapidly, potentially due to intentional transfers for harvest, very rapidly in the Sea of Marmara due to unaided spreading

Celtic Seas: slowly, all pathways involved

Baltic Sea: slowly, all pathways involved

**Qu. 3.12. Estimate the overall potential rate of spread in relevant biogeographical regions in foreseeable climate change conditions (provide quantitative data where possible).**

Thorough assessment of the risk of spread in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk, specifically if rates of spread are likely slowed down or accelerated.

RESPONSE		CONFIDENCE	
	very slowly		low
	slowly		<b>medium</b>
	moderately		high
	<b>rapidly</b>		
	very rapidly		

Response: The overall potential rate of spread is expected to remain rapid but this will likely apply to an even more extensive part of the RA area, which will, under future climate change, present the species with favourable conditions for larval development and dispersal. This is especially true for the western Iberian coast and the Bay of Biscay, as well as the southern North Sea coasts, which now present a marginal environment for *C. sapidus* but will offer more suitable conditions in a future warming scenario. This will further enhance the availability of propagules in these areas, and their subsequent uptake and spread through shipping vectors in particular. In the Celtic Sea, there will be some more possibilities for spread, due to natural dispersal, but these will still be limited by the low summer temperatures.

#### 4. MAGNITUDE OF IMPACT

Important instructions:

- Questions 4.1-4.5 relate to biodiversity and ecosystem impacts, 4.6-4.8 to impacts on ecosystem services, 4.9-4.13 to economic impact, 4.14-4.15 to social and human health impact, and 5.16-5.18 to other impacts. These impacts can be interlinked, for example, a disease may cause impacts on biodiversity and/or ecosystem functioning that leads to impacts on ecosystem services and finally economic impacts. In such cases the assessor should try to note the different impacts where most appropriate, cross-referencing between questions when needed.
- Each set of questions starts with the impact elsewhere in the world, then considers impacts in the risk assessment area (=EU excluding outermost regions) separating known impacts to date (i.e. past and current impacts) from potential future impacts (including foreseeable climate change).
- Only negative impacts are considered in this section (socio-economic benefits are considered in Qu. A.7)
- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”.

#### Biodiversity and ecosystem impacts

**Qu. 4.1. How important is the impact of the organism on biodiversity at all levels of organisation caused by the organism in its non-native range excluding the risk assessment area?**

including the following elements:

- Biodiversity means the variability among living organisms from all sources, including terrestrial, marine and other aquatic ecosystems and the ecological complexes of which they are part; this includes diversity within species, between species and of ecosystems
- impacted chemical, physical or structural characteristics and functioning of ecosystems

RESPONSE	minimal minor <b>moderate</b> major massive	CONFIDENCE	<b>low</b> medium high
----------	---	------------	------------------------------

Response: There are no reported impacts on local biodiversity caused by the species in areas of its non-native distribution areas outside the Mediterranean (excluding the risk assessment area) such as Japan.

In the Mediterranean, there are some alleged implications that *C. sapidus* is involved in changes in the ecosystem and biological balance in Bardawil lagoon (Egypt), as the increasing abundance of the crab in conjunction with variations in the ecological conditions prevailing in the lagoon, have negatively affected native invertebrate and fish stocks (Mehanna et al., 2019). In particular, annual catches of benthic invertebrate (e.g., the shrimp *Metapenaeus stebbingi*) and fish species (soles of the genus *Solea*) have remarkably declined in the decade 2008-2018 (Mehanna et al., 2020); these evidences are consistent with the diet of the species as observed in invaded Greek waters (Kampouris et al., 2019).

The observed variations, however, cannot be unequivocally ascribed to the concomitant increase in the blue crab stock, due to recent variations in the abiotic conditions of the Bardawil Lagoon, changes in fishing gear, and the contemporaneous occurrence in the lagoon of the Lessepsian portunid *Portunus segnis*. In Turkey, *C. sapidus* has well established populations, yet, its impacts on biodiversity have not been thoroughly assessed; nevertheless, based on qualitative observations and reports from fishermen, it is considered a voracious predator and is expected to impact the structure and dynamics of benthic food webs through predation on native species (AS Ateş, pers. comm).

**Qu. 4.2. How important is the current known impact of the organism on biodiversity at all levels of organisation (e.g. decline in native species, changes in native species communities, hybridisation) in the risk assessment area (include any past impact in your response)?**

Discuss impacts that are currently occurring or are likely occurring or have occurred in the past in the risk assessment area. Where there is no direct evidence of impact in the risk assessment area (for example no studies have been conducted), evidence from outside of the risk assessment area can be used to infer impacts within the risk assessment area.

RESPONSE	minimal minor moderate <b>major</b> massive	CONFIDENCE	low medium <b>high</b>
----------	---	------------	------------------------------

Response: Stable isotope studies performed in the risk assessment area have confirmed *Callinectes sapidus* as an omnivore feeding at different trophic levels, interacting - either by predation or competition - with a variety of native organisms and thus affecting in multiple ways the structure and dynamics of invaded food webs (Carrozzo et al. 2014; Mancinelli et al., 2013a, 2016, 2017c). In addition, it is characterized by remarkable ontogenetic diet shifts (Mancinelli et al. 2017c). Based on these evidences, a considerable ecological impact can be already expected for the species, as invasive omnivores are particularly threatening to ecosystem function because of their ability to directly and indirectly influence multiple trophic levels through resource consumption (Lodge et al. 1994; Thompson et al. 2007; Tumolo & Flinn 2017).

Under field conditions, the feeding habits and foraging behavior of the species have been clearly assessed in Greek waters by Kampouris et al. (2019). In their account the authors indicated for the species an extensive list of prey items, including algae, polychaetes, mollusks (15 species), crustaceans (9 taxa) and a wide variety of fish (16 taxa). In a small lagoon in North Aegean Sea Greece (Papapouli Lagoon, Platamonas) an analysis of a short time-series of fisheries data (2009–2014), suggested that *C. sapidus* may have extirpated the native *Carcinus aestuarii* (Kampouris et al., 2019). Moreover, there are anecdotal records that *C. sapidus* had the same effect on *Cerastoderma glaucum* (Kampouris et al., 2019). Furthermore, an analysis of a time series of invertebrate and fish catches in the Ebro Delta (Spain) currently under submission (Clavero et al., 2020) indicated that from 2011 to 2019 severe impacts (roughly estimable in the range of 30-90% decreases in catches) were exerted by the spread and increase in abundance of *C. sapidus* in the area on a wide spectrum of organisms, including bivalves and

gastropods (10 species), the green crab *Carcinus aestuarii*, the common goby *Pomatoschistus microps*, the eel *Anguilla anguilla*, the sandsmelt *Atherina boyeri*, the seabass *Dicentrarchus labrax*, and the sea bream *Sparus aurata*. Concomitantly, the blue crab has been representing an increasing proportion in the lagoon fisheries captures (López and Rodon, 2018), and indication of a strong top-down control of local communities.

The strong preference of the species for bivalves has been confirmed by laboratory experiments. *C. sapidus* caught in Portugal when fed with commercial bivalves such as *Donax trunculus*, *Spisula solida*, *Chamelea gallina*, *Cerastoderma edule*, *Ruditapes decussatus* and *Mytilus galloprovincialis* revealed no species specific preference but preference to thin-shelled species that were easier to handle and fastest to break than the more hard-shelled species (Vasconcelos et al., 2019). These observations have been corroborated by laboratory trials performed using *C. sapidus* individuals captured in the Ebro Delta and different sizes of the bivalves *Mytilus galloprovincialis*, *Crassostrea gigas*, and *Corbicula fluminea*, and the gastropod *Pomacea maculata* (Prado et al., 2020).

Considering feeding observations (Kampouris et al., 2019) and stable isotope analyses (e.g. Mancinelli et al., 2013a; 2016; Carrozzo et al., 2014), the targeted prey of *C. sapidus* overlap with that of several native crustacean and fish species [e.g. *Sparus aurata* (Carrozzo et al., 2014); *Eriphia verrucosa*, *Pachygrapsus marmoratus* (Mancinelli et al., 2013a); *Gobius niger*, *Lithognathus mormyrus*, and *Zosterisessor ophiocephalus* (Mancinelli et al., 2016)]. The species is also suspected to outcompete indigenous species of crabs (e.g. Gennaio et al., 2006; Mancinelli et al., 2013a; Petović et al., 2018; Kampouris et al., 2019).

Bioturbation of seagrass beds, in particular during winter months when *C. sapidus* responds to low temperatures by burrowing in the bottom sediments and entering a state of quiescence, is a further, rather overlooked impact that may be exerted by the species on local biodiversity. In invaded habitats no quantitative studies have been performed to date (but see Kampouris et al. 2019 for some examples of burrowing activities); however, one of the authors (GM) has personally verified that in the Lesina and Acquatina lagoons (Puglia Region, SE Italy), both characterized by high abundances of *C. sapidus*, *Nanostera noltei* and *Cymodocea nodosa* beds presented at the end of winter – early spring anomalous unvegetated spots where the vegetation had been uprooted. Even though other natural or human-determined causes cannot be excluded, these evidences are consistent with observations from native habitats, where the species has been indicated to create pits and bare areas in seagrass stands (e.g., *Thalassia testudinum* Valentine et al., 1994; *Zostera* spp.: Townsend & Fonseca, 1998) see also Sturdivant et al. 2012). Moreover, besides consuming seagrass seedlings and live plant material, *C. sapidus* has also the potential to impact seagrass beds by bioturbation while ambushing, hiding for predators and/or overwintering (Hines, 2007).

These information from the RA area are fully consistent with those available for *C. sapidus* native habitats, where the blue crab has long been recognized to influence the structure and function of benthic food webs, either as a keystone species regulating carbon flows, or by reducing prey abundance and inducing trophic cascades (Mancinelli et al., 2017c). Accordingly, a major response and a high ecological impact (throughout all its ontogeny) on coastal ecosystems is expected for the species, particularly for the Mediterranean and the southern Iberian Peninsula. In the isolated locations in Atlantic Europe where *C. sapidus* has established populations no impacts have been reported to date, presumably because of the limited distribution and density of the populations (e.g. in Normandy, France and the Westerschelde, Netherlands).

No hybridization with other species has been reported (e.g. Millikin & Williams, 1984). In fact, with the only exception of an episodic record of *Callinectes exasperatus* in European waters (Cuesta et al., 2015) no congeneric species occur in the RA area.

**Qu. 4.3. How important is the potential future impact of the organism on biodiversity at all levels of organisation likely to be in the risk assessment area?**

See comment above. The potential future impact shall be assessed only for the risk assessment area.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: The species is expanding its distribution range throughout the RA area; in addition, the establishment of blue crab populations in invaded areas are characterized, as generally occurs for invasive species, by anomalous increases in the abundance of the species. Given that the strength of the interactions highlighted in Qu. 4.2 - either competitive or predatory - are by definition density-dependent, a major impact is expected for the species in the future. The response is estimated with a medium level of confidence, as several factors may influence the ultimate magnitude of the impact. For example, the blue crab is likely to become established in the Atlantic (e.g. Bay of Seine) where some pressure on the native green crab *Carcinus maenas* through predation and competition are expected (Pezy et al., 2019). Even though considerable negative effects have been highlighted for *C. sapidus* on the congeneric *C. aestuarii* in the Mediterranean Sea (see Qu. 4.2), the actual outcome of biotic interactions of the blue crab with *C. maenas* is characterized by a certain level of indeterminacy, as Rogers et al. (2018) indicated that at low temperatures, *C. maenas* in invaded US waters had a competitive advantage on *C. sapidus* and intra-guild predation by blue crabs on green crabs was low. Thus, future oceanographic conditions within the RA area may affect the ultimate impact of the species; monitoring the presence, establishment and potential expansion of the species in the warming North Sea, is of significance especially under the light of how future establishment of *C. sapidus* populations would affect the local biodiversity (Nehring et al., 2008). Given the lower temperatures in the North Sea and Celtic Seas, even under future climate conditions, it is not considered very likely that the invasion will be as strong and wide-spread as in the Mediterranean, nevertheless some predation impacts on native molluscs in particular can be expected. Furthermore, while there exists information on the trophic position of the species in the risk assessment area (for details see Qu. 4.2), the interactions with higher trophic levels, and thus with native predators that may control the abundance and expansion of blue crab populations, are to date virtually unexplored (Mancinelli et al., 2017a). Several recorded predators of *C. sapidus* in its natural distribution areas (see Palomares & Pauly, 2019), are also found in the risk assessment area (e.g. turtles (*Lepidochelys kempii*), sharks (*Carcharhinus plumbeus*), bonyfish (e.g. *Dicentrarchus labrax*, *Lobotes surinamensis*, *Pomatomus saltatrix*), mammals (*Tursiops truncatus*). Yet, their interactions have not been studied in invaded environments, thus no predictions can be made as regard with their potential response, in terms of abundance and diversity, to the establishment of *C. sapidus*.

**Qu. 4.4. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism currently in the risk assessment area?**

including the following elements:

- native species impacted, including red list species, endemic species and species listed in the Birds and Habitats directives
- protected sites impacted, in particular Natura 2000
- habitats impacted, in particular habitats listed in the Habitats Directive, or red list habitats
- the ecological status of water bodies according to the Water Framework Directive and environmental status of the marine environment according to the Marine Strategy Framework Directive

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: The species has been recorded in lagoon areas that are of conservation value with regard to European and national nature conservation legislation sites, such as the Natura 2000 network and the Habitats Directive (lagoons listed in Annex I as priority habitats) and MPAs. In particular it has been reported from: Ugento, Salento peninsula-Lecce, Italy (Gennaio et al., 2006), Lesina and Varano lakes, Gargano National Park, Italy (Florio et al., 2008), Antinioti Lagoon, Corfu, Greece (Karachle in Bilecenoglu et al., 2013), s’Albufera de Mallorca Natural Park, Balearic Islands, Spain (Garcia et al., 2018), La Pletera salt marshes, part of the Natural Park “Montgrí, les Illes Medes i el Baix Ter”, Spain (Fuentes et al., 2019)] and The Ebro Delta Natural Park (Castejón & Guerao, 2013).

Currently, the overall decline in conservation value of these habitats has not been assessed, with only exception of the Ebro Delta area, where remarkable, community-wide negative impacts have been highlighted (Clavero et al. 2020). Given the impacts - verified and expected - of the species described in Qu. 4.2 and 4.3, major negative effects are likely to occur on the conservation value of invaded areas, as determined by changes induced on their functions and diversity. In particular, the high trophic plasticity and omnivorous trophic habits of the species imply that species of high conservation interest are likely to be included in its diet; in addition, seagrass beds may be threatened (listed under the code A5.53 in the EUNIS habitat type classification; related to habitat types 1110 and 1120, of the Annex I of the Habitats Directive) by bioturbation, as described in Qu 4.2.

With respect to the environmental status of the sites it has invaded, its impact could be related to the MSFD descriptors D1 (biodiversity), D2 (NIS), D3 (fishing), and D4 (food webs). Yet, the degree of *C. sapidus* impact on GES, based on the MSFD descriptors has not been quantitatively assessed. The only evident measured impact is presently the indicator D2 (criterion D2C1: number of new NIS per 6 years).

**Qu. 4.5. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.4.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: Warming and extent of suitable range could increase number of potentially suitable (hence vulnerable) estuaries, inlets and bays, mudflats, saltmarsh and seagrass beds. Provided the overall recorded (e.g. on biodiversity and habitat changes, impacts on the food webs) and perceived impacts of *C. sapidus* on biodiversity and ecosystems (see questions Qu 4.1-4.3), its presence and increased proportion in areas of conservation is likely to cause a decline in their overall value. Lower impacts may be expected in the North and Celtic Seas, where lower temperatures are likely to limit the magnitude of the invasive populations.

### Ecosystem Services impacts

**Qu. 4.6. How important is the impact of the organism on provisioning, regulating, and cultural services in its non-native range excluding the risk assessment area?**

- For a list of services use the CICES classification V5.1 provided in Annex V.
- Impacts on ecosystem services build on the observed impacts on biodiversity (habitat, species, genetic, functional) but focus exclusively on reflecting these changes in relation to their links with socio-economic well-being.
- Quantitative data should be provided whenever available and references duly reported.

<b>RESPONSE</b>	<b>minimal</b> minor moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: Very little information has been found on the issue, as the species has very few established permanent populations in other non-native locations where it was observed (see also Qu 4.1). The only impact that could be identified is related to “provisioning” in Turkey and Egypt. In Turkey, the species has been exploited since the 1980’s, In south west Turkey, *C. sapidus* has been reported in 15 lagoonal systems, supporting important commercial fisheries (Ayas & Özogul, 2011) while in Bardawil Lagoon, Sinai (Egypt) where it is also exploited the species comprised 19% to 42% of the total lagoon production (Abdel Razek et al., 2016; Mehanna et al., 2019). However, impact on protected slow moving benthic fish species (e.g. *Gobius cobitus* protected in UK) and alteration of the quality of protected bird feeding habitat (e.g. estuarine mudflats and offshore mussel/ cockle beds important for duck species due to predation on bivalves) can be anticipated.

**Qu. 4.7. How important is the impact of the organism on provisioning, regulating, and cultural services currently in the different biogeographic regions or marine sub-regions where the species has established in the risk assessment area (include any past impact in your response)?**

- See guidance to Qu. 4.6.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: The main impact that could be identified is related to “provisioning”. The species has been responsible for destruction of fishing gear and the fish being caught on the nets (e.g. Dulčić et al., 2011; Katselis & Koutsikopoulos, 2017; Mancinelli et al., 2017a; Kampouris et al., 2019), but also it preys upon other exploited species as the Pacific oyster *Magallana gigas*, the blue mussel *Mytilus* spp. (Labrune et al., 2019; Prado et al., 2020). This leads to reduced fisheries yields and thus impact on food provisioning to the local communities, as in the case of suspected local (?) extirpation of *Carcinus aestuarii* and anecdotal records of effects on *Cerastoderma glaucum* (Kampouris et al., 2019).

Other impacts that could potentially occur relate to Regulation-maintenance services and Cultural services. Where dense populations of the species develop, their heavy predation on filter feeding organisms may affect water quality and transparency, triggering a cascade of effects on macrophyte abundance and nutrient cycles. This potentially may affect (i) mediation of waters or toxic substances and (ii) hydrological cycle and water flow regulation. Additionally, damage to nets and fishing rods can reduce the amenity value to recreational fishing, impacting cultural services in the form of physical and experiential interactions with the natural environment. Such impacts however are still speculative as no concrete information could be found on these issues.

**Qu. 4.8. How important is the impact of the organism on provisioning, regulating, and cultural services likely to be in the different biogeographic regions or marine sub-regions where the species can establish in the risk assessment area in the future?**

- See guidance to Qu. 4.6.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: The main impact that could be identified is related to “provisioning”. The species is known to prey on various types of organisms, including economically important bivalves (Kampouris et al., 2019; Labrune et al., 2019). For this reason, its presence, and recent establishment (GM, pers. observ.) in the lagoons of north Italy, where clam aquaculture is one of the main activities, raise concerns about

future impacts of the bivalve production (e.g. Manfrin et al., 2015). Moreover, its feeding habits are alarming regarding the effects they might have on fisheries production of locally important resources (e.g. Vasconcelos et al., 2019). For example, in the Venice Lagoon and in the Lesina Lagoon (Puglia region) *Carcinus aestuarii* is a valuable shellfish product and established populations of *C. sapidus* in the area might impact the fisheries of *C. aestuarii* (GM, per. obser.). In the Atlantic and Continental biogeographic regions where the magnitude of establishment is still under consideration (see also ANNEX VIII), the anticipated pressure on commercial species (e.g. *Carcinus maenas*, *Magallana gigas*; Nehring et al., 2008, Pezy et al., 2019) is expected to be significant.

Impacts on Regulation-maintenance as well as Cultural services, as outlined in Qu. 4.7, may also occur.

**Economic impacts**

**Qu. 4.9. How great is the overall economic cost caused by the organism within its current area of distribution (excluding the risk assessment area), including both costs of / loss due to damage and the cost of current management.**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the world these should be reported here. The assessment of the potential costs of / loss due to damage shall describe those costs quantitatively and/or qualitatively depending on what information is available. Cost of / loss due to damage within different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage. As far as possible, it would be useful to separate costs of / loss due to the organism from costs of current management.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: In the Bardawil lagoon (Egypt), inconclusive evidences (see Qu. 4.2) suggest that the presence, establishment, and increase in abundance of *C. sapidus* had impacts on economically important fish species (Mehanna et al., 2019; 2020 and references therein). Before the 1990’s, the lagoon had a significant production of high valued fish species (e.g. seabream, flathead grey mullet and thinlip grey mullet). Yet in the early 1990’s, a period that coincides with the establishment of *C. sapidus* in the area, the fish catches declined significantly, with the crustacean ones – including *C. sapidus* as well as *Portunus segnis* catches -rising as high as 60% of the total yield production of Bardawil Lagoon, a fact that is also related to other factors as: change in the ecological conditions of the lagoon, uncontrolled fish exporting policy and overexploitation of resources (Mehanna et al., 2019). In order to mitigate the losses from the fish, *C. sapidus* is now an exploitable resource and it supports a valuable commercial fishery in Bardawil lagoon, mitigating the economic losses determined by the decrease observed in the stocks of other species of economic interest. In Turkey, *C. sapidus* has well established populations, yet, the economic impact on fisheries has not been assessed; nevertheless, fishers complain on gear damages and impacts on the native fish through predation and changing the food webs (AS Ateş, pers. comm).

**Qu. 4.10. How great is the economic cost of / loss due to damage (excluding costs of management) of the organism currently in the risk assessment area (include any past costs in your response)?**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the EU these should be reported here. Assessment of the potential costs of damage on human health, safety, and the economy, including the cost of non-action. A full economic assessment at EU scale might not be possible, but qualitative data or different case studies from across the EU (or third countries if relevant) may provide useful information to inform decision makers. In absence of specific studies or other direct evidence this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. Cost of / loss due to damage within different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

#### Response

In general, the blue crab has been claimed to be responsible for destruction of fishing gear and partial consumption of fish being caught in the gears (e.g. Dulčić et al., 2011; Katselis & Koutsikopoulos, 2017; Tutman et al., 2017b; Fuentes et al., 2019; Kampouris et al., 2019); in addition, the species preys upon bivalve species of economic interest as the Pacific oyster *Magallana gigas*, the blue mussel *Mytilus* spp. (e.g. Labruno et al., 2019) as well as on cuttlefish eggs (Martins et al., 2018). This is expected to considerably reduce catches of species of economic interest, as observed in the Ebro Delta (Clavero et al., 2020). There is currently no assessment of economic costs/losses, present or future. Nevertheless, actions to estimate these losses have been planned in the framework of running scientific projects (e.g. InvasiBES – Gallardo et al., 2019). Yet unpublished results from this project indicate that some fishers from the Ebro Delta have changed their way of fishing in order to avoid encounters, or started to capture the blue crab. Similarly, the population decline in many bivalve species, probably associated with the population increase of *C. sapidus*, is affecting many shellfish harvesters in the labor market (R. Bernardo-Madrid, pers.comm., May 2021). It should be noted here that bivalve cultivation constitutes one of the main local economic activities in the region (Prado et al., 2020).

In an unpublished survey conducted in Greece using questionnaires regarding the socio-economic impacts of alien species (Galanidi, Zenetos, Gavriil & Karachle, unpub. data), with respect to *C. sapidus*, professional small-scale fishers provided the following information: (a) approximately 42.5% of the fishers (28 out of the 66) captured the species; (b) 12 of them changed their way of fishing in order to avoid encounters with the species and damages to the nets and their catches; (c) 61 fishers reported economic losses ranging from 50 to 6500 euros per year per person (mean=1366; median=850 euros). It should be noted that in some member states blue crab fisheries are or will be allowed (e.g., Greece, Spain), a fact that may provide a counterbalance to monetary losses due to impacts on fishing gear or native species of economic interest. For example, in the Neretva Estuary (Croatia), no estimates of losses due to e.g., damage of fishing gear by blue crabs have been estimated, while a considerable (estimated

in the range of 20-30%) decrease in the catches of fish species of economic interest determined after the invasion of *C. sapidus*; however, a total income of approximately 7000 € for the July-December period has been estimated from the marketing of the blue crab (Glamuzina et al., 2020).

**Qu. 4.11. How great is the economic cost of / loss due to damage (excluding costs of management) of the organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.10.

<b>RESPONSE</b>	minimal	<b>CONFIDENCE</b>	low
	minor		<b>medium</b>
	<b>moderate</b>		high
	major		
	massive		

Response: There are currently no exact estimates of the economic costs/losses, present or future for the RA area, yet actions to estimate these losses are planned within the framework of scientific projects (e.g. InvasiBES – Gallardo et al., 2019). The estimates provided in Qu. 4.10 for Greece, where the species has a long history of establishment, can be taken as a reference and extended to other countries where the blue crab distribution is currently expanding.

Based on the existing literature on the feeding habits and potential competition of *C. sapidus* with mollusks, crabs and fish of commercial interest (see also Qu 4.2, 4.4, 4.7), it is very likely that the species will cause economic losses to both the fishery and mussel/oyster culture sectors. It should be noted that in some member states blue crab fisheries are or will be allowed (e.g., Greece, Spain), a fact that may help counterbalance any monetary losses due to impacts on native species of economic interest (see Qu. 4.10). The UK, government policy currently does not permit the exploitation of such fisheries, as in the case of *Eriocheir sinensis* that there is the current ban on exploiting it where established.

**Qu. 4.12. How great are the economic costs / losses associated with managing this organism currently in the risk assessment area (include any past costs in your response)?**

- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”.

<b>RESPONSE</b>	<b>minimal</b>	<b>CONFIDENCE</b>	low
	minor		medium
	moderate		<b>high</b>
	major		<b>N/A</b>
	massive		
	N/A		

Response: Currently, *C. sapidus* is not managed in the RA area, and no information is available on the issue. Accordingly, the economic costs related to management activities are expected to be negligible, with a high confidence.

**Qu. 4.13. How great are the economic costs / losses associated with managing this organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.12.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: No information has been found on the issue. Managing the species might be achieved through fishing, as a potential fisheries metier that will result to a new income source for the fishers. Nevertheless, this might be an option for some of the fishers and not for all of them (see also Qu 4.12). On the other hand, bivalve growers are expected to implement management measures to avoid/minimize predation losses by the blue crab. A variety of methods are available, including protective netting or cages, selecting seed size, stocking density etc. (e.g. see Grosholz & Ruiz, 2002) and their cost and effectiveness will depend on the species and cultivation method. Furthermore, a ban of imports or restrictions in the movement of shellfish seed/stock from infected areas could have potentially significant economic implications for bivalve producers.

It should be noted however, that bioaccumulation of heavy metals and other chemical contaminants (e.g. Türkmen et al., 2006; Mutlu et al., 2011; Genc & Yilmaz, 2015; Zotti et al., 2016; Çoğun et al., 2017) may also limit the potential for fisheries to be used as a management method, where incursions occur in industrialised water bodies with poor water quality.

### Social and human health impacts

**Qu. 4.14. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism for the risk assessment area and for third countries, if relevant (e.g. with similar eco-climatic conditions).**

The description of the known impact and the assessment of potential future impact on human health, safety and the economy, shall, if relevant, include information on

- illnesses, allergies or other affections to humans that may derive directly or indirectly from a species;
- damages provoked directly or indirectly by a species with consequences for the safety of people, property or infrastructure;
- direct or indirect disruption of, or other consequences for, an economic or social activity due to the presence of a species.

Social and human health impacts can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: Within the risk assessment area, the species poses a threat to fishers, due to its aggressive behavior that could lead to injuries especially when they are trying to remove it from the fishing gear (e.g. Milori et al., 2017; Galanidi, Zenetos, Gavriil & Karachle, unpub. data).

Based on a recent questionnaire-based survey on recreational fishers (Cerri et al., 2020) in Italy, Croatia and Montenegro, the perceived impacts of the species on fisheries and the environment were not clear for half of the participants. Only a small percentage could see negative impacts, whereas there was only a minority that anticipated positive impacts. Nevertheless, the survey clearly showed that the higher the abundance of the species, the more intense is the perception of *C. sapidus* as a threat to fisheries and the environment.

In its native area of distribution, several studies on the presence of heavy metals in various tissues have been conducted. It has been found that the accumulation of heavy metals varies between different areas and the accumulation is different in the various tissues examined (e.g. Adams & Engel, 2014 and references therein). Moreover, as humans consume *C. sapidus*, bioaccumulation of heavy metals is considered an important issue on human health (Lincoln et al., 2011). *Callinectes sapidus* has been found to be a carrier of *Vibrio cholerae* strains and has been related to outbreaks of human cholera in the USA (e.g. Welsh & Sizemore, 1985; Huq et al., 1986; Hill et al., 1989; Nehring, 2011). Yet, proper storing, processing and cooking will prevent any threats on human health (Hill et al., 1989). Therefore, should appropriate measures be taken, the likelihood of such incidences within the risk assessment area, could be considered as low.

Several studies exist on heavy metal bio-accumulation of *C. sapidus* from the environment (e.g. Türkmen et al., 2006; Mutlu et al., 2011; Genc & Yilmaz, 2015; Zotti et al., 2016; Çoğun et al., 2017), yet impact is considered as negligible.

**Qu. 4.15. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism in the future for the risk assessment area.**

- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”.

<b>RESPONSE</b>	<b>minimal</b> minor moderate major	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

	massive		
--	---------	--	--

Response: Given that in its native distribution the species has been related to outbreaks of human cholera (see Qu 4.14), *C. sapidus* could have negative effects on tourism and human health in the risk assessment area. Moreover, despite the fact that intoxication of heavy metal bioaccumulation in *C. sapidus* has not been recorded yet in the RA area, it might still be a threat to human health, and therefore harvesting of the species for consumption should be monitored and follow procedures similar to those for shellfish products (Zotti et al., 2016).

### Other impacts

**Qu. 4.16. How important is the organism in facilitating other damaging organisms (e.g. diseases) as food source, a host, a symbiont or a vector etc.?**

<b>RESPONSE</b>	minimal	<b>CONFIDENCE</b>	low
	minor		<b>medium</b>
	<b>moderate</b>		high
	major		
	massive		

Response: Several diseases, parasites, and commensals have been recorded to infect *C. sapidus* in its native range in the East coasts of the USA (for an extended account see Millikin & Williams, 1984, Flowers et al., 2016, and references therein). In the risk assessment area, apart from the unconfirmed record of the parasitic dinoflagellate *Hematodinium* sp. in Italy (Mancinelli et al., 2013b), nowadays several bacteria, parasites and fungi are reported for the species (Aldik & Cengizler, 2017). Overall, 21 bacteria have been found in hemolymph samples, including four *Vibrio* species, yet not *V. cholerae* (Aldik & Cengizler, 2017). In areas of its native distribution *C. sapidus* is a carrier of *V. cholerae* (see also Qu 4.14). To date in the risk assessment area, no records of infected *C. sapidus* have been made, but the possibility cannot be ruled out. Moreover, nine parasites and two fungi have also been identified in the species (Aldik & Cengizler, 2017). Nevertheless, none of the parasites found in *C. sapidus* is alien, and impacts on other species by transfer of diseases from *C. sapidus* has not been reported. Czerniejewski et al (2020) report *Trichodina* sp. on a *C. sapidus* specimen from the Baltic Sea. Protozoa of the genus *Trichodina* are common parasites of gills and body surfaces of fish in Western Pomerania. Thus *C. sapidus* could act as a vector spreading this parasite in the reservoir and thus could contribute to its transmission to fish, especially because *Trichodina* sp. proliferates exponentially and in favorable conditions a single specimen can reproduce very quickly by division and start a new invasion.

**Qu. 4.17. How important might other impacts not already covered by previous questions be resulting from introduction of the organism?**

<b>RESPONSE</b>	minimal	<b>CONFIDENCE</b>	low
	minor		medium

	moderate major massive		high
--	------------------------------	--	------

Response: No additional impacts could be identified.

**Qu. 4.18. How important are the expected impacts of the organism despite any natural control by other organisms, such as predators, parasites or pathogens that may already be present in the risk assessment area?**

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: The species in its native distribution areas has many natural predators (see Qu 2. 4, Qu. 4.1) as well as a number of parasites and diseases (see Qu 4.16). However, despite the fact that in the risk assessment area several of its natural predators exist (see also Qu. 4.3) and its contamination by parasites and diseases has been documented, their impact on *C. sapidus* has not been documented to date. Nevertheless, given the impacts of parasites and diseases on the wellbeing and status of *C. sapidus* stock in its native areas (e.g. Shields, 2003; CBSAC, 2014), such effects could be anticipated in the risk assessment area, and a reduction in the abundance and overall biomass might be observed.

**Qu. 4.19. Estimate the overall impact in the risk assessment area under current climate conditions. In addition, details of overall impact in relevant biogeographical regions should be provided.**

Thorough assessment of the overall impact on biodiversity and ecosystem services, with impacts on economy as well as social and human health as aggravating factors, in current conditions.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: The bulk of information regarding *C. sapidus* impacts on various aspects (i.e. biodiversity, areas of protection, cultural elements, socio-economics) exists from the Mediterranean biogeographical region, where it has a long invasion history and such impacts are apparent. The species is a voracious predator, feeding on a wide range of native animal and vegetal items occurring in invaded marine environments (Kampouris et al., 2019). Stable isotope studies identify *C. sapidus* as an omnivore feeding at multiple trophic levels; accordingly, a high ecological impact is expected to be exerted on native

benthic assemblages throughout its ontogeny (e.g. Nehring, 2011; Mancinelli et al., 2016). Molluscan, crustacean, and fish species (including those of economic and/or conservation interest) are the groups that should experience the major predatory impact; besides predation on other species, *C. sapidus* is highly competitive for food resources, with a diet overlapping with that of native crustacean and fish species (Mancinelli et al., 2013a; Mancinelli et al., 2016). In particular, the blue crab is assumed to outcompete indigenous species of crabs (e.g. Gennaio et al., 2006; Mancinelli et al., 2013a; Petović et al., 2018; Kampouris et al., 2019), as confirmed by recent research (e.g. Kampouris et al., 2019). In addition, with respect to effects on habitats of conservation value, *C. sapidus* has also the potential to impact seagrass beds (listed under the code A5.53 in the EUNIS habitat type classification; related to habitat types 1110 and 1120, of the Annex I of the Habitats Directive) by bioturbation, even though only anecdotal information is currently available and no quantitative studies have been carried out to date in the RA area.

With respect to ecosystem services, the aggressive behavior of *C. sapidus* combined with its voracious character, makes it a pest for the fisheries and aquaculture sector. The species has been recognized as responsible for destruction of fishing gear and reduced fisheries yields. Moreover, its aggressiveness and size poses a threat to the health and safety of fishers, as captured crabs might cause injuries especially when they are manipulated during retrieval of fishing gears. However, the perceived impacts of the species on fisheries and the environment of recreational fishers (Cerri et al., 2020: Italy, Croatia and Montenegro) are not yet clear.

To-date, the impact of *C. sapidus* to human health in the RA area is not assessed. In its native distribution area some relation of the species with outbreaks of human cholera (e.g. Welsh & Sizemore, 1985; Huq et al., 1986; Hill et al., 1989) has been reported. Heavy metal bioaccumulation of the species in the Mediterranean has been studied, yet low levels of contamination have been measured in the RA area (Zotti et al., 2016), and the potential impact on human health is to date considered negligible. Finally, *C. sapidus* could act as a vector spreading a parasite such as *Trichodina* sp. in reservoirs and thus could contribute to its transmission to fish, especially because *Trichodina* sp. proliferates exponentially and in favorable conditions a single specimen can reproduce very quickly by division and start a new invasion (Czerniejewski et al., 2020).

It should be noted that impacts from the sparse and isolated populations in the North Sea have not been reported and are not likely to have been significant due to the low population sizes.

**Qu. 4.20. Estimate the overall impact in the risk assessment area in foreseeable climate change conditions. In addition, details of overall impact in relevant biogeographical regions should be provided.**

Thorough assessment of the overall impact on biodiversity and ecosystem services, with impacts on economy as well as social and human health as aggravating factors, under future conditions.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: A predicted increase in seawater temperatures under foreseeable climate change conditions is anticipated to lead to a northward expansion/establishment of the species, extending the areas at risk

from localized strong populations and associated impacts in the Mediterranean and increasing the respective risks in Atlantic Europe and the Black Sea.

Provided the overall recorded and perceived impacts of *C. sapidus* on biodiversity and ecosystems (Qu. 4.18 and 4.19), its presence and further expansion in national nature conservation legislation sites (areas of conservation) is likely to cause a significant decline in their overall value (e.g. biodiversity loss due to competition with native species and/or predation; seagrass bed degradation due to bioturbation). In the Atlantic, under the light of population establishment (e.g. Bay of Seine: Pezy et al., 2019) questions are rising regarding the future impacts of *C. sapidus* and the significance of the anticipated pressure on (a) local biodiversity (b) native brachyurans (e.g. *Carcinus maenas* or *Hemigrapsus sanguineus*), (c) crustacean and bivalve species of economic interest (e.g. *Carcinus maenas*, *Magallana gigas*). Similarly, in the Mediterranean, the spread of the species in the Adriatic basin and recent establishment in lagoons and other transitional waters of north Italy, where clam and mussel aquaculture together with *Carcinus aestuarii* harvest represent activities of prime economic interest, raise serious concerns about future impacts, concerns that are beginning to be shared with other countries such as Spain experiencing a burst in the occurrence and abundance of the species. Finally, in the Black Sea area, the future establishment of thriving populations of *C. sapidus* is expected to impact on all levels of biodiversity, yet the effects on the structure of native organisms' communities is not considered to be of important magnitude (e.g. for the Romanian littoral, see Skolka & Preda, 2010).

<b>RISK SUMMARIES</b>			
	<b>RESPONSE</b>	<b>CONFIDENCE</b>	<b>COMMENT</b>
<b>Summarise Introduction and Entry*</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	low medium <b>high</b>	<i>Callinectes sapidus</i> has already been introduced in the RA area, presumably multiple times at different locations (Mediterranean Sea, North Sea, Black Sea, Iberian Coast and the Bay of Biscay). A variety of pathways have been proposed, with existing evidence indicating that ship-mediated vector (ballast waters and sediment) is the most likely means of introduction. Transfer in ship hulls is also a plausible, yet undocumented mode of introduction. Accidental escape from tanks or other packing where it is kept alive via the live food trade has also been suggested as a possible pathway and is considered still active, albeit less likely to contribute high propagule pressure. Similarly, introductions via rafting on floating debris, while possible, are not considered a likely event. Further introductions are very likely, given the high shipping traffic between the native area (east US coast) and EU ports and the ability of the species to survive during transport. Full implementation of the BWMC by 2024 is expected to greatly reduce the likelihood of introduction via ballast water.
<b>Summarise Establishment*</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	low medium <b>high</b>	<i>Callinectes sapidus</i> is already established in the RA area, with locally abundant populations, particularly in the Mediterranean Sea and the southern Iberian coast. The species has also established localised populations along the southern North Sea coast and appears to be established in the Black Sea. Under current climate conditions, further establishment is very likely in the western Mediterranean, further along the Iberian coast & the Bay of Biscay, while more local populations are also likely to establish in the Greater North Sea. Establishment in the Baltic Sea is expected to be prevented by low salinities and low winter temperatures, and in the

			Celtic Sea by low summer temperatures, conditions which prevent successful larval development. Under future climate conditions, further establishment may be expected in the North Sea and the southern Celtic Seas, where an increase in summer temperatures will likely allow larval survival over a wider area. Colonisation of the western Baltic may also be possible.
<b>Summarise Spread*</b>	very slowly slowly moderately <b>rapidly</b> very rapidly	low medium <b>high</b>	The increasing rate of appearance of new records, especially in the Mediterranean Sea, indicates a rapid rate of spread, which is most likely attributable to natural dispersal, although the contribution of other pathways of spread cannot be overlooked. In the Black Sea, human-assisted mechanisms of spread, particularly through shipping vectors and/or the live food trade and intentional releases for commercial exploitation are likely to maintain a moderately rapid rate of spread. In the Greater North Sea, due to the limited availability of suitable climatic conditions, anthropogenic pathways of spread are expected to be primarily responsible for the spreading of the species. Due to the high shipping traffic volume and the precedence of live food trade escape, a rapid rate of spread may be expected.
<b>Summarise Impact*</b>	minimal minor moderate <b>major</b> massive	low <b>medium</b> high	The species has a significant impact on biodiversity and ecosystem services (especially fisheries and aquaculture), mainly due to its size, aggressiveness, omnivorous feeding habits, and high adaptability to coastal habitats characterized by a wide range of salinities and temperatures. Moreover, its ethology (e.g. ambushing) and ecology (e.g. borrowing to avoid low temperatures during winter months) may exert negative impacts on seagrasses. These impacts have been demonstrated in the Mediterranean Sea, where it has been present for a long time and evidence exists, confirming and extending a wide literature available from native areas. In the future, the above

			mentioned impacts are anticipated in other areas where the species will expand its distribution.
<b>Conclusion of the risk assessment (overall risk)</b>	low moderate <b>high</b>	low <b>medium</b> high	<i>Callinectes sapidus</i> has already been established in the RA area (Mediterranean Sea, Iberian Coast and the Bay of Biscay, Black Sea, North Sea very localised) while it has exhibited invasive behaviour in the Mediterranean only. A variety of pathways have been implicated, with existing evidence indicating that ship-mediated vectors (ballast waters and sediment) is the most likely means of introduction. Transfer in ship hulls is also a plausible, yet undocumented mode of introduction. Accidental escape from the live food trade, introductions via rafting on floating debris, are also considered as potential pathway vectors. The aforementioned pathways along with natural dispersal are expected to lead to more local populations likely to establish in the Greater North Sea. Establishment in the Baltic Sea is expected to be prevented by low salinities and temperature. Under future climate conditions, further establishment may be expected in the North Sea and the southern Celtic Seas whereas colonisation of the western Baltic may also be possible. Considering its predatory and aggressive characteristics <i>C. sapidus</i> has a moderate impact on biodiversity and ecosystem services (especially fisheries and aquaculture), and thus it is considered a high-risk species for the EU.

\*in current climate conditions and in foreseeable future climate conditions

## DISTRIBUTION SUMMARY

Please answer as follows:

- Yes if recorded, established or invasive
- if not recorded, established or invasive
- ? Unknown; data deficient

The columns refer to the answers to Questions A5 to A12 under Section A.

For data on marine species at the Member State level, delete Member States that have no marine borders.

In all other cases, provide answers for all columns.

### Member States and the United Kingdom

	Recorded	Established (currently)	Possible establishment (under current climate)	Possible establishment (under foreseeable climate)	Invasive (currently)

## ANNEX I Scoring of Likelihoods of Events

(taken from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

<b>Score</b>	<b>Description</b>	<b>Frequency</b>
Very unlikely	This sort of event is theoretically possible, but is never known to have occurred and is not expected to occur	1 in 10,000 years
Unlikely	This sort of event has occurred somewhere at least once in the last millenium	1 in 1,000 years
Moderately likely	This sort of event has occurred somewhere at least once in the last century	1 in 100 years
Likely	This sort of event has happened on several occasions elsewhere, or on at least once in the last decade	1 in 10 years
Very likely	This sort of event happens continually and would be expected to occur	Once a year

## ANNEX II Scoring of Magnitude of Impacts

(modified from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

Score	Biodiversity and ecosystem impact	Ecosystem Services impact	Economic impact (Monetary loss and response costs per year)	Social and human health impact, and other impacts
	<i>Question 5.1-5</i>	<i>Question 5.6-8</i>	<i>Question 5.9-13</i>	<i>Question 5.14-18</i>
Minimal	Local, short-term population loss, no significant ecosystem effect	No services affected <sup>5</sup>	Up to 10,000 Euro	No social disruption. Local, mild, short-term reversible effects to individuals.
Minor	Some ecosystem impact, reversible changes, localised	Local and temporary, reversible effects to one or few services	10,000-100,000 Euro	Significant concern expressed at local level. Mild short-term reversible effects to identifiable groups, localised.
Moderate	Measureable long-term damage to populations and ecosystem, but reversible; little spread, no extinction	Measureable, temporary, local and reversible effects on one or several services	100,000-1,000,000 Euro	Temporary changes to normal activities at local level. Minor irreversible effects and/or larger numbers covered by reversible effects, localised.
Major	Long-term irreversible ecosystem change, spreading beyond local area	Local and irreversible or widespread and reversible effects on one / several services	1,000,000-10,000,000 Euro	Some permanent change of activity locally, concern expressed over wider area. Significant irreversible effects locally or reversible effects over large area.
Massive	Widespread, long-term population loss or extinction, affecting several species with serious ecosystem effects	Widespread and irreversible effects on one / several services	Above 10,000,000 Euro	Long-term social change, significant loss of employment, migration from affected area. Widespread, severe, long-term, irreversible health effects.

<sup>5</sup> Not to be confused with “no impact”.

### ANNEX III Scoring of Confidence Levels

(modified from Bacher et al. 2017)

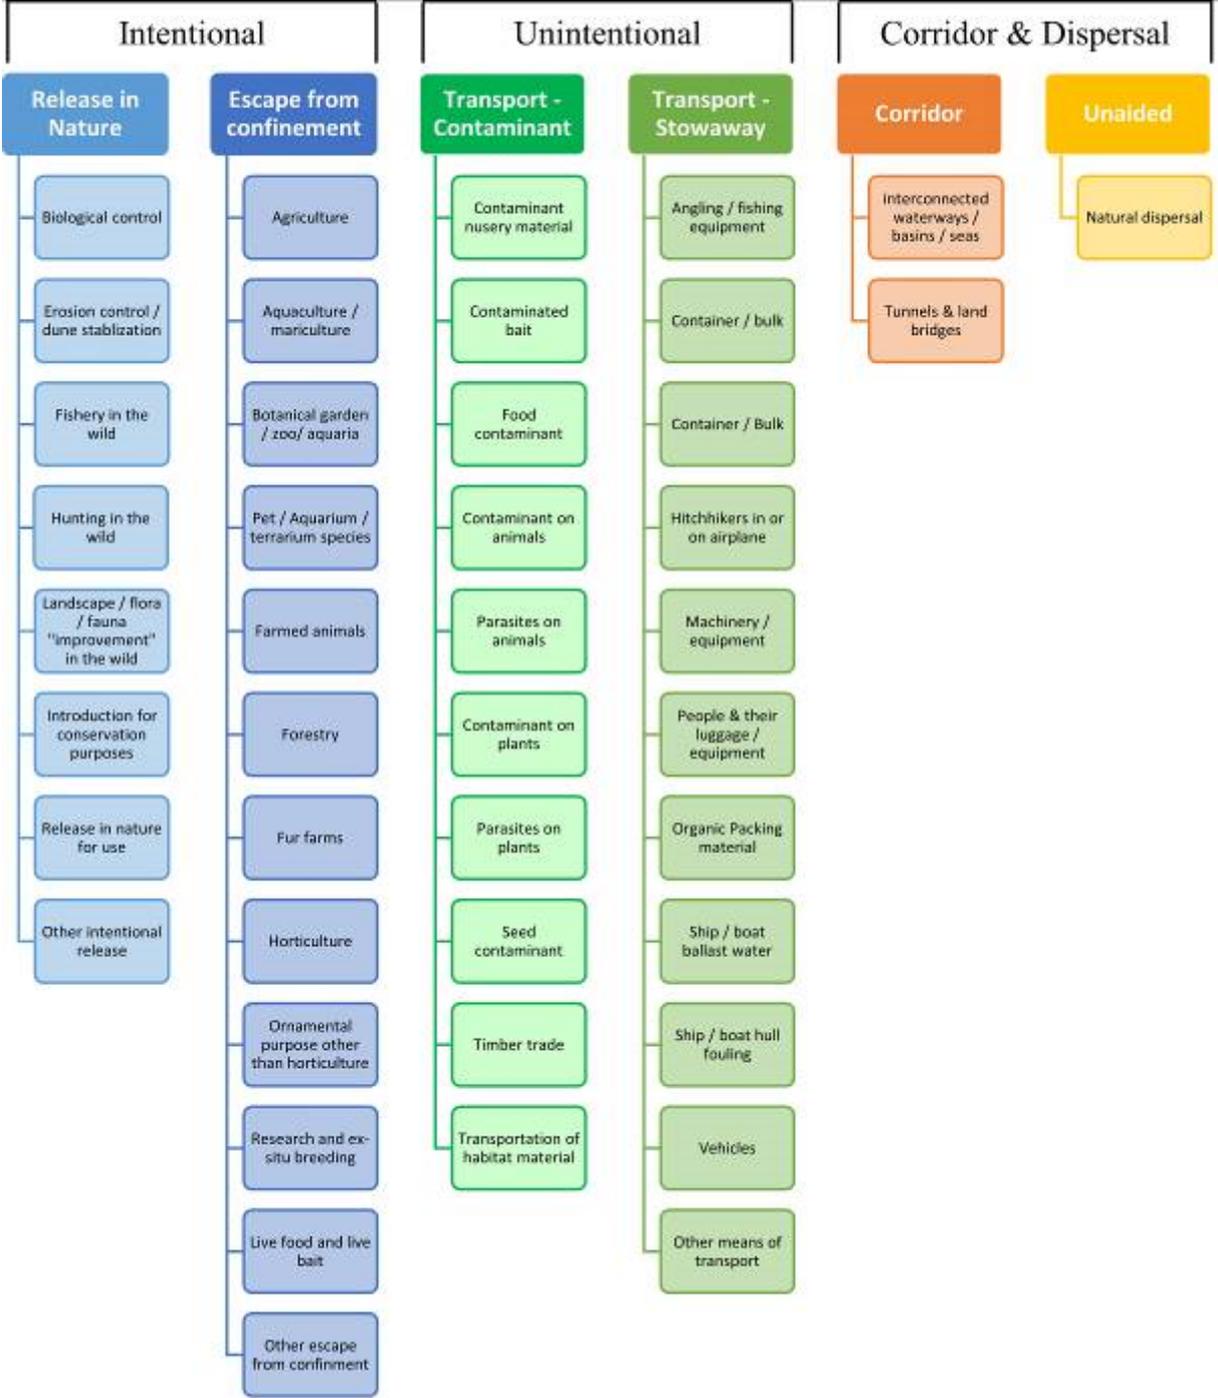

Each answer provided in the risk assessment must include an assessment of the level of confidence attached to that answer, reflecting the possibility that information needed for the answer is not available or is insufficient or available but conflicting.

The responses in the risk assessment should clearly support the choice of the confidence level.

<b>Confidence level</b>	<b>Description</b>
Low	There is no direct observational evidence to support the assessment, e.g. only inferred data have been used as supporting evidence <i>and/or</i> Impacts are recorded at a spatial scale which is unlikely to be relevant to the assessment area <i>and/or</i> Evidence is poor and difficult to interpret, e.g. because it is strongly ambiguous <i>and/or</i> The information sources are considered to be of low quality or contain information that is unreliable.
Medium	There is some direct observational evidence to support the assessment, but some information is inferred <i>and/or</i> Impacts are recorded at a small spatial scale, but rescaling of the data to relevant scales of the assessment area is considered reliable, or to embrace little uncertainty <i>and/or</i> The interpretation of the data is to some extent ambiguous or contradictory.
High	There is direct relevant observational evidence to support the assessment (including causality) <i>and</i> Impacts are recorded at a comparable scale <i>and/or</i> There are reliable/good quality data sources on impacts of the taxa <i>and</i> The interpretation of data/information is straightforward <i>and/or</i> Data/information are not controversial or contradictory.

**ANNEX IV CBD pathway categorisation scheme**

Overview of CBD pathway categorisation scheme showing how the 44 pathways relate to the six main pathway categories. All of the pathways can be broadly classified into 1) those that involve intentional transport (blue), 2) those in which the taxa are unintentionally transported (green) and 3) those where taxa moved between regions without direct transportation by humans and/or via artificial corridors (orange and yellow). **Note that the pathways in the category “Escape from confinement” can be considered intentional for the introduction into the risk assessment area and unintentional for the entry into the environment.**

## ANNEX V Ecosystem services classification (CICES V5.1, simplified) and examples

For the purposes of this risk assessment, please feel free to use what seems as the most appropriate category / level / combination of impact (Section – Division – Group), reflecting information available.

Section	Division	Group	Examples (i.e. relevant CICES “classes”)
Provisioning	Biomass	<b>Cultivated terrestrial plants</b>	<p>Cultivated terrestrial plants (including fungi, algae) grown for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from cultivated plants, fungi, algae and bacteria for direct use or processing (excluding genetic materials);            Cultivated plants (including fungi, algae) grown as a <u>source of energy</u></p> <p><i>Example: negative impacts of non-native organisms to crops, orchards, timber etc.</i></p>
		<b>Cultivated aquatic plants</b>	<p>Plants cultivated by in- situ aquaculture grown for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from in-situ aquaculture for direct use or processing (excluding genetic materials);            Plants cultivated by in- situ aquaculture grown as an <u>energy source</u>.</p> <p><i>Example: negative impacts of non-native organisms to aquatic plants cultivated for nutrition, gardening etc. purposes.</i></p>
		<b>Reared animals</b>	<p>Animals reared for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from reared animals for direct use or processing (excluding genetic materials);            Animals reared to provide <u>energy</u> (including mechanical)</p> <p><i>Example: negative impacts of non-native organisms to livestock</i></p>
		<b>Reared aquatic animals</b>	<p>Animals reared by in-situ aquaculture for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from animals grown by in-situ aquaculture for direct use or processing (excluding genetic materials);            Animals reared by in-situ aquaculture as an <u>energy source</u></p> <p><i>Example: negative impacts of non-native organisms to fish farming</i></p>
		<b>Wild plants (terrestrial and aquatic)</b>	<p>Wild plants (terrestrial and aquatic, including fungi, algae) used for <u>nutrition</u>;  <u>Fibres and other materials</u> from wild plants for direct use or processing (excluding genetic materials);            Wild plants (terrestrial and aquatic, including fungi, algae) used as a <u>source of energy</u></p>

			<p><i>Example: reduction in the availability of wild plants (e.g. wild berries, ornamentals) due to non-native organisms (competition, spread of disease etc.)</i></p>
		<b>Wild animals</b> (terrestrial and aquatic)	<p>Wild animals (terrestrial and aquatic) used for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from wild animals for direct use or processing (excluding genetic materials);  Wild animals (terrestrial and aquatic) used as a <u>source of energy</u></p> <p><i>Example: reduction in the availability of wild animals (e.g. fish stocks, game) due to non-native organisms (competition, predations, spread of disease etc.)</i></p>
	<b>Genetic material</b> from all biota	<b>Genetic material</b> from plants, algae or fungi	<p><u>Seeds, spores and other plant materials</u> collected for maintaining or establishing a population;  Higher and lower plants (whole organisms) used to <u>breed new strains or varieties</u>;  Individual genes extracted from higher and lower plants for the <u>design and construction of new biological entities</u></p> <p><i>Example: negative impacts of non-native organisms due to interbreeding</i></p>
		<b>Genetic material</b> from animals	<p>Animal material collected for the purposes of maintaining or establishing a population;  Wild animals (whole organisms) used to breed new strains or varieties;  Individual genes extracted from organisms for the design and construction of new biological entities</p> <p><i>Example: negative impacts of non-native organisms due to interbreeding</i></p>
	<b>Water</b> <sup>6</sup>	<b>Surface water</b> used for nutrition, materials or energy	<p>Surface water for <u>drinking</u>;  Surface water used as a material (<u>non-drinking purposes</u>);  Freshwater surface water, coastal and marine water used as an <u>energy source</u></p> <p><i>Example: loss of access to surface water due to spread of non-native organisms</i></p>
		<b>Ground water</b> for used for nutrition, materials or energy	<p>Ground (and subsurface) water for <u>drinking</u>;  Ground water (and subsurface) used as a material (<u>non-drinking purposes</u>);  Ground water (and subsurface) used as an <u>energy source</u></p>

<sup>6</sup> Note: in the CICES classification provisioning of water is considered as an abiotic service whereas the rest of ecosystem services listed here are considered biotic.

			<i>Example: reduced availability of ground water due to spread of non-native organisms and associated increase of ground water consumption by vegetation.</i>
<b>Regulation &amp; Maintenance</b>	Transformation of biochemical or physical inputs to ecosystems	<b>Mediation of wastes or toxic substances of anthropogenic origin by living processes</b>	<u>Bio-remediation</u> by micro-organisms, algae, plants, and animals; <u>Filtration/sequestration/storage/accumulation</u> by micro-organisms, algae, plants, and animals  <i>Example: changes caused by non-native organisms to ecosystem functioning and ability to filtrate etc. waste or toxics</i>
		<b>Mediation of nuisances of anthropogenic origin</b>	<u>Smell reduction</u> ; <u>noise attenuation</u> ; <u>visual screening</u> (e.g. by means of green infrastructure)  <i>Example: changes caused by non-native organisms to ecosystem structure, leading to reduced ability to mediate nuisances.</i>
	Regulation of physical, chemical, biological conditions	<b>Baseline flows and extreme event regulation</b>	<u>Control of erosion rates</u> ; <u>Buffering and attenuation of mass movement</u> ; <u>Hydrological cycle and water flow regulation</u> (Including flood control, and coastal protection); <u>Wind protection</u> ; <u>Fire protection</u>  <i>Example: changes caused by non-native organisms to ecosystem functioning or structure leading to, for example, destabilisation of soil, increased risk or intensity of wild fires etc.</i>
		<b>Lifecycle maintenance, habitat and gene pool protection</b>	<u>Pollination</u> (or 'gamete' dispersal in a marine context); <u>Seed dispersal</u> ; <u>Maintaining nursery populations and habitats</u> (Including gene pool protection)  <i>Example: changes caused by non-native organisms to the abundance and/or distribution of wild pollinators; changes to the availability / quality of nursery habitats for fisheries</i>
<b>Pest and disease control</b>		<u>Pest control</u> ; <u>Disease control</u>  <i>Example: changes caused by non-native organisms to the abundance and/or distribution of pests</i>	
		<b>Soil quality regulation</b>	<u>Weathering processes</u> and their effect on soil quality; <u>Decomposition and fixing processes</u> and their effect on soil quality  <i>Example: changes caused by non-native organisms to vegetation structure and/or soil fauna leading to reduced soil quality</i>

		<b>Water conditions</b>	<p>Regulation of the <u>chemical condition</u> of freshwaters by living processes;  Regulation of the chemical condition of salt waters by living processes</p> <p><i>Example: changes caused by non-native organisms to buffer strips along water courses that remove nutrients in runoff and/or fish communities that regulate the resilience and resistance of water bodies to eutrophication</i></p>
		<b>Atmospheric composition and conditions</b>	<p>Regulation of <u>chemical composition</u> of atmosphere and oceans;  Regulation of <u>temperature and humidity</u>, including ventilation and transpiration</p> <p><i>Example: changes caused by non-native organisms to ecosystems' ability to sequester carbon and/or evaporative cooling (e.g. by urban trees)</i></p>
<b>Cultural</b>	<b>Direct, in-situ and outdoor interactions</b> with living systems that depend on presence in the environmental setting	<b>Physical and experiential interactions</b> with natural environment	<p>Characteristics of living systems that enable activities promoting health, recuperation or enjoyment through <u>active or immersive interactions</u>;  Characteristics of living systems that enable activities promoting health, recuperation or enjoyment through <u>passive or observational interactions</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that make it attractive for recreation, wild life watching etc.</i></p>
		<b>Intellectual and representative interactions</b> with natural environment	<p>Characteristics of living systems that enable <u>scientific investigation</u> or the creation of traditional ecological knowledge;  Characteristics of living systems that enable <u>education and training</u>;  Characteristics of living systems that are resonant in terms of <u>culture or heritage</u>;  Characteristics of living systems that enable <u>aesthetic experiences</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have cultural importance</i></p>
	<b>Indirect, remote, often indoor interactions</b> with living systems that do not require	<b>Spiritual, symbolic and other interactions</b> with natural environment	<p>Elements of living systems that have <u>symbolic meaning</u>;  Elements of living systems that have <u>sacred or religious meaning</u>;  Elements of living systems used for <u>entertainment or representation</u></p>

	presence in the environmental setting		<i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have sacred or religious meaning</i>
		Other biotic characteristics that have a <b>non-use value</b>	<p>Characteristics or features of living systems that have an <u>existence value</u>;</p> <p>Characteristics or features of living systems that have an <u>option or bequest value</u></p> <p><i>Example: changes caused by non-native organisms to ecosystems designated as wilderness areas, habitats of endangered species etc.</i></p>

**ANNEX VII Delegated Regulation (EU) 2018/968 of 30 April 2018**

see <https://eur-lex.europa.eu/legal-content/en/TXT/?uri=CELEX%3A32018R0968>

## **ANNEX VIII *Callinectes sapidus* abiotic requirements and their availability in the Risk Assessment area**

The native range of *C. sapidus* in western Atlantic spans two continents, extending almost continuously from New England to Argentina (Millikin & Williams, 1984; Nehring, 2011), i.e., from 38.6S to 57.7N. Accordingly, the species experiences latitudinal variations in water temperature comprised between 0°C in winter at the extremes of its range and 32-33°C in transitional systems of the Caribbean area (Rodríguez, 2001; Johnson, 2015). In addition, populations in temperate areas generally experience comparable seasonal variations: in Chesapeake Bay, where one of the most abundant population in the US is established, water temperatures range between 3 and 32°C (e.g., Shiah and Ducklow, 1994). Winter temperatures appear to limit the native distribution of the species at high latitudes in both hemispheres, reflecting the thermal tolerance of the megalopa stage, as well the sensitivity of juveniles and mature females to water temperatures < 3°C (Rome et al., 2005; Hines et al., 2010). Thus, a northward expansion, as that observed in native ranges, should be expected also in European waters. Nevertheless, as with many other decapod species, the pelagic larval stages of *C. sapidus* have stricter abiotic requirements compared with the benthic adult and juveniles. Thus, in laboratory experiments *C. sapidus* larvae completed their development to the first crab at a minimum salinity of 20.1 psu (Costlow & Bookhout, 1959). This threshold is supported by field studies, where *C. sapidus* zoeae have been collected at salinities down to 20 psu in Chesapeake Bay (Sandifer, 1973) and the Mississippi Sound (Perry, 1973). Surface salinities in the Baltic Sea (beyond the western Baltic) and the Black Sea are lower than this threshold, most likely posing a limit for establishment in these marine regions. This is supported by the current lack of establishment of the species there, despite the repeated occurrence of adult specimens during the past few decades, particularly in the Black Sea (see section A of the RA for details). Casual populations are not unlikely to persist, given wider physiological tolerances and the lifespan of the adults. This is a provisional assessment because the Black Sea, with salinities in the range of 14-19 psu, presents a marginal environment for the species and a possible adaptation to slightly lower salinities cannot be discounted –

Temperatures suitable for spawning and larval development are reported as between 19-29°C in the native range and in the laboratory (Hill et al., 1989). Additionally, hatching of fertilised eggs from a locally captured specimen was reported by Nehring & van der Meer (2010) in a German aquarium at 19°C, which is a normal ambient summer temperature for the German Wadden Sea.

Thus, limiting factors for establishment were considered as:

Average surface temperature of the coldest month > 3°C

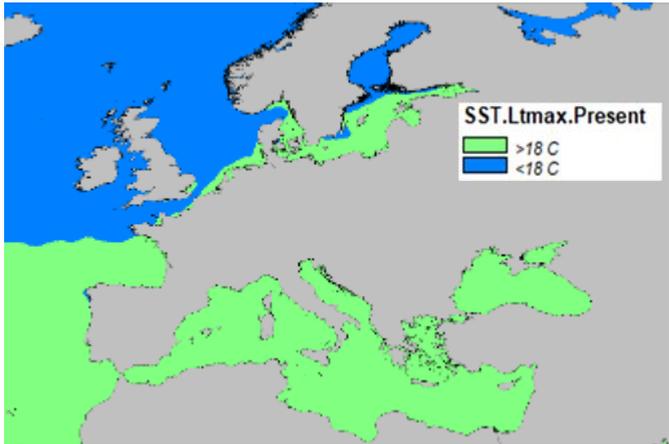

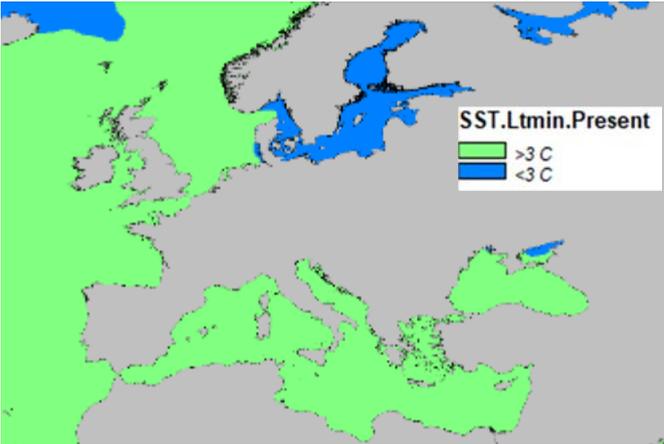

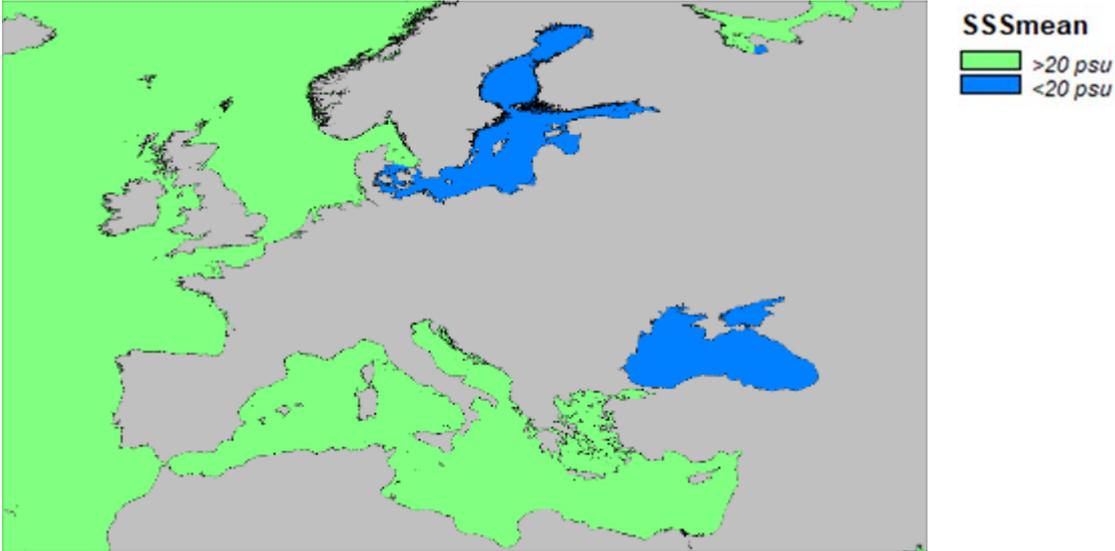

Average surface temperature of the warmest month > 18°C

Mean surface salinity > 20 psu

These limits are visualised in the maps below, prepared with data retrieved from BIO-ORACLE (Tyberghein et al., 2012, Assis et al. 2017).

Concerning the discrepancies between the produced binary maps and the predictions from the SDM

(see previous/following Annex), they are tentatively attributed to the following reasons; i) the high suitability of the low salinity marine subregions as predicted in the model is believed to be driven by an appreciable number of records in the Black Sea, which however refer to isolated captures of adult individuals. Additionally, small scale salinity variations are not likely to be reflected in the predictor data layer, which is modelled itself and not highly resolved, ii) the overwhelming contribution of the parameters bathymetry and maximum temperature to the model potentially masks the effect that minimum temperature can have on the predicted distribution of the species in areas where both parameters can act as limiting factors (i.e. the western Baltic Sea).

Accordingly, and taking into account the documented presence of the species currently in the RA area, the risk of establishment in the different marine subregions is assessed as follows:

#### **Present climatic conditions**

Baltic Sea: unlikely, high confidence (western Baltic – low winter temperatures)

Greater North Sea: likely, medium confidence (localized establishment, southern North Sea)

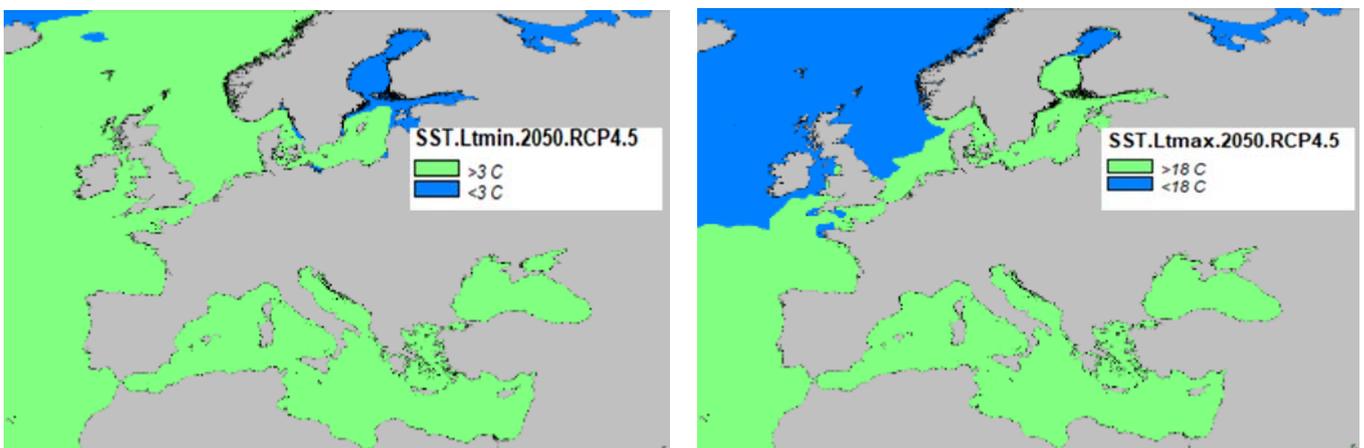

Celtic Seas: unlikely, medium confidence

Bay of Biscay and the Iberian coast: very likely, high confidence

Mediterranean Sea: very likely, high confidence

Black Sea: unlikely/moderately likely, medium confidence

#### **Future climatic conditions**

Baltic Sea: unlikely, high confidence (except for the western Baltic = likely)

Greater North Sea: very likely, high confidence

Celtic Seas: moderately likely, medium confidence

Bay of Biscay and the Iberian coast: very likely, high confidence

Mediterranean Sea: very likely, high confidence

Black Sea: unlikely/moderately likely, low confidence

## **ANNEX IX Species distribution model**

### **Projection of environmental suitability for *Callinectes sapidus* establishment in Europe**

Björn Beckmann, Argyro Zenetos, Giorgio Mancinelli, Marika Galanidi, Paraskevi Karachle and Dan Chapman

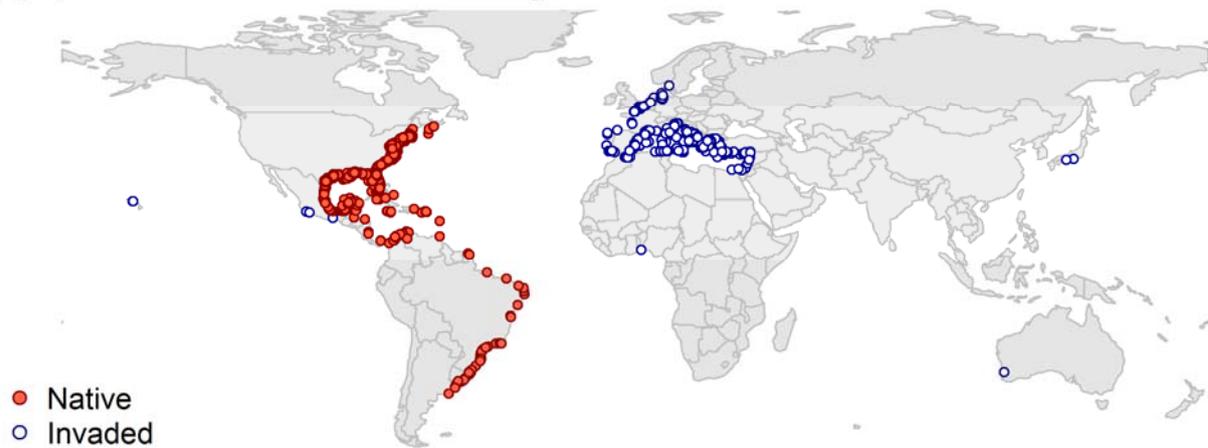

#### ***Aim***

To project the suitability for potential establishment of *Callinectes sapidus* in Europe, under current and predicted future climatic conditions.

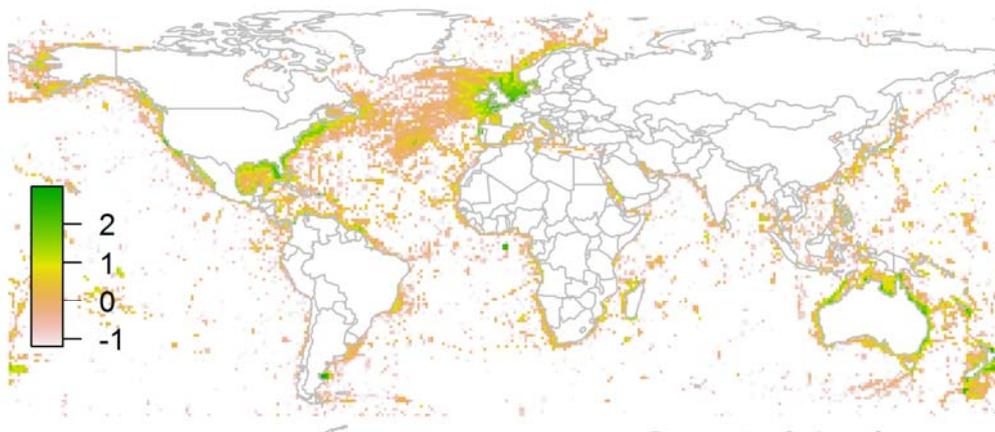

#### ***Data for modelling***

Species occurrence data were obtained from a recently published dataset of global occurrences of *Callinectes sapidus* comprising verified records from the Global Biodiversity Information Facility (GBIF) (23678 records), the Ocean Biogeographic Information System (OBIS) (834 records), the Biodiversity Information Serving Our Nation database (BISON) (784 records), iNaturalist (44 records), and a further 549 records from 177 publications (Mancinelli et al. 2020). We removed any occurrence records where the georeferencing was too imprecise or outside of the coverage of the predictor layers. We also removed any records at locations with sea depths below -1000m, and any with mean sea surface salinity values below 20 PSU, because these are likely to represent dispersing individuals, not established populations. The records were gridded at a 0.25 x 0.25 degree resolution for modelling, yielding 820 grid cells with occurrences (Figure 1a). As a proxy for recording effort, the density of Decapoda records held by GBIF was also compiled on the same grid (Figure 1b).

(a) Species distribution used in modelling

(b) Estimated recording effort (log10-scaled)

**Figure 1.** (a) Occurrence records obtained for *Callinectes sapidus* and used in the modelling, showing native and invaded distributions. (b) The recording density of Decapoda on GBIF, which was used as a proxy for recording effort.

Predictors describing the marine environment were selected from the ‘Bio-ORACLE2’ set of GIS rasters providing geophysical, biotic and environmental data for surface and benthic marine realms (Tyberghein et al., 2012, Assis et al. 2017), originally at 5 arcminute resolution (0.083 x 0.083 degrees of longitude/latitude) and aggregated to a 0.25 x 0.25 degree grid for use in the model.

Based on the biology of *Callinectes sapidus*, the following variables were used in the modelling:

- Maximum long-term temperature (templtmax\_ss)
- Minimum long-term temperature (templtmin\_ss)
- Mean salinity (salinitymean\_ss)
- Mean bathymetry (bathymean)

All parameters (except depth) are measured at the sea surface.

To estimate the effect of climate change on the potential distribution of *Callinectes sapidus*, equivalent modelled future conditions for the 2070s under the Representative Concentration Pathways (RCP) 2.6 and 4.5 were also obtained. These represent low and medium emissions scenarios, respectively. Projections for the 2070s were calculated as averages of projections for the 2040s and 2090s (which are the time periods available on Bio-ORACLE).

### *Species distribution model*

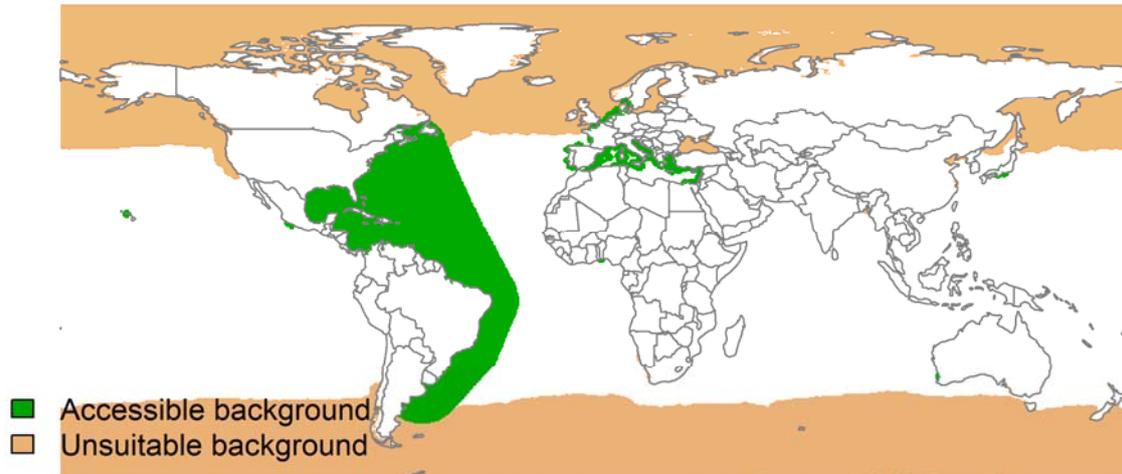

A presence-background (presence-only) ensemble modelling strategy was employed using the BIOMOD2 R package version 3.4.6 (Thuiller et al., 2020, Thuiller et al., 2009). These models contrast the environment at the species' occurrence locations against a random sample of the global background environmental conditions (often termed 'pseudo-absences') in order to characterise and project suitability for occurrence. This approach has been developed for distributions that are in equilibrium with the environment. Because invasive species' distributions are not at equilibrium and subject to dispersal constraints at a global scale, we took care to minimise the inclusion of locations suitable for the species but where it has not been able to disperse to (Chapman et al. 2019). Therefore the background sampling region included:

- The area accessible by native *Callinectes sapidus* populations, in which the species is likely to have had sufficient time to disperse to all locations. Based on presumed maximum dispersal distances, the accessible region was defined as a 1000km buffer around the native range occurrences (the Pacific Ocean was excluded from this area because *Callinectes sapidus* occurs only on the Atlantic coasts of North and South America and historically could not readily disperse to the Pacific side); AND
- A 150km buffer around the non-native occurrences, encompassing regions likely to have had high propagule pressure for introduction by humans and/or dispersal of the species; AND
- Regions where we have an *a priori* expectation of high unsuitability for the species so that absence is assumed irrespective of dispersal constraints (see Figure 2). The following rules were applied to define a region expected to be highly unsuitable for *Callinectes sapidus* at the spatial scale of the model:
  - Maximum long-term temperature (templtmax\_ss) < 18°C
  - Minimum long-term temperature (templtmin\_ss) < 3°C
  - Mean salinity (salinitymean\_ss) < 20 PSU

Altogether, 4.8% of occurrence grid cells were located in the unsuitable background region.

Within the unsuitable background region, 10 samples of 5000 randomly sampled grid cells were obtained. In the accessible background (comprising the accessible areas around native and non-native occurrences as detailed above), the same number of pseudo-absence samples were drawn as there were presence records (820), weighting the sampling by a proxy for recording effort (Figure 2).

**Figure 2.** The background from which pseudo-absence samples were taken in the modelling of *Callinectes sapidus*. Samples were taken from a 1000km buffer around the native range and a 150km buffer around non-native occurrences (together forming the accessible background), and from areas expected to be highly unsuitable for the species (the unsuitable background region). Samples from the accessible background were weighted by a proxy for recording effort (Figure 1(b)).

**Figure 2.** The background from which pseudo-absence samples were taken in the modelling of *Callinectes sapidus*. Samples were taken from a 1000km buffer around the native range and a 150km buffer around non-native occurrences (together forming the accessible background), and from areas expected to be highly unsuitable for the species (the unsuitable background region). Samples from the accessible background were weighted by a proxy for recording effort (Figure 1(b)).

Each dataset (i.e. combination of the presences and the individual background samples) was randomly split into 80% for model training and 20% for model evaluation. With each training dataset, five statistical algorithms were fitted with the default BIOMOD2 settings and rescaled using logistic regression, except where specified below:

- Generalised linear model (GLM)
- Generalised boosting model (GBM)
- Generalised additive model (GAM) with a maximum of four degrees of freedom per smoothing spline
- Random forest (RF)
- Maxent

Since the total background sample was larger than the number of occurrences, prevalence fitting weights were applied to give equal overall importance to the occurrences and the background. Normalised variable importance was assessed and variable response functions were produced using BIOMOD2's default procedure.

Model predictive performance was assessed by the following three measures:

- AUC, the area under the receiver operating characteristic curve (Fielding & Bell 1997). Predictions of presence-absence models can be compared with a subset of records set aside for model evaluation (here 20%) by constructing a confusion matrix with the number of true positive, false positive, false negative and true negative cases. For models generating non-dichotomous scores (as here) a threshold can be applied to transform the scores into a dichotomous set of presence-absence predictions. Two measures that can be derived from the confusion matrix are sensitivity (the proportion of observed presences that are predicted as such,

quantifying omission errors), and specificity (the proportion of observed absences that are predicted as such, quantifying commission errors). A receiver operating characteristic (ROC) curve can be constructed by using all possible thresholds to classify the scores into confusion matrices, obtaining sensitivity and specificity for each matrix, and plotting sensitivity against the corresponding proportion of false positives (equal to 1 - specificity). The use of all possible thresholds avoids the need for a selection of a single threshold, which is often arbitrary, and allows appreciation of the trade-off between sensitivity and specificity. The area under the ROC curve (AUC) is often used as a single threshold-independent measure for model performance (Manel, Williams & Ormerod 2001). AUC is the probability that a randomly selected presence has a higher model-predicted suitability than a randomly selected absence (Allouche et al. 2006).

- Cohen's Kappa (Cohen 1960). This measure corrects the overall accuracy of model predictions (ratio of the sum of true presences plus true absences to the total number of records) by the accuracy expected to occur by chance. The kappa statistic ranges from -1 to +1, where +1 indicates perfect agreement and values of zero or less indicate a performance no better than random. Advantages of kappa are its simplicity, the fact that both commission and omission errors are accounted for in one parameter, and its relative tolerance to zero values in the confusion matrix (Manel, Williams & Ormerod 2001). However, Kappa has been criticised for being sensitive to prevalence (the proportion of sites in which the species was recorded as present) and may therefore be inappropriate for comparisons of model accuracy between species or regions (McPherson, Jetz & Rogers 2004, Allouche et al. 2006).
- TSS, the true skill statistic (Allouche et al. 2006). TSS is defined as sensitivity + specificity - 1, and corrects for Kappa's dependency on prevalence. TSS compares the number of correct forecasts, minus those attributable to random guessing, to that of a hypothetical set of perfect forecasts. Like kappa, TSS takes into account both omission and commission errors, and success as a result of random guessing, and ranges from -1 to +1, where +1 indicates perfect agreement and values of zero or less indicate a performance no better than random (Allouche et al. 2006).

An ensemble model was created by first rejecting poorly performing algorithms with relatively extreme low AUC values and then averaging the predictions of the remaining algorithms, weighted by their AUC. To identify poorly performing algorithms, AUC values were converted into modified z-scores based on their difference to the median and the median absolute deviation across all algorithms (Iglewicz & Hoaglin, 1993). Algorithms with  $z < -2$  were rejected. In this way, ensemble projections were made for each dataset and then averaged to give an overall suitability, as well as its standard deviation. The projections were then classified into suitable and unsuitable regions using the 'minROCDist' method, which minimizes the distance between the ROC plot and the upper left corner of the plot (point (0,1)).

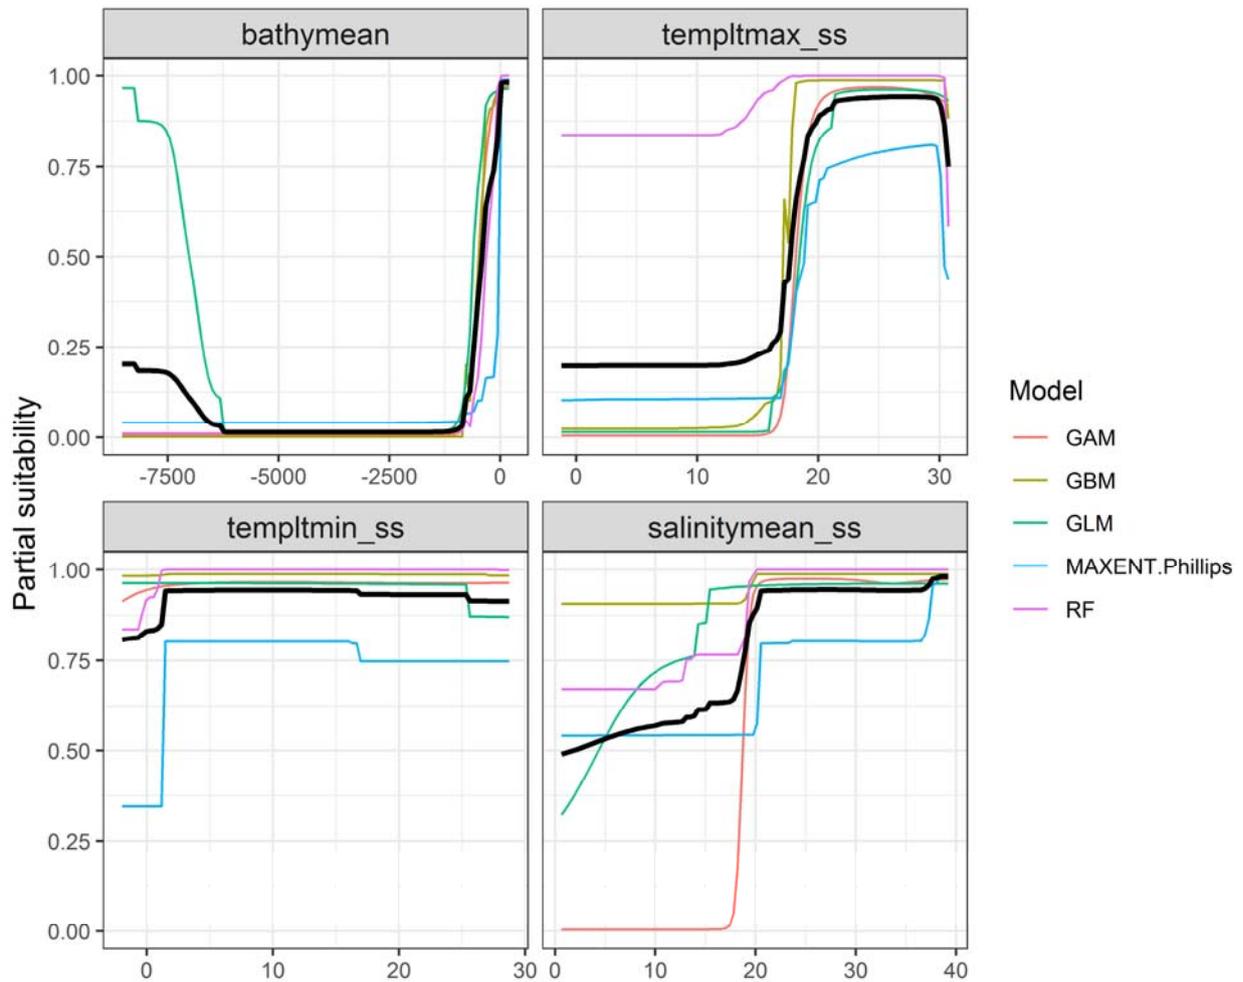

We also produced limiting factor maps for Europe following Elith et al. (2010). For this, projections were made separately with each individual variable fixed at a near-optimal value. These were chosen as the median values at the occurrence grid cells. Then, the most strongly limiting factors were identified as the one resulting in the highest increase in suitability in each grid cell.

## Results

The ensemble model suggested that suitability for *Callinectes sapidus* was most strongly determined by Mean bathymetry (bathymean), accounting for 54% of variation explained, followed by Maximum long-term temperature (templtmax\_ss) (40.4%), Minimum long-term temperature (templtmin\_ss) (3.3%) and Mean salinity (salinitymean\_ss) (2.3%) (Table 1, Figure 3).

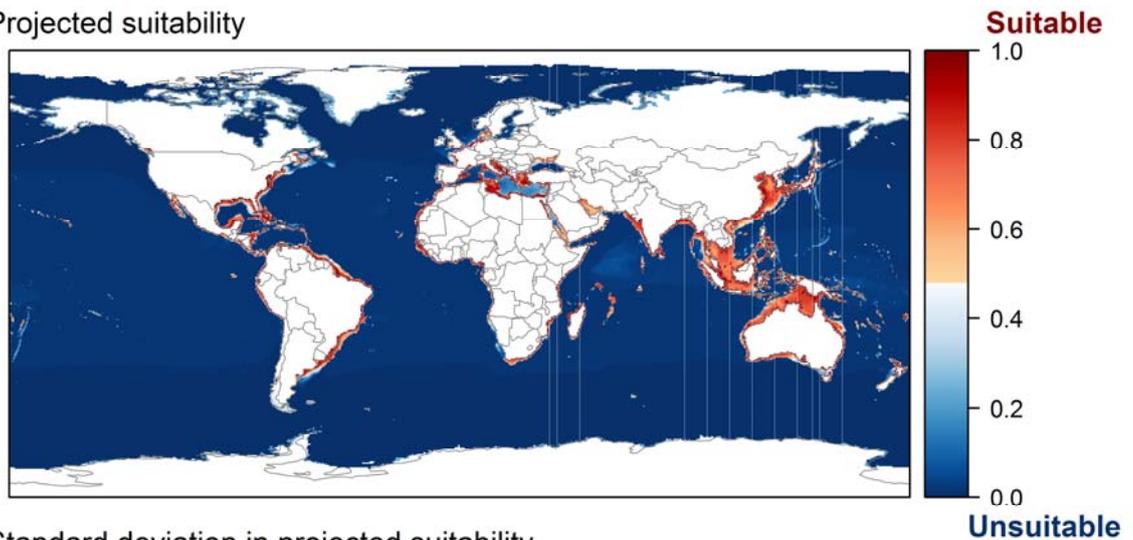

**Table 1.** Summary of the cross-validation predictive performance (ROC, Kappa, TSS) and variable importance of the fitted model algorithms and the ensemble (AUC-weighted average of the best performing algorithms). Results are the average from models fitted to 10 different background samples of the data.

Algorithm	AUC	Kappa	TSS	Used in the ensemble	Variable importance (%)			
					Mean bathymetry (bathymean)	Maximum long-term temperature (templtmax_ss)	Minimum long-term temperature (templtmin_ss)	Mean salinity (salinitymean_ss)
GLM	0.977	0.802	0.917	yes	40	58	1	1
GAM	0.986	0.825	0.928	yes	41	56	1	1
GBM	0.995	0.896	0.948	yes	47	51	1	1
RF	0.996	0.915	0.959	yes	73	17	7	3
Maxent	0.985	0.866	0.917	yes	68	21	6	5
<b>Ensemble</b>	<b>0.996</b>	<b>0.908</b>	<b>0.948</b>		<b>54</b>	<b>40</b>	<b>3</b>	<b>2</b>

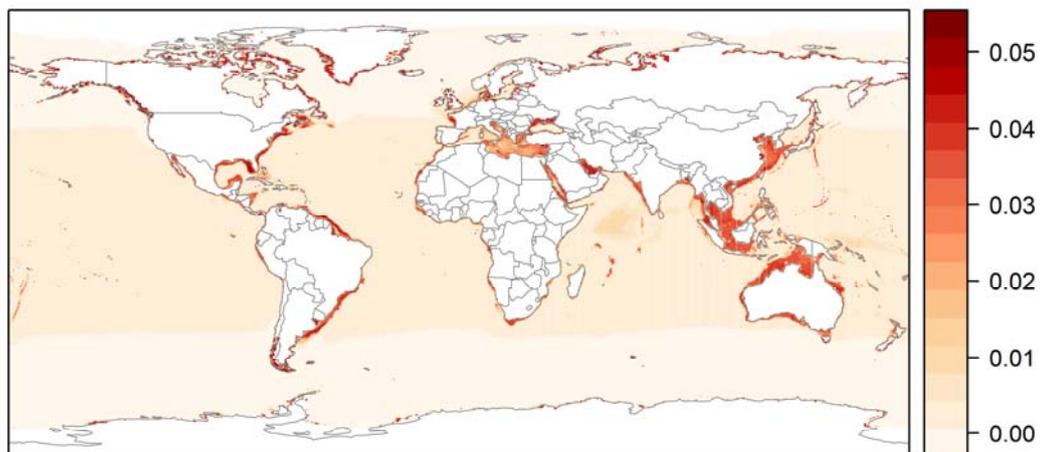

**Figure 3.** Partial response plots from the fitted models. Thin coloured lines show responses from the algorithms in the ensemble, while the thick black line is their ensemble. In each plot, other model variables are held at their median value in the training data. Some of the divergence among algorithms is because of their different treatment of interactions among variables.

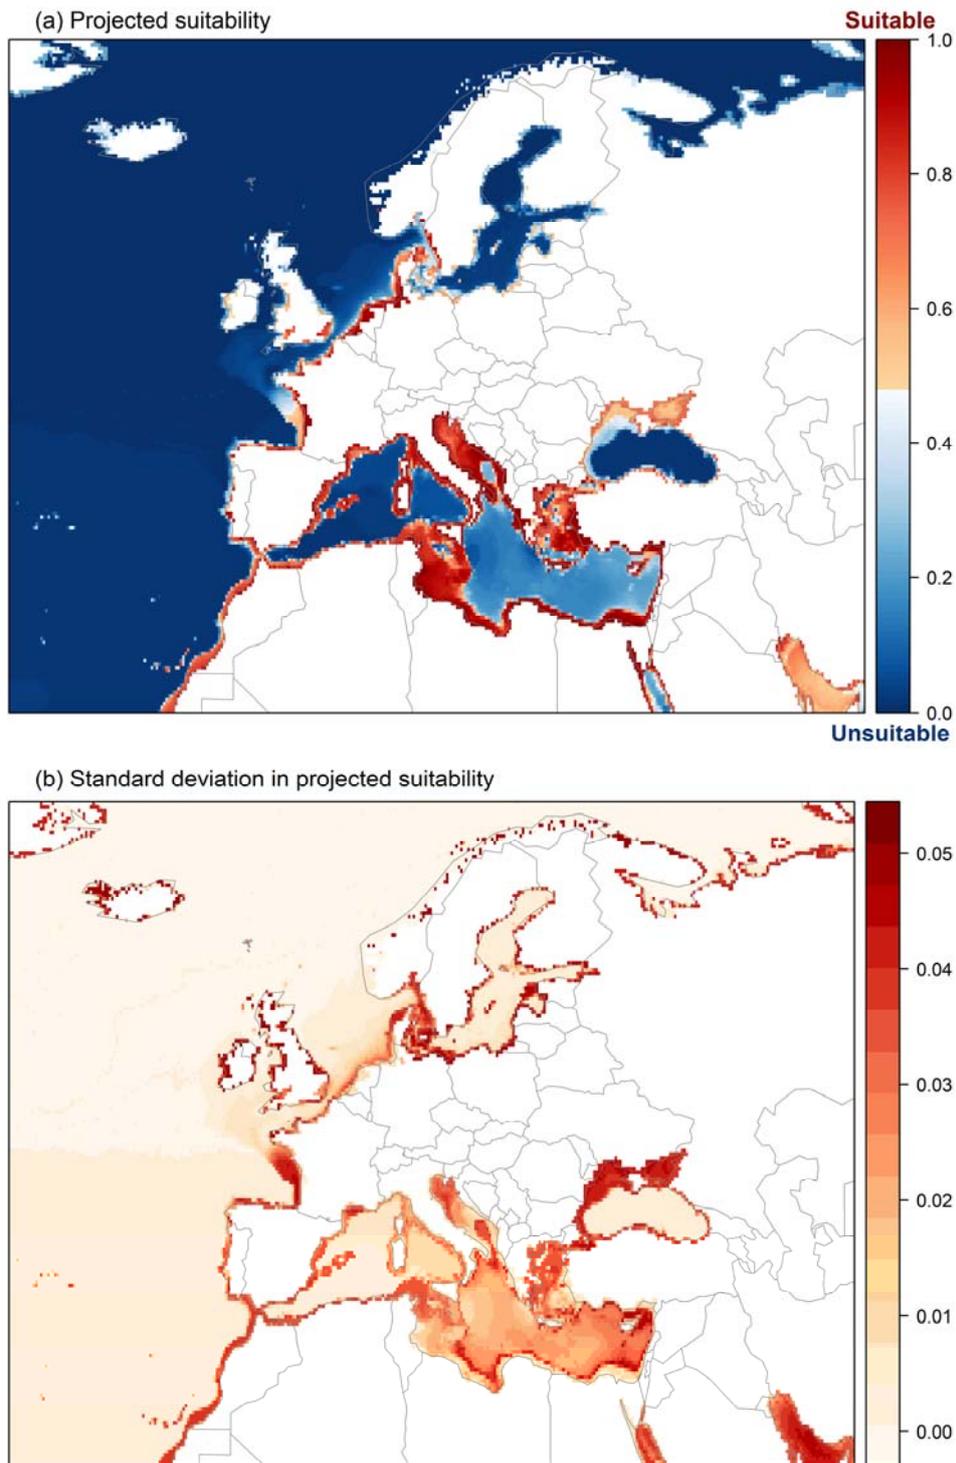

(a) Projected suitability

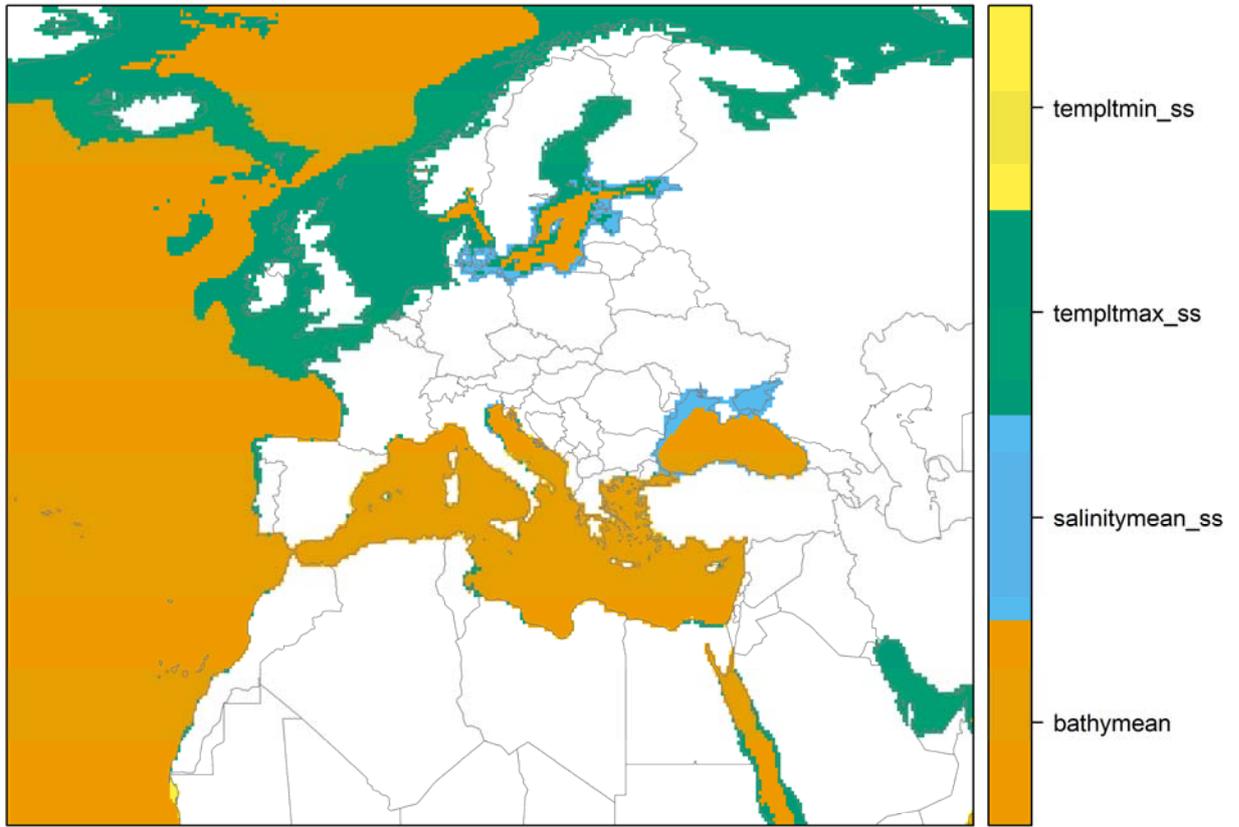

(b) Standard deviation in projected suitability

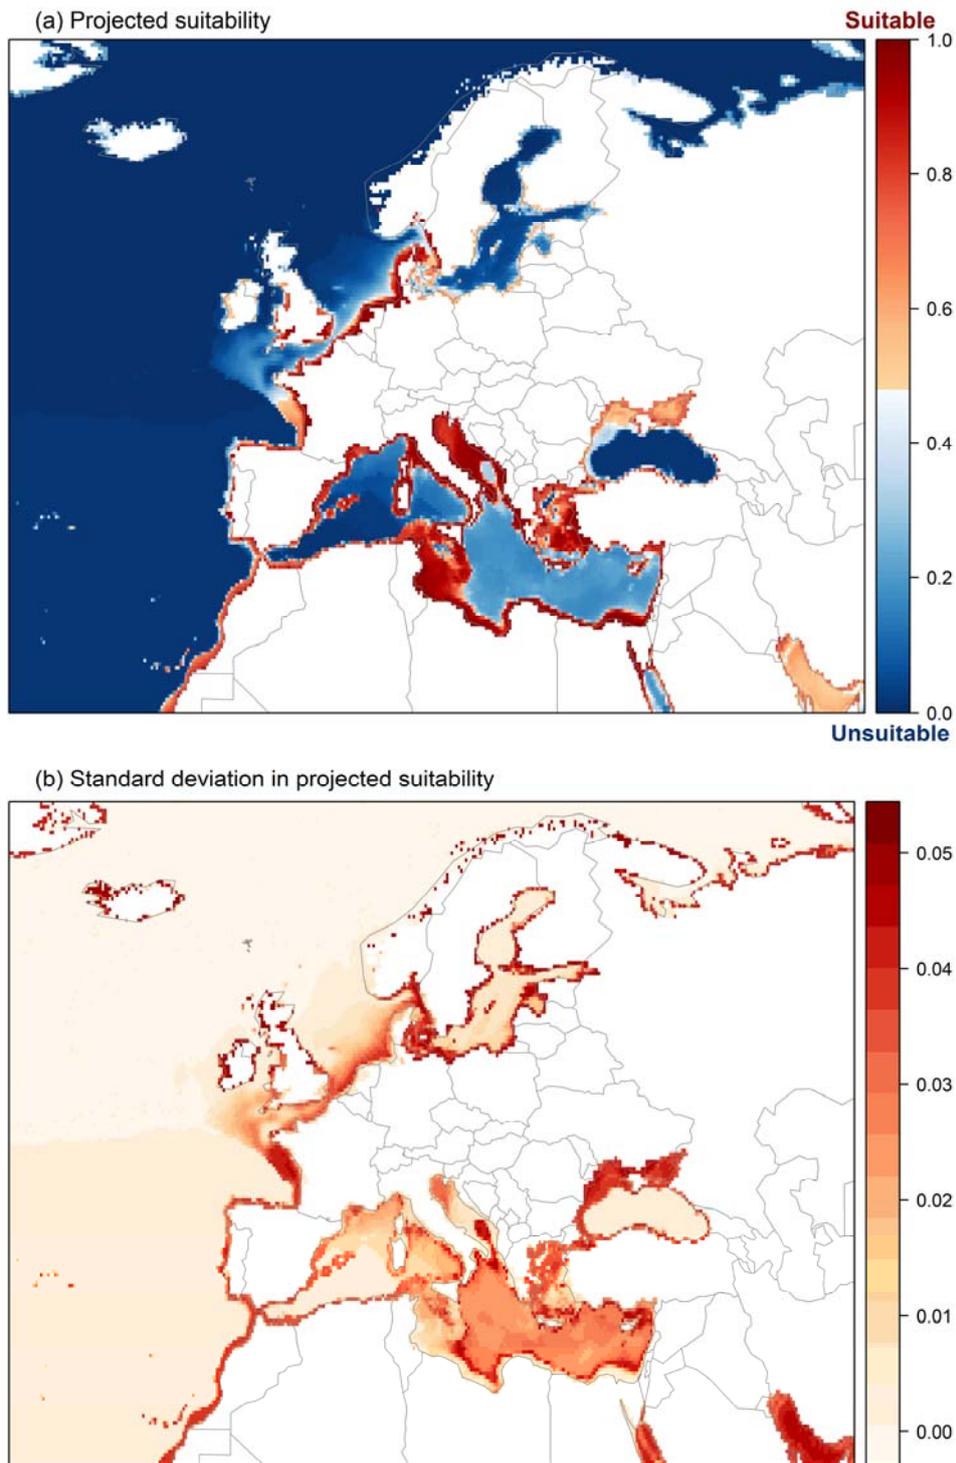

**Figure 4.** (a) Projected global suitability for *Callinectes sapidus* establishment in the current climate. For visualisation, the projection has been aggregated to a 0.5 x 0.5 degree resolution, by taking the maximum suitability of constituent higher resolution grid cells. Values > 0.48 may be suitable for the species. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

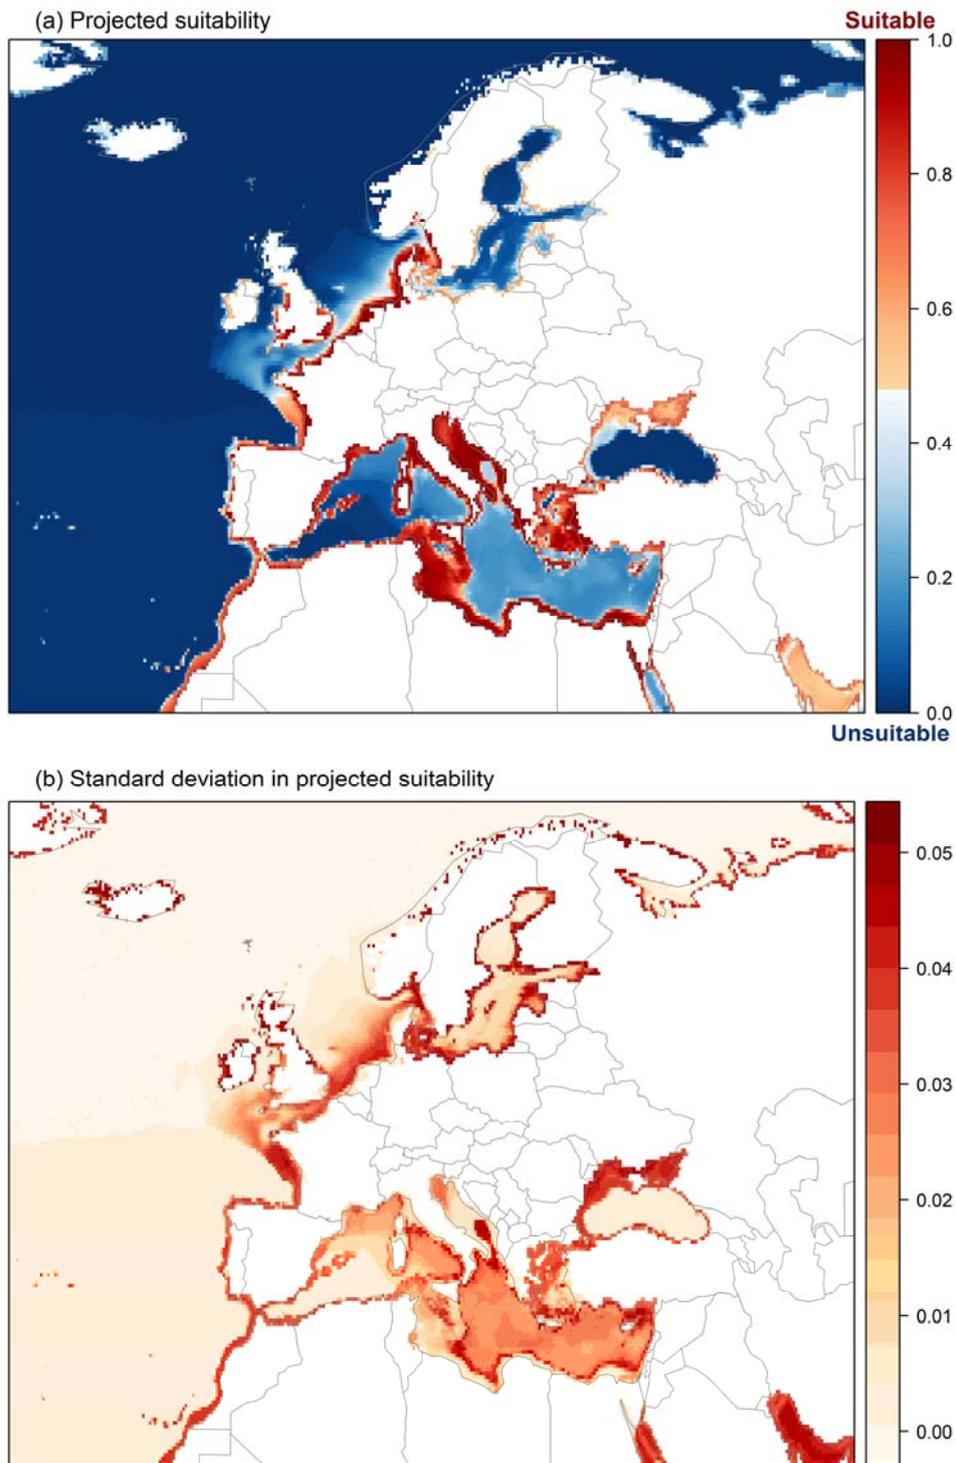

**Figure 5.** (a) Projected current suitability for *Callinectes sapidus* establishment in Europe and the Mediterranean region. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

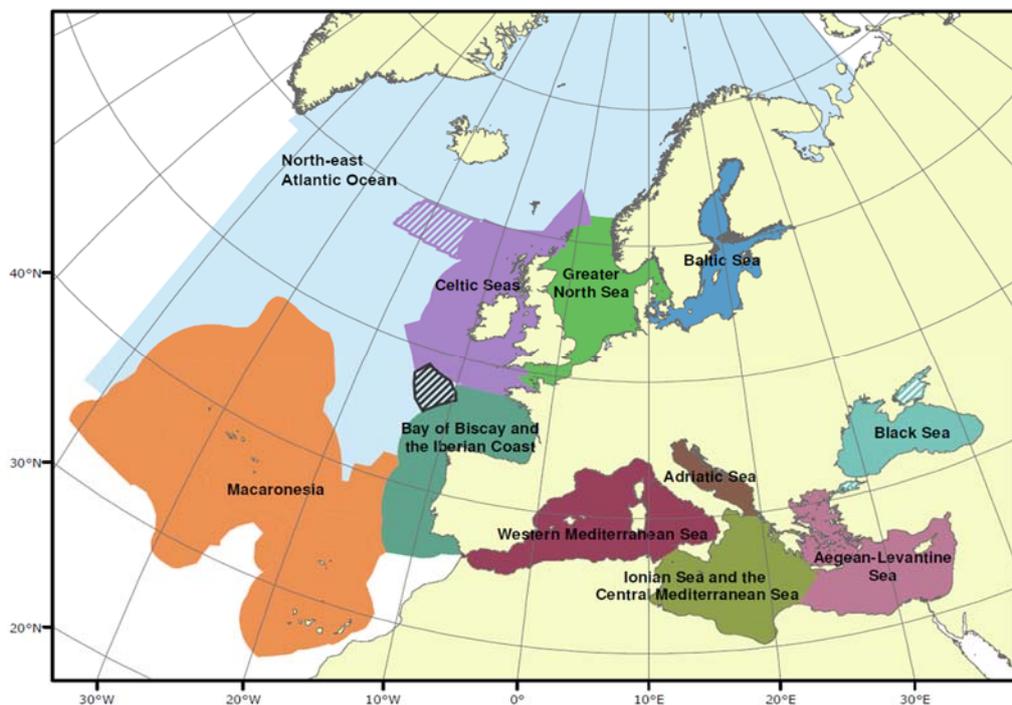

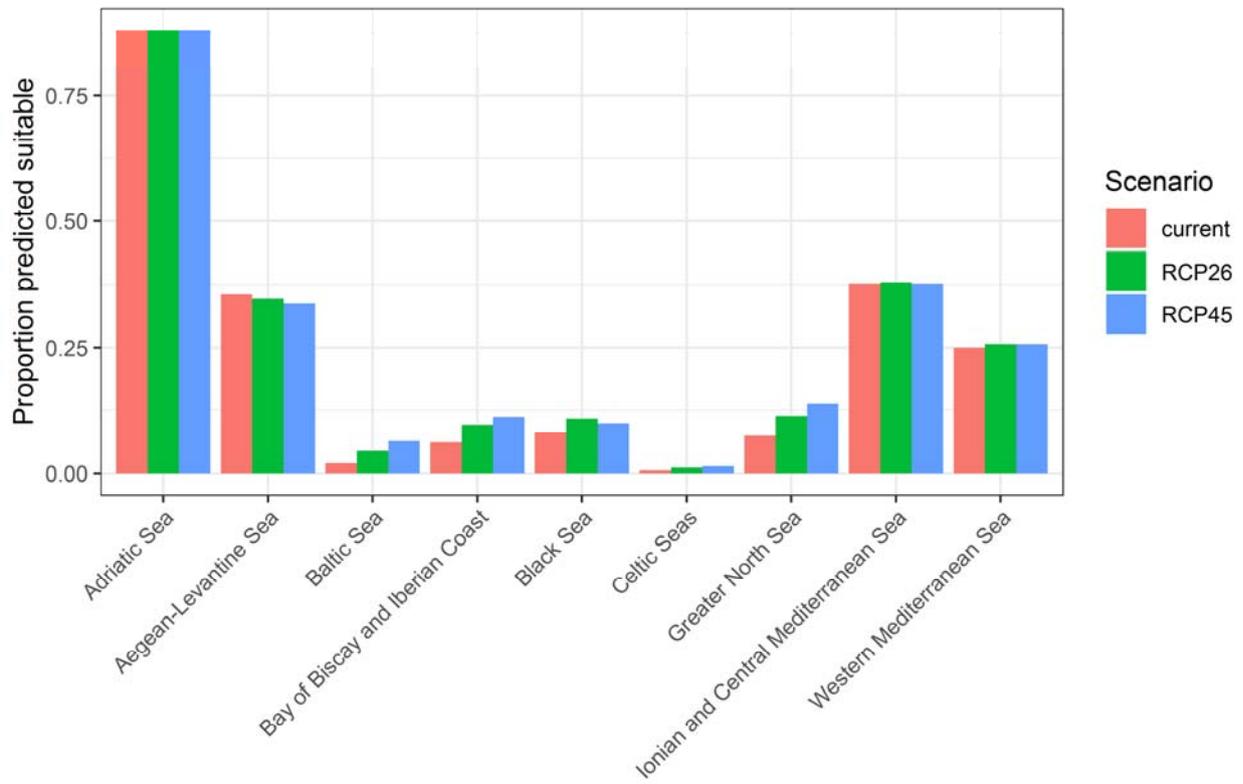

**Figure 6.** The most strongly limiting factors for *Callinectes sapidus* establishment estimated by the model in Europe and the Mediterranean region in current climatic conditions.

**Figure 7.** (a) Projected suitability for *Callinectes sapidus* establishment in Europe and the Mediterranean region in the 2070s under climate change scenario RCP2.6, equivalent to Figure 5. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

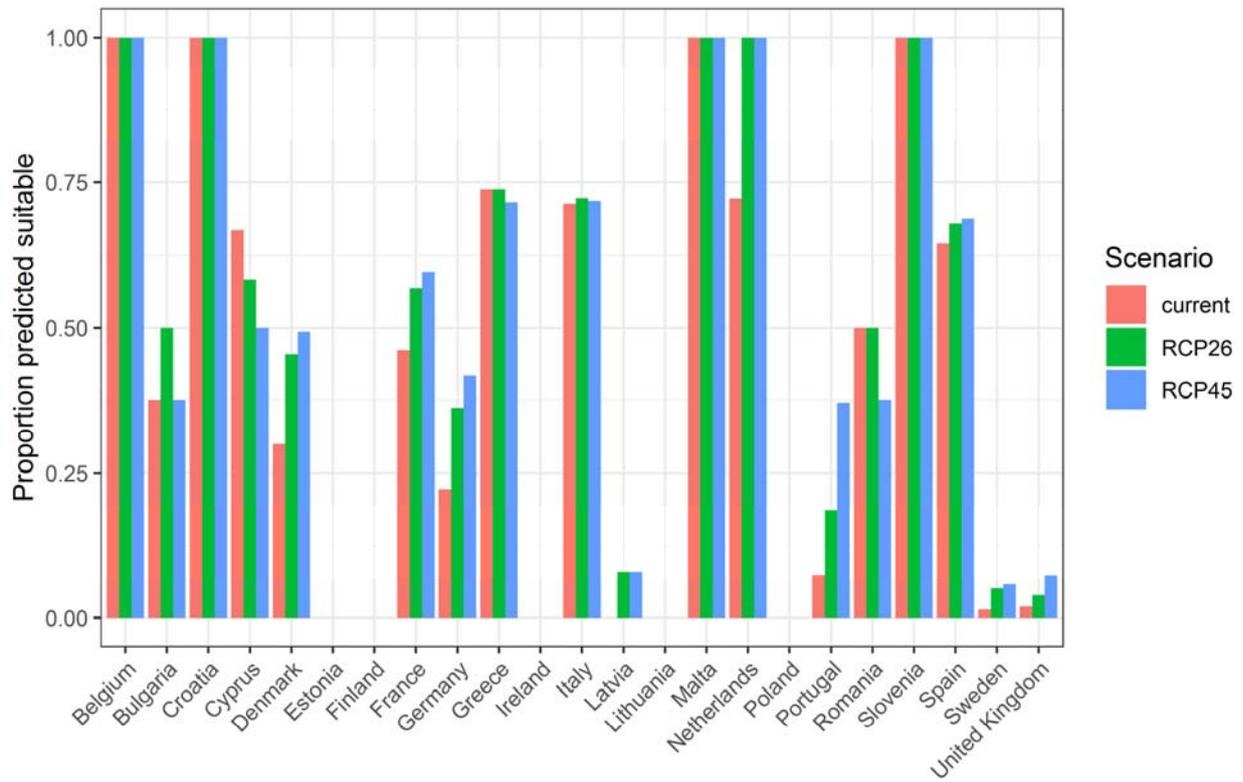

**Figure 8.** (a) Projected suitability for *Callinectes sapidus* establishment in Europe and the Mediterranean region in the 2070s under climate change scenario RCP4.5, equivalent to Figure 5. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

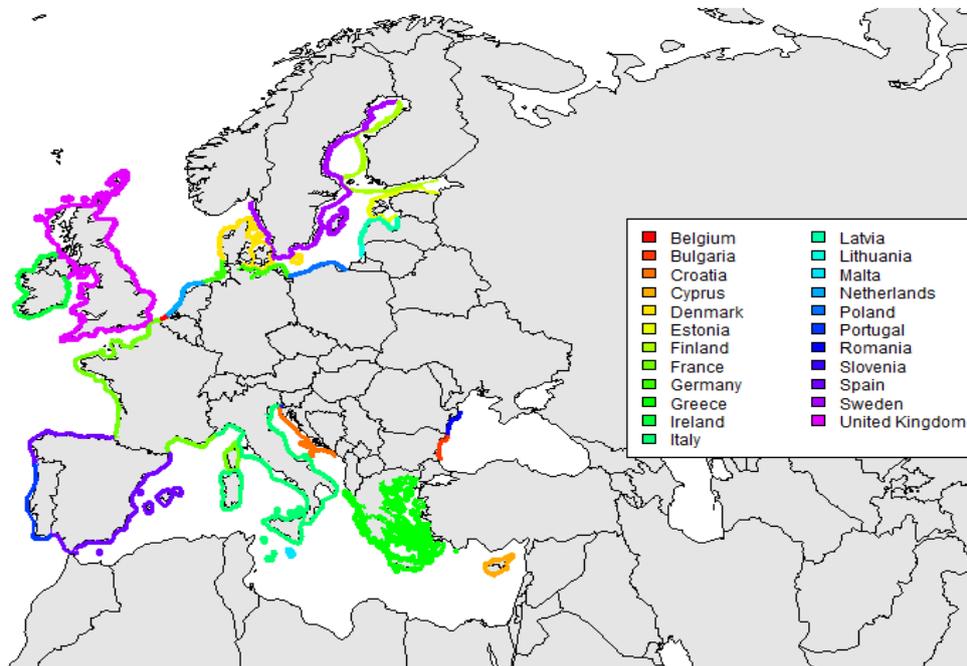

**Figure 9.** Variation in projected suitability for *Callinectes sapidus* establishment among marine subregions of Europe. The bar plots show the proportion of grid cells in each region classified as suitable in the current climate and projected climate for the 2070s under two RCP emissions scenarios. The location of each region is also shown. Macaronesia is excluded as it is not part of the study area.

**Table 2.** Variation in projected suitability for *Callinectes sapidus* establishment among marine subregions of Europe (numerical values of Figure 9 above). The numbers are the proportion of grid cells in each region classified as suitable in the current climate and projected climate for the 2070s under two RCP emissions scenarios.

<b>Region</b>	<b>current climate</b>	<b>RCP26</b>	<b>RCP45</b>
Adriatic Sea	0.88	0.88	0.88
Aegean-Levantine Sea	0.36	0.35	0.34
Baltic Sea	0.02	0.04	0.06
Bay of Biscay and Iberian Coast	0.06	0.10	0.11

### *Caveats to the modelling*

To remove spatial recording biases, the selection of the background sample from the accessible background was weighted by the density of Decapoda records on the Global Biodiversity Information Facility (GBIF). While this is preferable to not accounting for recording bias at all, it may not provide the perfect measure of recording bias.

There was substantial variation among modelling algorithms in the partial response plots (Figure 3). In part this will reflect their different treatment of interactions among variables. Since partial plots are made with other variables held at their median, there may be values of a particular variable at which this does not provide a realistic combination of variables to predict from.

Other variables potentially affecting the distribution of the species, such as underwater vegetation were not included in the model.

# Revision of the Risk assessment of the North American beaver (*Castor canadensis*), as based on Member State comments

## Introduction

This document explains how the comments received through the Scientific Forum and the consultation of stakeholders on the **Risk assessment of the North American beaver (*Castor canadensis*)** by Hollander et al. (2017)<sup>1</sup> have been considered.

Disclaimer: The authors of the present document have prepared this note with the only purpose of processing the Member States comments to the original Risk Assessment by Hollander et al. (2017), at the request of the European Commission. The present document does not represent an endorsement of the statements and scores given within the original document. Since the focus of this document was limited to the Member States comments, it cannot be considered as a comprehensive revision of the original document, whose contents remain the sole responsibility of the original authors.

Name of species assessed: <i>Castor canadensis</i> Kuhl, 1820
Date of completion of this document: 14/01/2021
Member States that provided comments: <ul style="list-style-type: none"><li>• <b>Austria</b> (AT)</li><li>• <b>Czech Republic</b> (CZ)</li><li>• <b>Finland</b> (FI)</li><li>• <b>France</b> (FR)</li><li>• <b>Hungary</b> (HU)</li><li>• <b>Luxembourg</b> (LU)</li></ul>
Stakeholder organizations that provided comments: none.

## Outline

The first part of this document highlights how the comments from Member States have been dealt with, in particular the general comments. Also, the few comments that were not processed are discussed in this part, providing explanations for not processing them.

The second part of this document deals with the specific comments from Member States. The text should be read as an addendum and corrigendum to the original risk assessment (Hollander et al. 2017). The headings from the original assessment are repeated to facilitate direct comparison.

(2017) Risk assessment of the alien North American beaver (*Castor canadensis*). © Department of Environmental Science, Radboud University, 6525 AJ Nijmegen, The Netherlands

References that were included in the original risk assessment are not repeated. New references are provided at the end of this document.

## Part 1: Comments per Member State

This part deals with the general comments provided by the Member States, and the (few) comments that were not processed.

### Austria (AT)

AT suggested a *minor revision*.

**Comment from Member State:** AT suggested to more clearly refer to the criteria for risk assessments set out by the Regulation, as it is sometimes difficult to find the necessary information.

**Answer:** The common elements of risk assessments are defined by Article 5 of the Regulation 1143/2014 of 22 October 2014. All elements are addressed in the assessment, though not necessarily in the prescribed order (Table 1).

Table 1 -- The elements of risk assessments as defined by Regulation 1143/2014, and the headings under which they are treated by Hollander et al. (2017)

Element	Headings
Art 5(1)(a) — <i>a description of the species with its taxonomic identity, its history, and its natural and potential range</i>	2.1, 2.2, 2.3
Art 5(1)(b) — <i>a description of its reproduction and spread patterns and dynamics including an assessment of whether the environmental conditions necessary for its reproduction and spread exist</i>	2.1, 2.3
Art 5(1)(c) — <i>a description of the potential pathways of introduction and spread of the species, both intentional and unintentional, including where relevant the commodities with which the species is generally associated</i>	2.4
Art 5(1)(d) — <i>a thorough assessment of the risk of introduction, establishment and spread in relevant biogeographical regions in current conditions and in foreseeable climate change conditions</i>	3.1, 3.2
Art 5(1)(e) — <i>a description of the current distribution of the species, including whether the species is already present in the Union or in neighbouring countries, and a projection of its likely future distribution</i>	2.2, 2.3
Art 5(1)(f) — <i>a description of the adverse impact on biodiversity and related ecosystem services, including on native species, protected sites, endangered habitats, as well as on human health, safety, and the economy including an assessment of the potential future impact having regard to available scientific knowledge</i>	2.5*
Art 5(1)(g) — <i>an assessment of the potential costs of damage</i>	2.5
Art 5(1)(h) — <i>a description of the known uses for the species and social and economic benefits deriving from those uses</i>	(2.5)

\*But note: section 2.5.7 is more on climate change effects on distribution rather than impact

**Comment from Member State:** The risk assessment argues that climate change is expected to have no effect on the risks related to *C. canadensis*. AT points out that this argument is questionable, since some breeding parameters do relate to climate.

**Answer:** *C. canadensis* produces 1 litter per year, irrespective of latitude or climate, but the severity of winter weather is indeed considered an important factor influencing litter size (Jenkins & Busher 1979). In this respect, the rate of spread might indeed be increased under future winter conditions. However, the risk of spread was already considered maximal under the Harmonia<sup>+</sup> and ISEIA scoring (Tables 3.1 and 3.2). The conclusion thus holds that climate change is not expected to alter the overall risk. As set out under 3.2.2, the ISEIA assessment was effectively repeated under the assumption of

future conditions. But since this gave the same results as when assuming current conditions, the table shows the results only once.

There is no dedicated species distribution model (SDM) for *C. canadensis* in Europe available. Alakoski et al. (2020) provide distribution models for Finland, but also highlight that the models have difficulty filtering out the invasion history. Therefore, to provide more insights if climate change might alter the overall risk, a dedicated SDM should be made. It should be mentioned, however, that a dedicated SDM is not required by Art. 5 of the Regulation (see Table 1).

**Comment from Member State:** AT points out that a risk assessment is available for Germany, based on the GABLIS method.

**Answer:** References to that assessment are included, and its results discussed (3.3, below).

**Comment from Member State:** AT suggests to explicitly list biogeographical regions and Member States in which the species is established, and is potentially able to establish in.

**Answer:** Although a bit scattered, this information is addressed under 2.2, 2.3.2 (current Member States); 2.3.4 (current regions); 2.3.4 and 2.3.5 (potential states and regions). The information is summarised in Tables 2 and 3 below. Not all Member States were explicitly considered by Hollander et al. (2017). As it is acknowledged that the distribution of *C. fiber* provides a useful proxy for the potential distribution of *C. canadensis* in Europe (2.3.4), the suitability for missing Member States is considered on that basis in Table 2 (Wróbel 2020). This leaves four Member States for which potential establishment of *C. canadensis* remains unascertained.

Table 2 – Summary of the status of *C. canadensis* in Member States of the European Union, and the United Kingdom

Pannonian	Yes	No	Yes <sup>2,3,4</sup>	No
Steppic	No	No	Yes <sup>3</sup>	No

(1) As Hollander et al. (2017) provide historic records at Member State level only, assigning them to biogeographic regions is somewhat complicated. (2) Based on informations given in Hollander et al. (2017: 2.3.4 and 2.3.5). (3) Based on the current presence of *Castor fiber*, the latest distribution map of which is provided by Halley et al. (2021). (4) Based on distributional data provided in GBIF (2020).

Other specific comments are dealt with in the second part of this document.

## Czech Republic (CZ)

CZ suggested a *minor revision*.

**Comment from Member State:** CZ would prefer to see more information that allows for comparisons among *C. canadensis* and *C. fiber* (e.g. costs and impact). Also, more detail on how local managers can differentiate between the two species would be useful.

**Answer:** The risk assessment (Hollander et al. 2017) already extensively compares *C. canadensis* with *C. fiber* in terms of species characteristics (2.1), habitat (2.3) and impacts (2.5). Two new references give supplementing information on *C. fiber* management in Europe (see addition to 2.5.5 below).

Without the necessary expertise, there is no means for local managers to reliably distinguish the two species. Reliable methods are based on DNA or anal gland secretion (Rosell & Sun 1999), or skull morphometry (Jenkins & Busher 1979). See 2.4.

Other specific comments are dealt with in the second part of this document.

## Finland (FI)

FI provided numerous specific comments, in large part with regard to northern areas, which are dealt with in the second part of this document.

## France (FR)

FR considered the risk assessment *fit-for-purpose*. All specific comments are dealt with in the second part of this document.

## Hungary (HU)

HU considered the risk assessment *fit-for-purpose*. There were no comments to process.

## Luxembourg (LU)

LU suggested a *minor revision*.

**Comment from Member State:** LU noted that the RA is not in the template format of the European Commission, though all questions from the template have been addressed.

**Answer:** Regulation 1143/2014 does not require any specific template to be adopted. See above (AT) for the compliance with Regulation 1143/2014 and Delegated Regulation 2018/968.

**Comment from Member State:** LU comments that, when referring to the Western European population of *C. canadensis*, it is appropriate to use more specific geographic designators rather than referring to e.g. Germany, Belgium or France. More specifically, it is recommended to refer to the German states of Rhineland-Palatinate, North Rhine-Westphalia and Saarland; the Belgian region of Wallonia; and north-eastern France.

**Answer:** This is indeed important when considering the current distribution, scale of spread and impact, among others. Care has been taken to use more precise geographic designators, where useful, in the corrections and additions (see above and second part: summary, 2.2, 2.3, 2.4, 3.1, 5). At other occasions, it seems appropriate to stick to the (coarse) level of Member States.

**Comment from Member State:** LU points out that the RA puts the interaction among *C. canadensis* and *C. fiber* forward as a key potential impact. Yet, the practical implications for the combined management of both species are not addressed, if *C. canadensis* were to mingle with *C. fiber* e.g. at the river catchment level.

**Answer:** Indeed, regional initiatives on policy, management and communication may be complicated in situations where *C. fiber* and *C. canadensis* occur together, since the targets set for these species might be opposite to one another. A statement is added under heading 2.5.5.

**Comment from Member State:** LU points out that *C. canadensis* has not been introduced into Luxembourg, but spread spontaneously from Rhineland-Palatinate (Germany). LU accordingly questions the description of the species' European range as the "*introduced range*", since the species was not introduced to each of the Member States. Also, the species has been subject to dedicated eradication efforts in Luxembourg, which are incompletely covered in the original assessment. In fact, the species is now considered eradicated from the country.

**Answer:** Numerous additions and corrections on introduction and management in LU are included in the second part of this document. With regard to the use of "*introduced range*", it might indeed be better to speak of the "*non-native range*". Yet, both terms are well-established in the narrative of the Regulation 1143/2014, and considered synonyms.

**Comment from Member State:** The risk analysis with the ISEIA protocol yields a lower total score for areas with *C. fiber*, than for areas without *C. fiber*. This may be surprising, since the biggest estimated impact is the competition among these species.

**Answer:** In the ISEIA protocol, the category for impacts on native species does not separate negative impacts on *C. fiber* from those on other species in the same community (e.g. aquatic species). If *C. fiber* is present in the area, it already accounts for impacts on such species, and the remaining effect for *C. canadensis* is lowered. The same reasoning applies to the category for impacts on ecosystem functions. This leads to a lower total score. Additionally, the lower score might be a consequence of higher uncertainty (see p. 28 of the Risk Assessment).

Other specific comments are dealt with in the second part of this document.

## Part 2: Specific comments

This part provides additions and corrections under the respective headings of the original assessment (Hollander et al. 2017). The Member State on whose comment it is based, is indicated between brackets.

## Summary

**Addition (AT):** Apart from describing the endangered area by habitat types, it is useful to describe it by biogeographical regions. See Table 3 (above) for an overview of the regions with potential for establishment.

**Addition (AT):** The summary of the risk for *C. canadensis* in the EU may be a bit confusing on the scenarios that were scored with the Harmonia<sup>+</sup> protocol, and those that were scored with the ISEIA protocol. We therefore provide an overview of the scenarios and their scores in Table 4.

Table 4 – An overview of the scores provided by Hollander et al. (2017)

Protocol	Harmonia <sup>+</sup>		ISEIA			
<i>C. fiber</i>	Without <i>C. fiber</i>		With <i>C. fiber</i>		Without <i>C. fiber</i>	
Conditions	Current	Future	Current	Future	Current	Future
Score	High (1.0)	High (1.0)	9 (of 12)	9 (of 12)	12 (of 12)	12 (of 12)

**Correction (LU):** It is incorrectly stated that *C. canadensis* has been introduced to Luxembourg, as the presence of the species is considered to be due to natural dispersal from Rhineland-Palatinate (Germany). The same is probably true for Belgium (Schley 2019).

**Addition (FI):** The Finnish population of *C. canadensis* was considered to comprise about 6.000 family groups in 2013 (Brommer et al. 2017). The population is viable, has generally spread westward, and is now partly sympatric with *C. fiber* (Alakoski et al. 2019, 2020).

## 2. Risk inventory

### 2.1 Species description

#### 2.1.1 Nomenclature and taxonomic status

**Addition** (LU): The original reference for the separation of the two *Castor* species is Lavrov & Orlov (1973), and that for the recognition of the subspecies is Hall & Kelson (1959), both of which are referred to in Jenkins & Busher (1979).

#### 2.1.2 Species characteristics

**Correction** (LU): The text under this heading supposes that *C. canadensis* is currently reproducing in Luxembourg. Yet, no reproduction has been observed for at least 5 years (Schley 2019).

**Correction** (LU): The oily substance Castoreum does not serve to waterproof the beaver's fur. (This is also not stated in the given reference of Jenkins & Busher 1979.) Castoreum is used for territorial marking, whereas the most likely candidate for waterproofing of the fur is the skin lipid squalene (Rosell 2002).

**Addition** (LU): No primary reference is provided for the breeding attempt between *C. canadensis* and *C. fiber* that has led to a stillborn kit. The reference is (probably) Lavrov (1996).

**Correction** (LU): It is probably more correct to state that North American beaver *sometimes* displaces the Eurasian species, rather than *often*, as the outcome of competition is unclear so far (Danilov et al. 2008, Alakoski et al. 2019).

**Addition** (FI): A recent reference that studied sympatrically occurring *C. canadensis* and *C. fiber* is Alakoski et al. (2019). Results from that study are discussed below under various headings.

**Addition** (FI): With regards to foraging behaviour, beavers also prefer birch (*Betula* spp.). Apart from aspen and willow species, banks of water bodies populated by birch thus also provide suitable habitat (Alakoski et al. 2019).

**Addition** (LU): For predation of American mink on beaver, references include Swank (1949) in Jenkins & Busher (1979), and Errington (1943). The first reference specifies that predation is on beaver kits, the second clarifies that mink frequently visit beaver lodges. The suggestion that European mink may predate on beaver only stems from analogy.

**Addition** (LU): As an additional source of natural mortality, heavy rainfall that leads to floods may cause newborn beavers to drown in the dens (Hoffmann 1967).

### 2.2 Probability of introduction

**Correction** (LU): It is incorrectly stated that *C. canadensis* has been introduced to Luxembourg. The presence of the species was due to natural dispersal from Rhineland-Palatinate (Germany). The first observation is from 2006 (not before). The last observation is from 2019, of one individual that was captured (Schley 2019). See below under 2.3.6 for an overview of captures.

**Addition** (FI): An additional reference for the population status in Finland (to be added in Table 2.3) is Brommer et al. (2017). The Finnish population of *C. canadensis* was considered to comprise about 6.000 family groups in 2013.

## 2.3 Probability of establishment

### 2.3.1 Current global distribution

**Correction** (LU): It is incorrectly stated that *C. canadensis* has been introduced to Luxembourg, as the presence of the species is considered to be due to natural dispersal from Rhineland-Palatinate (Germany). The same is probably true for Belgium (Schley 2019).

**Correction** (LU): Luxembourg should no longer be regarded as part of the non-native range, as the country is now considered free of *C. canadensis* (Schley 2019).

**Addition** (LU): As a reference for the natural range of *C. canadensis* in North America, Wikipedia (2016) should be replaced by Jenkins & Busher (1979).

**Addition** (LU): The statement that *C. canadensis* has left “*a swath of destruction*” (Hollander et al. 2017) in the Tierra del Fuego archipelago, is further elaborated under heading 2.5.1.

### 2.3.2 Current distribution in the European Union and neighbouring areas

**Addition** (LU): For France, the situation is discussed up to the reference of Dewas et al. (2012). Since then, hundreds of beaver samples have genetically been checked for *C. canadensis*, but all proved to be *C. fiber*. Such analyses are continued within the operation of France’s ‘beaver network’ (*Réseau Castor*; Bressan & Hurel 2018). The status as ‘eradicated’ thus holds.

**Addition** (LU): For Germany, the statement made by Parker et al. (2012) that *C. canadensis* was released in North Rhine-Westphalia is flawed: although the breeding farm housed both species, there is no proof that specimens of *C. canadensis* were involved in the releases (Schley 2019). Genetic investigations by the Senckenberg Museum in Frankfurt support that conclusion (Christiane Frosch, unpublished results). The only times *C. canadensis* was detected in North Rhine-Westphalia was in 2012 and 2014 on the southern border with Rhineland-Palatinate (where its presence is known). The specimens from 2012 disappeared without a trace, the 2014 specimen was caught (Schley 2019).

**Addition** (LU): The 2006 finding of a North American beaver on the Luxembourg-Germany border sparked a large-scale genetic study in the greater region of Wallonia (Belgium), northern France, Rhineland-Palatinate, southern North Rhine-Westphalia and Saarland (Germany), and Luxembourg. The result have not been published, though, but the relevant results are included in the following additions (Schley 2019).

**Addition** (LU): For Belgium, the statement of Dewas et al. (2012) that the known site in Wallonia could have been the source of spread in the area, is rather unlikely. Genetic analysis showed several sites in Wallonia, all of which were close to the border with Germany and Luxembourg. It is therefore more likely that they too spread from Rhineland-Palatinate (Germany, notably the Eifel-Zoo). Apart from that, all samples from elsewhere in Wallonia proved to be *C. fiber* (Schley 2019). This weakens the claim that the (illegal) releases of beavers from Bavaria into Belgium might separately have led to the presence of *C. canadensis* (Hollander et al. 2017: p. 18).

**Correction** (LU): For Luxembourg, it is incorrectly stated that *C. canadensis* has been introduced to Luxembourg, as the presence of the species is considered to be due to natural dispersal from Rhineland-Palatinate (Germany). Luxembourg is now considered free of *C. canadensis* (Schley 2019).

**Correction** (FI): For Finland, more recent information is provided by Alakoski et al. (2019) and Alakoski et al. (2020). There are three, rather than two, fronts where the distribution of *C. canadensis* and *C. fiber* have converged in Finland. These are the regions of Pirkanmaa, Etelä- Pohjanmaa and Lapland.

Hollander et al. (2017) suggest that it is expected that *C. canadensis* will spread towards Sweden from Finland. However, at present, it seems that *C. fiber* is spreading from Sweden to Finnish Lapland. It is currently unclear whether *C. canadensis* is still present in the region. Alakoski et al. (2020) and Halley et al. (2021) provide the latest maps for the known distribution of both species in Finland (as compared to the map shown in Figure 2.3).

**Correction (FI):** Hollander et al. (2017) state that “*in Finland, C. canadensis (...) seems to outcompete C. fiber in areas where the two species come into contact*”. Yet, for the Finnish river system where both species occur and that has been studied most extensively, the outcome of competition is not yet clear (Alakoski et al. 2019).

### 2.3.3 *Habitat description and physiological tolerance*

**Addition (FI):** With regard to the habitat of *C. fiber* as compared to *C. canadensis*, Alakoski et al. (2019) studied an area where both species occur, and found habitat use to be similar indeed. The most apparent difference between both species was the distance from agricultural areas to beaver lodges (with *C. fiber* occurring closer to agriculture than *C. canadensis*), and the volume of birch versus other deciduous trees (with *C. fiber* sites having comparatively more birch).

**Correction (LU):** The text under this heading suggests that it is unclear whether populations of *C. canadensis* are established in Luxembourg. However, there are currently no established populations (Schley 2019.).

**Correction (LU):** The subtitle “*Effects on establishment through competition or predation with other species*” (Hollander et al. 2017) should be “*Effects on establishment through competition with other species or predation*”. Under this subtitle, “*wolfs*” should be replaced by “*wolves*”.

### 2.3.4 *Climate match and biogeographical comparison*

**Addition (CZ):** As readers may want to consult the climate zone map (Figure 2.5) in greater detail, it is useful to inform that it is available online as a supplement to the article of Peel et al. (2007) at <https://hess.copernicus.org/articles/11/1633/2007/>. Beck et al. (2018) published an update of the climate zone map, that is downloadable from <http://www.gloh2o.org/koppen/>.

**Correction (LU):** The text under this heading suggests that *C. canadensis* currently occurs in Luxembourg. However, Luxembourg is now considered to be free of the species (Schley 2019).

### 2.3.5 *Endangered areas*

**Addition (LU):** The list with examples of Member States that make part of the endangered area can be supplemented with Mediterranean countries such as Spain, Croatia and Italy. The ability of *C. canadensis* to live in these countries is proven by the presence of *C. fiber*.

### 2.3.6 *Influence of management practices*

**Correction (LU):** The statement that “*there are no specific management practices for C. canadensis in the EU except for Scandinavia*” (Hollander et al. 2017) is not correct. The following information was provided by Schley (2019):

Following the discovery of the presence of *C. canadensis* in its border region, Luxembourg took the initiative to set up a group to deal with the issue. This group included representatives from Luxembourg; the Walloon Region (Belgium); the states of Rhineland-Palatinate, North Rhine-Westphalia and Saarland (Germany); the Lorraine Region (France); and the Netherlands. This group launched a large-scale genetic survey to delimit the geographic area colonized by *C. canadensis* and to investigate its origin, and decided on coherent management actions aimed at its eradication.

In Luxembourg, the eradication programme started in 2009. From 2009 to '14, 25 individuals were removed. From 2015 to '17, 6 were removed. From 2018 to '19, 1 was removed. In total, 12 sites were involved. Noteworthy, all individuals removed after 2014 were solitary at their site (Schley 2019). Luxembourg is now considered to be free of *C. canadensis*. The *C. fiber* population is growing rapidly, and every new site is tested genetically to confirm the species' identification.

In Wallonia, an eradication programme was launched in 2010, which initially consisted of trapping and euthanizing specimens. Since this method was very time consuming, it was decided to hunt the beavers instead. As of May 2019, a total of 43 Canadian beavers have been removed from 16 sites, all of which are situated on the watershed of the river Our along the country border. On two sites, there still seems to be activity (Schley 2019).

In Rhineland-Palatinate, where the problem originated from, the strategy is to capture and sterilize specimens, and release them again at the site of capture. This particular strategy does not follow the recommendation of the aforementioned beaver group, and was also heavily criticized by the Scientific Committee of the International Beaver Symposium of 2012.

In North Rhine-Westphalia, on the border with Rhineland-Palatinate, *C. canadensis* was detected by genetic testing in 2012 and again at another location in 2014. The beavers from 2012 disappeared without a trace, the single specimen from 2014 was caught. Other samples of beaver in the state, including more recent ones, turned out to be *C. fiber*, or were inconclusive so far.

In France, genetic testing of beaver samples for *C. canadensis* are continued within the operation the 'beaver network' (*Réseau Castor*; Bressan & Hurel 2018).

**Addition (FI):** In Finland, the hunting season runs from August 20 to April 30 for both *Castor* species. A license is needed to hunt *C. fiber* (with quota applying), but not *C. canadensis*. An analysis of census data over the period 1995-2013 suggested that *C. fiber* is numerically increasing in Finland, while *C. canadensis* is declining in numbers. It is very likely that hunting is contributing to these trends (Brommer et al. 2017).

Hollander et al. (2017) conclude that eradication in the European Union is difficult “*due to the similarity of morphological characteristics between C. canadensis and (...) C. fiber.*” In eastern Finland, the beavers are known to be exclusively *C. canadensis* (Alakoski et al. 2020), so that difficulty does not apply.

## 2.4 Pathways and vectors for spread within the EU

**Correction (LU):** The text under this heading involves Luxembourg as a potential source for further spread. However, Luxembourg is now considered to be free of the species (Schley 2019).

**Addition (LU):** It is stated that “*species identification is difficult without genetic analysis*” (Hollander et al. 2017). However, the use of anal gland secretion provides a helpful and reliable tool, too (Rosell & Sun 1999).

**Addition (FI):** In addition to the previous comment, also skull morphometry can be used to identify the species (Jenkins & Busher 1979).

## 2.5 Impacts

### 2.5.1 Environmental effects on biodiversity and ecosystems

**Correction (LU):** The word “*endemic*” must be replaced with “*native*”.

**Addition** (LU): With regard to the impact of beaver dams on water temperatures, a large-scale and long-term study has recently been published by Weber et al. (2017). They highlight that different complexities underly this relation, but generally found that increased dam and pond creation contributes to the moderation of daily temperature cycles (i.e., increasing minimum temperatures and decreasing maximum temperatures).

**Addition** (LU): A German review on the impact of *C. fiber* on biodiversity is provided by Sommer et al. (2019).

**Addition** (FI): When it comes to niche overlap among *C. fiber* and *C. canadensis* and the outcome of competition, Alakoski et al. (2019) provide a useful reference (see above; 2.3.2 and 2.3.3).

#### 2.5.4 *Effects on public health*

**Addition** (FR): Giardiasis, for which *Giardia* is the causative agent, is popularly known as “beaver fever” (Tsui et al. 2018).

#### 2.5.5 *Socio-economic effects*

**Correction** (LU): The text under this heading suggests that *C. canadensis* currently occurs in Luxembourg. However, Luxembourg is now considered to be free of the species (Schley 2019).

**Addition** (LU): The trapping data for Luxembourg and Belgium are outdated. An update is provided above (2.3.6).

**Addition** (LU): The text highlights the costs needed for *C. canadensis* control, where the species establishes. It deserves to be emphasized that control of *C. canadensis* can become complicated when the species establishes together with, or close to, *C. fiber*, as additional challenges in terms of species distinction and stakeholder communication arise in such situations.

**Addition** (CZ): As *C. canadensis* and *C. fiber* are very similar, it is of use to consider the costs of impact, and costs of management, for *C. fiber*. Campbell-Palmer et al. (2015) reviewed actual management options and associated costs across Europe. Additional references may be found in the overview of Brazier et al. (2021) on human–beaver conflicts.

#### 2.5.6 *Effects on ecosystem services*

**Addition** (AT): In the table on ecosystem services linked to *C. canadensis* (Table 2.5), a ‘climate regulating service’ may be added. Notably, the increase in surface area of standing water following beaver establishment leads to increased emissions of methane (CH<sub>4</sub>). The resulting methane flux is estimated to have increased 200-fold over the course of the 20<sup>th</sup> century (Whitfield et al., 2015).

## 3. Risk assessment

### 3.1 Risk assessment and classification with the Harmonia+ protocol

#### 3.1.1 *Classification for the current situation*

**Addition** (LU): It is *more* than likely that the presence of *C. canadensis* in Rhineland-Palatinate (and at least formerly in adjacent regions) is linked to the Eifelzoo, as all specimens analyzed during a large-scale genetic study that also included the animals kept at that zoo at that time, were of the same haplotype. The beavers that replaced *C. canadensis* at the zoo after they were removed have genetically been shown to be *C. fiber* (Schley 2019).

**Addition** (AT): The probability that *C. canadensis* will be introduced into the EU by intentional actions was scored low in the Harmonia<sup>+</sup> assessment (Table 3.1). The confidence was scored as medium, and not as high, the reason for which is not explained in detail. A medium confidence seems justified, though, since (illegal) releases as a game species or for “fauna improvement”, and confusion of both species in conservation reintroductions (as happened in the past) cannot be ruled out.

### 3.1.2 *Classification for future situation*

**Addition** (AT, FI): The severity of winter weather is considered a factor influencing litter size (Jenkins & Busher 1979). Although an increased rate of spread might thus be expected under future climate conditions, the overall risk score of *C. canadensis* remains the same, as the current risk of spread is already considered maximal.

## 3.2 Risk assessment and classification with the ISEIA protocol

### 3.2.1 *Classification for the current situation*

**Addition** (LU, FI): The text under this heading assumes that “*C. canadensis* is reported to build more dams” (Hollander et al. 2017). However, this point is not evident from scientific studies, and in practice depends very much on local conditions (e.g. Danilov & Fyodorov 2015).

## 3.3 Other available risk assessments

### 3.3.1 *EU Member States*

**Addition** (AT): Another risk assessment for EU Member States can be added to the overview. The risk of *C. canadensis* has been assessed for Germany (Nehring et al. 2015) using the GABLIS method (Essl et al. 2011). The assessment is much in line with the other European assessments. As a result of the assessment, the species is included in the Black list for Germany, and more specifically, the Action list for the country, which means that eradication is considered feasible and recommended (Nehring et al. 2015). The assessment for Germany, however, can not be extended to the entire EU without modifications.

**Addition** (LU): At the time of the ISEIA risk assessment in Luxembourg (Ries et al. 2014), *C. canadensis* was known to be present at four sites. Now, the country is considered free of the species (Schley 2019). Maintaining the same risk score, the species thus ends up on the Alert list (B0) instead of the Watch list (B1).

## 4. Discussion

### 4.2 Knowledge gaps and uncertainties

#### 4.3 *Management*

**Correction** (LU): The statement that in France, “a small population of *C. canadensis* co-occurring with *C. fiber* was successfully eradicated” (Hollander et al. 2017), is somewhat misleading. According to Dewas et al. (2011), *C. fiber* was present in the Loire river and *C. canadensis* in a tributary to the Loire. The statement that “there are no existing *C. canadensis* management programs in the EU” is also incorrect, as discussed under 2.3.6.

## 5. Conclusions

**Correction (LU):** It is incorrectly stated that *C. canadensis* has been introduced to Luxembourg, as the presence of the species is considered to be due to natural dispersal from Rhineland-Palatinate (Germany). The same is probably true for Belgium (Schley 2019).

**Correction (LU):** The text suggests that the species is present in the greater border region of Belgium, Germany and Luxembourg. To specify, however, it currently seems to be present with certainty only in Rhineland-Palatinate (Germany, Schley 2019). For measures in North Rhine-Westphalia (Germany), Luxembourg and Belgium, see above (2.3.6).

**Correction (FI):** It is not really to be “*expected that the species will spread towards Sweden*” (Hollander et al. 2017). At present, it seems that *C. fiber* is spreading from Sweden to Finland, and no observations of *C. canadensis* near the Swedish border have recently been made (Alakoski et al. 2020). As the outcome of competition is not clear (yet), this does not take away concerns of a possible range expansion of *C. canadensis*, though.

**Addition (FI):** *C. canadensis* may benefit from milder winters, as the severity of winter weather is considered a factor influencing litter size (Jenkins & Busher 1979). See under 3.1.2 for a discussion.

# Revision of the Risk assessment of the Staff-vine (*Celastrus orbiculatus*), as based on Member State comments

## Introduction

This document explains how the comments received through the Scientific Forum and the consultation of stakeholders on the **Risk assessment of the Staff-vine (*Celastrus orbiculatus*)** by Beringen et al. (2017)<sup>1</sup> have been considered.

Disclaimer: The authors of the present document have prepared this note with the only purpose to process the Member States comments to the original Risk Assessment by Beringen et al. 2017, on behalf of the European Commission. For the same reason, the present document does not represent an endorsement of the statements and scores given within the original document. Since the focus of this document was limited to the Member States comments, it cannot be considered as a revision of the original document, whose contents and bibliography have not been through a comprehensive check, and remain the sole responsibility of the original authors.

Name of species assessed: <i>Celastrus orbiculatus</i> Thunb.
Date of completion of this document: <b>01/03/2021</b>
Member States that provided comments: <ul style="list-style-type: none"><li>• <b>Austria</b> (AT)</li><li>• <b>Belgium</b> (BE)</li><li>• <b>Denmark</b> (DK)</li><li>• <b>Estonia</b> (EE)</li><li>• <b>Germany</b> (DE)</li><li>• <b>Poland</b> (PL)</li><li>• <b>Romania</b> (RO)</li></ul>
Stakeholder organizations that provided comments: none.

## Outline

The first part of this document highlights how the comments from Member States have been dealt with. The second part of this document deals with the specific comments from Member States. The text should be read as an addendum and corrigendum to the original risk assessment (Beringen et al. 2017). The headings from the original assessment are repeated to facilitate direct comparison.

---

<sup>1</sup> Beringen R., van Duinen G.A., de Hoop L., de Hullu P.C., Matthews J., Odé B., van Valkenburg J.L.C.H., van der Velde G., Leuven R.S.E.W. (2017) Risk assessment of the alien Staff-vine (*Celastrus orbiculatus*). © Department of Environmental Science, Radboud University, 6525 AJ Nijmegen, The Netherlands

References that were included in the original risk assessment are not repeated. New references are provided at the end of this document.

## **Part 1: Comments per Member State**

### **Austria (AT)**

AT suggested a *minor revision*. Specific comments are dealt with in the second part of this document.

### **Belgium (BE)**

BE considered the risk assessment was *fit-for-purpose* and had no additional comments.

### **Denmark (DK)**

DK suggested a *major revision*. Specific comments are dealt with in the second part of this document.

### **Estonia (EE)**

EE considered the risk assessment was *fit-for-purpose* and had no additional comments.

### **Germany (DE)**

DE provided additional informations, which are dealt with in the second part of this document.

### **Poland (PL)**

PL suggested a *minor revision*. Specific comments, especially on the distribution of the species in Poland, are dealt with in the second part of this document.

### **Romania (RO)**

RO considered the risk assessment was *fit-for-purpose* and had no additional comments.

## **Part 2: Specific comments**

This part provides additions and corrections under the respective headings of the original assessment (Beringen et al. 2017). The Member State on whose comment it is based, is indicated between brackets.

The following table provides details of where the common elements of risk assessments defined by Article 5 of the Regulation 1143/2014 of 22 October 2014 can be found in the *Celastrus orbiculatus* risk assessment.

Table 1 -- The elements of risk assessments as defined by Regulation 1143/2014, and the headings under which they are treated by Beringen et al. (2017)

Element	Headings
Art 5(1)(a) — <i>a description of the species with its taxonomic identity, its history, and its natural and potential range</i>	2.2.1
Art 5(1)(b) — <i>a description of its reproduction and spread patterns and dynamics including an assessment of whether the environmental conditions necessary for its reproduction and spread exist</i>	2.1.2
Art 5(1)(c) — <i>a description of the potential pathways of introduction and spread of the species, both intentional and unintentional, including where relevant the commodities with which the species is generally associated</i>	2.4
Art 5(1)(d) — <i>a thorough assessment of the risk of introduction, establishment and spread in relevant biogeographical regions in current conditions and in foreseeable climate change conditions</i>	3.1, 3.2
Art 5(1)(e) — <i>a description of the current distribution of the species, including whether the species is already present in the Union or in neighbouring countries, and a projection of its likely future distribution</i>	2.3.1, 2.3.2, 3.1.2
Art 5(1)(f) — <i>a description of the adverse impact on biodiversity and related ecosystem services, including on native species, protected sites, endangered habitats, as well as on human health, safety, and the economy including an assessment of the potential future impact having regard to available scientific knowledge</i>	2.5
Art 5(1)(g) — <i>an assessment of the potential costs of damage</i>	2.5
Art 5(1)(h) — <i>a description of the known uses for the species and social and economic benefits deriving from those uses</i>	2.5

## Overarching comments from Germany

DE provided additional information from recent studies that should be included in the risk assessment. The following text details the comments and includes suggestions of text and its position in the risk assessment.

- In Germany, male and female plants occur together in the field. Seed formation and first spread were observed.

### Page 10 (reproduction)

Flowers of *Celastrus* species frequently become unisexual through the abortion of male or female organs. Plants are often functionally dioecious (Brizicky 1964, Burnham & Santanna 2015). Occasionally monoecious plants, with both male and female flowers, are reported (Hou, 1955), and occasionally plants develop both unisexual and perfect flowers on the same plant (polygamodioecious) (Dreyer et al. 1987). In Germany, male and female plants occur together in the natural environment which enables reproduction and seed production (Alberternst & Nawrath 2018). The cultivar *C. orbiculatus* 'Hermaphroditus' is self-pollinating. The cultivar *C. orbiculatus* 'Diana' is a female clone and only sets fruit if a male clone is present locally. *C. orbiculatus* 'Hercules' is a male clone and is used as a pollinator for female plants (e.g., Marczyński 2016).

### Page 21 (2.4.1. Dispersal potential by natural means)

- A zoochore spread by birds is to be assumed on the basis of the distribution pattern and the growth place.

### Page 43 (probability of spread)

The unintentional distribution of plants from gardens into the wild, caused by berry eating birds can contribute to the spread of *C. orbiculatus*. In Germany, bird dispersal has been recorded at 400 m from

the parent plants (Alberternst & Nawrath, 2018). Additionally, the improper disposal of (bonsai) trees or decorations outdoors or in compost can contribute to spread.

- In Hesse similar habitats are already populated as in the USA, where the species is classified as invasive.

Page 16

In Europe, most sites are situated in or near urban areas. Therefore, it is not clear in which EU habitats *C. orbiculatus* will establish. The most likely areas for establishment are forest habitats on moist, fertile, neutral soils like 91E0: “Alluvial forests with *Alnus glutinosa* and *Fraxinus excelsior* (Alno-Padion, Alnion incanae, Salicion albae)” or 91F0 “Riparian mixed forests of *Quercus robur*, *Ulmus laevis* and *Ulmus minor*, *Fraxinus excelsior* or *Fraxinus angustifolia*, along major rivers (*Ulmenion minoris*)”.

A detailed survey in Hessen, Germany (Alberternst & Nawrath, 2018) recorded dominant stands with vegetative and generative regeneration. One stand originated from a nursery and has spread into an area protected under the EU Habitats Directive and classified as Annex I habitat type code 91E0. Another stand occurs in a nature protection area of light pine forest on sandy soils resembling 91T0. Regeneration and spread of the species was observed in three of the four stands. Another stand was found on railway land, where the plant covers unused tracks. Such mentioned habitats are similar to those where the species occurs in the USA.

## Summary (p. 3/4)

**Comment (AT):** The authors assume that the applied risk assessment method (internet version of Harmonia+) is compliant with the criteria for RA derived from Reg 1143/2014. This review confirms this assumption in large parts; however, it also identified some gaps that need revision. While the risk assessment is very clear and well written in general, it is sometimes difficult to find the necessary information related to the specific criteria of the Regulation. It would be helpful to modify (or add) the Summary accordingly. The summary lacks explicitly clear information related to current and possible future occurrences with regard to Member States and biogeographical regions.

**Answer:** The following text should be included in the summary:

*Celastrus orbiculatus* currently occurs in ten EU countries (Austria, Belgium, the Czech Republic, Denmark, Germany, Latvia, Lithuania, the Netherlands, Poland, Sweden), and the United Kingdom. Under climate change, in the future, the entire Atlantic, Continental and southern Boreal biogeographical regions of Europe are likely to be suitable for the establishment of the species. Therefore, this has the potential to increase the future occurrence of *C. orbiculatus* to the following countries: Austria, Belgium, Bulgaria, Czech Republic, Denmark, Estonia, Finland, France, Germany, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, the Netherlands, Poland, Romania, Slovakia, Slovenia, Sweden, Spain, and the United Kingdom.

**Comment (AT):** The summary lacks indications for the associated levels of uncertainty of the scorings.

**Answer:** The only score that is detailed in the summary section is the overall score, which is medium. This score was produced with the Harmonia system which does not provide an uncertainty score associated with the overall score.

**Comment (DK):** On p. 3, it is stated that the report also includes a risk assessment of *C. orbiculatus* focussed on the Netherlands, we question whether it is the right place to publish a national risk assessment.

**Answer:** The inclusion of the statement is a decision of the authors and does not impact the results of the risk assessment and therefore there is no change suggested.

**Comment (DK):** On p. 3 it is stated that “Suitable habitats in the EU are most likely forests on moist, fertile, and neutral soils...”, from the sections 2.3.3 and 2.3.4 it is not clear why e.g. urban sites, former agricultural fields, reforested agricultural fields and sand dunes are not suitable habitats in the EU as they are in other parts of the its introduced range. Furthermore, the RA (p. 29) states that “the species thrives best in recently disturbed habitats” and forests may not be regarded as recently disturbed.

**Answer:** The sentence should be amended to read:

“The most suitable habitats in the EU are most likely forests on moist, fertile, and neutral soils...”

## **Species description (p. 7)**

**Comment (DK):** There are difficulties in distinguish *C. orbiculatus* from *C. scandens*, except when the species are fertile. The species, however, forms a “seedling bank” (mentioned on p. 12) that may last for many years especially in forest ecosystems (shaded habitats). This problem should be mentioned because it also have implications for early identification and eradication. Furthermore, *C. orbiculatus* from *C. scandens* hybridize (Pooler et al. 2002). The Ra needs to mention problems separating hybrids from parental species.

**Answer:** On page 9 of the RA, it is clearly stated that folding of the leaves is a useful identifying characteristic and therefore it is not correct to say the species can only be told apart when they are fertile. Additionally, there is no evidence that hybrids occur in the risk assessment area, and therefore identifying characteristics of hybrids and parent species is not required.

## **2.1.2 Species characteristics (p. 10)**

*Reproduction:*

**Comment (DK):** It should be mentioned in the section on reproduction that *C. orbiculatus* requires gaps in the canopy for sexual reproduction (flowering and fruiting) as mentioned on p. 21 (reference to study by Silveri et al. (2001).

**Answer:** The paragraph should be amended to read:

Gaps in the canopy are required for sexual reproduction, flowering and fruiting (Silveri et al. 2001).

## **2.2 Probability of introduction (p. 13)**

**Comment (DK):** It is stated that *C. orbiculatus* has been cultivated for many years in several member states”. How many? And which?

**Answer:** This is a general statement which is then further elaborated in the remaining text of section 2.2 giving the information Denmark requests.

## 2.3 Probability of establishment (p. 13)

**Comment (AT):** An explicit answer to which Member States and biogeographical regions are suitable under current and foreseeable future conditions is missing. This information should also be provided in the Summary.

**Answer:** The following text should be included:

*Celastrus orbiculatus* currently occurs in ten EU countries (Austria, Belgium, the Czech Republic, Denmark, Germany, Latvia, Lithuania, the Netherlands, Poland, Sweden), and the United Kingdom. Under climate change, in the future, the entire Atlantic, Continental and southern Boreal biogeographical regions of Europe are likely to be suitable for the establishment of the species. Therefore, this has the potential to increase the future occurrence of *C. orbiculatus* to the following countries: Austria, Belgium, Bulgaria, Czech Republic, Denmark, Estonia, Finland, France, Germany, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, the Netherlands, Poland, Romania, Slovakia, Slovenia, Sweden, Spain, and the United Kingdom.

Table 2 – Summary of the status of *C. orbiculatus* in Member States of the European Union, and the United Kingdom

Member State	Recorded	Currently established	Potential establishment	Currently invasive
Austria	Yes	Yes (locally)	Yes	No
Belgium	Yes	Yes (locally)	Yes	No
Bulgaria	No	No	Yes	No
Croatia	No	No	No	No
Cyprus	No	No	No	No
Czech Republic	Yes	No	Yes	No
Denmark	Yes	Yes (locally)	Yes	No
Estonia	No	No	Yes	No
Finland	No	<del>Yes</del> -No	Yes	No
France	No	No	Yes	No
Germany	Yes	Yes	Yes	No
Greece	No	No	No	No
Hungary	No	No	Yes	No
Ireland	No	No	Yes	No
Italy	No	No	Yes	No
Latvia	Yes	Yes (locally)	Yes	No
Lithuania	Yes	Yes	Yes	Yes
Luxembourg	No	No	Yes	No
Malta	No	No	No	No
Netherlands	Yes	Yes (locally)	Yes	No
Poland	Yes	Yes	Yes	Yes
Portugal	No	No	No	No
Romania	No	No	Yes	No
Slovakia	No	No	Yes	No
Slovenia	No	No	Yes	No
Spain	No	No	Yes	No
Sweden	Yes	Yes (locally)	Yes	No
United Kingdom	Yes	Yes (locally)	Yes	No

Table 3 -- Summary of the status of *C. orbiculatus* in biogeographical regions of the European Union

Biogeographical region	Recorded	Currently established	Potential establishment	Currently invasive
Alpine	Yes	Yes	Yes	No
Atlantic	Yes	Yes	Yes	No

Black Sea	No	No	No	No
Boreal	Yes	Yes	Yes	Yes
Continental	Yes	Yes	Yes	Yes
Mediterranean	No	No	No	No
Pannonian	No	No	No	No
Steppic	No	No	No	No

### 2.3.2 Current distribution in the European Union (p. 14/15)

**Addition (PL):** *Celastrus orbiculatus* is currently recorded in the central segment of the Międzyrzecz Reinforced Region and its expansion has been observed near Panzerwerkes (Purcel, 2010, 2011).

**Comment (DK):** Six records in Denmark (Hartvig, P. 2015 Atlas Flora Danica, Gyldendal, København. See also GBIF<sup>2</sup>. First record 1981. Map p. 14 need correction.

**Answer:** The maps cannot be updated within this document due to copyright issues.

**Comment (DK):** In Denmark, *C. orbiculatus* is also found in woodland (Hartvig, 2015).

**Answer:** The first paragraph on page 15 should be amended to include the following sentence at the end of the paragraph: In Denmark, the species is also found in woodland (Hartvig 2015).

### 2.3.3 Habitat description and physiological tolerance (p. 15/16)

**Comment (DK):** In Denmark, the species is found in forest habitats (coniferous forest, thicket, park), along railways and in urban areas (Hartvig 2015).

**Answer:** The second paragraph on page 16 should be amended to include the text below at the end of the paragraph: In Denmark, the species is found in forest habitats (coniferous forest, thicket, park), along railways and in urban areas (Hartvig 2015).

### 2.3.4. Climate match and bio-geographical comparison (p. 17)

*Endangered areas:*

**Comment (AT):** The statement that the area with suitable climate will expand northward (in 2.3.4) needs be expanded with information on possible changes in the biogeographic regions.

**Answer:** The paragraph should be amended to read:

Based on expert opinion (authors of the current risk assessment), under climate change, in the future, the entire Atlantic, Continental and southern Boreal biogeographical regions of Europe are likely to be suitable for the establishment of the species.

<sup>2</sup> [https://www.gbif.org/occurrence/search?country=DK&taxon\\_key=8104460](https://www.gbif.org/occurrence/search?country=DK&taxon_key=8104460)

### 2.4.1 Dispersal potential by natural means (p. 21/22)

**Comment (DK):** We wonder why starlings are the only seed eating birds mentioned as potentially contributing significantly to spread of the species? Other berry-eating birds may serve as vector as well?

**Answer:** Starlings are the only specific bird species mentioned in the risk assessment as this is where there is evidence. Throughout the RA, berry eating birds are mentioned often with the example of Starlings, therefore confirming that other bird species may spread seed.

**Comment (DK):** Although the scoring might be right, the fact that “to date the species has not shown considerable spread at the current recorded locations in Europe” should be discussed and reflected in the section on spread.

**Answer:** The first paragraph in the spread section (p. 31) can be amended as follows:

It should be noted, that to date the species has not shown considerable spread at the current recorded locations in Europe. Reasons for this could include that the propagule pressure is not currently that high, or the species is in its lag phase.

### 2.5. Impacts (p. 22)

**Comment (DK):** Referring to Gederaas et al. (2012) (the Norwegian species database) is not a valid reference for the mentioned biodiversity effects. Furthermore, the reference indicate that *C. orbiculatus* is a low risk species, i.e. the reference is not correctly cited.

**Answer:** The reference to Gederaas et al. (2012) can be deleted from the reference list as it is only cited in the above case. The paragraph can be amended to read:

Fryer (2011) regard *C. orbiculatus* as a severe invasive species, mainly because of detrimental interactions with indigenous endangered or rare species and endangered or rare habitats.

**Comment (DK):** Referring to Glastonbury Partners in Planting (GPIP 2013) is not a valid reference for effects of the species.

**Answer:** The reference to GPIP (2013) can be deleted from the reference list as it is only cited in the above case and can be replaced by Fryer (2011).

**Comment (DK):** It should be noted that the observations by Lutz (1943) are made on the related species *C. scandens*. Just above the photo (Fig. 2.10) it is stated that: “Hardwoods are more commonly damaged than conifers because the relatively dense canopy of conifers offers unfavourable light conditions for *C. orbiculatus* (Lutz 1934)”. Looking into another study cited in the RA (Ellsworth et al. 2004b) it is, however, found that survival and growth the first year did not differ between 2%, 28% and 100% sun, at the second season growth and biomass were greater in the 100% and 28% sun treatments than 2% sun...” and furthermore “The ability of *C. orbiculatus* to survive under deep shade despite its slow growth implies that intact forest are vulnerable to invasion and that established understory populations should be controlled before harvesting or thinning the forest”

**Answer:** The paragraph should be amended as follows:

For *C. scandens*, hardwoods are more commonly damaged than conifers because the relatively dense canopy of conifers offers unfavourable light conditions [for the species to establish] (Lutz 1943). This is also likely to be the case for *C. orbiculatus* due to similarities in form, function and requirements. *Celastrus orbiculatus* can persist in forest understories in the USA for a number of years and following a disturbance in the canopy (i.e. tree or limb falls causing canopy gaps), rapid growth can occur

(Patterson, 1973). *Celastrus orbiculatus* “uses a ‘sit and wait’ invasion strategy” (Greenberg *et al.*, 2004).

**Comment (DK):** The study by Dreyer *et al.* (1987) should not be used as reference for “the competition and hybridization effects of introduced *C. orbiculatus*”. This study does not include hybridization but tells that “this is being investigated”. The study by Pooler *et al.* (2002) found in the reference list, however, deals with hybridization and vigour of the interspecific seedlings. This study should be mentioned here.

**Answer:** In the paragraph on page 23, Dryer *et al.* (1987) is not referring to hybridization but in fact the latter sentence. Pooler *et al.* (2002) can however be added to the paragraph.

**Comment (DK):** Zaya *et al.* (2015) is cited for the conclusion that interspecific hybrids between *C. orbiculatus* and *C. scandens* do not have increased invasiveness and vigour. The study by Pooler *et al.* (2002), however, found that seedlings from interspecific crosses had less dormancy and were more vigorous than the intraspecific seedlings. This should be discussed.

**Answer:** In the paragraph on page 35 the following text should be amended to read:

It should be noted that Pooler *et al.* (2002) found that seedlings from interspecific crosses had less dormancy and were more vigorous than the intraspecific seedlings.

**Comment (DK):** The study by Leicht-Young and Pavlovic (2012) is not correctly cited. It does not support that “*C. orbiculatus* has the ability to move out from the forest into the open dune habitats”. Actually, it states (p. 172) “In full sun, we have often observed *C. orbiculatus* growing under the shade of shrubs, tree saplings, or grapes with ramets extending out into open habitats. These ecotonal habitats are where the threat to *C. pitcheri* is likely greatest from *C. orbiculatus*, because without some type of cover for *C. orbiculatus* to establish under, this species does not grow as well in wide open dunes where *C. pitcheri* is also present”.

**Answer:** In the paragraph on page 35 the following text should be amended to read:

Along Lake Michigan. *C. orbiculatus* has the ability to encroach into the dune habitat which may be a threat to the endangered *Cirsium pitcheri* (Leicht-Young & Pavlovic 2012).

**Comment (DK):** Looking at effects on cultivated plants (chap. 2.5.2), effects on socio-economy (chap. 2.5.5) and effects on provisioning services (chap. 2.5.6) seem to be an overrepresentation of the same impact.

**Comment (DK):** As commented for section on impacts, there seem to be an over-assessment of effects on plant crops/provisioning services.

**Answer:** This is a common problem with evaluating ecosystem services. We don’t have information on how the authors of the risk assessment weighted these scores and therefore cannot suggest a revision. The overall conclusion of the RA are nevertheless not affected.

**Comment (DK):** Section 2.5.4 Effects on public health states that no information regarding the effects of *C. orbiculatus* was found, however WOS have numerous citations of studies of the efficacy of extracts from the species against gastric cancer. The section on Provisioning services (P. 26) also document use in the treatment of poisoning, infectious disease and as an antidote for snakebites. This should also be mentioned here.

**Answer:** A risk assessment details negative effects. Although benefits are detailed as a requirement of the Regulation, they are not included in the scoring of this section.

**Comment (DK):** The study by Pavlovic *et al.* 2016. Oriental bittersweet (*Celastrus orbiculatus*): Spreading by fire. *Forest Ecology and Management* 364, 183-194) clearly documents that fire is not a

good measure for control of *C. orbiculatus*. This needs to be reflected in the section on Physical measures. Pavlovic et al. (2016) also tested other methods such as cutting and herbicide application and the study should be mentioned in these paragraphs as well.

**Answer:** In the paragraph on page 26 the following text should be amended to read:

#### *Physical measures*

Prescribed burning is not considered a viable option for control. It is likely that *C. orbiculatus* is actually favored by fire due to rapid growth in response to opening the canopy and the large nutrient flushes that usually occur after fires (Pavlovic et al. 2016). However, if fire management is properly applied, the year's crop of seeds would be essentially eliminated (Leicht-Young et al. 2013). Cutting and herbicide application can be used to control the species (Pavlovic et al. 2016).

**Comment (DK):** Section 2.5.6 Effects on ecosystem services have very few references. The part on Provisioning services could be supplemented by numerous references on use extracts against gastric cancer.

**Answer:** The risk assessment scores negative impacts not positive impacts.

**Comment (DK):** The section on Supporting services should refer to the study by Leicht-Young et al. 2009 (found in the reference list) on effects of *C. orbiculatus* on soil composition and processes.

**Answer:** In the paragraph on page 28 the following text should be amended to read:

The species has a negative effect on ecosystem nutrient cycling due to the plant's ability to function like a nutrient pump (Leicht-Young et al. 2009). Minerals become available to other species as the *C. orbiculatus* litter layer degrades easily and enriches the soil (Leicht-Young et al. 2009).

### **3. Risk assessment (p. 29ff)**

**Comment (DK):** There is little reasoning and justification of the statements and scoring of the species in the risk assessment section. One needs to seek around in the scientific section. That is not optimal.

**Answer:** The structure of the risk assessment cannot be addressed by this document.

#### **3.1 Risk assessment and classification with Harmonia+ (p. 30)**

**Comment (AT):** Table 3.1. does not correspond to the recommended pathway terminology (while Table 2.4 does).

**Answer:** In Table 3.1 the following text could be inserted between the line:

A06. Probability of introduction by natural means

Escape from confinement

A07. Probability of introduction by unintentional human actions

However, since Table 3.1. refers to the Harmonia+ protocol, no change to the wording of the categories should be made.

**Comment (AT):** Why the medium score for probability of intentional human actions (A08) was given a “high confidence”? According to the explanation in the text (3.1.1.), in comparison with A06 and A07, a “medium” confidence would fit better.

**Answer:** Under this pathway, the species is the commodity itself, and therefore any movement and planting of the species in the RA area can lead to the medium risk of entry. The confidence of high remains supported. It should be noted that no other reviewers highlighted this as an issue.

**Comment (AT):** Why is the confidence for establishment in habitats only “medium” and for climate “high”? There seems to be no difference in the explanation in 3.1.1. I think both should be scored identical as “medium”. Detailed information on probability of spread is equally uncertain, and was scored with “medium” confidence.

**Answer:** The paragraph on establishment (p. 29) should be amended to read:

The confidence differs though (habitats: medium and climate: high) which reflects the uncertainty of the species finding a suitable habitat and difference in habitats of the species in North America compared to the EU. For climate, the Köppen-Geiger system shows a strong suitability.

*Environment: biodiversity and ecosystems (p. 31)*

**Comment (DK):** The conclusion that *C. orbiculatus* cause medium effect on native species (“at worst, severe population declines in species that are not of conservation concern or limited population declines in species that are of conservation concern”) might be right but it could not be drawn based on the information given in chapter 2.5.1. Chapter 2.5.1 needs to be elaborated to support the conclusion.

**Answer:** The current score is considered appropriate and the point was not raised by other reviewers. Section 2.5.1 is detailed giving numerous examples to support a ‘medium’ impact.

**Comment (DK):** The risk of adverse effects on ecosystem integrity due to changes to biotic properties is estimated to medium. Again, that might be right but virtually no references are given on such effects. Even though, the risk estimates are based on professional knowledge the confidence should be “low” as effects on ecosystem biotic parameters might be highly variable.

**Answer:** Based on the fact that there are no supporting references, the suggestion to change the confidence score to low is reasonable.

*Ecosystem services (p. 32)*

**Comment (DK):** The scoring of effects on provisioning services as moderately negative should maybe be re-evaluated, as effects on timber might be severe. The outweighing of positive effect on pharmaceuticals, natural medicine and bio-chemicals against negative effects on timber production is not really a good idea.

**Answer:** Only negative effects are evaluated and thus, the sentence ‘The positive effect of the species on bio-chemicals, natural medicines, and pharmaceuticals was outweighed by its negative effect on timber production’ should be removed from the paragraph.

**Comment (DK):** Effect on plant crops should be mentioned in a section on effects on socio-economy, which is missing? Why does the section on “Plant crops” not include effects on forest? Consequences for other crops are more speculative as it needs structures such as trees, shrubs, tree saplings, or grapes as support but may have ramets extending out into open habitats. Therefore, the score “medium impact” might be an overestimation if forest is not included.

**Answer:** An additional sentence should be added to the paragraph on plant crops on p. 32:

Additionally, *C. orbiculatus* can have negative impacts on tree species in forest systems, potentially killing trees by smothering them.

### 3.1.1 Classification for current situation (p. 29)

#### *Species introduction*

**Comment (DK):** The only pathway described is escape from cultivation/horticulture. On p. 29 the RA states that “Introductions via natural pathways are expected to occur less than once every 30 years, because it is highly unlikely that the species will enter the EU via earth-moving activities”. Is this statement based on the knowledge that the species does not form a persistent seedbank (p. 12)? (This is an example that the reviewer need to seek around in the RA to find the relevant information, which is not optimal).

**Answer:** This statement is more related to the fact that soil as a pathway into the EU is mainly closed due to phytosanitary regulations. The paragraph should be amended to read:

Introductions via natural pathways are expected to occur less than once every 30 years, because it is highly unlikely that the species will enter the EU via earth-moving activities (due to the pathway of soil into the EU being mainly closed and regulated).

**Comment (DK):** *C. orbiculatus* is also recorded from Denmark (see below), therefore number of MS where the species has been recorded should be changed from “eight” to “nine”.

**Answer:** Denmark should be added as a country where the species has been recorded, but it remains eight MS, excluding the United Kingdom.

**Comment (DK):** The finding that “to date the species has not shown considerable spread at the current recorded locations in Europe” (p. 29) is not an argument for establishment (where it is put now). Actually, it should be discussed in the section on spread that scores the capacity of *C. orbiculatus* to disperse within the EU by natural means as high.

**Answer I:** The paragraph on establishment (p. 29) should be amended to read:

This criterion is scored with medium confidence considering that there is no relevant information available within the EU and that the species thrives best in recently disturbed habitats.

**Answer II:** The paragraph on spread (p. 31) should be amended to read:

It should be noted, that to date the species has not shown considerable spread at the current recorded locations in Europe. Reasons for this could include that the propagule pressure is not currently that high, or the species is in its lag phase.

**Comment (DK):** What is the conclusion about probability of introduction to the EU’s wild habitats being medium (between 1 and 9 events per decade) based on?

**Answer:** It appears to be expert opinion of the authors as documented information is not available.

### 3.1.2 Classification for future situation (p. 33)

**Comment (AT):** On the one hand the assessment (2.3.3, also 2.3.4 and 2.5.7) states that temperature/climate is relevant (... climate change may render high-elevation sites increasingly vulnerable ...), but on the other hand (3.1.2) expects no effects on the risk scores (based on a conservative climate change scenario). This expectation should be backed up with some arguments. Is the argument still valid under more severe (>2°C) climate change scenarios?

**Answer:** It must be assumed that uncertainty increases, but the argument seems still valid under more severe scenarios.

### 3.2 Risk assessment and classification with ISEIA-protocol (p. 35)

**Comment (DK):** Only the study by Zaya et al. (2015) that found no evidence that invasiveness increases is cited in the section on adverse impacts on native species. The study by Pooler et al. (2002), however, showed increased vigour of hybrids.

**Answer:** Pooler et al. (2002) should be added in the paragraph on page 35 (see above).

## 5. Conclusions (p. 42)

**Comment (AT):** The RA is not organized in a question-answer-way, which makes it sometimes difficult to find the relevant information. An extended summary page with the relevant information (according to the requirements of the Regulation) would be helpful.

**Answer:** This is outside the scope of this document.

**Comment (DK):** As mentioned in the comments on the summary, the RA could be much improved if the structure was changed so sections on studies of relevant risks were put next to sections evaluating and scoring the respective risks. As it is now the reviewer/reader needs to do a lot of page turning in order to seek and eventually find the relevant information for the reasoning and the scoring.

**Answer:** This is outside the scope of this document.

**Comment (DK):** Including the Danish records, the species has been recorded in nine countries.

**Answer:** ~~It~~ Following more recent information, it is recorded in still eighteen EU Member States, and the United Kingdom.

## Appendix 3 (p. 68)

**Comment (DK):** *C. orbiculatus* is present in Denmark

**Answer:** Appendix 3 should be amended to include Denmark

## SECTION A – Organism Information and Screening

### A1. Identify the organism. Is it clearly a single taxonomic entity and can it be adequately distinguished from other entities of the same rank?

including the following elements:

- the taxonomic family, order and class to which the species belongs;
- the scientific name and author of the species, as well as a list of the most common synonym names;
- names used in commerce (if any)
- a list of the most common subspecies, lower taxa, varieties, breeds or hybrids

As a general rule, one risk assessment should be developed for a single species. However, there may be cases where it may be justified to develop one risk assessment covering more than one species (e.g. species belonging to the same genus with comparable or identical features and impact). It shall be clearly stated if the risk assessment covers more than one species, or if it excludes or only includes certain subspecies, lower taxa, hybrids, varieties or breeds (and if so, which subspecies, lower taxa, hybrids, varieties or breeds). Any such choice must be properly justified.

Response: This risk assessment covers one species, the Pampas grass *Cortaderia selloana* (Schult. & Schult.f.) Asch. & Graebn. Testoni and Villamil (2014) provided evidence that *Cortaderia jubata* (Lemoine ex Carrière) Stapf “represents only a portion of the morphologic variability of *C. selloana* s.l.” and should therefore be recognised as a subspecies of the latter (*Cortaderia selloana* subsp. *jubata* (Lemoine) Testoni and Villamil), and clearly distinguished from *Cortaderia selloana* subsp. *selloana* (the autonymic subspecies). In the most recent revision of the genus *Cortaderia*, Testoni and Linder (2017) upheld this reclassification. There is also considerable identification uncertainty in regions where both taxa are introduced (e.g. DiTomaso et al. 2003; DiTomaso et al. 2010; Houliston and Goeke 2017), and Lambrinos (2001) suggested that the floral traits of *C. selloana* in California have gradually become more similar to that of *C. jubata* over the previous 80 years. However, apart from the two aforementioned references in all of the literature, web references and databases assessed during the preparation of this PRA, *C. selloana* and *C. jubata* are still referred to at the species level. Moreover, regardless of the specific or sub-specific classification of *C. selloana* and *C. jubata* diagnostic morphological, reproductive and phenological characters are used to distinguish these two taxa (e.g. Houliston and Goeke 2017, Lambrinos 2001; Testoni and Linder 2017). This PRA therefore follows the previous nomenclature by Ascherson and Graebner (1900) for this taxon: *Cortaderia selloana* (Schult. & Schult.f.) Asch. & Graebn. [Syn. Mitteleur. Fl. [Ascherson & Graebner]. 2(1): 325].

“*Cortaderia jubata* (Lemoine ex Carrière) Stapf” is already listed as an invasive alien species of Union concern (second update of the Union list entered into force on 15 August 2019<sup>2</sup>), therefore, the focus of this risk assessment is especially on *Cortaderia selloana* (Schult. & Schult.f.) Asch. & Graebn. subsp. *selloana* [Syn. Mitteleur. Fl. 2(1): 325. 1900.] hereafter *C. selloana*.

Class: *Monocotyledons* (*Monocots*, *Liliopsida*)

Order: *Poales* Small (*sensu* APG IV, Chase et al. 2016)

Family: *Poaceae* (R. Br.) Barnhart, *nom. cons.* (=Gramineae Juss., *nom. alt.*)

Subfamily: *Danthonioideae* N.P.Baker and P.H.Linder

<sup>2</sup> Commission Implementing Regulation (EU) 2019/1262 of 25 July 2019 amending Implementing Regulation (EU) 2016/1141 to update the list of invasive alien species of Union concern, C/2019/5360, OJ L 199, 26.7.2019, p. 1–4.

Genus: *Cortaderia* Stapf, Gard. Chron. ser. 3. 22: 378 (1897), *nom. cons.*

Synonyms:

*Arundo dioeca* Spreng., Syst. Veg. (ed. 16) 1: 361. 1825 [1824], *nom. illeg.* (non Lour. 1790);

*Arundo selloana* Schult. & Schult.f., Mant. 3(1): 605. 1827; [Basionym];

*Gynerium argenteum* Nees, Agrost. Bras. 462. 1829, *nom. illeg.*;

*Moorea argentea* (Nees) Lemaire, Ill. Hort. 2: 14. 1855;

*Cortaderia argentea* (Nees) Stapf, Gard. Chron. ser. 3, 22: 396. 1897, *nom. illeg.*;

*Cortaderia dioeca* (Spreng.) Speg., Anales Mus. Nac. Buenos Aires 7: 194. 1902.

Common names and names used in commerce: carrizo de las pampas (Spanish, Castillian), carrizos de las pampas (Spanish, Castillian), gineri (Catalan), hierba de la pampa (Spanish, Castillian), hierba de las pampas (Spanish, Castillian), panpa-lezka (Euskera), planta de les plomes (Catalan), plomalls (Catalan), plomes (Catalan), plumeros (Asturian), plumeros (Catalan), plumeros (Spanish, Castillian); pampová tráva (Czech Republic); pampasgræs (Denmark); pampaheinä (Finnish); Cortaderia, erba della Pampa, erba delle Pampas (Italy); Pampasgräs (Sweden); Trawa pampasowa (Poland); iarba de Pampas (Romanian); Pampuzāle (Latvian), Ezüstös pampafű (Hungarian), (Euro+Med (2006-2020). Amerikanisches Pampasgras (German).

List of the most common subspecies, lower taxa, varieties, breeds or hybrids (note, no hybrids are known): There are many cultigens (a plant species or variety only known in cultivation) of *Cortaderia selloana*. A number of these cultigens were assessed in a genetic study by Okada et al. (2007): Most cultivars (a plant variety produced in cultivation by selective breeding) are propagated asexually by division or tissue culture to maintain morphological and phenological uniformity. Such clonally propagated cultigens are female or hermaphroditic (but functionally male) in sex expression. In addition, a few cultivars and most named selections (i.e. selected genotypes that do not have cultivar status) are propagated by seed and consist of both sexes.

The most common traded cultigens are: 'Albolineata' ('Silver Stripe'), 'Andes Silver', 'Aurolineata' ('Gold Band'), 'Blue Bayou', 'Candy Floss', 'Carnea', 'Cool Ice', 'Evita', 'Ivory Feathers', 'Golden Goblin', 'Monstrosa', 'Monvin', 'Patagonia', 'Pink Feather', 'Point du Raz', 'Pumila', 'Rendatleri' ('Carminea Rendatleri'), 'Silver Comet', 'Splendid Star', 'Sunningdale Silver', 'Usballata', 'White Feather' (Okada et al. 2007; Lucas 2011). However, although a few studies exist, it must be noted that no specific (genetic) study has attributed each of all the above listed cultigens to *Cortaderia selloana*. A dedicated DNA fingerprinting analysis would be required.

**A2. Provide information on the existence of other species that look very similar [that may be detected in the risk assessment area, either in the environment, in confinement or associated with a pathway of introduction]**

Include both native and non-native species that could be confused with the species being assessed, including the following elements:

- other alien species with similar invasive characteristics, to be avoided as substitute species (in this case preparing a risk assessment for more than one species together may be considered);
- other alien species without similar invasive characteristics, potential substitute species;
- native species, potential misidentification and mis-targeting

Response: According to the synoptic taxonomic study on the genus *Cortaderia* Stapf recently published by Testoni and Linder (2017) the *Selloana* group includes three morphologically and anatomically similar species, with both gynodioecious and apomictic breeding systems. They are easily distinguishable from other species in the genus *Cortaderia*: they form big tussocks 1.5 to 3 m in diameter and up to 4 m in height, and the leaf edges are strongly cutting. The panicles are large and plumose, very showy, and much larger than in most of the other species. The spikelets have 1-veined glumes, the lemmas are long-acuminate, with or without evident awns, unlobed, 3-veined and with long hairs only in female plants (hermaphrodites glabrous) (Testoni and Linder 2017). These three species in the *Selloana* group are *Cortaderia selloana* (Schult. & Schult.f.) Asch. & Graebn. s.l., *Cortaderia araucana* Stapf, and *Cortaderia speciosa* (Nees & Meyen) Stapf. According to Testoni and Linder (2017) *Cortaderia selloana* (Schult. & Schult.f.) Asch. & Graebn. s.l. includes two different subspecies, *Cortaderia selloana* (Schult. & Schult.f.) Asch. & Graebn. subsp. *selloana*, and *Cortaderia selloana* subsp. *jubata* (Lemoine) Testoni & Villamil [syn.: *Cortaderia jubata* (Lemoine) Stapf]. However, as stated in section A1, we will use the name *C. selloana* for *C. selloana* subsp. *selloana* in the whole RA, apart from a few parts in the text, such as here (A2), where we specifically cite and refer to Testoni and Linder (2017) synopsis.

It is generally agreed that specific morphological, reproductive and phenological characters are required to distinguish these two subspecies, but identification in the field might be challenging. According to Testoni and Linder (2017), *C. selloana* subsp. *selloana* can be diagnosed by the glumes about as tall as the basal lemma, and lemma without a distinct awn. The plants are generally larger than those of *C. araucana* and *C. speciosa*, and the panicles are larger (0.5 to 1 m long), laxer, and coloured white, pink or yellowish. The similar size of basal lemmas and glumes (6–15 mm) further separates *C. selloana* subsp. *selloana* from *C. araucana* (glumes 9–17 mm long, ca.  $\frac{1}{2}$  length of basal lemmas), whereas the larger glumes separate it from *C. speciosa* (glumes 6–8 mm, ca.  $\frac{3}{4}$  length of basal lemmas). The large size may also lead to confusion with *C. nitida*<sup>3</sup>, but it is easily separated by the larger and laxer panicles, 3-veined, awnless (mutic) lemmas that are glabrous on hermaphrodite plants; and female plants with tiny staminodes (Testoni and Linder 2017).

*Cortaderia selloana* was originally described as dioecious (de Vargas 1959; Connor 1965, 1983, under the name of *C. selloana*), but Astegiano et al. (1995) showed that it is functionally-gynodioecious (i.e., co-occurrence of plants with hermaphrodite flowers and plants with female pistillate flowers), and Testoni and Villamil (2014) recorded several populations with only pistillate individuals (so presumably apomictic) in central and northern Argentina. Both types of individuals (hermaphrodite plants and female plants) could be morphologically differentiated by their size and spike dimensions, resulting in less robust hermaphrodite plants with narrower spikes. Hermaphrodite plants are only pollen donors whereas female plants are responsible for the seed production (Doménech-Carbó et al. 2018).

According to Costas-Lippmann (1979), in its naturalized habitats in New Zealand, *C. selloana* is described as functionally gynodioecious. In cultivation in California, it is considered dioecious or imperfectly dioecious because only a few seeds are found in some predominantly staminate plants, while thoroughly pistillate individuals also occur (Costas-Lippmann 1976).

---

<sup>3</sup> Within the *Nitida* group, *Cortaderia nitida* does approach the *Selloana* group by its large size, big plumose inflorescences, and especially by the lemma shape (Testoni and Linder 2017).

*Cortaderia selloana* presents the greatest morphological variability and geographical range in the genus. The morphological characterization is also complicated by interbreeding between natural populations and cultivated plants (Testoni and Linder 2017).

*Cortaderia jubata* is generally similar to *C. selloana*, and includes all the morphologically homogeneous apomictic populations of the Yungas region (Bolivia). It can be separated from *C. selloana* by the inflorescences which extend far beyond the foliage, and the pink, 75–90 cm long, very lax, pyramidal and nodding panicles. In Ecuador it is sympatric with *C. nitida*, from which it can be separated by its larger size and its spectacular pink panicles. They can also easily be distinguished by the leaves: in *Cortaderia jubata*, they are flat and folded V-shaped, while in *C. nitida* leaves are enrolled from both margins (Testoni and Linder 2017).

*Cortaderia selloana* and *Cortaderia jubata* have been described as readily distinguishable genetically by Houlston and Goeke (2017), although the amount of genetic variation present in each differs markedly. According to Houlston and Goeke (2017), this pattern is not surprising given the difference in breeding systems of the two species. An earlier study on the genetics of invasive *C. jubata* from around the world, Okada et al. (2007) suggested that *C. jubata* in New Zealand was almost clonal; a finding consistent with its apomictic reproductive mode (Houlston and Goeke 2017).

In addition to *Cortaderia selloana* and *Cortaderia jubata*, according to (Verloove 2020) another species in cultivation in Europe is the New Zealand endemic *Cortaderia richardii* (Endl.) Zotov (syn.: *Arundo richardii* Endl.) (a species not reviewed in the synopsis by Testoni and Linder 2017, which focuses on South American species). It has been reported as increasingly self-seeding in the British Isles, especially in Scotland (Clement 2005). Other *Cortaderia* species are traded as ornamental and are also available on-line (see above).

In the EU, two native species might cause potential misidentification and mis-targeting, also due to the fact that they thrive in similar habitats: in particular *Saccharum ravennae* (L.) L. (syn: *Tripidium ravennae* (L.) H.Scholz), and *Ampelodesmos mauritanicus* (Poir.) T.Durand & Schinz (both belonging to Poaceae). These two are also potential substitute species, limited to the MS (or to the regions of the MS) where they are native.

Other species of *Cortaderia* that are traded as ornamental plants are *Cortaderia jubata*, *Cortaderia fulvida*, *Cortaderia richardii*, *Cortaderia toetoe* (Lucas 2011).

**A3. Does a relevant earlier risk assessment exist? Give details of any previous risk assessment, including the final scores and its validity in relation to the risk assessment area.**

Response: There are a number of risk assessments available which in general rank *C. selloana* as an invasive species. All of the risk assessments below assess the species *C. selloana*. These documents include:

- The 2015 GB Non-native species Rapid Risk Assessment (NNS 2015). In this document it is reported that *C. selloana* is already present and well established in Great Britain. Records of the species have been increasing considerably in recent years and it seems likely that this trend will continue in the future. Environmental, economic and social impacts are discussed. *C. selloana* is ranked as a high risk alien plant to Great Britain.

- The National Biodiversity Data Centre Ireland (Kelly et al. 2013) assessed the risk of *C. selloana* for Ireland and scored the species 15. Species scored between 14-17 are species with a medium risk.
- For Spain, Gassó et al. (2010), applying the Australian Weed Risk Assessment tool calculated a score of 26. This would mean that the species would be rejected from import for Spain.
- Pacific Island Ecosystems at Risk (PIER, 2001), (Reject, Score: 24). The reject score indicates for Australia, the species is likely to be of high risk and should be rejected from import.
- The Big Island Invasive Species Committee (2020) (Hawaii, US) award a HPWRA score of 24-26 which results in the species being listed as an invasive species.
- United States Department of Agriculture - Animal and Plant Health Inspection Service (USDA-APHIS), February 18, 2014, RA result = high risk to the USA. The 2014 document remarks that Hawaiian researchers also obtained a result of 24 (high risk) when they evaluated this species with the Australian weed risk assessment system (UH 2013).
- UF/IFAS Assessment of Non-Native Plants in Florida's Natural Areas (University of Florida, 2020). Results = High Invasion Risk. This tool is a predicted tool that evaluates the risk of the species to the risk assessment area of Florida.
- Invasiveness Assessment in Victoria (Agriculture Victoria 2020) assesses plant invasiveness by evaluating the plants biology and ecological characteristics against criteria that encompass establishment requirements, growth rates and competitive ability, methods of reproduction and dispersal mechanisms. Pampas grasses (*C. jubata* and *C. selloana*) are declared under the Natural Resources Management Act, 2004 throughout the whole of the State of South Australia, so that cultivation, sale and movement of plants can be prevented.
- The Canadian Food Inspection Agency (CFIA) conducts weed risk analyses in accordance with international guidelines for pest risk analysis established by the International Plant Protection Convention (IPPC) of the Food and Agriculture Organization of the United Nations (FAO). The CFIA is preparing a weed risk analysis for *Cortaderia selloana*. However, the “Environmental” impact is considered the most important impact for this species.

All of the above risk assessments highlight that *Cortaderia selloana* poses a risk to areas throughout the world. In particular, the two assessments from Europe (Great Britain and Spain) detail a high risk.

#### **A4. Where is the organism native?**

including the following elements:

- an indication of the continent or part of a continent, climatic zone and habitat where the species is naturally occurring
- if applicable, indicate whether the species could naturally spread into the risk assessment area

Response: *Cortaderia selloana* is endemic to Argentina, Chile, central-west and southern Brazil and Uruguay (de Vargas 1959; Linder et al. 2010; Filgueiras et al. 2015; Testoni and Linder 2017; Flora Argentina 2020; Flora do Brasil 2020). In its native range, it is found in alluvial plains, and it is common to riparian areas, hydromorphic and sandy soils, humid dune slacks (de Vargas 1959; Monserrat et al. 2012; Prina et al. 2015; Oyarzabal et al. 2018), but in Argentina it can be found also in mountain areas above 2,400 m a.s.l. (Tucumán, Depto. Chicligasta, Serra de Aconquija) (Cabido et al. 2010; Testoni and Villamil

2014). In Argentina, the native range extends from the north of the country to Patagonia, Neuquén region, Río Negro and the Atlantic coast at Chubut region (Astegiano et al. 1995). In the native range a considerable association of *C. selloana* to fire disturbance is known (Sirolli and Kalesnik 2011). In Uruguay, on the Atlantic coast, the typical plant communities of humid dune slacks are called *pajonales* (Delfino and Masciadri 2005; Fagúndez and Lezama 2005). According to Flora do Brasil (2020) *Cortaderia selloana* is present in the following states: Distrito Federal, Goiás, Minas Gerais, Rio de Janeiro, São Paulo, Paraná, Rio Grande do Sul, Santa Catarina. It is found in several habitats and vegetation types in the Central Brazilian Savanna, and in the Atlantic Rainforest, including high altitude grasslands and coastal forest (*restinga*), but also in man-disturbed areas (Filgueiras et al. 2015). In Chile (de Vargas 1959) it is found in the Cordillera de Nahuelbuta region, and Contulmo area (Arauco), on sandy soils and riparian sites. De Vargas (1959), in her monographic work on the *Cortaderia* genus in Chile, described this species as also in cultivation, e.g. at Ñuñoa (Santiago).

The native range is primarily located in the warm temperate climates (Cfa Cfa = [Humid subtropical climate](#), Cfb [oceanic climate](#), Cwa [Monsoon-influenced humid subtropical climate](#)), extending northwards to the equatorial (Aw Tropical wet and dry or [savanna climate](#), Af, [Tropical rainforest climate](#): southern Brazil) and southwards to arid climates (BSk [Cold semi-arid climate](#), BWk [Cold desert climate](#)), according to the Köppen-Geiger climate classification.

*C. selloana* grows best in open ground in full sun but it can tolerate light shade.

*Cortaderia selloana* could not naturally spread from the native range to the risk assessment area.

**A5. What is the global non-native distribution of the organism outside the risk assessment area?**

Response:

**Africa and Indian Ocean**

**A6. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species been recorded and where is it established? The information needs be given separately for recorded (including casual or transient occurrences) and established occurrences. “Established” means the process of an alien species successfully producing viable offspring with the likelihood of continued survival<sup>4</sup>.**

**A6a. Recorded: List regions**

**A6b. Established: List regions**

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

- Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea.

Comment on the sources of information on which the response is based and discuss any uncertainty in the response.

For delimitation of EU biogeographical regions please refer to <https://www.eea.europa.eu/data-and-maps/figures/biogeographical-regions-in-europe-2> (see also Annex VI).

For delimitation of EU marine regions and subregions consider the Marine Strategy Framework Directive areas; please refer to <https://www.eea.europa.eu/data-and-maps/data/msfd-regions-and-subregions/technical-document/pdf> (see also Annex VI).

Response (6a): Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Steppic

It should be noted that *C. selloana* is likely to be present in confined environments (gardens, parks etc.) in all biogeographical regions within the risk assessment area as a garden ornamental but confirmed records are lacking.

Response (6b): Atlantic, Continental, Mediterranean.

**A7. In which biogeographic region(s) or marine subregion(s) in the risk assessment area could the species establish in the future under current climate and under foreseeable climate change? The information needs be given separately for current climate and under foreseeable climate change conditions.**

**A7a. Current climate: List regions**

**A7b. Future climate: List regions**

With regard to EU biogeographic and marine (sub)regions, see above.

<sup>4</sup> Convention on Biological Diversity, Decision VI/23

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

Response (7a): Atlantic, Continental, Mediterranean (Annex VIII).

Response (7b): Under future climatic conditions (projection: 2070: RCP 2.6), *C. selloana* can establish in the following biogeographical regions: Alpine, Atlantic, Black Sea, Continental, Boreal, Mediterranean, Pannonian and Steppic. Under the climatic projection of RCP 2.6 by 2070, *C. selloana* has a high potential to establish in the Mediterranean and Pannonian biogeographical regions. The Atlantic, Black Sea, Continental, and Steppic biogeographical regions all have a moderate likelihood of establishment. Establishment is also moderately likely outside the risk assessment area in the Anatolian and Macaronesian biogeographical regions. (Annex VIII).

The main aspects of climatic change which may influence the occurrence of *C. selloana* include increased minimum temperature of winter months, increased spring and summer temperatures and increased precipitation. Increased frequency of fire, as the result of increased temperatures, may promote the establishment of the species in natural areas where otherwise it would not be able to get a foothold. If climate change promotes local increased rainfall this may act to increase the spread of the species within the risk assessment area. If climate change promotes higher wind frequency and velocity this may act to spread seeds over longer distances than currently shown.

**A8. In which EU Member States has the species been recorded and in which EU Member States has it established? List them with an indication of the timeline of observations. The information needs be given separately for recorded and established occurrences.**

**A8a. Recorded: List Member States**

**A8b. Established: List Member States**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden

The description of the invasion history of the species shall include information on countries invaded and an indication of the timeline of the first observations, establishment and spread.

Response (8a):

<b>United Kingdom</b>	Introduced and Established	Smyth (1908)

Introduction to Europe dates back to the first half of the 19th Century. During Moore's curatorship of Glasnevin Botanic Gardens in Ireland (David Moore was born in Dundee on 23 April 1807), many new plants were introduced into cultivation in the British Isles through Glasnevin; among these was *Cortaderia selloana* from South America (Nelson and Seaward 1981). John Tweedie, a Scot resident in Buenos Aires, in 1839 sent some packages of seed collected in Argentina. The seeds were planted out in the open at Glasnevin in 1840. They produced flowering spikes for the first time in the autumn of 1842. Soon after, Moore sent plants and pressed specimens to the Royal Botanic Gardens, Kew (Stapf 1897; Nelson 1982). It was introduced, from the UK, to the Netherlands in 1848 in the Japanese garden at Clingendael, The Hague (Van der Eb-Brongersma 2012). *Cortaderia selloana* was introduced in Italy in 1850 (Saccardo, cited in Maniero 2000) and it features in the *Index seminum* 1906-1923 of the Botanic Garden of Modena (Delectus seminum horti botanici R. Universitatis Mutinensis). *Cortaderia selloana* was first introduced to France in the Montpellier Botanical Garden in 1857 and was commercialised after 1874 (Bossard et al. 2000). It was listed in the 1905 edition of the plant list of the Botanic Garden of Amsterdam (Zeijlstra

1905). The first record as escaped from cultivation for Spain dates back to Guinea (1953) in the gulf area of quien la Santander, and the first herbarium sample was collected by Loriente at Liencres (Cantabria) in 1969 (Herrera Gallastegui and Campos Prieto 2006). In Portugal the species was first mentioned as naturalised in 1955 (LIFE STOP Cortaderia, 2020).

Response (8b): As specified in the above table *C. selloana* is established in the following Member States: France, Ireland, Italy, Portugal, Spain; and in the United Kingdom.

In this case, adding a timeline for establishment of *C. selloana* is not possible as records do not indicate the year when the species first established.

**A9. In which EU Member States could the species establish in the future under current climate and under foreseeable climate change? The information needs be given separately for current climate and under foreseeable climate change conditions.**

**A9a. Current climate: List Member States**

**A9b. Future climate: List Member States**

With regard to EU Member States, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6 °C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0 °C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

Response (9a): Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, France, Germany, Greece, Hungary, Ireland, Italy, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden; and in the United Kingdom (see Annex VIII).

Response (9b): Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden; and in the United Kingdom (see Annex VIII).

**A10. Is the organism known to be invasive (i.e. to threaten or adversely impact upon biodiversity and related ecosystem services) anywhere outside the risk assessment area?**

Response: *Cortaderia selloana* is recognized as an invasive pest in California (USA) where it can invade natural habitats and outcompete native biodiversity and has frequently occupied non-ruderal habitats over

the past 50 years (Lambrinos 2001). In the U.S., in addition to California, *C. selloana* is listed as a noxious weed in:

Washington State <https://www.nwcb.wa.gov/weeds/pampas-grass>

Hawaii: <https://dlnr.hawaii.gov/hisc/info/invasive-species-profiles/pampas-grass/>

In New Zealand, *C. selloana* is recorded as a weed of concern (invasive). It displaces native plant species and can create fire hazards.

*Cortaderia selloana* is recognised as one of the main priority invasive weeds in bushland reserves and native forestry in Tasmania (Young 1993). In Australia it replaces natural plant communities and excludes plants through shading and below ground competition since the root system of a single plant is estimated to occupy 103 cubic meters of soil (Parsons and Cuthbertson 2001).

*Cortaderia selloana* competes with and replaces native plants in South Africa (Wells et al. 1986). The aforementioned author highlights undesirable characteristics as competing for space, light, nutrients and water.

**A11. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea

Response: Atlantic, Continental, Mediterranean

The endangered area includes natural and ruderal habitats in the Mediterranean biogeographical region.

**A12. In which EU Member States has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden

Response: France, Ireland, Italy, Portugal, Spain; and in the United Kingdom.

The area endangered includes countries in the Mediterranean biogeographical region.

**A13. Describe any known socio-economic benefits of the organism.**

including the following elements:

- Description of known uses for the species, including a list and description of known uses in the risk assessment area and third countries, if relevant.
  - Description of social and economic benefits deriving from those uses, including a description of the environmental, social and economic relevance of each of those uses and an indication of associated beneficiaries, quantitatively and/or qualitatively depending on what information is available.
- If the information available is not sufficient to provide a description of those benefits for the entire risk assessment area, qualitative data or different case studies from across the risk assessment area or third countries shall be used, if available.

Response: *Cortaderia selloana* is a widely traded and used ornamental species. Ornamental use includes the use for fencing and protecting the garden or property, due to its sharp leaves (“green guardian”, Brigham 2002). The European Nursery Stock Association have provided quantitative data on the production and value of *C. selloana* in the horticulture trade in the risk assessment area. They detail:

- In the Netherlands circa 8 000 000 to 10 000 000 plants a year are grown at approximately 50 nurseries. We estimate the trade value approximately at 80 – 100 million Euro’s (based on consumer prices at garden centre’s and internet-sale),
- Approximately 20 -25 million plants a year of *C. selloana* are cultivated at nurseries in Europe, with an estimated value of 200 million Euro’s,
- Some new varieties of *Cortaderia selloana* are coming from ‘tissue culture’ these varieties can not be grown from seed. We estimate the number of plants coming from tissue culture at 2 – 3 million a year, with a value around 50 – 60 million Euro.

There is a trade in the dried plumes of the species. These are used for decorative purposes mainly indoors and are available via e-commerce. There is no quantitative data on the value in the trade of dried plumes.

*Cortaderia selloana*, due to its high phytolith (minute mineral particle formed inside the plant) production and its capacity to absorb silica soluble particles in plant tissues, has been used in constructed wetland systems and phytoremediation applications (e.g., Gholipour et al. 2020). In South Africa it has been used to dry up and stabilise the slimes dams in mines (Grillo and Venora 2011). There has also been some research on using *C. selloana* as fibre components in composite material (Jordá-Vilaplana et al. 2017).

## SECTION B – Detailed assessment

### Important instructions:

- In the case of lack of information the assessors are requested to use a standardized answer: “No information has been found.”
- With regard to the scoring of the likelihood of events or the magnitude of impacts see Annexes I and II.
- With regard to the confidence levels, see Annex III.
- Highlight the selected response score and confidence level in **bold** but keep the other scores in normal text (so that the selected score is evident in the final document).

## 1 PROBABILITY OF INTRODUCTION AND ENTRY

### Important instructions:

- **Introduction** is the movement of the species into the risk assessment area (it may be either in captive conditions and/or in the environment, depending on the relevant pathways).
- **Entry** is the release/escape/arrival in the environment, i.e. occurrence in the wild
- Introduction and entry may coincide for species entering through pathways such as “corridor” or “unaided”, but it also may differ. If different, please consider all relevant pathways, both for the introduction into the risk assessment area and the entry in the environment.
- The classification of pathways developed by the Convention of Biological Diversity (CBD) should be used (see Annex IV). For detailed explanations of the CBD pathway classification scheme consult the IUCN/CEH guidance document<sup>5</sup> and the provided key to pathways<sup>6</sup>.
- For organisms which are already present (recorded or established) in the risk assessment area, the likelihood of introduction and entry should be scored as “very likely” by default.
- Repeated (independent) introductions and entries at separate locations in the risk assessment area should be considered here (see Qu. 1.7).

**Qu. 1.1. List relevant pathways through which the organism could be introduced into the risk assessment area and/or enter into the environment. Where possible give details about the specific origins and end points of the pathways as well as a description of any associated commodities.**

For each pathway answer questions 1.2 to 1.7 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 1.2a, 1.3a, etc. and then 1.2b, 1.3b etc. for the next pathway.

In this context a pathway is the route or mechanism of introduction and/or entry of the species.

The description of commodities with which the introduction of the species is generally associated shall include a list and description of commodities with an indication of associated risks (e.g. the volume of trade; the likelihood of a commodity being contaminated or acting as vector).

<sup>5</sup> <https://circabc.europa.eu/sd/a/738e82a8-f0a6-47c6-8f3b-aeddb535b83b/TSSR-2016-010%20CBD%20categories%20on%20pathways%20Final.pdf>

<sup>6</sup> <https://circabc.europa.eu/sd/a/0aeba7f1-c8c2-45a1-9ba3-bcb91a9f039d/TSSR-2016-010%20CBD%20pathways%20key%20full%20only.pdf>

If there are no active pathways or potential future pathways this should be stated explicitly here, and there is no need to answer the questions 1.2-1.9.

The following introduction/entry pathways are identified for *Cortaderia selloana* and are discussed within this section. Pathways are detailed in order of importance. Pathway categories are in brackets.

**Pathways are listed in order of importance**

- (1): Horticulture (escape from confinement)**
- (2): Ornamental purpose other than horticulture: (escape from confinement)**
- (3): Landscape / flora / fauna (improvement in the wild)**
- (4): Transport of habitat material (soil, vegetation) (transport – contaminant)**
- (5): People and their luggage/equipment in particular tourism (transport - stowaway)**

**Pathways considered but excluded from the risk assessment.**

USDA (2014) detail that *C. selloana* seeds can attach to kiwi fruit destined for export. In New Zealand, kiwifruit (*Actinidia deliciosa*) have been intercepted with seeds of *C. selloana* attached to the fruit. Subsequently, these consignments have been rejected for export (Knowles and Tombleson 1987). This pathway was not considered for the risk assessment as there was no further evidence that this is an (active) pathway neither in New Zealand nor in the EU. In any case, phytosanitary measures at export and import in the risk assessment area would likely identify and remove contaminants before the fruit enters the risk assessment area.

Historically, *C. selloana* has been planted for erosion control and as a dune stabilizing plant (CABI 2020, GISD 2020, NNSS 2015, Di Tomaso et al. 2010). There is little evidence of use of the species for these aspects in the risk assessment area in recent times (e.g. last 30 years) but the aforementioned references, and in particular, Domènech et al. (2006) highlights that this has previously occurred in the risk assessment area. Due to the awareness of the invasiveness of the species and the overall public awareness of their impacts, planting of *C. selloana* for such purposes as erosion control and windbreaks is less attractive now, than historically. For example, EU funded projects such as LIFE STOP Cortaderia - Urgent measures for controlling the spread of Pampa Grass (*Cortaderia selloana*) in Atlantic area (see: <http://stopcortaderia.org/language/en/stop-cortaderia-en/>) act to raise awareness of the invasive behavior of the species. As there is no evidence that this is an active pathway, it is not considered further in this risk assessment.

**Pathway name: (1) Horticulture (escape from confinement)**

**Qu. 1.2a. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	Unintentional <b>intentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response: Horticulture is the intentional introduction of the species into the risk assessment area for commercial culturing. *Cortaderia selloana* has been utilized as a garden ornamental species in the risk assessment area since the early to mid-1800s.

The Horticulture pathway should be applied to plants escaping from commercial culturing facilities (nurseries, greenhouses) (including the deliberate dumping of plant material) or during transport to/from the nursery trade. Therefore, this pathway includes the bulk shipment of live plants for nurseries and gardens centres, and the intentional introduction of seeds (and potentially rhizomes) for planting.

**Qu. 1.3a. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?** including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: The species is a popular ornamental species (one of the most popular ornamental grass species in cultivation) and grown throughout the risk assessment area (Bacchetta et al. 2010; Missouri Botanical Garden 2020; NNSS 2015). Numerous suppliers are listed throughout EU Member states.

The pathway horticulture is the deliberate movement of the plant into the risk assessment area for use as an ornamental species. However, it should be noted that the frequency and volume of individuals entering the risk assessment area is potentially low as much of the material sold in nurseries and garden centres is likely to be propagated within the risk assessment area.

It is moderately likely that the species will enter the natural environment via this pathway. Potentially, if planted in nurseries and garden centres, plant material may escape from confined areas into the natural environment. Additionally, dumping of material into the natural environment may occur though unlikely with good horticulture industry practise.

If eradication measures are taken following dumping, there is the potential that the species can re-establish if it is dumped again. As one female plant can produce up to 1 million seeds, only a small population is needed to result in subsequent establishment. However, the fecundity depends on the gender composition of the population, and the sex ratios could be very skewed in a small population.

**Qu. 1.4a. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: The pathway ‘Horticulture’ is the deliberate movement of plant material into the risk assessment area and as such plant material would be maintained and moved to ensure survival.

Three types of material can potentially enter the risk assessment area via this pathway (1) seed, (2) live plants and (2) rhizomes. Although seed import cannot be ruled out, it is unlikely as part of the horticulture pathway for the commercial production of the species.

**Seed (caryopsis)**

It is very likely that seeds (caryopsis) will survive along the pathway. It would not be possible for the species to reproduce or increase during transport and storage along this pathway. When dried, the seeds of *C. selloana* can remain viable approximately 12 months and therefore this will increase the chance of survival during transport. Seeds can germinate under a wide range of environmental conditions, yet germination rates can be improved under shading, in sandy soils and with high water availability (Domènech and Vilà, 2007). Seeds would need to be dumped on the ground substrate, or near to the ground surface to facilitate germination.

**Live plants**

Live plants will be moved along the pathway and packaged to promote their survival. It is unlikely the plants will reproduce or increase during their transport along this pathway. The end result of the pathway is the planting of the species in a suitable area (garden) to promote its growth. From this, seeds can enter the environment via escape/release.

**Rhizomes**

Rhizomes may be moved along the pathway and packaged to promote their survival. There is no data on the survival of the rhizomes but it is likely that they will survive during transportation as industry will ensure they are packaged appropriately to ensure survival. Rhizomes are robust and if placed near the soil surface, this can increase the chances of the rhizomes to germinate after they are dumped. If plant material is placed in areas where there is disturbance, there may be a greater chance that the species can survive in these habitats. Often dumping of plant material takes place in ruderal habitats.

**Qu. 1.5a. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

	likely very likely		
--	-----------------------	--	--

Response: Plant material is the commodity itself and it is deliberately moved for sale within the risk assessment area. Therefore, management practices before and during transport are not considered in this question. Management practices during storage at the end point (nursery and garden centre) may affect the survival of the species for example cleaning, temperature storage etc. However, the species is likely to survive.

**Qu. 1.6a. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: It is unlikely that the organism will enter the risk assessment area undetected via this pathway as this concerns the intentional movement of plant material into the risk assessment area.

The species could enter the environment undetected (likely) as the species may escape from garden centres and nurseries via seed or the dumping of plant material. Although there is no direct evidence of actual movement of the species along this pathway it is highlighted in Pausas et al. (2006). Additionally, *C. selloana* is found growing in or around rubbish dumps in the Mediterranean region of the risk assessment area (Saura-Mas and Lloret, 2005).

An overall score of moderately likely has been given combining both of the scores for entry into the risk assessment area and entry into the environment.

**Qu. 1.7a. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: For live plant imports in the risk assessment area (introduction), each EU Member country has official entry points where plant material can be imported into. Therefore, these introduction points are widespread in the risk assessment area.

*Cortaderia selloana* can enter the environment from nurseries and gardens centres (the end point of this pathway) which are widespread within the risk assessment area.

**Qu. 1.8a. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The pathway horticulture involves the movement of plant material for planting from outside of the risk assessment area via nurseries and garden centres.

This pathway is active and there is firm evidence that the species is being moved along the pathway into the risk assessment area and there is the potential for the species to enter the natural environment.

Live plant material may be imported into the risk assessment area for sale in the horticulture industry. However, it should be noted that this is probably more of a historic pathway as the species is likely to be propagated within the risk assessment area as the species can be easily grown from root fragments.

The overall likelihood of *C. selloana* entering the risk assessment area is scored as very likely as the species is already present.

**Pathway name: (2) Ornamental purposes other than horticulture (escape from confinement)**

**Qu. 1.2b. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	Unintentional <b>intentional</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	-------------------------------------	-------------------	------------------------------

Response: This pathway includes the two ornamental purposes as detailed below. These ornamental purposes involve the intentional introduction of the species, though entry into the natural environment would be unintentional. This pathway includes the movement of all plant parts (live plants, seed and rhizomes) into the risk assessment area. The pathway includes the movement of plant material via e-commerce.

For escape/entry into the environment, this pathway includes the dumping of plant material into the natural environment.

**(1) Planting in private gardens (intentional introduction, unintentional entry)**

*Cortaderia selloana* has been utilized as a garden ornamental species since the early to mid-1800s within the risk assessment area. The species is a popular ornamental species (one of the most popular ornamental grass species in cultivation) and grown throughout the risk assessment area (Bacchetta et al. 2010; Missouri Botanical Garden 2020; NNSS 2015). Domenech et al. (2005) highlighted clear evidence that *C. selloana*

invasion in Spain is highest in areas close to urban landscapes, indicating that planting the species can facilitate spread into other areas.

**(2) Dried panicles (intentional introduction, unintentional entry)**

Dried panicles of *C. selloana* are available via e-commerce both within the risk assessment area and from outside the risk assessment area from suppliers like eBay and Amazon.

**Qu. 1.3b. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?** including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Fig. 1 An example of *Cortaderia selloana* seeds available via online suppliers.

Response:

**Planting in private gardens**

There is no information on frequency or volumes entering the risk assessment area or the environment.

The species is available for sale via e-commerce sites such as:

eBay [https://www.ebay.com/b/cortaderia-selloana/bn\\_7024827254](https://www.ebay.com/b/cortaderia-selloana/bn_7024827254))

Amazon <https://www.amazon.com/PAMPAS-GRASS-WHITE-Cortaderia-selloana/dp/B00480FHXS>)

B&T Seeds: <https://b-and-t-world-seeds.com/carth.asp?species=Cortaderia%20selloana&sref=73>.

These sites will ship seeds from outside of the risk assessment area into the risk assessment area.

There are numerous suppliers listed on the e-commerce sites that advertise various color forms of the species, both full size and in dwarf form. Fig. 1 highlights examples which can be purchased via an online supplier in China. Seeds are also available via e-commerce from North America. These suppliers sell seeds directly to the buyer and are popular for buyers wanting different color forms.

Entry into the natural environment is very likely as the species will be planted in gardens, sometimes in close proximity to the natural environment. Wind dispersal can act to move the species from gardens into the natural areas.

If eradication measures are taken following planting, there is the potential that the species can re-establish if replanted. As one female plant can produce up to 1 million seeds, only a small population is needed to result in subsequent establishment.

### Dried panicles

There is no information on frequency or volumes entering the risk assessment area or the environment.

Dried panicles of *C. selloana* are available via e-commerce both within the risk assessment area and from outside the risk assessment area from suppliers like eBay and Amazon. The panicles may be color dyed and sold as decorative plumes for indoor use: <https://lamboodrieddeco.com/new-in-coloured-pampas-grass/>

This pathway is highlighted within the risk assessment for *C. selloana* conducted by the USDA (2014).

Lambrinos (2001) highlights the historical production and export of *C. selloana* plumes in California (USA) in the late-1800s. Up to 1 000 000 plumes were exported each year throughout the United States.

For introduction into the risk assessment area, full, fluffy white plumes without seeds shedding would be the preferred state. It is likely that premature female inflorescences would be harvested (this was one of the “innovations” that helped spark the dried plume craze in the late 1880’s). If current commercial methods are the same, fertilization of the embryos and the viability of any seed should be near zero in a floral trade inflorescence. Of course, there may be errors, particularly since it depends on harvest timing. But in a commercial operation the quality control is probably pretty good. Therefore, for dried plumes the overall risk is low (John Lambrinos, pers. comm. 2020).

If eradication measures are taken following planting, there is the potential that the species can re-establish if replanted. As one female plant can produce up to 1 million seeds, only a small population is needed to result in subsequent establishment. The number of potential areas where the species can escape from increases the difficulty of eradication at a large scale.

**Qu. 1.4b. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Plant material is the commodity itself and it is deliberately moved for sale within the risk assessment area. Therefore, plant parts or whole parts are likely to survive along the pathway.

The following section lists the plant parts of concern:

**Seed**

It is very likely that seeds (caryopsis) will survive along the pathway. It would not be possible for the species to reproduce or increase during transport and storage along this pathway. When dried, the seeds of *C. selloana* can remain viable approximately 12 months and therefore this will increase the chance of survival during transport. However, DiTomaso et al. (2003) highlight that seeds typically survive for less than six months under field conditions.

**Live plants**

Live plants will be moved along the pathway and packaged to promote their survival. It is unlikely the plants will reproduce or increase during their transport along this pathway. The end result of the pathway is the planting of the species in a suitable area (garden) to promote its growth. From this, seeds can enter the environment via escape/release.

**Rhizomes**

Rhizomes may be moved along the pathway and packaged to promote their survival. There is no data on the survival of the rhizomes but it is likely that they will survive during transportation as industry will ensure they are packaged appropriately to ensure survival.

**Dried plumes**

Dried plumes are unlikely to contain viable seeds (1.3b) due to the timing of the harvest.

**Qu. 1.5b. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low medium high
-----------------	--	-------------------	-----------------------

Response: Management practices before and during transport are very likely to facilitate the survival of the species as it is the commodity itself. Management practices during storage may affect the survival of the species and this could increase or decrease the length of time seed is viable. For example, temperature may affect the survival of the seed. As the panicles are delicate, care would be taken to transport the product and if seeds remain viable the seed can remain attached to the panicle. There would not be any management practices conducted along this pathway.

Management practices, i.e. removal and dumping, in gardens and waste disposal may increase the survival of the species and facilitate the reproduction as the species. CABI (2020) note that vegetative reproduction can occur when tillers are fragmented and receive adequate moisture. Therefore, management practices such as physical removal or cutting above and below ground material may lead to fragmentation of the

rhizome material. Thus, below ground plant material is likely to survive the movement and dumping when placed in a suitable habitat.

Other management practices (e.g. chemical control of weeds in gardens), may have an impact on the survival and reproduction of the species.

**Qu. 1.6b. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: It is unlikely that the organism will be introduced into the risk assessment area undetected as this is the deliberate movement of plant material into the risk assessment area.

The species can enter the risk environment via natural spread (wind) and via the dumping of garden waste. If plant waste has mature flowers this would increase the likelihood to likely. Female plants can produce up to 1 million seeds, large numbers of propagules can enter the natural environment as a result of a single dumping of one plant, if the plant contains plumes that contain viable seeds. *C. selloana* can grow in dense stands where numerous plants would be managed and controlled and potentially dumped.

For dried plumes, it is unlikely that the species would be introduced into the risk assessment area undetected as the dried plumes are the commodity. However, the species could be introduced into the environment undetected if fragments of the dried material are accidentally moved. As the dried plumes are for use mainly in an indoor environment, it is unlikely that this would occur.

An overall score of moderately likely has been given combining both of the scores for entry into the risk assessment area and entry into the environment.

**Qu. 1.7b. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: For the introduction of seed imports and dried plumes via e-commerce, the entry points are widespread as anyone with an internet connection and a postal address can obtain seeds of the species from

outside the risk assessment area. Therefore, introduction points are widespread within the risk assessment area.

In 2016, 85% of European households had an internet connection. 189.8 million people had a broadband connection in Europe in 2016 (Statista, 2020). Private gardens associated with households are high. For example, data from 2014 shows that 58% of houses have a garden or outside space in France, 81% in the United Kingdom, 80.3% in Poland and 27% in Spain (Statista, 2020).

**Qu. 1.8b. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: Seed is the most likely plant material that would be imported into the risk assessment area and they have the highest likeliness of entry into the natural environment as they are wind dispersed. This introduction pathway is active and there is firm evidence that the species is being moved along the pathway into the risk assessment area. Especially, the species is already present (recorded or established) in the risk assessment area, hence the likelihood of introduction and entry should be scored as “very likely” by default.

For dried plumes, the overall likelihood of the species entering the risk assessment and enter into the environment is unlikely. This score reflects the fact that viable seeds are unlikely to be present, and it is for use in an indoor environment. Additionally, there is no evidence that viable seeds are moved along this pathway. As previously discussed, plumes are harvested before seed would reach maturity.

The score above is based on the worst case scenario (seeds).

**Pathway name (3): Landscape / flora / fauna improvement in the wild**

**Qu. 1.2c. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	intentional unintentional	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	------------------------------	-------------------	------------------------------

Response: Introduction via this pathway is intentional. Entry into the environment is unintentional. The species may be planted on transportation networks and other semi-urban habitats but not intentionally in the natural environment.

**Qu. 1.3c. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: There is no data on the frequency and volume of movement along this pathway.

It is very likely that the number of individuals introduced will be sufficient to originate a viable population that can escape from the origin over the course of one year. As already highlighted, a single female plant can produce up to 1 000 000 seeds in the first year of growth. These seeds are wind spread and seeds are robust and can germinate in a variety of soil types.

*C. selloana* has been planted in urban and semi-urban environments in the risk assessment area for a number of purposes including as (1) a boundary or barrier species for properties, or transportation route and (2) landscape improvement (Domènech et al. 2006).

In the Mediterranean region, the species has been repeatedly planted along transportation routes to hide roads from bordering properties. For example, in Galicia (North West Spain), *C. selloana* was planted along the main highways during the 1980s where it was used as an ornamental species along the side or central strip of the road. The species is commonly grown on roundabouts (Charpentier et al. 2020). Planting along urban transportation routes has aided its spread in the Mediterranean region (Domènech and Vilà 2007).

If eradication measures are taken following planting, there is the potential that the species can reestablish if replanted. As one female plant can produce up to 1 million seeds, only a small population is needed to result in subsequent establishment.

**Qu. 1.4c. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: There is no data on the effect of movement along this pathway on the survival or reproduction of *C. selloana* along this pathway. This pathway involves the deliberate movement of plant material into the risk assessment area and as such plant material would be maintained and moved to ensure the survival of plant material.

Planting of live plants would be the most likely type of material used in this practice. Once planted in urban or semi-urban habitats, the species will be able to reproduce and increase.

**Qu. 1.5c. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: Along the pathway, management practices will not be applied to the species and existing practices are unlikely to affect the survival of the species as it will be deliberately planted.

Vegetation management along road networks may affect the survival of the species. This would include general vegetation management and along roads and roundabouts. Road works and management of the bank side vegetation may increase the survival of the species and increase its potential to survive in the environment as such management may increase disturbance which can promote the establishment of the species.

**Qu. 1.6c. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: It is unlikely that the organism will be introduced into the risk assessment area undetected as this is the deliberate movement of plant material within the risk assessment area.

For entry into the environment, it is likely that *C. selloana* could enter the environment undetected as seed has the potential to escape from planted populations via wind movement. Any seeds that find a suitable habitat are likely to remain undetected until the plants develop into a more mature plant. In Spain and France the species has been shown to have spread from urban and semi-urban plantings (Charpentier et al. 2020; Pardo-Primoy and Fagúndez 2019).

**Qu. 1.7c. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: The possible entry points of introduction are widespread within the risk assessment area. Urban and semi-urban areas are widespread within the risk assessment area. Transportation networks are widespread throughout the risk assessment area.

**Qu. 1.8c. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The overall likelihood of *C. selloana* entering the environment from the pathway landscape / flora / fauna improvement in the wild is very likely with a high confidence. The species can be planted as (1) a boundary or barrier species for properties, or transportation route and (2) landscape improvement (Domènech et al. 2006). There is a long history of planting *C. selloana* for this purpose in the risk assessment area.

**Pathway name (4): Transport – Contaminant (transport of habitat material (soil, vegetation))**

**Qu. 1.2d. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response: Entry via this pathway is unintentional movement of the species via the contamination of habitat material (soil and vegetation).

**Qu. 1.3d. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year? including the following elements:**

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: There is no information available on the volumes of movement along this pathway. The transport of topsoil, sand and or other contaminated habitat material with seed or rhizome could facilitate entry into the RA area. However, the pathway is mainly closed within the RA as there are prohibitions of the movement of soil into the EU from many countries.

Such material is likely to be placed in suitable habitats in the risk assessment area for the establishment of the species. Both seed and rhizome fragments can be introduced and enter the environment via this pathway.

*Cortaderia selloana* can produce a large biomass of rhizomes which may regenerate into viable plants. These rhizomes can be buried in soil and included in habitat material which is then transported both into the risk assessment area and within the risk assessment area.

Seed may be included in soil and habitat material. Although there is no evidence, seed may be less of a risk than rhizome material as the seeds would be less robust and their viability decreases over time.

**Qu. 1.4d. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: The seeds of the species are small and therefore they could survive during transport along this pathway. The species has been shown to germinate in a range of soil substrates which may aid survival along this pathway (Domènech and Vilà 2007). Rhizome material can remain viable within soil material.

**Qu. 1.5d. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: The species is moderately likely to survive existing management practices along this pathway. However, there is no information available for this pathway.

Management practices such as those that cause disturbance (roadworks, development, laying new electric or water pipes) to the habitat are likely to facilitate the entry of the species into the environment.

**Qu. 1.6d. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: The seeds are relatively small and potentially can remain undetected within soil. Similarly, rhizomes can be viable at a small size and buried in soil and other material, making them difficult to detect.

**Qu. 1.7d. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated	<b>CONFIDENCE</b>	low
	<b>widespread</b>		medium
	ubiquitous		high

Response: There are no specific data on the points of introduction or entry.

Points of introduction can include road routes which join countries and other international transportation hubs. These are widespread throughout the risk assessment area. Urbanization and the management of land is increasing through the risk assessment area.

**Qu. 1.8d. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
	unlikely		medium
	<b>moderately likely</b>		high
	likely		
	very likely		

Response: Both seed and rhizome may be able to move through this pathway, and the commodity is placed within the environment where the propagules have the opportunity to establish. However, there is no direct evidence that the species has moved along this pathway and therefore it is scored moderately likely with a low uncertainty.

**Pathway name (5): People and their luggage/equipment (in particular tourism)**

**Qu. 1.2e. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	intentional	<b>CONFIDENCE</b>	low
	<b>unintentional</b>		medium
			<b>high</b>

Response: This pathway involves the unintentional introduction and entry into the environment of plant material (seeds or rhizomes) as a contaminant of people's luggage and their equipment.

**Qu. 1.3e. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year? including the following elements:**

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: Seeds of *C. selloana* can be moved along this pathway as a contaminant of recreational equipment which can adhere to surfaces like Velcro or on hiking boots (Weeds of Southern Tasmania, n.d.). Recreationalists would need to be in the natural environment when the seeds are being dispersed by wind (autumn months) and the seeds would need to be transferred to the environment at a time when conditions are suitable for germination and growth. There is a low confidence on the number of propagules that may be transported along this pathway as this depends on a number of factors including walking close to monocultures of the species, the direction of wind, etc.

**Qu. 1.4e. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: The seeds of the species are small and could survive during transport along this pathway. The substrate would be conducive to maintain survival. The species would not reproduce along this pathway or increase.

**Qu. 1.5e. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: Careful methodical management practices coupled with inspection of boots and clothing would be needed to ensure that the species is not introduced.

**Qu. 1.6e. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: The seeds are small and potentially may potentially remain undetected within the tread of hiking boots and on other surfaces of recreational equipment. Additionally, the seeds may not be easily identifiable to non-botanists and thus may be overlooked.

**Qu. 1.7e. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: Introduction points into the risk assessment area can include airports, international railway stations but also road networks that join with non-EU countries. The entry points which can include any area that is used for recreational purposes in the EU.

**Qu. 1.8e. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: A rating of moderately likely with a low confidence is given to this pathway. As previously mentioned, several factors can influence the movement along this pathway (wind, proximity of travellers to stands of *C. selloana*, etc.) and there is a number of unknowns, for example can seed attach to recreational equipment.

**Qu. 1.9. Estimate the overall likelihood of introduction into the risk assessment area or entry into the environment based on all pathways and specify if different in relevant biogeographical regions in current conditions.**

Provide a thorough assessment of the risk of introduction in relevant biogeographical regions in current conditions: providing insight in to the risk of introduction into the risk assessment area.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The overall likelihood of *C. selloana* being introduced into the risk assessment area is very likely with a high confidence especially because the species is already present (recorded or established) in the risk assessment area, hence the likelihood of introduction and entry should be scored as “very likely” by default. The species has been known to be introduced into the risk assessment area by Horticulture (escape from confinement), Ornamental purpose other than horticulture (e.g. planting the species along roads and for private gardeners). *C. selloana* has the potential of being dumped in the environment as the species produces a lot of above ground biomass which can be difficult to dispose of in the proper means. Dried plumes of the species are available for purchase and can be imported into the risk assessment area. People and their luggage/equipment (in particular tourism) (movement into the risk assessment area) can act to move the species into the environment if seeds are attached to recreational equipment.

As the highest occurrences of the species in the environment are in the Atlantic, Continental and Mediterranean biogeographical regions, it is these regions that would potentially see a higher likelihood of entry into the environment. The species distribution modelling shows that the boreal and alpine biogeographical regions are currently unsuitable for the establishment of the species and therefore the likelihood of the species traded for horticultural purposes in these regions is low.

**Qu. 1.10. Estimate the overall likelihood of introduction into the risk assessment area or entry into the environment based on all pathways in foreseeable climate change conditions?**

Thorough assessment of the risk of introduction in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of introduction (e.g. change in trade or user preferences)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely introduction within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The main aspects of climatic change which will influence the entry of *C. selloana* into the risk assessment area include increased minimum temperature of winter months, increased spring and summer temperatures.

Climate change (RCP 2.6 2070) will expand the potential distribution the species can establish in, making the species more available to gardeners. For example, the southern areas of Sweden may become more suitable for growing the species and the horticulture pathway may expand in this area to meet further demand. Ornamental plants traded for private gardens and landscape improvements may also see a higher volume and frequency.

## 2 PROBABILITY OF ESTABLISHMENT

### Important instructions:

- For organisms which are already established in parts of the risk assessment area or have previously been eradicated, the likelihood of establishment should be scored as “very likely” by default.
- Discuss the risk also for those parts of the risk assessment area, where the species is not yet established.

**Qu. 2.1. How likely is it that the organism will be able to establish in the risk assessment area based on similarity of climatic and abiotic conditions in its distribution elsewhere in the world?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: *Cortaderia selloana* is already established in the natural environment in the risk assessment area (France, Ireland, Italy, Portugal, Spain, United Kingdom). It is likely that further countries where the species could potentially establish are present within the RA area.

The SDM (Annex VIII) shows the potential distribution of the species based on the current occurrence of the species both in the risk assessment area and elsewhere in the world. The model shows that there is a large area of the EU that is suitable for the establishment of *C. selloana*.

In the native and introduced ranges (outside of the EU), *C. selloana* occurs predominantly in the Köppen-Geiger climate classifications of Cfa ([Humid subtropical climate](#)), Cfb (Temperate [oceanic climate](#)), CSb ([Warm-summer Mediterranean climate](#)) and Bsk ([Cold semi-arid climate](#)). MacLeod and Korycinska (2019) estimate that the percentage of 5-minute grid cells for each aforementioned climate category occurring in the EU are as follows: Cfa 6.31 %, Cfb 48.62 %, CSb 3.8% and Bsk 1.46. Based on this almost 60% of the EU plus the United Kingdom is climatically suitable.

*Cortaderia selloana* seeds have been shown to germinate under a range of temperatures from 15 °C to 30 °C. Within this range, 100% germination was demonstrated (Domènech and Vilà 2007). In northern, humid areas of Spain, population size can increase two-fold in a year (Herrera Gallastegui and Campos Prieto 2006). Seeds can germinate under a wide range of environmental conditions (light, soil types and varying water availability), however, shading, high levels of sand in soil and water availability all act to improved germinations rates (Domènech and Vilà 2008a).

**Qu. 2.2. How widespread are habitats or species necessary for the survival, development and multiplication of the organism in the risk assessment area? Consider if the organism specifically requires another species to complete its life cycle.**

<b>RESPONSE</b>	very isolated isolated	<b>CONFIDENCE</b>	low medium
-----------------	---------------------------	-------------------	---------------

	moderately widespread <b>widespread</b> ubiquitous		<b>high</b>
--	--	--	-------------

Response: In the risk assessment area, *C. selloana* is found in ruderal habitats (Domènech and Vilà 2007) and natural habitats. The species benefits from habitat disturbance which can promote the establishment (Pausas et al. 2006). *Cortaderia selloana* has established in urban and semi-urban habitats in the Mediterranean region, including industrial areas and waste/abandoned lands. The species can be found growing along transportation infrastructure including railways and road networks (where in the case of the latter the species has been deliberately planted).

The species can invade wetlands, coastal dune systems and coastal grasslands. Additionally, the species can grow in scrubland and shrubland (CABI 2020). It can grow along the side of rivers, also in the case of Mediterranean temporary rivers.

*Cortaderia selloana* does not need any other species to complete its life cycle. Seeds of *C. selloana* can withstand salt exposure. At 3% NaCl concentration seeds showed 90% viability. Seedling survival showed decreases with 2 and 3% NaCl. Laboratory tests conducted in Sardinia (Italy) on seeds collected from naturalised populations of *Cortaderia selloana* showed that salinity did not prevent seeds from germinating, but it affected germination rate and seedling vigour (Bacchetta et al. 2010). Seeds can germinate in a wide range of substrates which promote the establishment of the species in a wide range of habitats. An analysis of soil characteristics across 27 populations along a 300 km area, found soil N ranging from 0.03-0.3%, organic C from 0.09-4.6% and pH 7.4-8.5 (CABI 2020). The species can tolerate free draining soils and soaked soils (wetlands). *Cortaderia selloana* can also grow in light and medium soil textures (CABI 2020). In the introduced range, the proportion of juvenile plants has been shown to be positively correlated to percentage bare ground (Domènech and Vilà 2007).

Domènech and Vilà (2008a) showed that *C. selloana* is adapted to water stress as the species can maximize water uptake and minimize water loss when water becomes scarce. This can enable the species to establish in both wetlands and ruderal habitats where in the case of the latter water may be scarce. This factor can also act to help establishment in Mediterranean ecosystems where the climate is hot and dry and water availability can be limited.

*C. selloana* grows best in open ground in full sun but it can tolerate light shade. CABI (2020) highlights that in its introduced range, *C. selloana* can be found from sea level to around altitudes of 400 m.

**Qu. 2.3. How likely is it that establishment will occur despite competition from existing species in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: *Cortaderia selloana* is a highly competitive species which can form dense monodominant stands and outcompete native vegetation. *Cortaderia selloana* increases its density and colonizes semi-natural

areas in a short period of time, changing the vertical structure of the vegetation and competing with native plants (Sinnassamy 2001; Campos et al. 2004). Its invasion reduces plant species, life form richness and native species cover; the similarity of native species composition with non-invaded areas can decrease by more than 50% (Domènech and Vilà, 2008b). The plant is spreading along roads and within fragile dune ecosystems in Portugal (Marchante et al. 2005). In France it is recognised that its rapid growth allows it to form dense colonies, accumulating significant above and below ground biomass thereby competing with native plants for access to resources including light, space, nutrients and water to the detriment of these species (AME 2003).

**Qu. 2.4. How likely is it that establishment will occur despite predators, parasites or pathogens already present in the risk assessment area?**

<b>RESPONSE</b>	N/A very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: It is very likely that establishment will occur despite predators, parasites or pathogens already present in the risk assessment area. *Cortaderia selloana* does not have any host specific natural enemies in the risk assessment area and there is no evidence that native organisms feed or infect the species in substantial levels to inflict any damage on the species.

**Qu. 2.5. How likely is the organism to establish despite existing management practices in the risk assessment area? Explain if existing management practices could facilitate establishment.**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: As detailed in section (3.2), the establishment of *C. selloana* is suited to disturbed habitats especially abandoned land (Domènech and Vilà 2007; Domènech et al., 2005). It is therefore likely that the current urbanization trend occurring in Europe may favour the establishment of the species.

Domènech et al. (2006) noted that the invasiveness of *C. selloana* decreased with distance from urban areas, highlighting that the source of many invasions is a result of propagule pressure from urban areas.

**Qu. 2.6. How likely is it that biological properties of the organism would allow it to survive eradication campaigns in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Wind dispersal of seed, and underground rhizomes which can spread vegetatively, can promote the survival of the species during eradication campaigns.

Although the seed is relatively short lived, and there is no long-lived seed bank (Company et al. 2019; Bacchetta et al. 2010), the species produces large amounts of small seeds which can colonise areas where eradication efforts could potentially miss (Company et al. 2019).

**Qu. 2.7. How likely are the biological characteristics of the organism to facilitate its establishment in the risk assessment area?**

including the following elements:

- a list and description of the reproduction mechanisms of the species in relation to the environmental conditions in the risk assessment area
- an indication of the propagule pressure of the species (e.g. number of gametes, seeds, eggs or propagules, number of reproductive cycles per year) of each of those reproduction mechanisms in relation to the environmental conditions in the risk assessment area.
- If relevant, comment on the likelihood of establishment based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in establishment whereas for others high propagule pressure (many thousands of individuals) may not.
- If relevant, comment on the adaptability of the organism to facilitate its establishment and if low genetic diversity in the founder population would have an influence on establishment.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: *Cortaderia selloana* has two reproductive mechanisms (sexual via seed and asexual via rhizomes). However, CABI (2020) citing (DiTomaso 2000) detail that vegetative reproduction hardly occurs in nature, though it is not clear if this US reference applies to the risk assessment area. The rhizomes are short and contribute to the gradual lateral growth of individual clumps. Old specimens in botanical gardens can get quite large in part through shoot growth from rhizomes along the outer edge of the clump. Often the center of old plants will die leaving a ring of new clones. But in contrast to some other species, new vegetative propagules develop far from the parent plant/clump. So in a practical sense almost all population growth at a location is from sexual reproduction. Seeds that are wind blown can increase the likelihood of propagules finding a suitable habitat in which to establish. Each female plant can produce up to 1 million seeds. According to CABI (2020) “It flowers in late summer, and hermaphrodite panicles appear 1 or 2 weeks before female panicles (Parsons and Cuthbertson 2001). Seed dispersal occurs in the autumn and seeds germinate in the early spring”. Thus, one flowering period occurs within the risk

assessment area in one year. The species can be long lived with references to the rhizomes being able to survive up to 40 years (Costas Lippmann, 1976). However, Moore (1994) suggest under normal conditions plants may live between 10 and 15 years. Parsons and Cuthbertson (2001) state: Rhizome fragments, severed during cultivation, tend to take root and establish new colonies wherever they are deposited. Grubbed crowns, carelessly dumped in tips and waste places, re-establish easily if moisture is available, and provide a potential seed source for future spread". CABI (2020) citing (DiTomaso 2000) detail that vegetative reproduction hardly occurs in nature, but plant propagation through the division of mature plants has traditionally been used for ornamental purposes.

There is no information on the establishment potential in relation to genetic diversity.

**Qu. 2.8. If the organism does not establish, then how likely is it that casual populations will continue to occur?**

Consider, for example, a species which cannot reproduce in the risk assessment area, because of unsuitable climatic conditions or host plants, but is present because of recurring introduction, entry and release events. This may also apply for long-living organisms.

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: In areas where *C. selloana* is not present, casual populations may occur if propagule pressure is high in urban habitats or semi-urban habitats (Domènech *et al.*, 2005). Casual populations may occur in surrounding habitats. Casual populations are likely to occur in areas outside the optimum climatic conditions. For example, this may include areas in Figure 5 of Appendix 4 at the margin of suitable and unsuitable areas. Countries where casual populations may occur include Germany, Poland, Lithuania, Slovakia, Southern Sweden and the coastline of Norway.

**Qu. 2.9. Estimate the overall likelihood of establishment in the risk assessment area under current climatic conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under current climatic conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in current conditions: providing insight in the risk of establishment in (new areas in) the risk assessment area.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The overall likelihood of *C. selloana* establishing in the risk assessment area is very likely with high confidence. The species is already established in the Mediterranean, Continental and Atlantic

biogeographical regions. Countries where the species is established include: France, Ireland, Italy, Spain, Portugal and the United Kingdom. Both the Mediterranean and Pannonian biogeographical regions have a high proportion of area suitable for the establishment of the species and thus further establishment is likely in these areas under the current climatic conditions. Likewise, the Macaronesia, Continental, Black Sea, and Atlantic biogeographical regions have a moderate proportion of area available for the establishment of the species. Within the EU, the boreal biogeographical region has a very low area available for establishment.

**Qu. 2.10. Estimate the overall likelihood of establishment in the risk assessment area under foreseeable climate change conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under foreseeable climate change conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of establishment (e.g. increase in average winter temperature, increase in drought periods)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely establishment within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6 °C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0 °C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The overall likelihood of *C. selloana* establishing in the risk assessment area under future climatic conditions (2070 RCP. 2.6) is very likely with high confidence. The species is already established in the Mediterranean, Continental and Atlantic biogeographical regions. Both the Mediterranean and Pannonian biogeographical regions have a high proportion of area suitable to the establishment of the species and thus further establishment is likely in these areas under future climatic conditions. Some areas within the aforementioned, increase in sustainability. Likewise, areas of suitability are shown to increase in both area and local density in the following biogeographical regions: Macaronesia, Continental, Black Sea and Atlantic. Within the EU, southern areas of the Boreal biogeographical region show potential for establishment and small coastal areas of Norway (Alpine biogeographical region) under future climatic conditions (see Annex VIII).

The main aspects of climatic change which will influence the establishment of *C. selloana* include increased minimum temperature of winter months, increased spring and summer temperatures and increased

precipitation. Increased frequency of fire, as the result of increased temperatures, may promote the establishment of the species in natural areas where otherwise it would not be able to get a foothold.

### 3 PROBABILITY OF SPREAD

**Important instructions:**

- Spread is defined as the expansion of the geographical distribution of an alien species within the risk assessment area.
- Repeated releases at separate locations do not represent continuous spread and should be considered in the probability of introduction and entry section (Qu. 1.7).

**Qu. 3.1. How important is the expected spread of this organism within the risk assessment area by natural means? (List and comment on each of the mechanisms for natural spread.)**

including the following elements:

- a list and description of the natural spread mechanisms of the species in relation to the environmental conditions in the risk assessment area.
- an indication of the rate of spread discussed in relation to the species biology and the environmental conditions in the risk assessment area.

The description of spread patterns here refers to the CBD pathway category “Unaided (Natural Spread)”. It should include elements of the species life history and behavioural traits able to explain its ability to spread, including: reproduction or growth strategy, dispersal capacity, longevity, dietary requirements, environmental and climatic requirements, specialist or generalist characteristics.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: There are two main reproductive modes for the natural spread of *Cortaderia selloana* (1) seed and (2) vegetative propagation via basal-stem-rhizome fragments.

**via seeds:**

It is interesting to note that historically both in the USA and the RA area, only female plants were imported for cultivation, and later seeds were traded which grew into hermaphrodite plants (Bossard et al. 2000; LIFE STOP Cortaderia, 2020).

Caryopsis and glumettes (hereafter seeds) of *C. selloana* are light and dispersed by wind and human activity (DiTomasto et al. 2010. Seeds are hairy (due to the presence of long hairs on lemmas, only in female plants) narrowly elliptical and small (0.6 mm by 2mm, Parsons and Cuthbertson 2001). From studies in the United States, WSNWCB (2014) state ‘Saura-Mas and Lloret’s (2005) research on wind dispersal of seeds found wind-affected seed from 1 to 20 meters away from the sources, and there was no effect at distances greater than 20 meters. The distance from the source plant significantly reduced the number of seeds reaching the soil’.

According to CABI (2009) ‘Seeds can disperse to at least 40 m away from mother plants, and local wind direction determines the spatial distribution of seedlings (Saura-Mas and Lloret 2005). Typically though, the effect of wind on seeds moved them relatively short distances (1-20 m) (Saura-Mas and Lloret 2005). However, NNSS (2015) quote larger distance of wind dispersal, established seed producing plants in gardens, parks and outside cultivation can be sources for natural spread through the dispersal of the

lightweight seeds with distances to up to 25 km (Parsons and Cuthbertson 2001)'. Difference in wind speed, intensity, direction and physical barriers to the movement of seed, can all affect the distance seed will be able to travel. Wind currents produced by traffic should also be considered as a factor of seed spread where the species occurs along transportation routes. For the risk assessment region, the natural spread by wind should be considered for up to 40 m though in coastal areas this may be greater.

If planted, or if the species escapes into habitats in the risk assessment area, natural spread is likely to facilitate movement to suitable habitats as the seed can be carried over long distances. Locally, in the Mediterranean region, the volume of seed production will support spread as the species occurs in high numbers in this area. USDA (2014), citing Muyt (2001), highlight that seeds can spread in water bodies, but no evidence has been found for water dispersal of the seeds. USDA (2014) also detail that there is no evidence for bird or animal (external or internal) dispersal, however, CAL IPC (2020) detail that seed can adhere to the fur of animals.

Seed dispersal occurs late in the year following flowering and fruiting usually in October to mid-November in the Atlantic biogeographical region.

#### **via rhizomes:**

Natural spread via rhizome fragments is likely to be only local and over short distances. There is no exact information available on the size of a viable rhizome fragment. However, it is cited throughout the literature that fragments can be viable and regenerate from the node. Therefore, based on the knowledge of the authors of this risk assessment, it is possible that small rhizome fragments (e.g. 2-3 cm in length with a node) can produce a viable plant. CABI (2020) citing (DiTomaso 2000) detail that vegetative reproduction hardly occurs in nature.

#### **Spread within the risk assessment area**

*Cortaderia selloana* has shown a rapid range expansion within the Mediterranean region (Company et al. 2019). Bacchetta et al. (2010) highlight that much of the spread of the species in the Mediterranean regions is facilitated by the change in land use. Presumably, increased urbanisation has resulted in existing populations being disturbed, and along with a combination of natural dispersal and potential movement of contaminated habitat material, has promoted the spread of the species within the region. Much of this spread can be attributed to natural dispersal of seeds via wind movement, but also due to the propagule pressure within the region.

In Galicia (North West Spain), *C. selloana* spread along the main highways during the 1980s where it was used as an ornamental species along the side or central strip of the road. Therefore, wind currents produced by traffic should also be considered as a factor of seed spread where the species occurs along transportation routes. Domènech et al. (2006) assessed the invasion of *C. selloana* in Catalonia (NE Spain) between 1998 to 2003. The number of invaded fields increased 1.85 times during 5 years (from 12.05% in 1998 to 22.30% in 2003), at a mean rate of 0.37 fields per year (Domènech et al. 2006). Invasion in agricultural fields increased from 17 in 1998 to 40 in 2003, pastures increased from 18 to 27 from 1998 to 2003 and old fields increased from 5 to 7 from 1998 to 2003.

**Qu. 3.2a. List and describe relevant pathways of spread other than "unaided". For each pathway answer questions 3.3 to 3.9 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 3.3a, 3.4a, etc. and then 3.3b, 3.4b etc. for the next pathway.**

including the following elements:

- a list and description of pathways of spread with an indication of their importance and associated risks (e.g. the likelihood of spread in the risk assessment area, based on these pathways; likelihood of survival, or reproduction, or increase during transport and storage; ability and likelihood of transfer from the pathway to a suitable habitat or host) in relation to the environmental conditions in the risk assessment area.
- an indication of the rate of spread for each pathway discussed in relation to the species biology and the environmental conditions in the risk assessment area.
- All relevant pathways of spread (except “Unaided (Natural Spread)”, which is assessed in Qu. 4.1) should be considered. The classification of pathways developed by the Convention of Biological Diversity shall be used (see Annex IV).

**Spread pathways are detailed in order of importance**

**Ornamental purposes other than horticulture (escape from confinement)**

This spread pathway is the intentional spread of the species for private gardening and urban and semi-urban plantings (roadsides and roundabouts for example). This pathway would be the most relevant for spread and include the highest movement of plant propagules.

**Transport – Contaminant (transport of habitat material (soil, vegetation))**

This spread pathway deals with the potential spread of contaminated habitat material. There is no quantitative evidence/ interceptions to support the movement of the species along this spread pathway but where urbanisation has occurred in the Mediterranean region the species has shown significant spread.

**Transport – stowaway: Machinery/ equipment**

This pathway details the potential spread of contaminated machinery and equipment. There is no quantitative evidence/ interceptions to support the movement of the species along this spread pathway but where urbanisation has occurred in the Mediterranean region the species has shown significant spread.

**People and their luggage/ equipment (in particular tourism)**

This pathway details the potential spread of contaminated luggage and equipment. There is no quantitative evidence/ interceptions to support the movement of the species along this spread pathway but it is considered as a potential pathway.

**Pathway name: (1) Ornamental purposes other than horticulture (escape from confinement)**

**Qu. 3.3a. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	Unintentional <b>intentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response: *Cortaderia selloana* is a popular ornamental species within the risk assessment area and has been spread throughout the region as a garden ornamental species. Additionally, the species is planted in urban and semi-urban habitats (for example along roads and on roundabouts).

**Qu. 3.4a. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Question A13 highlights that there are significant sales of the species within the risk assessment area (whole plants). Sales of the species can also be from seed. Seeds are sold in packets of multiple seeds. Plants can be purchased from garden centers within the risk assessment area and moved to gardens where they are planted. The species may also be dumped from waste garden material into the natural environment, though again, there is no details and the volume of movement or frequency.

**Qu. 3.5a. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: It is very likely that *C. selloana* plant material will survive during transport and storage along this pathway. A high seed viability would be an important factor for the suppliers to sell and continue to sell their stock. Once planted in a garden, the species would be planted and cared for so that the species grows and thrives. When dried, the seeds of *C. selloana* can remain viable approximately 12 months (USDA, 2014) and therefore this will increase the chance of survival during transport. Live plants will be moved along the pathway and packaged to promote their survival. It is unlikely the plants will reproduce or increase during their transport along this pathway.

**Qu. 3.6a. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: *Cortaderia selloana* is very likely to survive existing management practises during spread. Large amounts of seed are produced. Management of urban and semi-urban habitats is likely to increase disturbance of the habitat, which is favoured by the species (Pausas et al. 2006). Urbanisation has been shown to facilitate the spread of the species in the Mediterranean region (Domènech and Vilà 2007). If dumped, the species is likely to be deposited in ruderal habitats and potentially on waste ground where management practices may be minimal and the native vegetation sparse, this may make the survival of the species in these areas more likely. Soil disturbance (which may result from management activities) has been shown to increase the survival and biomass of plants (Domènech and Vilà 2006).

**Qu. 3.7a. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Seeds of the species are small and wind dispersed which can help to facilitate there spread undetected in the risk assessment area. Small rhizome fragments (e.g. 2-3 cm in length with a node) can produce a viable plant. These fragments may be spread via dumping of garden waste and therefore may be spread in the risk assessment area undetected.

**Qu. 3.8a. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: Seeds of the species are wind dispersed and there is a high potential that seeds could move outside the confines of the garden before being planted. The large amount of seeds produced increases the likelihood of some seeds finding a suitable habitat. The species has been shown to spread to ruderal habitats (Domènech and Vilà 2007) and natural habitats. The presence of the species in urban and semi-urban

habitats in the Mediterranean region, including industrial areas and waste/abandoned lands highlights the species spread (Pardo-Primoy and Fagúndez 2019). In Galicia (North West Spain), *C. selloana* spread along the main highways during the 1980s where it was used as an ornamental species along the side or central strip of the road (Pardo-Primoy and Fagúndez 2019).

The species can invade wetlands, coastal dune systems and coastal grasslands. Additionally, the species can grow in scrubland and shrubland (CABI 2020). It can grow along the side of rivers, also in the case of Mediterranean temporary rivers. There is also the potential for transfer from the pathway during movement but this should be considered as unlikely as seed would be packaged.

**Qu. 3.9a. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area. (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly slowly moderately <b>rapidly</b> very rapidly	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: *Cortaderia selloana* is a popular garden ornamental species which is sold and grows throughout the risk assessment area. It has also been planted in urban and semi-urban habitats. Spread has been recorded in Catalonia (NE Spain) between 1998 to 2003 where the number of invaded fields increased 1.85 times during 5 years (from 12.05% in 1998 to 22.30% in 2003), at a mean rate of 0.37 fields per year (Domènech et al. 2006). Invasion in agricultural fields increased from 17 in 1998 to 40 in 2003, pastures increased from 18 to 27 from 1998 to 2003 and old fields increased from 5 to 7 from 1998 to 2003. The species has also been shown to spread in industrial sites in Spain (Pardo-Primoy and Fagúndez 2019).

**Pathway name: (2) Transport – Contaminant (transport of habitat material (soil, vegetation))**

**Qu. 3.3b. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	-------------------------------------	-------------------	------------------------------

Response: The spread of *C. selloana* via transport of habitat material (soil, vegetation) is the unintentional spread of the species within the risk assessment area. Both seed material and rhizome fragments can be spread via this pathway.

**Qu. 3.4b. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium high
-----------------	--	-------------------	-----------------------

Response: There is no information available on the volumes of movement along this pathway. However, individual female plants produce a high number of seeds which can become incorporated into soil and attached to vegetation material. Additionally, rhizomes can be present in the soil. Soil disturbance has been shown to increase the survival and biomass of plants (Domènech and Vilà 2006).

**Qu. 3.5b. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: There is no quantitative evidence for *C. selloana*, for the survival, reproduction or increase as a contaminant of habitat material. The seeds of the species are small and therefore they could survive during transport along this spread pathway. Habitat material would be suitable for the survival of the species over short periods. The species has been shown to germinate in a range of soil substrates which will aid survival along this spread pathway. Rhizome material can remain viable within soil material.

**Qu. 3.6b. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low medium high
-----------------	--	-------------------	-----------------------

Response: Careful methodical management practices coupled with inspection would be needed to ensure that the species did not spread with contaminated soil and vegetation. This is often not feasible with such small seeds and small rhizome fragments.

**Qu. 3.7b. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: The seeds are relatively small and potentially can remain undetected within soil. Soil and other habitat material can be moved throughout the RA area and seeds can be spread within such material. Similar, rhizomes may be small and buried in soil and other material, making them difficult to detect.

**Qu. 3.8b. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: It would be likely that *C. selloana* can transfer to a suitable habitat if seed and rhizome material of the species is incorporated in soil. Topsoil and habitat material is often physically transferred to suitable habitats and thus it is very likely that the species will transfer to suitable habitats. This fact that the species is often recorded in urban development areas further supports the hypothesis that the species can be moved by soil and habitat material.

**Qu. 3.9b. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area. (provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: There is no quantitative data on the spread of the species in relation to habitat material.

Habitat material can move freely within the single market in the EU enabling contaminated material to spread over long distances. Both seeds and rhizome material may be included as a contaminant. Because of the lack of quantitative data, confidence is low.

**Pathway name: (3) Transport – stowaway: Machinery/ equipment**

**Qu. 3.3c. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response: Stowaway on machinery and equipment is the unintentional spread of the species within the risk assessment area.

**Qu. 3.4c. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: There is no information available on the volumes of movement along this pathway. However, in areas where the species is present, the amount of windblown seed can be high and thus there is a potential for spread as a high number of seeds can become incorporated into tread of tyres and other parts of machinery.

**Qu. 3.5c. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	<b>low</b>
-----------------	---------------	-------------------	------------

	unlikely <b>moderately likely</b> likely very likely		medium high
--	---	--	----------------

Response: The seeds of the species are small and therefore they could survive during transport along this spread pathway. However, there is no evidence if seeds are robust enough to survive movement along this pathway. The species is unlikely to increase along the pathway until it finds a suitable habitat.

**Qu. 3.6c. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: The seeds are relatively small and potentially can remain hidden in soil in cracks and crevices in machinery and equipment. Such machinery can be moved within the RA area transporting the seeds to new areas. ISPM 41 (IPPC 2017) ‘Intentional movement of machinery and equipment’ provides international measures for cleaning, which can be applied to local level movement also.

**Qu. 3.7c. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: The seeds and rhizome fragments are relatively small and potentially can remain hidden in soil in cracks and crevices in machinery and equipment. Such machinery can be moved within the RA area transporting the seed to new areas.

**Qu. 3.8c. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: It would be likely that *C. selloana* can transfer to a suitable habitat if the species is a stowaway on machinery/ equipment. Landscaping machinery and construction machinery is used in suitable habitats of the species, especially in the Mediterranean region. The fact that the species is often recorded in urban development areas further supports the hypothesis that the species can be moved by used machinery and equipment.

**Qu. 3.9c. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area. (provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: Used machinery and equipment can be moved within the RA area at a local and long distances scale. Any seed and rhizome material attached could be spread at a fast rate. However, it is only scored moderately likely as a number of measures can be adopted against this spread pathway to reduce the spread of the species. Inspections of used machinery and equipment coupled with cleaning will reduce the potential of spread of the species. A low uncertainty has been given as there is no quantitative data.

**Pathway name: (4) People and their luggage/ equipment (in particular tourism)**

**Qu. 3.3d. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	Low <b>medium</b> high
-----------------	-------------------------------------	-------------------	------------------------------

Response: The spread of *C. selloana* via people and their luggage/equipment, in particular tourism, is for this species, considered the unintentional spread of the species. In the sense of this pathway, spread of the species could be facilitated by seeds being incorporated into the tread of hiking boots or other equipment and moved accidentally to other areas within the risk assessment area.

**Qu. 3.4d. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**  
including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication

- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: There is no information available on the volumes of movement along this pathway. The seeds are hairy and extremely lightweight. They readily adhere to any rough surface such as clothing (John Lambrinos, pers. comm. 2020). However, the seed could adhere to Velcro or other material used by recreationalists.

**Qu. 3.5d. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: The seeds of the species are small and therefore they could survive during transport along this spread pathway. The substrate i.e. leisure equipment could be conducive to maintain survival. The species would not reproduce along this pathway or increase.

**Qu. 3.6d. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: Existing management practices occurring in the risk assessment area are unlikely to affect the spread of the species. Wind blown seeds, if anything are likely to benefit from management practices due to distance.

**Qu. 3.7d. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: The seeds are relatively small and potentially can remain undetected within the tread of hiking boots. Additionally, the seeds may not be easily identifiable to non-botanists and thus may be overlooked.

**Qu. 3.8d. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: It would be unlikely that *C. selloana* can transfer to a suitable habitat if the seed of the species is attached to hiking boots, clothes or camping equipment for example. This type of equipment may be re-used outside in a habitat suitable for the establishment of the species.

**Qu. 3.9d. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area.(please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly <b>slowly</b> moderately rapidly very rapidly	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: The overall potential rate of spread via this pathway is estimated as slowly with a low confidence. Recreationalists would also need to be in the natural environment when the seed are dispersed by wind (autumn months) and the seed would need to attach to clothes or equipment for propagules to spread.

**Qu. 3.10. Within the risk assessment area, how difficult would it be to contain the organism in relation to these pathways of spread?**

<b>RESPONSE</b>	very easy easy	<b>CONFIDENCE</b>	low <b>medium</b>
-----------------	-------------------	-------------------	----------------------

	with some difficulty <b>difficult</b> very difficult		high
--	--	--	------

Response: Natural spread would be difficult to control within the risk assessment area. Seeds are wind dispersed and can be spread over long distances. The high number of populations where the species can spread from is also a limiting factor for controlling the spread of the species. The species is found throughout the risk assessment area and is frequently planted in gardens. As the species can spread as a contaminant of soil and habitat material, machinery and equipment and recreational equipment, biosecurity measures and inspections would need to be adopted where these spread pathways are active, and the species is present. This would involve multiple stakeholders and communication and awareness raising to reduce the spread pathways. A ban on sale could act to prevent further spread of the species within the risk assessment area.

Preventing the spread from already established populations, including those in private gardens will be difficult due to the wide planting of the species. Measures could include preventing the plant from flowering but this would be practically impossible to implement.

**Qu. 3.11. Estimate the overall potential rate of spread in relevant biogeographical regions under current conditions for this organism in the risk assessment area (indicate any key issues and provide quantitative data where possible).**

Thorough assessment of the risk of spread in relevant biogeographical regions in current conditions, providing insight in the risk of spread into (new areas in) the risk assessment area.

<b>RESPONSE</b>	very slowly slowly moderately <b>rapidly</b> very rapidly	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: As a wind dispersed species that can spread up to 25 km by seed (Parsons and Cuthbertson 2001) and can be spread much further distance by human mediated activities (both deliberate: horticulture and unintentional: contaminant of habitat material and used machinery and equipment), the overall rate of spread can be estimated as very rapidly. Land use change in the Mediterranean region has promoted the spread of the species in recent years and if this trend continues further spread in this region and other suitable biogeographical regions (i.e. Atlantic and Continental biogeographical regions) is likely.

**Qu. 3.12. Estimate the overall potential rate of spread in relevant biogeographical regions in foreseeable climate change conditions (provide quantitative data where possible).**

Thorough assessment of the risk of spread in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk, specifically if rates of spread are likely slowed down or accelerated.

<b>RESPONSE</b>	very slowly	<b>CONFIDENCE</b>	<b>low</b>
-----------------	-------------	-------------------	------------

	slowly moderately <b>rapidly</b> very rapidly		medium high
--	--	--	----------------

Response: The SDM (see Annex VIII) shows that the area suitable for the establishment of *C. selloana* expands under climate change projections RCP 2.6 and 4.5 within areas of the Mediterranean, Atlantic and Continental biogeographical regions becoming more suitable. The potential distribution for establishment increases northwards into the Boreal biogeographical region. This can cause an increase of the use of the species as a garden ornamental species in areas where it had not previously occurred and this can increase the risk of spread. In addition, rate of urbanization and land development is likely to increase as the human population increases and this can act to facilitate the spread of the species. Biogeographical regions with established populations and high levels of urbanization may see high levels of spread as seen in the Mediterranean region.

Higher latitudes of the Boreal biogeographical region are likely to see lower spread rates as established populations will not be present.

## 4 MAGNITUDE OF IMPACT

<p>Important instructions:</p> <ul style="list-style-type: none"> <li>• Questions 5.1-5.5 relate to biodiversity and ecosystem impacts, 5.6-5.8 to impacts on ecosystem services, 5.9-5.13 to economic impact, 5.14-5.15 to social and human health impact, and 5.16-5.18 to other impacts. These impacts can be interlinked, for example, a disease may cause impacts on biodiversity and/or ecosystem functioning that leads to impacts on ecosystem services and finally economic impacts. In such cases the assessor should try to note the different impacts where most appropriate, cross-referencing between questions when needed.</li> <li>• Each set of questions starts with the impact elsewhere in the world, then considers impacts in the risk assessment area (=EU excluding outermost regions) separating known impacts to date (i.e. past and current impacts) from potential future impacts (including foreseeable climate change).</li> <li>• Only negative impacts are considered in this section (socio-economic benefits are considered in Qu. A.7)</li> <li>• In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”.</li> </ul>
---

### Biodiversity and ecosystem impacts

<p><b>Qu. 4.1. How important is the impact of the organism on biodiversity at all levels of organisation caused by the organism in its non-native range excluding the risk assessment area?</b></p> <p>including the following elements:</p> <ul style="list-style-type: none"> <li>• Biodiversity means the variability among living organisms from all sources, including terrestrial, marine and other aquatic ecosystems and the ecological complexes of which they are part; this includes diversity within species, between species and of ecosystems</li> <li>• impacted chemical, physical or structural characteristics and functioning of ecosystems</li> </ul>
---

<b>RESPONSE</b>	Minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: There is considerable evidence that *C. selloana* has a detrimental impact on biodiversity in its invaded range excluding the risk assessment area. Although known for ruderal invasions *C. selloana* is recognized as an invasive pest in California where it has frequently occupied non-ruderal habitats over the past 50 years (Lambrinos 2001) and can easily invade waste areas, open and disturbed areas in Australia (Harradine 1991). Once established, mature plants along with the congeneric *C. jubata*, are very competitive. Large infestations of *C. selloana* and *C. jubata* threaten California's coastal ecosystems by crowding out native species, particularly in sensitive coastal dune areas (Di Tomaso 2010). The plant is reported to displace native plant communities in coastal habitats in California (Motooka et al. 2003). It becomes dense and can suppress the growth of other species, replacing ground cover, shrubs, and ferns in

New Zealand (MPI 2012). *Cortaderia selloana* competes with and replaces native plants in South Africa (Wells et al. 1986).

A US Fish and Wildlife Service report (2010a, 2010b) record it as a danger to a Threatened and Endangered species *Streptanthus glandulosus* subsp. *niger* in California “strangling the plant” as well as competing with *Verbesina dissita* (big-leaved crownbeard) by monopolising resources.

In New Zealand, *C. selloana* is recorded as a weed of concern, i.e. known to be affecting the structure, species composition or regeneration of native plants (Owen 1996) based on publications by Humphries et al. (1991) and Mooney et al. (1986). The database also provides a weediness score and *C. selloana* ranks 27<sup>th</sup> among 160 species. In a review, Gosling et al. (2000) carried out a survey of pampas grass control staff who reported the following habitats as being vulnerable to the effects of pampas grass: dunelands, off-shore islands, coastal cliffs, river flats, geothermal sites and wetlands. The perceived impacts were displacement of natural flora and fauna including one Giant Weta (Orthoptera: Anostomatidae) site.

*Cortaderia selloana* is recognised as one of the main priority invasive weeds in bushland reserves and native forestry in Tasmania (Young 1993). In Australia it replaces natural plant communities and excludes plants through shading and below ground competition since the root system of a single plant is estimated to occupy 103 cubic meters of soil (Parsons and Cuthbertson 2001).

**Qu. 4.2. How important is the current known impact of the organism on biodiversity at all levels of organisation (e.g. decline in native species, changes in native species communities, hybridisation) in the risk assessment area (include any past impact in your response)?**

Discuss impacts that are currently occurring or are likely occurring or have occurred in the past in the risk assessment area. Where there is no direct evidence of impact in the risk assessment area (for example no studies have been conducted), evidence from outside of the risk assessment area can be used to infer impacts within the risk assessment area.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: *Cortaderia selloana* has a major impact on biodiversity in Mediterranean countries in the risk assessment area. It is a common invader of both natural and ruderal habitats in Mediterranean coastal regions (Domènech and Vilà 2007). However, Pardo-Primoy and Fagúndez (2019) noted that the best predictor of *Cortaderia* invasion on industrial sites in Galicia was closeness to another invaded industrial site and low elevation. In Spain *C. selloana* invasion of old fields prevents their restoration to wetlands where some rare or endemic plant species<sup>7</sup> occur (Pausas et al. 2006) such as *Spirodela polyrrhiza*, a floating plant thought to be extinct in the region until recently. *C. selloana* on the island of Corsica (France), seriously threatens the endemic species *Centranthus trinervis*, one of the endemic and critically endangered Mediterranean plants from the IUCN ‘Top 50 Mediterranean Island Plant’ list (de Montmollin and Strahm (2005); Brundu (2013)).

<sup>7</sup> Pausas et al. (2006) do not specify specific species

Due to low decomposition of litter and standing dead leaves reduce the total soil N and increase C:N ratios due to low decomposition of litter, changes the relative frequencies of plant growth forms, reduces total plant cover, and alters soil nutrient properties (Domènech et al. 2006).

*Cortaderia selloana* increases its density and colonizes semi-natural areas in a short period of time, changing the vertical structure of the vegetation, altering ecosystem naturalness by competing with native plants (Sinnassamy 2001; Herrera Gallastegui and Campos Prieto 2006; Campos et al. 2004). Its invasion reduces plant species, life form richness and native species cover; the similarity of native species composition with non-invaded areas can decrease by more than 50% (Domènech et al. 2006). The plant is spreading along roads and within fragile dune ecosystems in Portugal (Marchante et al. 2005)

In France it is recognised that its rapid growth allows it to form dense colonies, accumulating significant above and below ground biomass thereby competing with native plants for access to resources including light, space, nutrients and water to the detriment of these species (AME 2003). It is believed to have a particular impact on low light-loving vegetation, especially on coastal sites where the vegetation is more likely to be endemic or of high conservation value (Petit 2011).

The authors and reviewers consider that the major score given to impact on biodiversity is justified even with the lack of scientific publications to quantify the negative impacts to biodiversity. In the invaded areas, stands of *C. selloana* occur with high levels of covering which exclude native plant species and in many cases these dense stands are present in sensitive areas which harbour rare and endangered species. Monospecific dense stands of any perennial species is a good proxy for negative impact on biodiversity. Additionally, the inclusion of the species in an EU LIFE biodiversity project supports the presence of negative impact on biodiversity that can be reversed on local control and eradication.

However, due to the limited amount of scientific evidence, a medium confidence has been given.

**Qu. 4.3. How important is the potential future impact of the organism on biodiversity at all levels of organisation likely to be in the risk assessment area?**  
 See comment above. The potential future impact shall be assessed only for the risk assessment area.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: It is likely that *C. selloana* will continue to spread within the risk assessment area and is likely to establish in new areas. Therefore, in these areas, there will be additional impacts as seen in the current area of distribution. These are likely to initially be localised around urban development and human disturbed habitats but once established there is more likelihood of spread into more sensitive habitats.

**Qu. 4.4. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism currently in the risk assessment area?**  
 including the following elements:

- native species impacted, including red list species, endemic species and species listed in the Birds and Habitats directives

- protected sites impacted, in particular Natura 2000
- habitats impacted, in particular habitats listed in the Habitats Directive, or red list habitats
- the ecological status of water bodies according to the Water Framework Directive and environmental status of the marine environment according to the Marine Strategy Framework Directive

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: The Mediterranean is a biodiversity hotspot (e.g., Médail and Quézel 1999) and in this biogeographical region many coastal and sand dune ecosystems are home to endemic (and narrow endemic plants, also known as micro-endemic) and rare flora and associated fauna and their displacement by *C. selloana* would very likely be impacting on the current conservation status (e.g., on the Habitats directive priority habitat 2130\*, i.e. fixed coastal dunes with herbaceous vegetation or "grey dunes"). For these reasons, the plant is the subject of an EU LIFE project, "StopCortaderia", which aims to stop the spread of *Cortaderia selloana* and reduce its presence in coastal Natura 2000 network sites, to safeguard sensitive habitats and native species (www.stopcortaderia.org). Targeted sites in Cantabria include the Special Conservation Areas of Dunas de Liencres y estuarios del río Pas (ES1300004); Río Agüera (ES1300012); Marismas de Santoña, Victoria y Joyel (ES1300007); Rías occidentales y dunas de Oyambre (ES1300003); Dunas del Puntal y Estuario del Miera (ES1300005); Costa Central y Ría de Ajo (ES1300006). In Spain, according to Asensi et al. (2014), in recent decades, the increase of *Cortaderia selloana* populations in coastal areas of Andalusia has been observed. Although generally occupying anthropic environments, its presence was detected near to *Retama monosperma* [*Retamion monospermae* Rivas-Mart. et Cantó in Rivas-Mart et al. 2002] and *Pinus pinea* wooded dunes communities in Huelva. Since 2007, the Ministry of Environment of the Junta de Andalucía has performed various programmes for the eradication of these species in ecosystems of interest (Asensi et al. 2014). Another LIFE project (Spain, LIFE Miera - Biodiversity conservation in river Miera - LIFE13 NAT/ES/000899) is dealing with *Baccharis halimifolia* and *Cortaderia selloana* as they are displacing indigenous riverbank species, affecting estuary habitats (1330 and 1410), dune ecosystems (2120 and 2130) and coastal heathland habitat (4040) (Scalera et al. 2017). As described by Herrera Gallastegui and Campos Prieto (2006), *C. selloana* is widespread in the Basque Country, where it invades large areas inside protected areas and environmentally sensitive areas, such as in the case of the Biosphere Reserve Urdaibai, the natural Park Armañon (Herrera Gallastegui and Campos Prieto 2006), and the estuarine area of río Butroe. In the Biosphere Reserve of Urdaibai (Bizkaia), *C. selloana* is very abundant in natural and semi-natural habitats: subalkaline zones of the marshes, scrubs, edges of holm oak, sands and meadows. It colonizes large areas in the upper estuary of the Oka River, mainly artificially drained lands, and expands into high marsh habitats, such as reed beds, and salt grasslands. Furthermore, it has spread to areas where removal work of another invasive species (*Baccharis halimifolia*) was carried out and no subsequent restoration work was carried out (Herrera Gallastegui and Campos Prieto 2006).

According to de Montmollin and Strahm (2005) and as reported in Brundu (2013) *Cortaderia selloana*, on the island of Corsica (France), seriously threatens the endemic species *Centranthus trinervis*, one of the endemic and critically endangered Mediterranean plants from the IUCN 'Top 50 Mediterranean Island Plant' list.

It is likely to displace ground nesting birds that favour dune ecosystems with low ground cover as the tall *C. selloana* would provide very different structure and resources though no published evidence has been found relating to individual species.

**Qu. 4.5. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.4.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: Future impacts are likely to be seen in the Mediterranean biogeographical region. Native species, habitats and protected sites at risk are detailed in 4.4. The climate modelling shows areas of the Mediterranean, Atlantic and Continental biogeographical regions becoming more suitable as well as the new inclusion of Boreal biogeographical region. Biogeographical regions with established populations and high levels of urbanization may see high levels of spread as seen in the Mediterranean region.

**Ecosystem Services impacts**

**Qu. 4.6. How important is the impact of the organism on provisioning, regulating, and cultural services in its non-native range excluding the risk assessment area?**

- For a list of services use the CICES classification V5.1 provided in Annex V.
- Impacts on ecosystem services build on the observed impacts on biodiversity (habitat, species, genetic, functional) but focus exclusively on reflecting these changes in relation to their links with socio-economic well-being.
- Quantitative data should be provided whenever available and references duly reported.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> <b>medium</b> high
-----------------	---	-------------------	-------------------------------------

Response: *C. selloana* has an impact on provisioning of biomass in the form of wild plants and associated specialist animals as it is known to form extensive monospecific stands in coastal sage scrub drainages and riparian areas in California (Vourlitis and Kroon 2013) which will also have an impact on provisioning of water. The reduction in biodiversity associated with *C. selloana* invasions that have been reported from USA, (Lambrinos 2001; Di Tomaso 2010) South Africa (Wells et al. 1986), New Zealand (Owen 1996) and Australia (Young 1993). Since the root system of a single plant is estimated to occupy 103 cubic meters

of soil (Parsons and Cuthbertson 2001) it will have an impact on regulation through altered soil quality. It is known to form extensive monospecific stands in coastal sage scrub drainages and riparian areas in California (Vourlitis and Kroon 2013) which will also have an impact on regulation through altered water quality.

It has an impact on cultural ecosystem services that are physical and experiential through reduction biodiversity, amenity values (by reducing access to and the value of natural habitats for recreation) as well as on the non-use value of wilderness areas that have an intrinsic value and has a small impact on human health.

**Qu. 4.7. How important is the impact of the organism on provisioning, regulating, and cultural services currently in the different biogeographic regions or marine sub-regions where the species has established in the risk assessment area (include any past impact in your response)?**

- See guidance to Qu. 4.6.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: *Cortaderia selloana* has impacts upon provisioning through the reduction in availability and diversity of wild plants. Its invasion reduces plant species, life form richness and native species cover; the similarity of native species composition with non-invaded areas can decrease by more than 50% (Domènech et al. 2006).

It also has an impact of regulation and maintenance of ecosystem services, impacting on baseline flows e.g. it is known to modify nutrient regimes (Domènech, et al. 2006) as well as extreme events such as fire (Starr et al. 2003; Harradine 1991). In the Mediterranean this potential for increased fire risk resulting from the dry leaves of tussocks is noted (Arianoutsou and Vilà 2012). Both of these impacts on regulation further affect succession patterns and thereby provisioning. Although there is no published data, there is the potential of impact on hydrology in riparian areas, in particular in the case of temporary (intermittent) Mediterranean rivers and temporary ponds through the large scale growth of a much larger transpiring plant than is usually found in the habitat. Impacts on cultural ecosystem services in the risk assessment area include reduced amenity value and biodiversity intrinsic value.

**Qu. 4.8. How important is the impact of the organism on provisioning, regulating, and cultural services likely to be in the different biogeographic regions or marine sub-regions where the species can establish in the risk assessment area in the future?**

- See guidance to Qu. 4.6.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

	massive		
--	---------	--	--

Response: The impacts would be similar but on a larger scale. There is the potential of increased fire regimes (and increased intensity) in the risk assessment area as the area of establishment of the species expands with the climate change projection (Annex VIII). Further spread into natural habitats can have negative impacts on cultural ecosystem services through reduced amenity value and biodiversity intrinsic value. There will also be expanded impacts on regulation through altered water and soil quality.

## Economic impacts

**Qu. 4.9. How great is the overall economic cost caused by the organism within its current area of distribution (excluding the risk assessment area), including both costs of / loss due to damage and the cost of current management.**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the world these should be reported here. The assessment of the potential costs of / loss due to damage shall describe those costs quantitatively and/or qualitatively depending on what information is available. Cost of / loss due to damage within different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage. As far as possible, it would be useful to separate costs of / loss due to the organism from costs of current management.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: In Australian forest plantations, pampas grass competes with seedling trees, especially softwood species, reducing establishment and retarding growth. In older forests, pampas grass increases the fire hazard (Harradine 1991 which increases expenditure on preventative measures and preparedness for outbreaks). Pampas grasses have been estimated to increase silvicultural tending costs by 144% in New Zealand and impedes access for silviculture (Gadcil et al, 1984). In 1983 these control costs, which were reported as “barely assuring tree survival”, were \$NZ350/ha (Gadcil et al. 1984) which accounting for inflation would be \$NZ 1,220/ha today, which equates to €675/ha. In 1987 the Tasmanian Inter-departmental Pampa Grass Committee estimated the cost of Pampas grass control in pine and eucalyptus plantations as being \$400 Aus/ha which would add \$1.4m to the cost of plantation establishment in the State, \$3.6m today (€2.15m) though this is not assumed to be an annual cost.

Pampas grass infestations on roadsides and waste areas are usually controlled by application of glyphosate. In the early 1990s herbicide cost varied from \$65 per hectare (\$128 today or €78) for seedlings to \$260 per hectare (\$512 today or €300) for established plants (Harradine 1991). Labour and equipment costs for the application may far exceed these herbicide costs in many areas where access is difficult.

In New Zealand, kiwifruit [*Actinidia deliciosa*] have been rejected for export as it was contaminated with *Cortaderia* seed which was attached to the fruit (Knowles and Tombleson 1987).

**Qu. 4.10. How great is the economic cost of / loss due to damage (excluding costs of management) of the organism currently in the risk assessment area (include any past costs in your response)?**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the EU these should be reported here. Assessment of the potential costs of damage on human health, safety, and the economy, including the cost of non-action. A full economic assessment at EU scale might not be possible, but qualitative data or different case studies from across the EU (or third countries if relevant) may provide useful information to inform decision making. In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. Cost of / loss due to damage within different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: There is no published literature on incurred costs in the risk assessment area besides those relating to control efforts. The reduction in pasture quality and the injuries to humans will have a cost (AME-CBNPM 2003) but this has not been quantified. Nor has the financial and social cost of fires made more significant by the plant’s dry biomass. Given its common invasion on roadsides it is probable that the resultant lack of visibility for drivers may cause accidents which would have a significant economic and social impact but not evidence has been published. It is however, highly likely that any of the above costs incurred across the invaded range in the risk assessment area will be more than €10,000 making it more than minimal and probably more than the €100,000 per year threshold provided in the guidance for a score of “moderate” but a conservative score with a low confidence is given.

**Qu. 4.11. How great is the economic cost of / loss due to damage (excluding costs of management) of the organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.10.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: The economic cost is likely to moderately increase in the future as there will be more areas available for the species to establish. Spread of the species may also increase as urbanisation and development increases. However, there is no evidence for this so no increase in score is given.

**Qu. 4.12. How great are the economic costs / losses associated with managing this organism currently in the risk assessment area (include any past costs in your response)?**

- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: Costs of control are significant in Spain (Andreu et al. 2009). The plant is the subject of a 4 year €3.6m EU Life project, Stop Cortaderia, ([www.stopcortaderia.org](http://www.stopcortaderia.org)). Other LIFE projects which included an element of Cortaderia management include EmysTer - Recovery of the habitat of amphibians and Emys orbicularis in the Baix Ter (LIFE04 NAT/ES/000059) Estuarios del Pais Vasco - Restoration of habitats of Community interest in the Basque Country's estuaries.( LIFE08 NAT/E/000055), BRIGHT - Bussacos Recovery from Invasions Generating Habitat Threats (BIODIV) (LIFE10 NAT/PT/000075) Life Anillo Verde - Green Belt of Bay of Santander: connecting nature and city (LIFE14 NAT/ES/000699) and LIFE SALLINA - Sustainable Actions on Loire Lagoons for Improvement aNd Assessment (LIFE17 NAT/FR/000519). Though the exact value of the Cortaderia actions is not presented here it is unlikely to take the control cost beyond €10m. Another financial impact is the fact that it reduces the aesthetic and recreational value of conservation areas (Bossard et al. 2000) though this has not been quantified.

**Qu. 4.13. How great are the economic costs / losses associated with managing this organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.12.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: Costs are likely to increase as the plant continues to spread and the need to manage it increases. Awareness for the need to manage the plant will be raised by the StopCortaderia LIFE project which in turn will be likely to drive demands for action from the public initially on a local scale but concerned citizens and land managers from other invaded areas are likely to become more aware and more demanding for action.

## Social and human health impacts

**Qu. 4.14. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism for the risk assessment area and for third countries, if relevant (e.g. with similar eco-climatic conditions).**

The description of the known impact and the assessment of potential future impact on human health, safety and the economy, shall, if relevant, include information on

- illnesses, allergies or other affections to humans that may derive directly or indirectly from a species;
- damages provoked directly or indirectly by a species with consequences for the safety of people, property or infrastructure;
- direct or indirect disruption of, or other consequences for, an economic or social activity due to the presence of a species.

Social and human health impacts can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: *Cortaderia selloana* has been recognised as a clinically-significant allergen (Street et al. 1979) and is recorded as a common allergenic ornamental species in a selection of Spanish Cities (Velasco-Jiménez et al. 2014). *Cortaderia selloana* can cause superficial skin injuries that tend to cause inflammatory reactions but may also impact on animals that feed on the plant in pasturelands (Di-Tomaso et al. 2010; AME-CBNPM 2003; Peloté and Haury 2008). It can also have negative aesthetic impacts through changes to the appearance of the landscape, rendering the landscape uninteresting (Le Moigne and Magnanon 2007) and on lake margins in NZ it prevents public access and dominates the ecosystem (Gosling et al. 2000).

**Qu. 4.15. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism in the future for the risk assessment area.**

- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: No information has been found on the issue.

## Other impacts

**Qu. 4.16. How important is the organism in facilitating other damaging organisms (e.g. diseases) as food source, a host, a symbiont or a vector etc.?**

<b>RESPONSE</b>	<b>minimal</b> minor moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: No information has been found on the issue. It is likely that *C. selloana* is not important in facilitating other damaging organisms and therefore a minimal score is given with a low level of confidence.

However, it should be noted that a survey and study in New Zealand on *C. selloana* and *C. jubata* revealed a wide range of native and introduced invertebrates associated with pampas grass in New Zealand. In particular, 62 fungal species were identified, based upon cultural morphology and diagnostic spore characters and confirmed by ITS sequencing. Of these, 33 are considered primary plant pathogens. The pathogens are a mix of grass- and crop-pathogens. Some have been known to cause a range of serious stem cankers and foliar blights on their target-host(s) – many of which are not grasses. The most frequently isolated grass-pathogen was *Nigrospora oryzae* – a seed-borne fungus causing minute leaf and grain spot in rice. *Leptosphaerulina chartarum*, a common pathogen from grassland vegetation, was also recovered. Other significant non-grass pathogens include *Neofusicoccum australe* – also identified as the cause of grapevine dieback in New Zealand (Bellgard et al. 2010).

**Qu. 4.17. How important might other impacts not already covered by previous questions be resulting from introduction of the organism?**

<b>RESPONSE</b>	<b>minimal</b> minor moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: No information has been found on other impacts not already covered in the risk assessment. Any additional impacts are however likely to be minimal as if not, they would be detailed in other regions of the world where the species is invasive.

**Qu. 4.18. How important are the expected impacts of the organism despite any natural control by other organisms, such as predators, parasites or pathogens that may already be present in the risk assessment area?**

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: Since there are no known specialist natural enemies in the risk assessment area the expected impacts will not change. Only recently biocontrol agents have been sought in the native south American range and two smut fungi and some leafhopper species show some potential (Hayes 2015) so in future, were biocontrol agents to be introduced, then natural enemies may have an influence on the impact of *C. selloana* in the risk assessment area.

**Qu. 4.19. Estimate the overall impact in the risk assessment area under current climate conditions. In addition, details of overall impact in relevant biogeographical regions should be provided.**

Thorough assessment of the overall impact on biodiversity and ecosystem services, with impacts on economy as well as social and human health as aggravating factors, in current conditions.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: Impacts include above and below ground transformation of structure and nutrients with recorded negative impacts on fragile and protected ecosystems and displacement of species in the risk assessment area. This mirrors major impacts recorded in other invaded ranges. Since these are technically reversible (unless a narrow endemic plant species is lost) with enough resources a moderate score is given despite the vulnerable ecosystems at risk and the number of initiatives aimed at stopping its spread in such habitats. The impacts will be greatest where the species is currently established: Atlantic, Continental and Mediterranean biogeographical regions as these areas will have the greatest propagule pressure.

**Qu. 4.20. Estimate the overall impact in the risk assessment area in foreseeable climate change conditions. In addition, details of overall impact in relevant biogeographical regions should be provided.**

Thorough assessment of the overall impact on biodiversity and ecosystem services, with impacts on economy as well as social and human health as aggravating factors, under future conditions.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: There is no evidence that future impacts will be any less reversible despite the likelihood of them being on a much larger scale so a moderate score is retained with medium confidence. The impacts will be greatest where the species is currently established: Atlantic, Continental and Mediterranean biogeographical regions as these areas will have the greatest propagule pressure.

<b>RISK SUMMARIES</b>			
	<b>RESPONSE</b>	<b>CONFIDENCE</b>	<b>COMMENT</b>
<b>Summarise Introduction and Entry*</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	low medium <b>high</b>	The species has been introduced and entered the risk assessment area in the past. A number of active pathways exist (e.g. horticulture, ornamental purposes other than horticulture, contaminant of habitat material and contaminant of tourists). The plant is a very popular ornamental species in the risk assessment area. The very likely score is given by default as the species is already established in the risk assessment area.
<b>Summarise Establishment*</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	low medium <b>high</b>	The species is established in the risk assessment area and further establishment is likely in both current and future climatic conditions. The species has a wide tolerance of habitats and other abiotic parameters which promotes its establishment.
<b>Summarise Spread*</b>	very slowly slowly moderately <b>rapidly</b> very rapidly	low <b>medium</b> high	Natural spread of wind dispersed seeds can distribute the species over long distances. Human mediated spread other than horticulture and contamination of habitat material and equipment contribute to the spread throughout the risk assessment area. Further spread is likely as there is a large suitable area for establishment for <i>C. selloana</i> in the risk assessment area. The overall rapidly score with medium confidence is based on the worst-case scenario detailed in section 3 for 'Ornamental purposes other than horticulture (escape from confinement)'
<b>Summarise Impact*</b>	minimal minor moderate <b>major</b> massive	low <b>medium</b> high	An overall major score has been given due to the major impacts reported on biodiversity and conservation value. Impacts include above and below ground transformation of structure and nutrients with recorded negative impacts on fragile and protected ecosystems and displacement of species in the risk assessment area, as well as significant socioeconomic impacts.

			In future climate scenarios the invaded area is expected to expand but again impacts tend to be most felt in ruderal habitats and none are irreversible.
Conclusion of the risk assessment (overall risk)	low moderate <b>high</b>	low <b>medium</b> high	Overall, <i>C. selloana</i> has a high risk to the EU with medium uncertainty. This score takes in account the major impact the species has in the risk assessment area with regard to impact on biodiversity.

\*in current climate conditions and in foreseeable future climate conditions

## Distribution Summary

Please answer as follows:

- Yes if recorded, established or invasive
- if not recorded, established or invasive
- ? Unknown; data deficient

The columns refer to the answers to Questions A5 to A12 under Section A.

For data on marine species at the Member State level, delete Member States that have no marine borders.

In all other cases, provide answers for all columns.

### Member States and the United Kingdom

	Recorded	Established (currently)	Possible establishment (under current climate)	Possible establishment (under foreseeable climate)	Invasive (currently)
Austria	YES	NO	YES	YES	NO
Belgium	YES	NO	YES	YES	NO
Bulgaria	YES	NO	YES	YES	NO
Croatia	YES	NO	YES	YES	NO
Cyprus	YES	NO	YES	YES	NO

## ANNEX I Scoring of Likelihoods of Events

(taken from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

<b>Score</b>	<b>Description</b>	<b>Frequency</b>
Very unlikely	This sort of event is theoretically possible, but is never known to have occurred and is not expected to occur	1 in 10,000 years
Unlikely	This sort of event has occurred somewhere at least once in the last millenium	1 in 1,000 years
Moderately likely	This sort of event has occurred somewhere at least once in the last century	1 in 100 years
Likely	This sort of event has happened on several occasions elsewhere, or on at least once in the last decade	1 in 10 years
Very likely	This sort of event happens continually and would be expected to occur	Once a year

## ANNEX II Scoring of Magnitude of Impacts

(modified from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

Score	Biodiversity and ecosystem impact	Ecosystem Services impact	Economic impact (Monetary loss and response costs per year)	Social and human health impact, and other impacts
	<i>Question 5.1-5</i>	<i>Question 5.6-8</i>	<i>Question 5.9-13</i>	<i>Question 5.14-18</i>
Minimal	Local, short-term population loss, no significant ecosystem effect	No services affected <sup>8</sup>	Up to 10,000 Euro	No social disruption. Local, mild, short-term reversible effects to individuals.
Minor	Some ecosystem impact, reversible changes, localised	Local and temporary, reversible effects to one or few services	10,000-100,000 Euro	Significant concern expressed at local level. Mild short-term reversible effects to identifiable groups, localised.
Moderate	Measureable long-term damage to populations and ecosystem, but reversible; little spread, no extinction	Measureable, temporary, local and reversible effects on one or several services	100,000-1,000,000 Euro	Temporary changes to normal activities at local level. Minor irreversible effects and/or larger numbers covered by reversible effects, localised.
Major	Long-term irreversible ecosystem change, spreading beyond local area	Local and irreversible or widespread and reversible effects on one / several services	1,000,000-10,000,000 Euro	Some permanent change of activity locally, concern expressed over wider area. Significant irreversible effects locally or reversible effects over large area.
Massive	Widespread, long-term population loss or extinction, affecting several species with serious ecosystem effects	Widespread and irreversible effects on one / several services	Above 10,000,000 Euro	Long-term social change, significant loss of employment, migration from affected area. Widespread, severe, long-term, irreversible health effects.

<sup>8</sup> Not to be confused with "no impact".

## ANNEX III Scoring of Confidence Levels

(modified from Bacher et al. 2017)

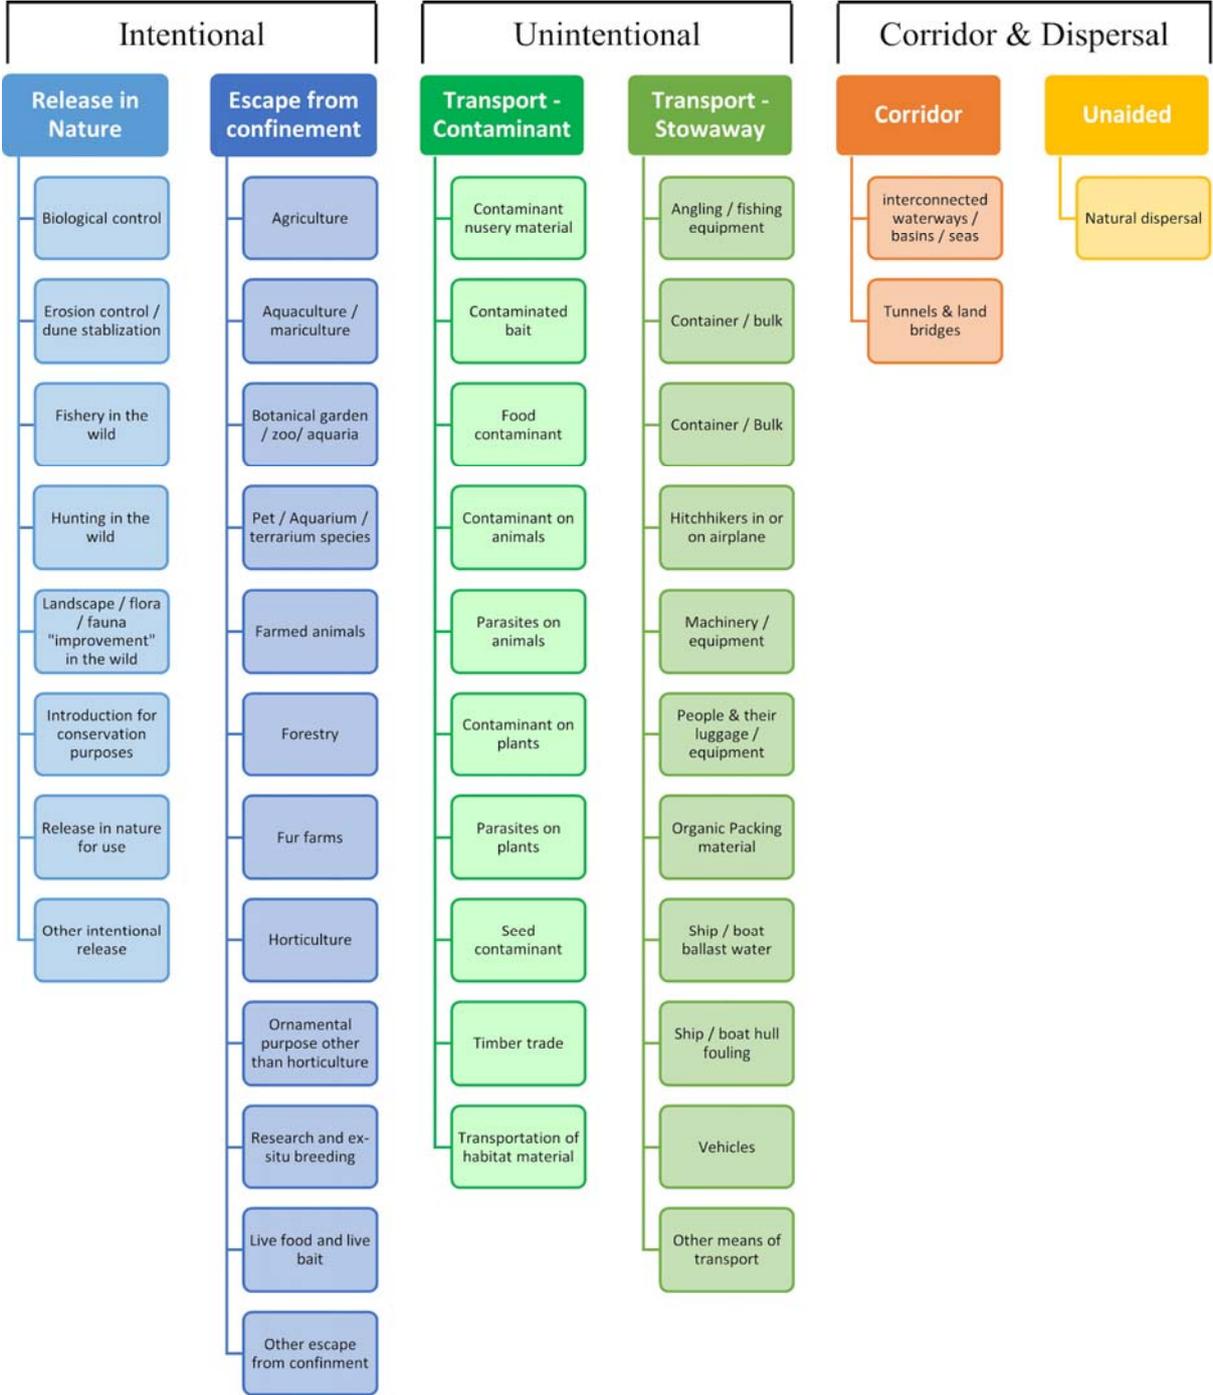

Each answer provided in the risk assessment must include an assessment of the level of confidence attached to that answer, reflecting the possibility that information needed for the answer is not available or is insufficient or available but conflicting.

The responses in the risk assessment should clearly support the choice of the confidence level.

Confidence level	Description
Low	There is no direct observational evidence to support the assessment, e.g. only inferred data have been used as supporting evidence <i>and/or</i> Impacts are recorded at a spatial scale which is unlikely to be relevant to the assessment area <i>and/or</i> Evidence is poor and difficult to interpret, e.g. because it is strongly ambiguous <i>and/or</i> The information sources are considered to be of low quality or contain information that is unreliable.
Medium	There is some direct observational evidence to support the assessment, but some information is inferred <i>and/or</i> Impacts are recorded at a small spatial scale, but rescaling of the data to relevant scales of the assessment area is considered reliable, or to embrace little uncertainty <i>and/or</i> The interpretation of the data is to some extent ambiguous or contradictory.
High	There is direct relevant observational evidence to support the assessment (including causality) <i>and</i> Impacts are recorded at a comparable scale <i>and/or</i> There are reliable/good quality data sources on impacts of the taxa <i>and</i> The interpretation of data/information is straightforward <i>and/or</i> Data/information are not controversial or contradictory.

# ANNEX IV CBD pathway categorisation scheme

Overview of CBD pathway categorisation scheme showing how the 44 pathways relate to the six main pathway categories. All of the pathways can be broadly classified into 1) those that involve intentional transport (blue), 2) those in which the taxa are unintentionally transported (green) and 3) those where taxa moved between regions without direct transportation by humans and/or via artificial corridors (orange and yellow). **Note that the pathways in the category “Escape from confinement” can be considered intentional for the introduction into the risk assessment area and unintentional for the entry into the environment.**

## ANNEX V Ecosystem services classification (CICES V5.1, simplified) and examples

For the purposes of this risk assessment, please feel free to use what seems as the most appropriate category / level / combination of impact (Section – Division – Group), reflecting information available.

Section	Division	Group	Examples (i.e. relevant CICES “classes”)
Provisioning	Biomass	<b>Cultivated <i>terrestrial</i> plants</b>	Cultivated terrestrial plants (including fungi, algae) grown for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from cultivated plants, fungi, algae and bacteria for direct use or processing (excluding genetic materials); Cultivated plants (including fungi, algae) grown as a <u>source of energy</u>  <i>Example: negative impacts of non-native organisms to crops, orchards, timber etc.</i>
		<b>Cultivated <i>aquatic</i> plants</b>	Plants cultivated by in- situ aquaculture grown for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from in-situ aquaculture for direct use or processing (excluding genetic materials); Plants cultivated by in- situ aquaculture grown as an <u>energy source</u> .  <i>Example: negative impacts of non-native organisms to aquatic plants cultivated for nutrition, gardening etc. purposes.</i>
		<b>Reared animals</b>	Animals reared for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from reared animals for direct use or processing (excluding genetic materials); Animals reared to provide <u>energy</u> (including mechanical)  <i>Example: negative impacts of non-native organisms to livestock</i>
		<b>Reared <i>aquatic</i> animals</b>	Animals reared by in-situ aquaculture for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from animals grown by in-situ aquaculture for direct use or processing (excluding genetic materials); Animals reared by in-situ aquaculture as an <u>energy source</u>  <i>Example: negative impacts of non-native organisms to fish farming</i>
		<b>Wild plants</b> (terrestrial and aquatic)	Wild plants (terrestrial and aquatic, including fungi, algae) used for <u>nutrition</u> ; <u>Fibres and other materials</u> from wild plants for direct use or processing (excluding genetic materials); Wild plants (terrestrial and aquatic, including fungi, algae) used as a <u>source of energy</u>  <i>Example: reduction in the availability of wild plants (e.g. wild berries, ornamentals) due to non-native organisms (competition, spread of disease etc.)</i>
		<b>Wild animals</b> (terrestrial and aquatic)	Wild animals (terrestrial and aquatic) used for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from wild animals for direct use or processing (excluding genetic materials); Wild animals (terrestrial and aquatic) used as a <u>source of energy</u>

			<i>Example: reduction in the availability of wild animals (e.g. fish stocks, game) due to non-native organisms (competition, predations, spread of disease etc.)</i>
	<b>Genetic material</b> from all biota	<b>Genetic material</b> from plants, algae or fungi	<u>Seeds, spores and other plant materials</u> collected for maintaining or establishing a population; Higher and lower plants (whole organisms) used to <u>breed new strains or varieties</u> ; Individual genes extracted from higher and lower plants for the <u>design and construction of new biological entities</u>  <i>Example: negative impacts of non-native organisms due to interbreeding</i>
		<b>Genetic material</b> from animals	Animal material collected for the purposes of maintaining or establishing a population; Wild animals (whole organisms) used to breed new strains or varieties; Individual genes extracted from organisms for the design and construction of new biological entities  <i>Example: negative impacts of non-native organisms due to interbreeding</i>
	<b>Water</b> <sup>9</sup>	<b>Surface water</b> used for nutrition, materials or energy	Surface water for <u>drinking</u> ; Surface water used as a material ( <u>non-drinking purposes</u> ); Freshwater surface water, coastal and marine water used as an <u>energy source</u>  <i>Example: loss of access to surface water due to spread of non-native organisms</i>
		<b>Ground water</b> for used for nutrition, materials or energy	Ground (and subsurface) water for <u>drinking</u> ; Ground water (and subsurface) used as a material ( <u>non-drinking purposes</u> ); Ground water (and subsurface) used as an <u>energy source</u>  <i>Example: reduced availability of ground water due to spread of non-native organisms and associated increase of ground water consumption by vegetation.</i>
<b>Regulation and Maintenance</b>	<b>Transformation</b> of biochemical or physical inputs to ecosystems	<b>Mediation of wastes or toxic substances</b> of anthropogenic origin by living processes	<u>Bio-remediation</u> by micro-organisms, algae, plants, and animals; <u>Filtration/sequestration/storage/accumulation</u> by micro-organisms, algae, plants, and animals  <i>Example: changes caused by non-native organisms to ecosystem functioning and ability to filtrate etc. waste or toxics</i>
		<b>Mediation of nuisances</b> of anthropogenic origin	Smell reduction; noise attenuation; visual screening (e.g. by means of green infrastructure)  <i>Example: changes caused by non-native organisms to ecosystem structure, leading to reduced ability to mediate nuisances.</i>
	<b>Regulation</b> of physical, chemical, biological conditions	<b>Baseline flows and extreme event</b> regulation	Control of <u>erosion</u> rates; Buffering and attenuation of <u>mass movement</u> ; <u>Hydrological cycle and water flow regulation</u> (Including flood control, and coastal protection); <u>Wind</u> protection; <u>Fire</u> protection

<sup>9</sup> Note: in the CICES classification provisioning of water is considered as an abiotic service whereas the rest of ecosystem services listed here are considered biotic.

			<p><i>Example: changes caused by non-native organisms to ecosystem functioning or structure leading to, for example, destabilisation of soil, increased risk or intensity of wild fires etc.</i></p>
		<p><b>Lifecycle maintenance, habitat and gene pool protection</b></p>	<p><u>Pollination</u> (or 'gamete' dispersal in a marine context); <u>Seed dispersal</u>; Maintaining <u>nursery populations and habitats</u> (Including gene pool protection)</p> <p><i>Example: changes caused by non-native organisms to the abundance and/or distribution of wild pollinators; changes to the availability / quality of nursery habitats for fisheries</i></p>
		<p><b>Pest and disease control</b></p>	<p>Pest control; Disease control</p> <p><i>Example: changes caused by non-native organisms to the abundance and/or distribution of pests</i></p>
		<p><b>Soil quality regulation</b></p>	<p><u>Weathering processes</u> and their effect on soil quality; <u>Decomposition and fixing processes</u> and their effect on soil quality</p> <p><i>Example: changes caused by non-native organisms to vegetation structure and/or soil fauna leading to reduced soil quality</i></p>
		<p><b>Water conditions</b></p>	<p>Regulation of the <u>chemical condition</u> of freshwaters by living processes; Regulation of the chemical condition of salt waters by living processes</p> <p><i>Example: changes caused by non-native organisms to buffer strips along water courses that remove nutrients in runoff and/or fish communities that regulate the resilience and resistance of water bodies to eutrophication</i></p>
		<p><b>Atmospheric composition and conditions</b></p>	<p>Regulation of <u>chemical composition</u> of atmosphere and oceans; Regulation of <u>temperature and humidity</u>, including ventilation and transpiration</p> <p><i>Example: changes caused by non-native organisms to ecosystems' ability to sequester carbon and/or evaporative cooling (e.g. by urban trees)</i></p>
Cultural	Direct, in-situ and outdoor interactions with living systems that depend on presence in the environmental setting	<p><b>Physical and experiential</b> interactions with natural environment</p>	<p>Characteristics of living systems that that enable activities promoting health, recuperation or enjoyment through <u>active or immersive interactions</u>; Characteristics of living systems that enable activities promoting health, recuperation or enjoyment through <u>passive or observational interactions</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that make it attractive for recreation, wild life watching etc.</i></p>
		<p><b>Intellectual and representative</b> interactions with natural environment</p>	<p>Characteristics of living systems that enable <u>scientific investigation</u> or the creation of traditional ecological knowledge; Characteristics of living systems that enable <u>education and training</u>; Characteristics of living systems that are resonant in terms of <u>culture or heritage</u>; Characteristics of living systems that enable <u>aesthetic experiences</u></p>

			<i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have cultural importance</i>
Indirect, remote, often indoor interactions with living systems that do not require presence in the environmental setting	Spiritual, symbolic and other interactions with natural environment		Elements of living systems that have <u>symbolic meaning</u> ; Elements of living systems that have <u>sacred or religious meaning</u> ; Elements of living systems used for <u>entertainment or representation</u>
			<i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have sacred or religious meaning</i>
	Other biotic characteristics that have a <b>non-use value</b>		Characteristics or features of living systems that have an <u>existence value</u> ; Characteristics or features of living systems that have an <u>option or bequest value</u>  <i>Example: changes caused by non-native organisms to ecosystems designated as wilderness areas, habitats of endangered species etc.</i>

## **ANNEX VIII Species Distribution Model**

### **Projection of climatic suitability for *Cortaderia selloana* establishment in Europe**

Björn Beckmann, Rob Tanner, Giuseppe Brundu, Richard Shaw, Beth Purse and Dan Chapman

30 March 2020

#### ***Aim***

To project the suitability for potential establishment of *Cortaderia selloana* in Europe, under current and predicted future climatic conditions.

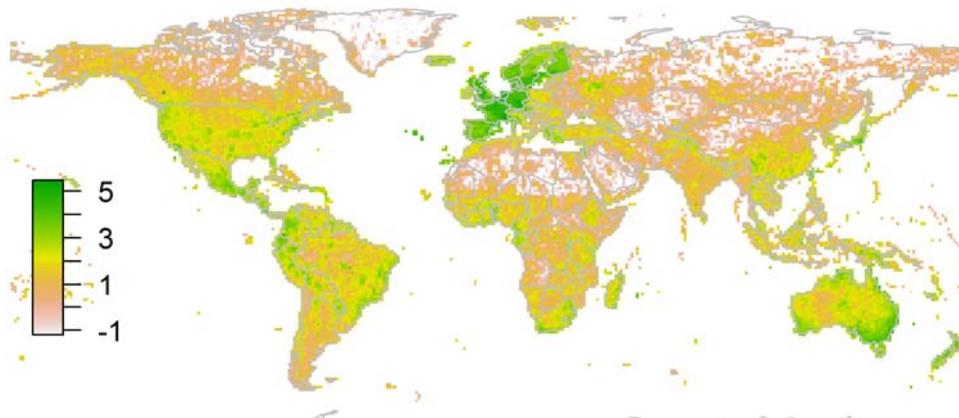

#### ***Data for modelling***

Species occurrence data were obtained from the Global Biodiversity Information Facility (GBIF) (9771 records), iNaturalist (4206 records), the Atlas of Living Australia (1521 records), the Biodiversity Information Serving Our Nation database (BISON) (481 records), the Integrated Digitized Biocollections (iDigBio) (221 records), ITSAR (175 records), the Berkeley Ecoinformatics Engine database (98 records), and a small number of additional records from the risk assessment team. We scrutinised occurrence records from regions where the species is not known to be established and removed any dubious records (e.g. fossils) or where the georeferencing was too imprecise (e.g. records referenced to a country or island centroid) or outside of the coverage of the predictor layers (e.g. small island or coastal occurrences). The remaining records were gridded at a 0.25 x 0.25 degree resolution for modelling, yielding 1925 grid cells with occurrences (Figure 1a). As a proxy for recording effort, the density of Tracheophyta records held by GBIF was also compiled on the same grid (Figure 1b).

(a) Species distribution used in modelling

(b) Estimated recording effort (log10-scaled)

**Figure 1.** (a) Occurrence records obtained for *Cortaderia selloana* and used in the modelling, showing native and invaded distributions. (b) The recording density of Tracheophyta on GBIF, which was used as a proxy for recording effort.

Climate data were selected from the ‘Bioclim’ variables contained within the WorldClim database (Hijmans et al., 2005), originally at 5 arcminute resolution (0.083 x 0.083 degrees of longitude/latitude) and aggregated to a 0.25 x 0.25 degree grid for use in the model.

Based on the biology of *Cortaderia selloana*, the following climate variables were used in the modelling:

- Minimum temperature of the coldest month (Bio6)
- Mean temperature of the warmest quarter (Bio10)
- Climatic moisture index (CMI): ratio of mean annual precipitation to potential evapotranspiration, log+1 transformed. For its calculation, monthly potential evapotranspirations were estimated from the WorldClim monthly temperature data and solar radiation using the simple method of Zomer et al. (2008) which is based on the Hargreaves evapotranspiration equation (Hargreaves, 1994).

To estimate the effect of climate change on the potential distribution, equivalent modelled future climate conditions for the 2070s under the Representative Concentration Pathways (RCP) 2.6 and 4.5

were also obtained. There represent low and medium emissions scenarios, respectively. The above variables were obtained as averages of outputs of eight Global Climate Models (BCC-CSM1-1, CCSM4, GISS-E2-R, HadGEM2-AO, IPSL-CM5A-LR, MIROC-ESM, MRI-CGCM3, NorESM1-M), downscaled and calibrated against the WorldClim baseline (see [http://www.worldclim.org/cmip5\\_5m](http://www.worldclim.org/cmip5_5m) ).

The following habitat layers were also used:

- Human influence index (HII): As many non-native invasive species associate with anthropogenically disturbed habitats. We used the Global Human Influence Index Dataset of the Last of the Wild Project (Wildlife Conservation Society - WCS & Center for International Earth Science Information Network - CIESIN - Columbia University, 2005), which is developed from nine global data layers covering human population pressure (population density), human land use and infrastructure (built-up areas, nighttime lights, land use/land cover) and human access (coastlines, roads, railroads, navigable rivers). The index ranges between 0 and 1 and was ln+1 transformed for the modelling to improve normality.

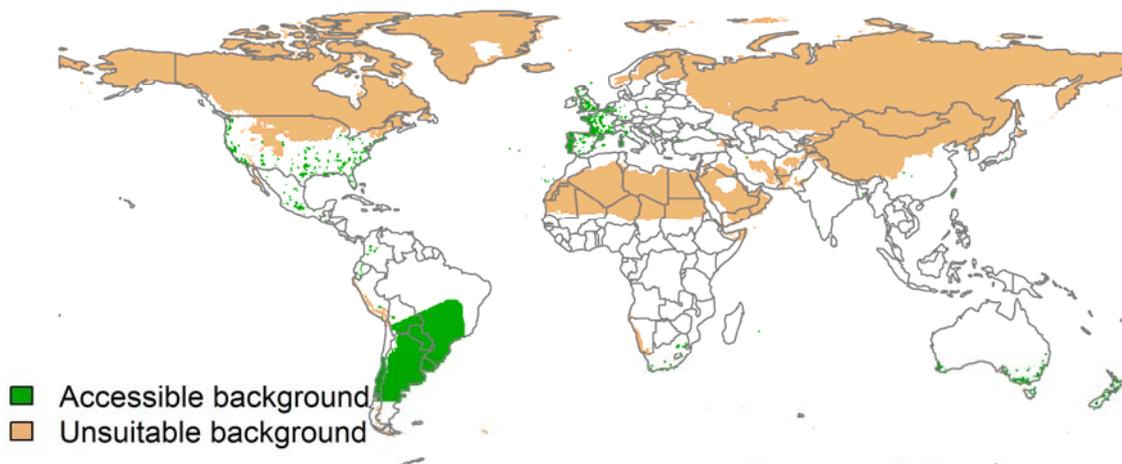

### *Species distribution model*

A presence-background (presence-only) ensemble modelling strategy was employed using the BIOMOD2 R package version 3.4.6 (Thuiller et al., 2020, Thuiller et al., 2009). These models contrast the environment at the species' occurrence locations against a random sample of the global background environmental conditions (often termed 'pseudo-absences') in order to characterise and project suitability for occurrence. This approach has been developed for distributions that are in equilibrium with the environment. Because invasive species' distributions are not at equilibrium and subject to dispersal constraints at a global scale, we took care to minimise the inclusion of locations suitable for the species but where it has not been able to disperse to (Chapman et al. 2019). Therefore the background sampling region included:

- The area accessible by native *Cortaderia selloana* populations, in which the species is likely to have had sufficient time to disperse to all locations. Based on presumed maximum dispersal distances, the accessible region was defined as a 400km buffer around the native range occurrences; AND
- A 30km buffer around the non-native occurrences, encompassing regions likely to have had high propagule pressure for introduction by humans and/or dispersal of the species; AND
- Regions where we have an *a priori* expectation of high unsuitability for the species so that absence is assumed irrespective of dispersal constraints (see Figure 2). The following rules were applied to define a region expected to be highly unsuitable for *Cortaderia selloana* at the spatial scale of the model:
  - Minimum temperature of the coldest month (Bio6) < -12
  - Mean temperature of the warmest quarter (Bio10) < 8.5
  - Climatic moisture index (CMI) < log1p(0.07)

Altogether, only 0.7% of occurrence grid cells were located in the unsuitable background region.

Within the background region, 3 samples of 5000 randomly sampled grid cells were obtained, weighting the sampling by recording effort (Figure 2).

**Figure 2.** The background from which pseudo-absence samples were taken in the modelling of *Cortaderia selloana*. Samples were taken from a 400km buffer around the native range and a 30km buffer around non-native occurrences (together forming the accessible background), and from areas expected to be highly unsuitable for the species (the unsuitable background region). Samples were weighted by a proxy for recording effort (Figure 1(b)).

Each dataset (i.e. combination of the presences and the individual background samples) was randomly split into 80% for model training and 20% for model evaluation. With each training dataset, seven statistical algorithms were fitted with the default BIOMOD2 settings and rescaled using logistic regression, except where specified below:

- Generalised linear model (GLM)
- Generalised boosting model (GBM)
- Generalised additive model (GAM) with a maximum of four degrees of freedom per smoothing spline
- Random forest (RF)
- Maxent

Since the background sample was larger than the number of occurrences, prevalence fitting weights were applied to give equal overall importance to the occurrences and the background. Normalised variable importance was assessed and variable response functions were produced using BIOMOD2's default procedure.

Model predictive performance was assessed by the following three measures:

- AUC, the area under the receiver operating characteristic curve (Fielding & Bell 1997). Predictions of presence-absence models can be compared with a subset of records set aside for model evaluation (here 20%) by constructing a confusion matrix with the number of true positive, false positive, false negative and true negative cases. For models generating non-dichotomous scores (as here) a threshold can be applied to transform the scores into a dichotomous set of presence-absence predictions. Two measures that can be derived from the confusion matrix are sensitivity (the proportion of observed presences that are predicted as such, quantifying omission errors), and specificity (the proportion of observed absences that are predicted as such, quantifying commission errors). A receiver

operating characteristic (ROC) curve can be constructed by using all possible thresholds to classify the scores into confusion matrices, obtaining sensitivity and specificity for each matrix, and plotting sensitivity against the corresponding proportion of false positives (equal to  $1 - \text{specificity}$ ). The use of all possible thresholds avoids the need for a selection of a single threshold, which is often arbitrary, and allows appreciation of the trade-off between sensitivity and specificity. The area under the ROC curve (AUC) is often used as a single threshold-independent measure for model performance (Manel, Williams & Ormerod 2001). AUC is the probability that a randomly selected presence has a higher model-predicted suitability than a randomly selected absence (Allouche et al. 2006).

- Cohen's Kappa (Cohen 1960). This measure corrects the overall accuracy of model predictions (ratio of the sum of true presences plus true absences to the total number of records) by the accuracy expected to occur by chance. The kappa statistic ranges from -1 to +1, where +1 indicates perfect agreement and values of zero or less indicate a performance no better than random. Advantages of kappa are its simplicity, the fact that both commission and omission errors are accounted for in one parameter, and its relative tolerance to zero values in the confusion matrix (Manel, Williams & Ormerod 2001). However, Kappa has been criticised for being sensitive to prevalence (the proportion of sites in which the species was recorded as present) and may therefore be inappropriate for comparisons of model accuracy between species or regions (McPherson, Jetz & Rogers 2004, Allouche et al. 2006).
- TSS, the true skill statistic (Allouche et al. 2006). TSS is defined as sensitivity + specificity - 1, and corrects for Kappa's dependency on prevalence. TSS compares the number of correct forecasts, minus those attributable to random guessing, to that of a hypothetical set of perfect forecasts. Like kappa, TSS takes into account both omission and commission errors, and success as a result of random guessing, and ranges from -1 to +1, where +1 indicates perfect agreement and values of zero or less indicate a performance no better than random (Allouche et al. 2006).

An ensemble model was created by first rejecting poorly performing algorithms with relatively extreme low AUC values and then averaging the predictions of the remaining algorithms, weighted by their AUC. To identify poorly performing algorithms, AUC values were converted into modified z-scores based on their difference to the median and the median absolute deviation across all algorithms (Iglewicz & Hoaglin, 1993). Algorithms with  $z < -2$  were rejected. In this way, ensemble projections were made for each dataset and then averaged to give an overall suitability, as well as its standard deviation. The projections were then classified into suitable and unsuitable regions using the 'minROCDist' method, which minimizes the distance between the ROC plot and the upper left corner of the plot (point (0,1)).

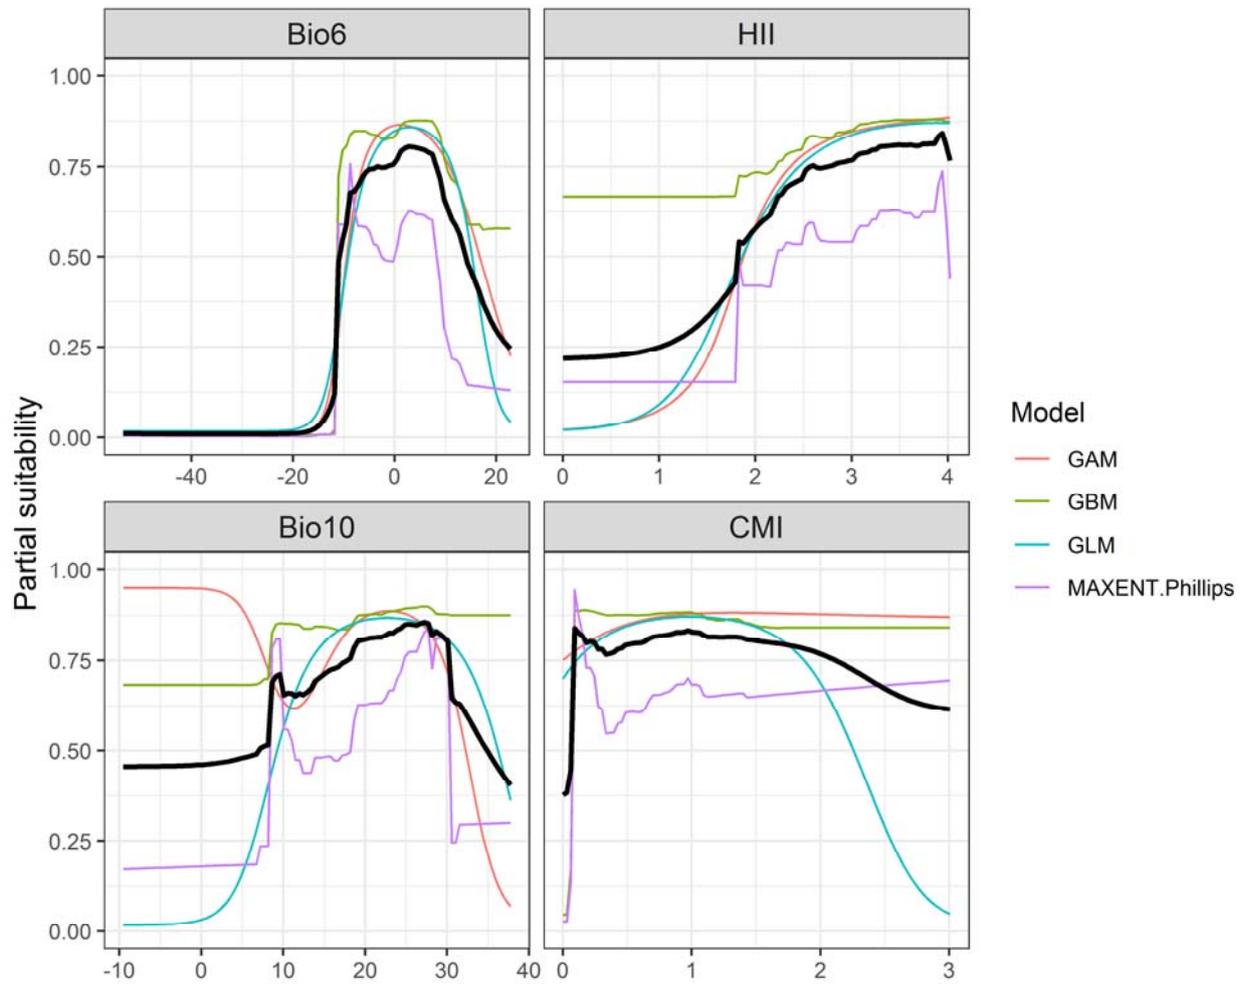

We also produced limiting factor maps for Europe following Elith et al. (2010). For this, projections were made separately with each individual variable fixed at a near-optimal value. These were chosen as the median values at the occurrence grid cells. Then, the most strongly limiting factors were identified as the one resulting in the highest increase in suitability in each grid cell.

## Results

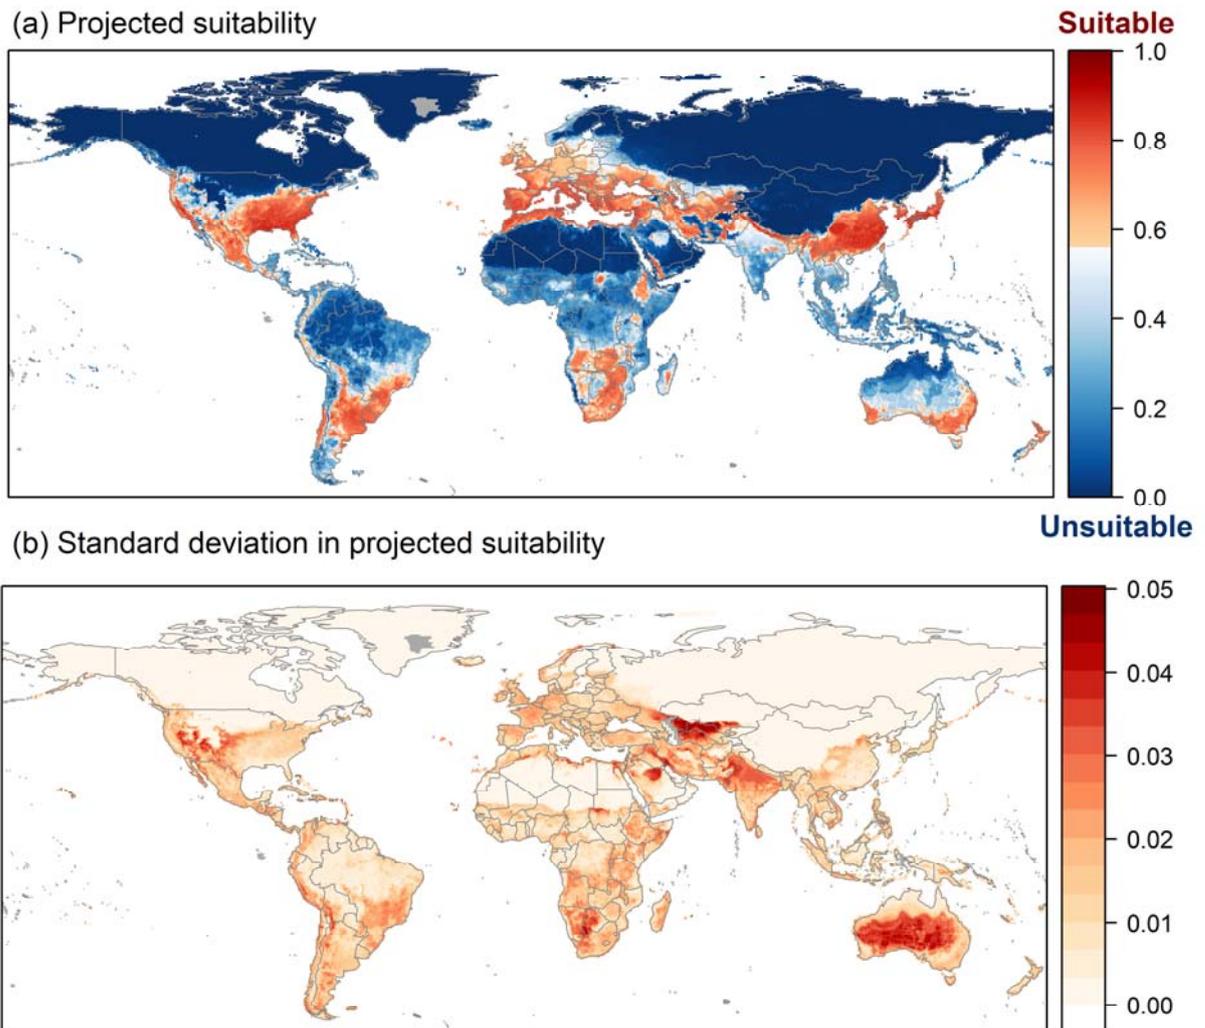

The ensemble model suggested that suitability for *Cortaderia selloana* was most strongly determined by Minimum temperature of the coldest month (Bio6), accounting for 64% of variation explained, followed by Human influence index (HII) (18%), Mean temperature of the warmest quarter (Bio10) (11%) and Climatic moisture index (CMI) (7%) (Table 1, Figure 3).

**Table 1.** Summary of the cross-validation predictive performance (AUC, Kappa, TSS) and variable importance of the fitted model algorithms and the ensemble (AUC-weighted average of the best performing algorithms). Results are the average from models fitted to 3 different background samples of the data.

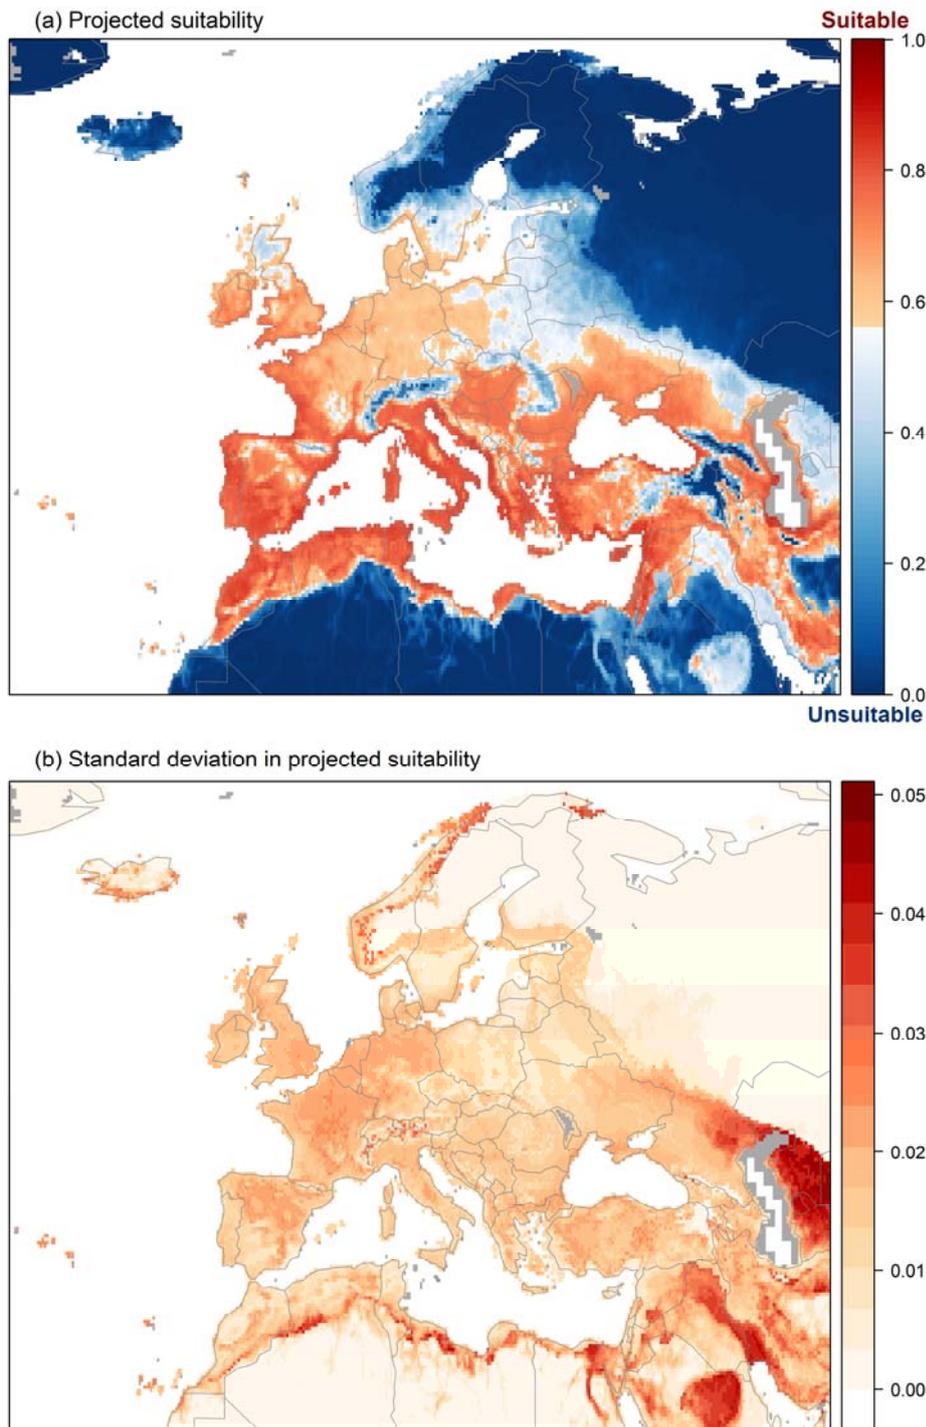

Algorithm	AUC	Kappa	TSS	Used in the ensemble	Variable importance (%)			
					Minimum temperature of the coldest month (Bio6)	Human influence index (HII)	Mean temperature of the warmest quarter (Bio10)	Climatic moisture index (CMI)
GLM	0.867	0.507	0.686	yes	56	28	14	2
GAM	0.870	0.509	0.696	yes	63	27	8	1
GBM	0.894	0.550	0.712	yes	77	4	4	15
RF	0.832	0.505	0.697	no	59	10	15	16
Maxent	0.890	0.540	0.704	yes	58	15	16	11
<b>Ensemble</b>	<b>0.886</b>	<b>0.532</b>	<b>0.707</b>		<b>64</b>	<b>18</b>	<b>11</b>	<b>7</b>

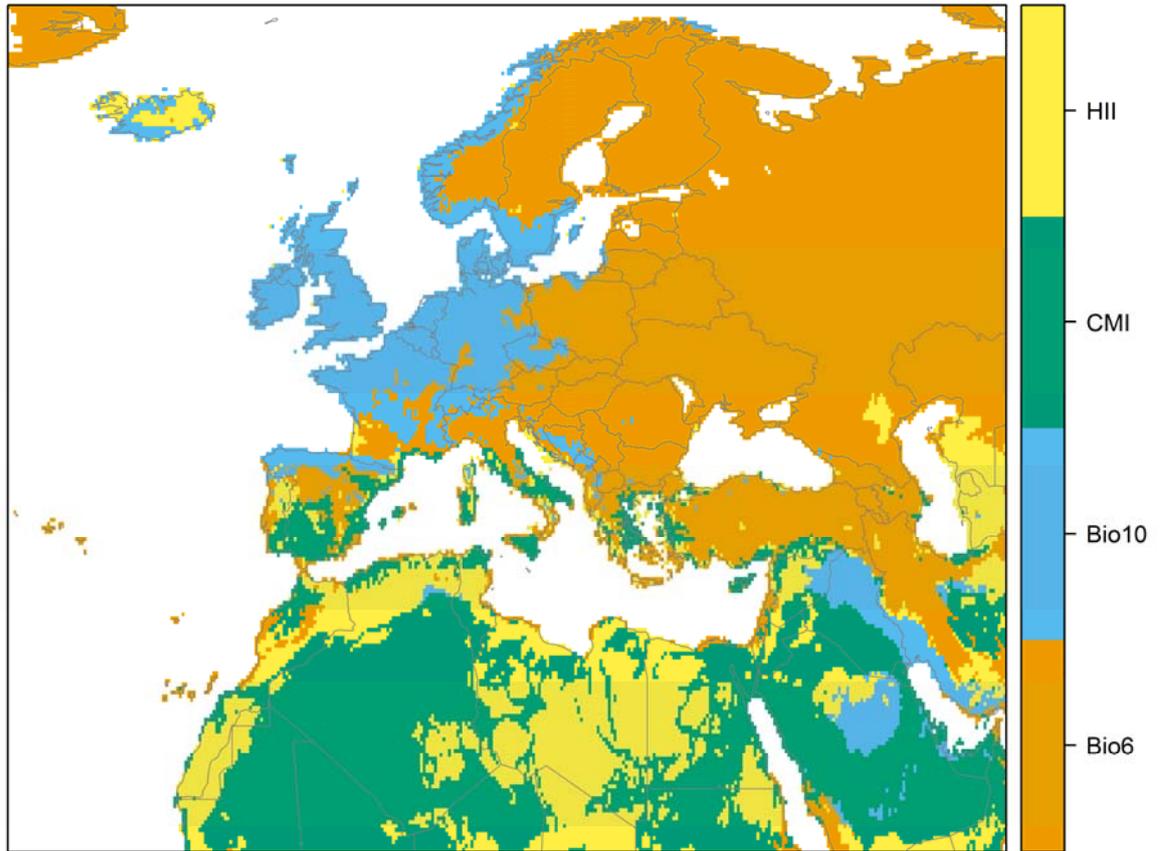

**Figure 3.** Partial response plots from the fitted models. Thin coloured lines show responses from the algorithms in the ensemble, while the thick black line is their ensemble. In each plot, other model variables are held at their median value in the training data. Some of the divergence among algorithms is because of their different treatment of interactions among variables.

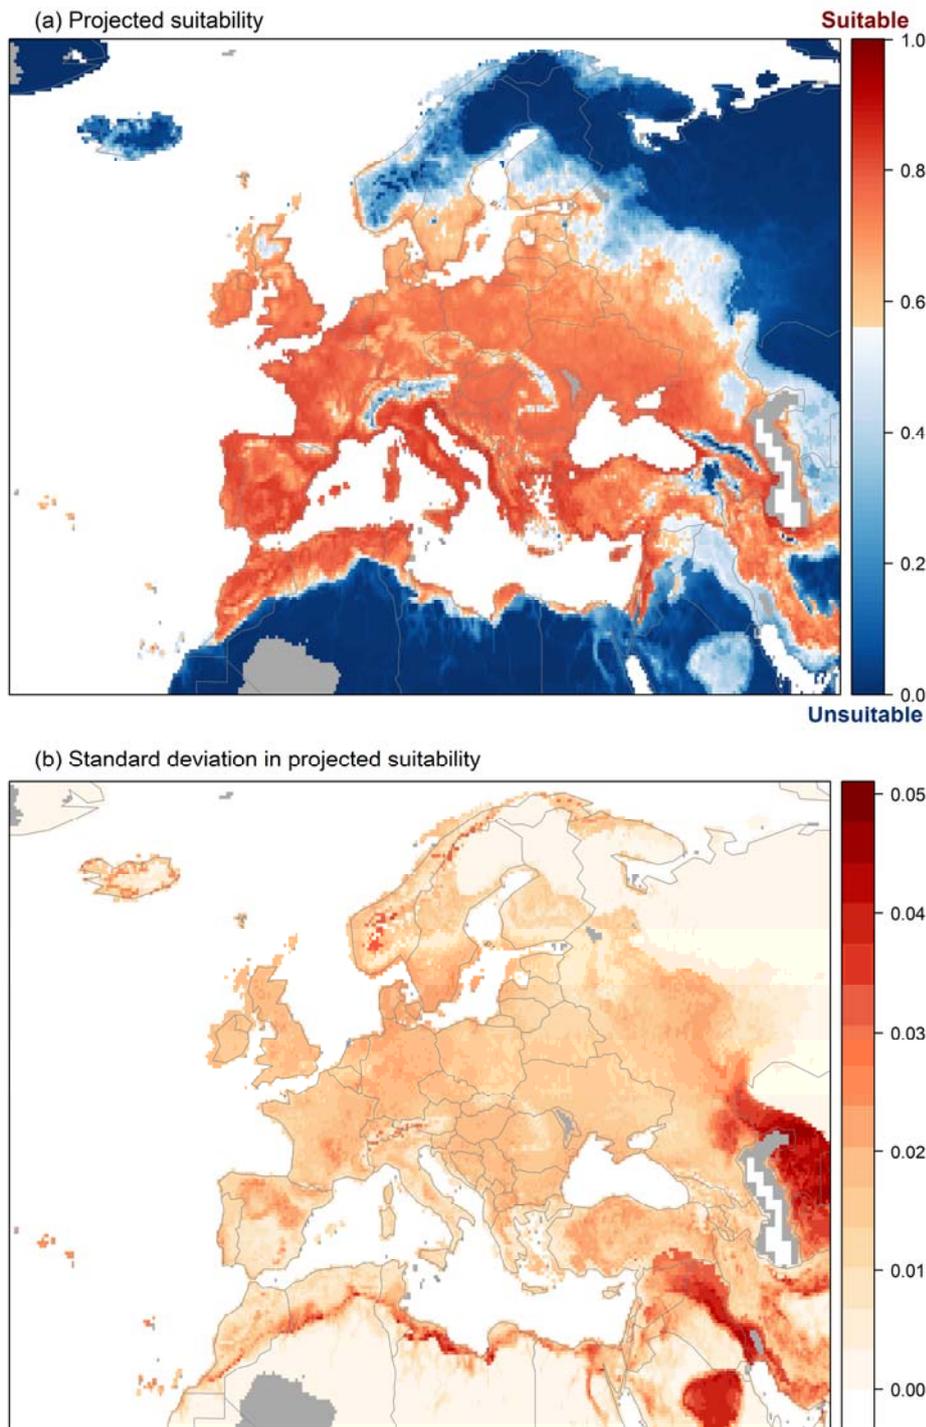

**Figure 4.** (a) Projected global suitability for *Cortaderia selloana* establishment in the current climate. For visualisation, the projection has been aggregated to a 0.5 x 0.5 degree resolution, by taking the maximum suitability of constituent higher resolution grid cells. Values > 0.56 may be suitable for the species. Grey areas have climatic conditions outside the range of the training data and were excluded from the projection. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 3 datasets.

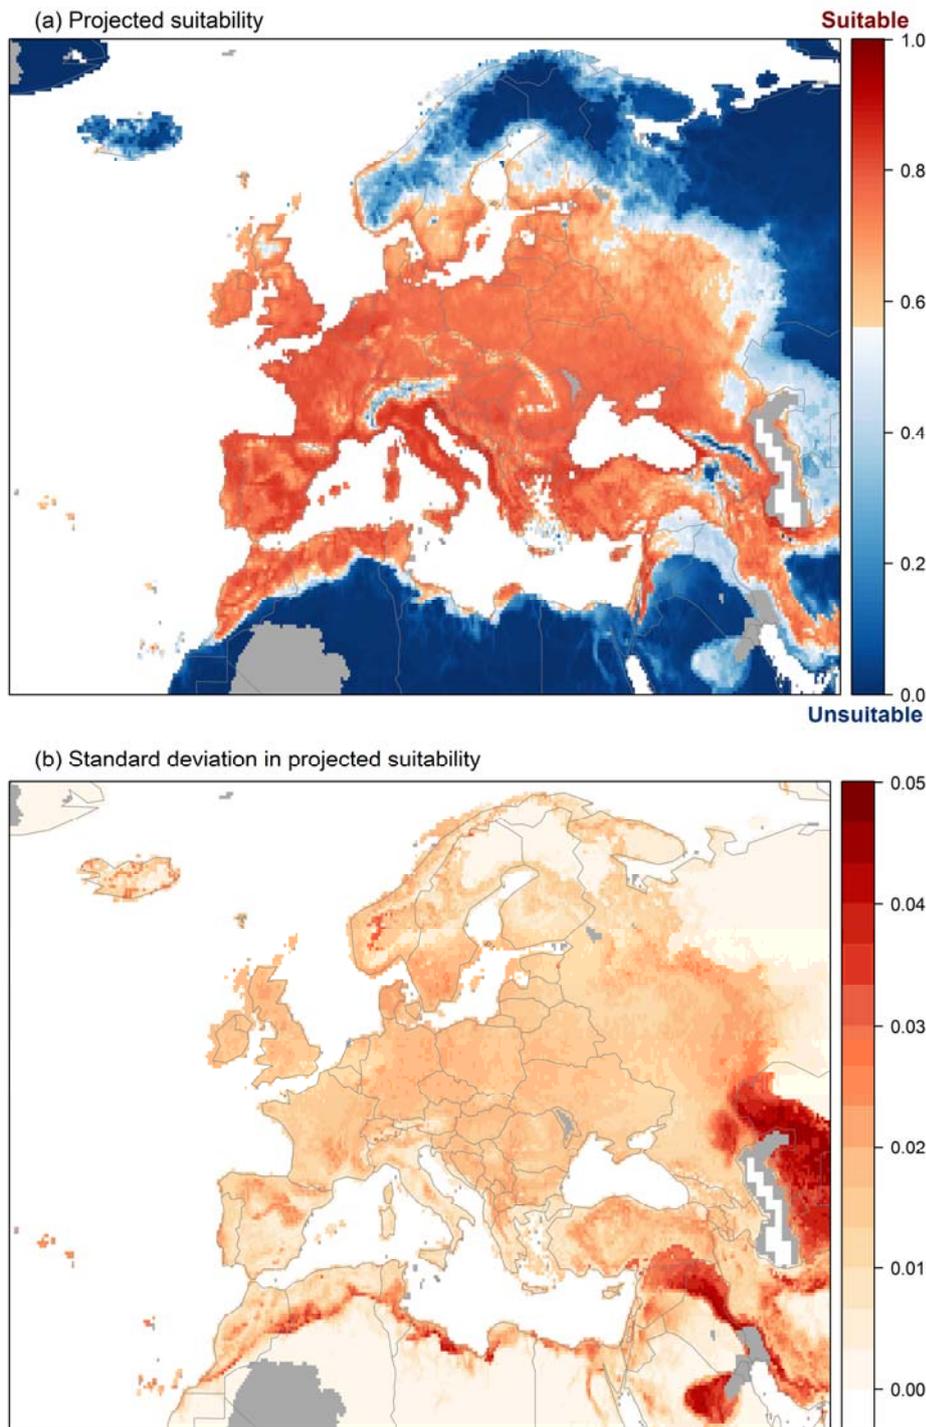

**Figure 5.** (a) Projected current suitability for *Cortaderia selloana* establishment in Europe and the Mediterranean region. Grey areas have climatic conditions outside the range of the training data and were excluded from the projection. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 3 datasets.

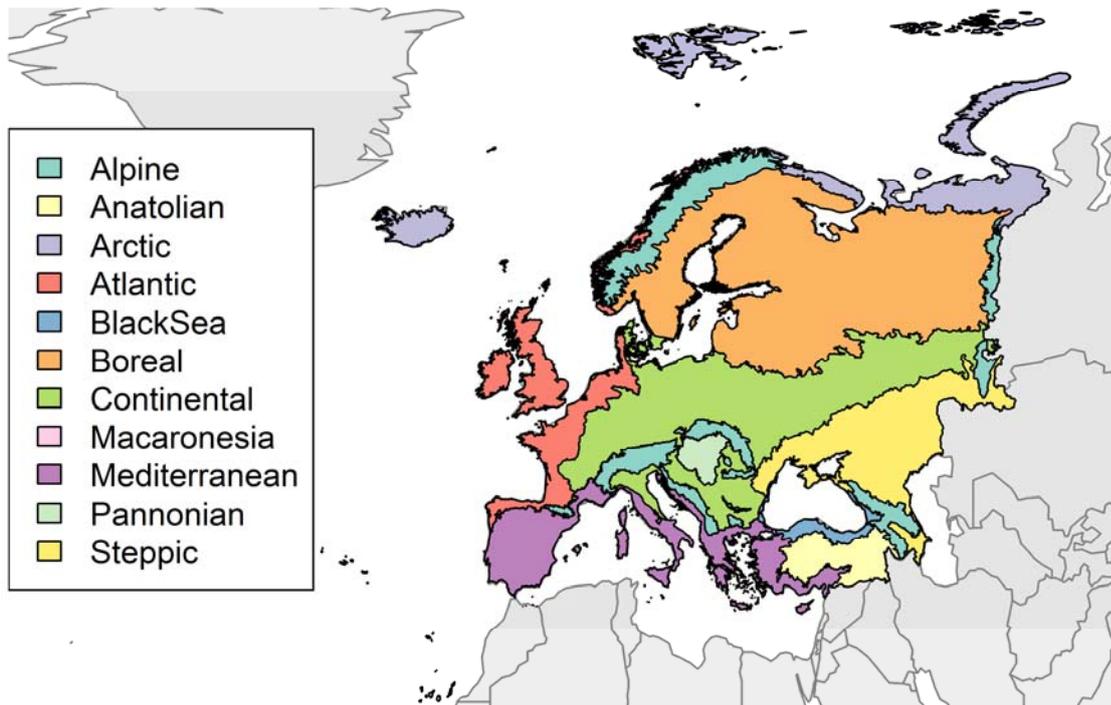

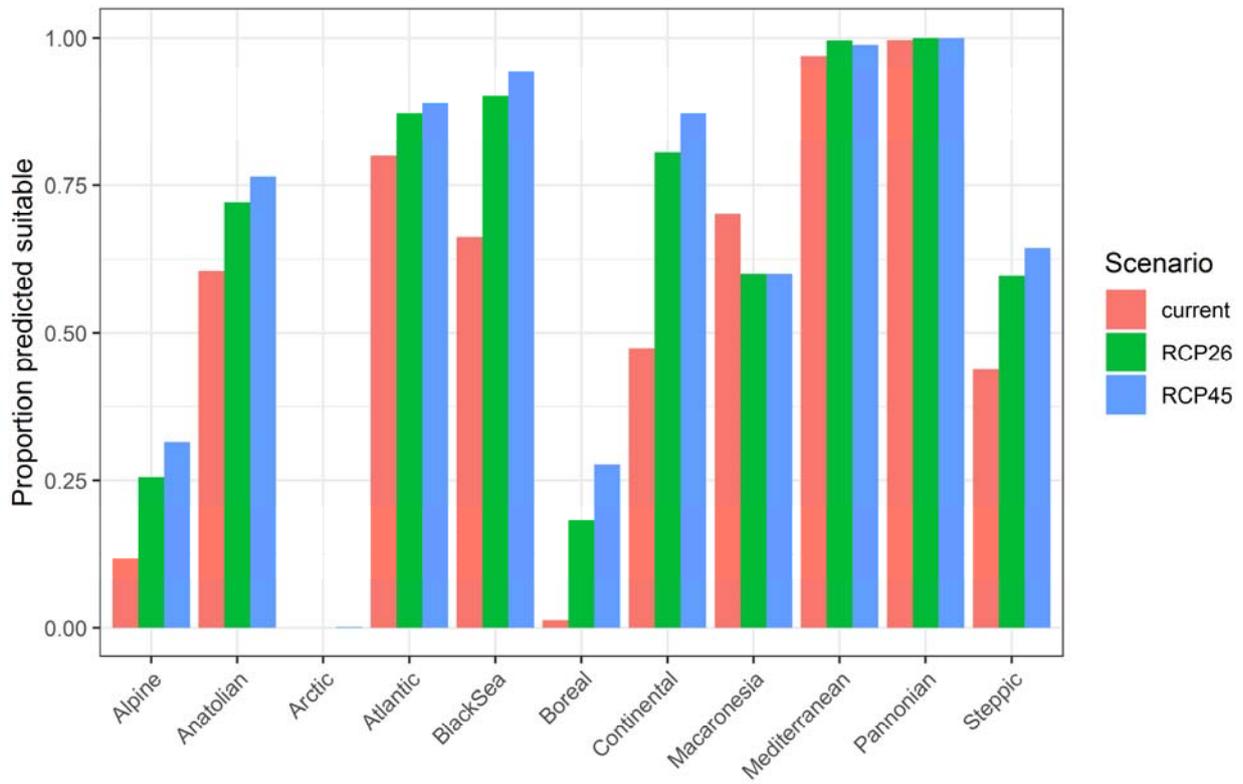

**Figure 6.** The most strongly limiting factors for *Cortaderia selloana* establishment estimated by the model in Europe and the Mediterranean region in current climatic conditions.

**Figure 7.** (a) Projected suitability for *Cortaderia selloana* establishment in Europe and the Mediterranean region in the 2070s under climate change scenario RCP2.6, equivalent to Figure 5. Grey areas have climatic conditions outside the range of the training data and were excluded from the projection. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 3 datasets.

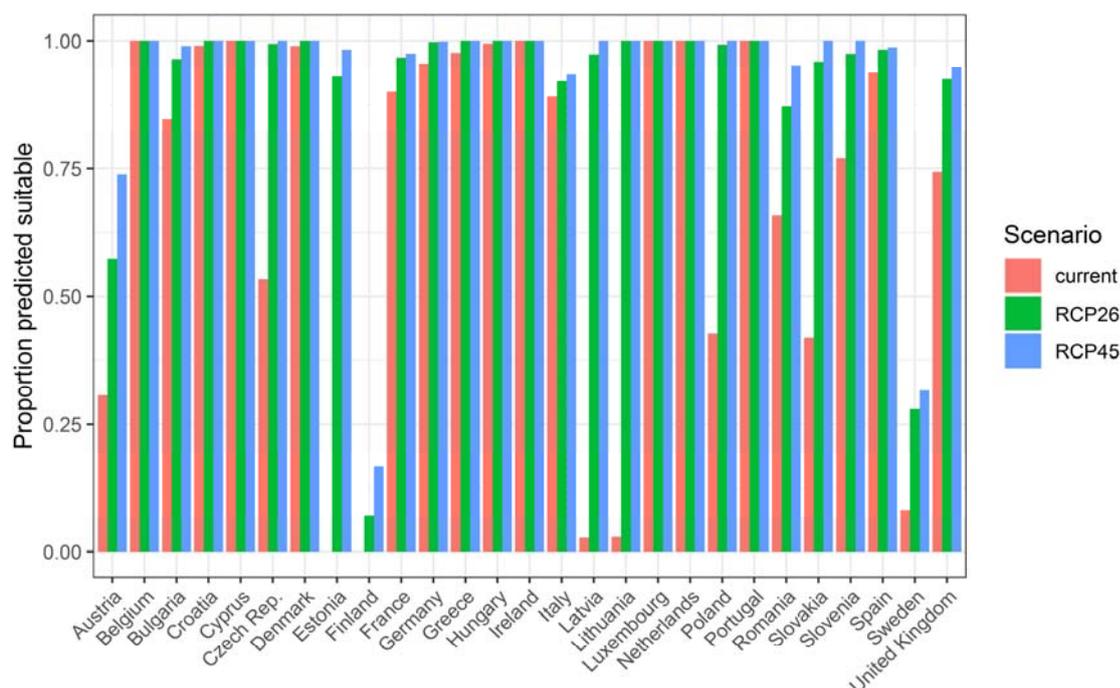

**Figure 8.** (a) Projected suitability for *Cortaderia selloana* establishment in Europe and the Mediterranean region in the 2070s under climate change scenario RCP4.5, equivalent to Figure 5. Grey areas have climatic conditions outside the range of the training data and were excluded from the projection. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 3 datasets.

**Figure 9.** Variation in projected suitability for *Cortaderia selloana* establishment among Biogeographical regions of Europe (Bundesamt für Naturschutz (BfN), 2003). The bar plots show the proportion of grid cells in each region classified as suitable in the current climate and projected climate for the 2070s under two RCP emissions scenarios. The location of each region is also shown. The Arctic and Macaronesian biogeographical regions are not part of the study area, but are included for completeness.

**Table 2.** Variation in projected suitability for *Cortaderia selloana* establishment among Biogeographical regions of Europe (numerical values of Figure 9 above). The numbers are the proportion of grid cells in each region classified as suitable in the current climate and projected climate for the 2070s under two RCP emissions scenarios. The Arctic and Macaronesian biogeographical regions are not part of the study area, but are included for completeness.

Region	current	RCP26	RCP45
Alpine	0.12	0.26	0.31
Anatolian	0.61	0.72	0.76
Arctic	0.00	0.00	0.00
Atlantic	0.80	0.87	0.89
BlackSea	0.66	0.90	0.94
Boreal	0.01	0.18	0.28
Continental	0.47	0.80	0.87
Macaronesia	0.70	0.60	0.60
Mediterranean	0.97	1.00	0.99
Pannonian	1.00	1.00	1.00
Steppic	0.44	0.60	0.64

**Figure 10.** Variation in projected suitability for *Cortaderia selloana* establishment among European Union countries. The bar plots show the proportion of grid cells in each country classified as suitable in the current climate and projected climate for the 2070s under two RCP emissions scenarios. Malta has been excluded because the Human Influence Index dataset lacks coverage for Malta.

**Table 3.** Variation in projected suitability for *Cortaderia selloana* establishment among European Union countries and the UK (numerical values of Figure 10 above). The numbers are the proportion of grid cells in each country classified as suitable in the current climate and projected climate for the 2070s under two RCP emissions scenarios. Malta has been excluded because the Human Influence Index dataset lacks coverage for Malta.

<b>Region</b>	<b>current</b>	<b>RCP26</b>	<b>RCP45</b>

## *Caveats to the modelling*

To remove spatial recording biases, the selection of the background sample was weighted by the density of Tracheophyta records on the Global Biodiversity Information Facility (GBIF). While this is preferable to not accounting for recording bias at all, it may not provide the perfect measure of recording bias.

There was substantial variation among modelling algorithms in the partial response plots (Figure 3). In part this will reflect their different treatment of interactions among variables. Since partial plots are made with other variables held at their median, there may be values of a particular variable at which this does not provide a realistic combination of variables to predict from.

Other variables potentially affecting the distribution of the species, such as land cover were not included in the model.

## SECTION A – Organism Information and Screening

### **A1. Identify the organism. Is it clearly a single taxonomic entity and can it be adequately distinguished from other entities of the same rank?**

including the following elements:

- the taxonomic family, order and class to which the species belongs;
- the scientific name and author of the species, as well as a list of the most common synonym names;
- names used in commerce (if any)
- a list of the most common subspecies, lower taxa, varieties, breeds or hybrids

As a general rule, one risk assessment should be developed for a single species. However, there may be cases where it may be justified to develop one risk assessment covering more than one species (e.g. species belonging to the same genus with comparable or identical features and impact). It shall be clearly stated if the risk assessment covers more than one species, or if it excludes or only includes certain subspecies, lower taxa, hybrids, varieties or breeds (and if so, which subspecies, lower taxa, hybrids, varieties or breeds). Any such choice must be properly justified.

Response: The species is a single taxonomic entity, and it can be distinguished from other entities. The genus *Orconectes* (except cave-dwelling species) is now classified as *Faxonius* (Crandall & De Grave 2017).

*Faxonius immunis* (Hagen, 1870) (Malacostraca, Decapoda, Cambaridae)

Maiynomymys: *Orconectes immunis*, *Cambarus immunis*, *Cambarus signifer*

Common names: calico crayfish, papershell crayfish, mud crayfish (EN), Kalikokrebs (GE), Ecrevisse calicot, Écrevisse calico, Écrevisse à carapace fine (FR)

No hybrids with congeneric *Faxonius* species have been reported. No subspecies, lower taxa, varieties or breeds are currently known. Genetic studies using cytochrome c oxidase subunit I (COI) on European and North American specimens of *F. immunis* suggested that calico crayfish might represent a cryptic species complex (Filipová et al. 2011a).

### **A2. Provide information on the existence of other species that look very similar [that may be detected in the risk assessment area, either in the environment, in confinement or associated with a pathway of introduction]**

Include both native and non-native species that could be confused with the species being assessed, including the following elements:

- other alien species with similar invasive characteristics, to be avoided as substitute species (in this case preparing a risk assessment for more than one species together may be considered);
- other alien species without similar invasive characteristics, potential substitute species;
- native species, potential misidentification and mis-targeting

Response: Native and non-native crayfish species present in the risk assessment area can be distinguished based on morphological and colour characteristics (Souty-Grosset et al. 2006; Kouba et al. 2014; IUCN 2018). The hair tufts on the ventral side of the chelae joints of the 1<sup>st</sup> and 2<sup>nd</sup> pereiopod are key features for recognizing the species together with a distinct tooth followed by a notch on the dactylus (movable finger) of the chelipeds. In addition, *F. immunis* features a very narrow areola (dorsal gap between the branchiocardiac grooves on the carapace), which – among other morphological characteristics of cambarid crayfish – clearly separates it from any native crayfish species, even if for non-experts sometimes difficulties can arise.

These are the other non-native *Faxonius* species present in Europe:

- *Faxonius juvenilis* (France) (Kouba et al. 2014);
- *Faxonius limosus*, present in Europe since the end of 19<sup>th</sup> Century, and established in Austria, Belarus, Belgium, Bulgaria, Croatia, Czech Republic, France, Germany, Hungary, Italy, Latvia, Lithuania, Luxembourg, Montenegro, Netherlands, Poland, Romania, Russia, Serbia, Slovakia, Slovenia, Spain, Switzerland, United Kingdom (Kouba et al. 2014; CABI 2020);
- *Faxonius virilis* (in the Netherlands and UK; Kouba et al. 2014);
- *Faxonius rusticus*, reported in 2019 in France (<http://especies-exotiques-envahissantes.fr/espece/faxonius-rusticus/?lang=en> )

*Faxonius immunis* has a brown or grey-green body with a less pronounced rostrum than *F. limosus*, no hepatic spines on lateral margins of carapace in front of the cervical groove, a typical pale zone in the middle of the carapace and pleon with four dark bands running along dorsal surface of pleon, and broad, flattened tuberculate chela with red/orange tips, with inner side of the dactylus straight at the distal part, followed by the distinct tooth and notch straight margin of movable finger and hair tufts on the ventral side of the chelae joints of the 1<sup>st</sup> and 2<sup>nd</sup> pereiopod (Souty-Grosset et al. 2006). Another key identification character of the species is the shape of the first pleopod of a Form I male: the corneous tip is short and sharply curved with an almost 90-degree bend. Form II pleopods retain this sharp curve (Schainost 2016).

**A3. Does a relevant earlier risk assessment exist? Give details of any previous risk assessment, including the final scores and its validity in relation to the risk assessment area.**

Response: For Europe, the species has been screened using FI-ISK, a tool for identifying potentially invasive freshwater invertebrates, with Italy used as the risk assessment area (Tricarico et al. 2010); the final outcome for *F. immunis* was high risk of invasiveness, and this is relevant to EU countries having similar conditions to Italy. For Germany, the species was assessed using a modified version of the GABLIS-protocol, with the outcome “Invasive species-Action List”, based on the transmission of crayfish plague and the localized distribution (Rabitsch & Nehring 2017). Species on the Action list should be eradicated immediately. For the Rhine-Meuse river district, in the Netherlands, the species has been screened using the internet-based Harmonia+ risk assessment protocol (D’hondt et al. 2015), with an outcome of high risk (Lemmers et al. 2021). For USA, the species has been screened by U.S. Fish and Wildlife Service (2015) with an uncertain outcome: “The biology and ecology of *O. immunis* have some documentation in the scientific literature. Controlled studies on the ecological impacts of *O. immunis* suggest that introduction of this species outside its native range could have detrimental

impacts to native flora and fauna, but the only documented impacts to date have been on another non-native species. Certainty of this assessment is low”.

**A4. Where is the organism native?**

including the following elements:

- an indication of the continent or part of a continent, climatic zone and habitat where the species is naturally occurring
- if applicable, indicate whether the species could naturally spread into the risk assessment area

Response: The species is native to North America, ranging from southern Quebec and New England westward across the upper Midwest to Wyoming and eastern Colorado and south to extreme northwestern Tennessee (Hobbs 1989; Hosabettu & Daniel 2020), and covering different climatic zones (following the classification of Köppen: oceanic; warm summer/humid continental; hot summer/humid continental; cold semi-arid; warm summer/mediterranean continental). It occurs in ponds, roadside ditches, flood plains, stagnant waters and sluggish streams with abundant aquatic plants and plant debris for cover; it has a preference for soft substrate and can tolerate high turbidity. The species usually avoids fast flowing, summer-cool streams (Souty-Grosset et al. 2006; Adams et al. 2010; but see Bovbjerg 1970). It is able to construct deep burrows and spread along the watercourses; in Germany the species has been found to actively disperse over land, moving from pond to pond (no dispersal rate has been reported in the study), over the entire year, especially between March and May, during the spawning season of this species, and between September and November, when *F. immunis* is mating (Hermann et al. 2018).

**A5. What is the global non-native distribution of the organism outside the risk assessment area?**

Response: The species has been probably introduced in the USA in New England, New Hampshire, Rhode Island, Vermont and Massachusetts. Its presence in Connecticut is uncertain (Taylor et al. 2007; Adam et al. 2010; <https://nas.er.usgs.gov/viewer/omap.aspx?speciesID=210>).

**A6. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species been recorded and where is it established? The information needs be given separately for recorded (including casual or transient occurrences) and established occurrences. “Established” means the process of an alien species successfully producing viable offspring with the likelihood of continued survival<sup>2</sup>.**

**A6a. Recorded: List regions**

**A6b. Established: List regions**

---

<sup>2</sup> Convention on Biological Diversity, Decision VI/23

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

- Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea.

Comment on the sources of information on which the response is based and discuss any uncertainty in the response.

For delimitation of EU biogeographical regions please refer to <https://www.eea.europa.eu/data-and-maps/figures/biogeographical-regions-in-europe-2> (see also Annex VI).

For delimitation of EU marine regions and subregions consider the Marine Strategy Framework Directive areas; please refer to <https://www.eea.europa.eu/data-and-maps/data/msfd-regions-and-subregions/technical-document/pdf> (see also Annex VI).

Response (6a): Continental (Gelmar et al. 2006; Collas et al. 2011) and Atlantic (Vermiert 2020). The response is based on publications reporting the presence of the species in these biogeographic regions, so the level of confidence is high.

Response (6b): Continental (Gelmar et al. 2006; Collas et al. 2011; Chucholl 2012) and Atlantic (Vermiert 2020). The response is based on publications reporting the presence and establishment of the species in these biogeographic regions, so the level of confidence is high.

**A7. In which biogeographic region(s) or marine subregion(s) in the risk assessment area could the species establish in the future under current climate and under foreseeable climate change? The information needs be given separately for current climate and under foreseeable climate change conditions.**

**A7a. Current climate: List regions**

**A7b. Future climate: List regions**

With regard to EU biogeographic and marine (sub)regions, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided.

However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

Response (7a): Alpine (very few areas), Atlantic (very few areas), Black Sea, Boreal (very few areas), Continental, Mediterranean, Pannonian, Steppic

Response (7b): 2070 RCP 2.6/RCP 4.5 Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic. The differences between the two RCPs are, compared to the current situation, that under RCP 2.6 scenario there would be an increase of suitable areas in all the listed biogeographic regions (except a slight decrease in Pannonian), especially in Alpine, Atlantic, Black Sea, Boreal, Continental. On the contrary, under RCP 4.5, there would be an increase of suitable areas in Alpine, Atlantic, Boreal, Continental regions (more than under RCP 2.6), an increase similar to those under RCP 2.6 in Black Sea and Pannonian regions, but a decrease in Mediterranean and Steppic regions compared to RCP 2.6.

These responses are based on the SDM (Annex VIII). The model indicates that maximum temperature of the warmest month is the climatic variable currently limiting the establishment in the northern and coldest biogeographic regions. Temperature increase will favour the species establishment in the future, even if the increase forecasted under RCP 4.5 would decrease the percentage of suitable areas in Mediterranean region, that probably would become too warm for the species. The importance of temperature as predictor, followed by terrain slope, has been confirmed also by SDMs conducted on the species for southwestern Germany (Chucholl 2016).

**A8. In which EU Member States has the species been recorded and in which EU Member States has it established? List them with an indication of the timeline of observations. The information needs be given separately for recorded and established occurrences.**

**A8a. Recorded: List Member States**

**A8b. Established: List Member States**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden

The description of the invasion history of the species shall include information on countries invaded and an indication of the timeline of the first observations, establishment and spread.

Response (8a): the first reliable record of the species was in Germany in 1993 in the catchment of the Upper Rhine Plain, followed by another record in 1997, always in the same region (Dehus et al. 1999; Gelmar et al. 2006); in France the first record was in 2010 in Alsace, in the Rothbach river, a tributary of the Rhine river (Collas et al. 2011). The species has been reported for the Netherlands in 2019 (Ottburg et al. 2019) but, after a check with German experts, it seemed to be a misidentification (Fran Oficialdegui, pers. comm.).

Response (8b): Germany, France (Gelmar et al. 2006; Collas et al. 2011; Chucholl 2012; Hermann et al. 2018a). In Germany, the species, after the two records in 1993 and 1997, established and started expanding along the Upper Rhine Plain. The species is reported also in the area of the Black Forest (Chucholl & Brinker 2017). In 2018, new records of the species were reported in the floodplain of the River Rhine between Wiesbaden and Ginsheim, being the first records for the federal state of Hesse, 53 kilometres from the next known locality (Herrmann et al. 2018b). In 2010, an established population was reported for the first time in France; the origin of French population is uncertain. Natural dispersal from Germany could have not occurred as this first French record was far from the areas where the species was reported for Germany. The hypotheses are two: some alive individuals were introduced from Germany or some individuals, kept at home for ornamental reasons, were dumped into the water (Collas et al. 2011). After this first record in France, the species started colonizing the French part of Rhine, some tributaries, and canals.

The species is currently colonizing a stretch of more than 150 km along the Upper Rhine plain in south-western Germany and eastern France (Filipová et al. 2011a; Ott 2017). In addition, there is an apparently disjunct occurrence downstream in the lower section of the Rhine (Düssel catchment) in western Germany (Vermiert 2020). Further isolated occurrences outside of the Upper Rhine Plain were recently reported from south-western Germany (i.e. near the city of Sindelfingen: Chucholl, unpubl. data, 2020).

In the Netherlands seven individuals were reported for three localities (Ottburg et al. 2019; Lemmers et al. 2021), but it was a misidentification.

**A9. In which EU Member States could the species establish in the future under current climate and under foreseeable climate change? The information needs be given separately for current climate and under foreseeable climate change conditions.**

**A9a. Current climate: List Member States**

**A9b. Future climate: List Member States**

With regard to EU Member States, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

Response (9a): Austria, Bulgaria, Croatia, Czech Republic, France, Germany, Greece, Hungary, Italy, Poland, Portugal, Romania, Slovakia, Slovenia, Spain

Response (9b): 2070 RCP 2.6 Austria, Belgium, Bulgaria, Croatia, Czech Republic, Estonia, Finland, France, Germany, Greece, Hungary, Italy, Latvia, Lithuania, Luxembourg, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, and Sweden; 2070 RCP 4.5: Austria, Belgium, Bulgaria, Croatia, Czech Republic, Estonia, Finland, France, Germany, Greece, Hungary, Italy, Latvia, Lithuania, Luxembourg, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden; and in the United Kingdom. Under RCP 2.6, compared to the current situation, there will be an increase of suitable areas in all the listed countries (but slightly in Greece, Italy and Sweden), except in Austria, Croatia, Hungary, Portugal, Slovenia, Spain that will experience a decrease. Under RCP 4.5, compared to the current situation, there will be a much more marked increase of suitable areas in the listed countries (but very slightly in the United Kingdom), except Croatia, Greece, Hungary, Portugal, Spain, that will experience a decrease, and Austria and Slovenia that will remain the same.

These responses are based on the SDM (Annex VIII). Maximum temperature of the warmest month is resulted to be the climatic variable currently limiting the spread in the northern and coldest biogeographic regions. Temperature increase will favour the species spread in the future, but not Croatia, Greece, Hungary, Portugal, Spain, that probably would become too warm for the species.

**A10. Is the organism known to be invasive (i.e. to threaten or adversely impact upon biodiversity and related ecosystem services) anywhere outside the risk assessment area?**

Response: In USA, the species has been hypothesized to possibly cause impacts in its US introduced range (Jansen et al. 2009), being omnivorous and more aggressive than *F. limosus*, but up to now there are no published data of adverse impacts for this area.

**A11. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea

Response: Continental and Atlantic: in Germany, the species has been proved to carry the crayfish plague lethal for European native crayfish (Filipová et al. 2013; Schrimpf et al. 2013) and to reduce native amphibians and macroinvertebrates, especially dragonfly larvae, other insects and molluscs (Ott 2016; Martens et al. 2018). Please see also Section 4 of the present Risk Assessment on impacts.

**A12. In which EU Member States has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden

Response: Germany; the species has been proved to carry the crayfish plague lethal for European native crayfish (Filipová et al. 2013; Schrimpf et al. 2013) and to reduce native amphibians and macroinvertebrates, especially dragonfly larvae, other insects and molluscs (Ott 2016; Martens et al. 2018). In France, turbid waters are reported in invaded ponds due to the species burrowing activity (Francois et al. 2019). Moreover, it could outcompete the congeneric alien *F. limosus* (Chucholl et al. 2008).

**A13. Describe any known socio-economic benefits of the organism.**

including the following elements:

- Description of known uses for the species, including a list and description of known uses in the risk assessment area and third countries, if relevant.
- Description of social and economic benefits deriving from those uses, including a description of the environmental, social and economic relevance of each of those uses and an indication of associated beneficiaries, quantitatively and/or qualitatively depending on what information is available.

If the information available is not sufficient to provide a description of those benefits for the entire risk assessment area, qualitative data or different case studies from across the risk assessment area or third countries shall be used, if available.

Response: In North America, the species was grown and sold as bait (Huner 1994). Estimated 175 metric tonnes of crayfish were cultivated and another estimated 400-500 metric tonnes were harvested for this purpose (Huner 1997). It has been proposed that this species can be used to control submerged aquatic vegetation but the high numbers of required crayfish plus the possible impacts caused by its introduction has prevented promotion of its use (Letson & Makarewicz 1994).

No detailed economic data have been found on the use of the species in the ornamental pet trade, even though its presence in such trade has been reported (Chucholl 2013; Faulkes 2015).

## SECTION B – Detailed assessment

### Important instructions:

- In the case of lack of information the assessors are requested to use a standardized answer: “No information has been found.”
- With regard to the scoring of the likelihood of events or the magnitude of impacts see Annexes I and II.
- With regard to the confidence levels, see Annex III.
- Highlight the selected response score and confidence level in **bold** but keep the other scores in normal text (so that the selected score is evident in the final document).

## 1 PROBABILITY OF INTRODUCTION AND ENTRY

### Important instructions:

- **Introduction** is the movement of the species into the risk assessment area (it may be either in captive conditions and/or in the environment, depending on the relevant pathways).
- **Entry** is the release/escape/arrival in the environment, i.e. occurrence in the wild
- Introduction and entry may coincide for species entering through pathways such as “corridor” or “unaided”, but it also may differ. If different, please consider all relevant pathways, both for the introduction into the risk assessment area and the entry in the environment.
- The classification of pathways developed by the Convention of Biological Diversity (CBD) should be used (see Annex IV). For detailed explanations of the CBD pathway classification scheme consult the IUCN/CEH guidance document<sup>3</sup> and the provided key to pathways<sup>4</sup>.
- For organisms which are already present (recorded or established) in the risk assessment area, the likelihood of introduction and entry should be scored as “very likely” by default.
- Repeated (independent) introductions and entries at separate locations in the risk assessment area should be considered here (see Qu. 1.7).

**Qu. 1.1. List relevant pathways through which the organism could be introduced into the risk assessment area and/or enter into the environment. Where possible give details about the specific origins and end points of the pathways as well as a description of any associated commodities.**

For each pathway answer questions 1.2 to 1.7 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 1.2a, 1.3a, etc. and then 1.2b, 1.3b etc. for the next pathway.

In this context a pathway is the route or mechanism of introduction and/or entry of the species.

<sup>3</sup> <https://circabc.europa.eu/sd/a/738e82a8-f0a6-47c6-8f3b-aeddb535b83b/TSSR-2016-010%20CBD%20categories%20on%20pathways%20Final.pdf>

<sup>4</sup> <https://circabc.europa.eu/sd/a/0aeba7f1-c8c2-45a1-9ba3-bcb91a9f039d/TSSR-2016-010%20CBD%20pathways%20key%20full%20only.pdf>

The description of commodities with which the introduction of the species is generally associated shall include a list and description of commodities with an indication of associated risks (e.g. the volume of trade; the likelihood of a commodity being contaminated or acting as vector).

If there are no active pathways or potential future pathways this should be stated explicitly here, and there is no need to answer the questions 1.2-1.9.

Pathway name: Escape from confinement: Live food and live bait; Pet/aquarium/terrarium species; Contaminant on animals.

The introduction pathway to Europe is unknown; both pet trade and as live bait have been suggested (Dehus et al. 1999; Gelmar et al. 2006). As underlined by Gelmar et al. (2006) and Chucholl (2012), the species was not known in the German pet trade before its establishment in the Upper Rhine, it is however a common and popular species for fishing bait in the USA and Canada, therefore the introduction as live bait seems more likely. The “ornamental” trade became active only since its establishment in Germany (Chucholl 2013) and could well lead to repeated introductions, even if until now the species spread has mainly been reported as occurring naturally along the Rhine basin (Kouba et al. 2014; Hermann et al. 2018; but see France and recent findings in southwestern Germany: Collas et al. 2011; Vermiert 2020). The species seems to have been introduced in France as contaminant of fish stocks (Collas et al. 2015).

**Escape from confinement: Live food and live bait**

**Qu. 1.2a. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	<b>intentional</b>	<b>CONFIDENCE</b>	low
	unintentional		medium
			<b>high</b>

Response: The species probably was introduced as fishing bait, possibly by Canadian soldiers, who had been stationed at an airbase near the two localities where the species was first discovered (Chucholl 2013). The entry could have been intentional too, but unintentional escapes were also possible.

**Qu. 1.3a. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication

- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Introduction of crayfish as food and bait in Europe has decreased in importance through the years, although still continues in some areas (Kouba et al. 2014). Considering the possibility of repeated and independent introductions via this pathway, the probability of introducing a large number of individuals is moderately likely. Source of these repeated introductions could be individuals from North America (even if there is a ban for using crayfish as a bait in numerous North American states) or from populations already established in Europe (Germany and France). No data are available of numbers of crayfish introduced as living bait into the risk assessment area. Likelihood of reinvasion is also moderately likely because of the possible repeated use as live bait.

**Qu. 1.4a. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: The species is established in the wild, proving that it can survive during the transport along this pathway (Dehus et al. 1999; Chucholl 2012). Reproduction and increase during the transport and storage, however, are unlikely, unless specimens are specifically kept and multiplied for use as baits. There is however no information that this has happened in the risk assessment area.

**Qu. 1.5a. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

	<b>very likely</b>		
--	--------------------	--	--

Response: There are no biosecurity measures targeting the species before and during the transport; there could be border inspections for checking the introduction of crayfish already in the list of species of Union concern, and possibly during these checks also *F. immunis* could be intercepted. But up to now no interceptions have been reported for this species. Also for the entry there are no biosecurity measures, except for the code of conducts on IAS and recreational angling.

**Qu. 1.6a. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The species was previously detected in the wild only after its introduction and entry (Gelmar et al. 2006), so the probability of being introduced and released undetected is very likely. Even if the introduction would be carried out by anglers (intentionally or accidentally), it would not be reported, and thus the species would be undetected for the majority of people. Usually, the species would be detected only after establishing or when spreading.

**Qu. 1.7a. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: Repeated introductions and entry are linked to widespread release/escape by citizens/anglers, wherever they have access to rivers, lakes and any other suitable water bodies. The recent findings in southwestern Germany, and in the Netherlands, disjunct from the other records, confirms the likelihood of repeated introductions (Ottburg et al., 2019; Vermiert 2020).

**Qu. 1.8a. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
-----------------	---------------	-------------------	-----

	unlikely moderately likely <b>likely</b> very likely		<b>medium</b> high
--	---	--	-----------------------

Response: The species presumably entered the risk assessment area via this pathway; however, this pathway is decreasing in importance for crayfish, because their use as bait is currently forbidden in many U.S. states (the native area of many alien crayfish), so we can hypothesize that repeated and independent introductions as live bait are less frequent compared to the past (Kouba et al. 2014). However, we cannot completely discard the possibility that high abundance of the species in invaded European waterbodies means easy access to anglers who can use it as bait (C. Chucholl, pers. comm.)

**Escape from confinement: Pet/aquarium/terrarium species**

**Qu. 1.2b. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	<b>intentional</b> unintentional	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response: For this pathway, we are considering the possibility of repeated and independent introductions in the risk assessment area, as the species is already present in Europe. The species is deliberately introduced for ornamental reasons in aquaria and garden ponds (Holdich et al. 2009). The entry into the environment can be either intentional or unintentional, depending on whether it is the result of deliberate releases or accidental escapes.

**Qu. 1.3b. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	<b>low</b>
-----------------	---------------	-------------------	------------

	unlikely moderately likely <b>likely</b> very likely		medium high
--	---	--	----------------

Response: The species is already used as an ornamental species in Europe (Holdich et al. 2009; Chucholl 2013), even if numbers in trade may be lower compared to other more colorful alien crayfish (e.g. *Cambarellus* spp., *Procambarus* spp., *Cherax* spp.: Chucholl & Wendler 2017). Source of these repeated introductions could be specimens from populations established in Europe (Germany and France). For introductions and entry, we can hypothesize few crayfish, as they are bought by a single person and then eventually released by them as unwanted pets. Likelihood of reinvasion is likely because of the use as pet and the possibility of owners dumping unwanted pets into the wild. In addition, the species requires cold winter temperatures for reproduction, which may prompt deliberate releases into garden ponds, from where the species can easily escape (e.g., by over land migration).

**Qu. 1.4b. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: As testified by other alien crayfish introduced for this purpose (and established in the wild) and the use of the species in aquaria and ponds (Kouba et al. 2014), it can survive during the transport along this pathway. There is no reproduction or increase during transport, but the species could reproduce during storage in aquaria.

**Qu. 1.5b. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: There are no biosecurity measures targeting the species before and during the transport; there could be border inspections for checking the introduction of crayfish already in the list of species of Union concern, and possibly during these checks also *F. immunis* could be intercepted. But up to

now no interceptions have been reported for this species. Also for the entry there are no biosecurity measures, except for the code of conducts on IAS and pets. The introduction of the species in France testified its survival to any possible management practices (Chucholl 2012).

**Qu. 1.6b. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
	unlikely		medium
	moderately likely		<b>high</b>
	<b>likely</b>		
	very likely		

Response: Pet owners can purchase the species online and can release individuals into the wild “secretly”, so the species is usually detected only once established. Calico crayfish could have been introduced and released into the wild in France as ornamental species (Chucholl 2013). This has happened also for many other invasive crayfish already present in Europe (Kouba et al. 2014).

**Qu. 1.7b. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated	<b>CONFIDENCE</b>	low
	<b>widespread</b>		medium
	ubiquitous		<b>high</b>

Response: As there are no restrictions and it can be purchased online, its repeated introductions could be widespread; also entry could be widespread, being linked to release by private citizens potentially in all lakes, rivers and other suitable water bodies wherever they can have access. Urban waters are in general more prone to this phenomenon (Chucholl 2015; Patoka et al. 2016; Weiperth et al. 2017).

**Qu. 1.8b. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
	unlikely		<b>medium</b>
	moderately likely		high
	<b>likely</b>		
	very likely		

Response: The species is used in aquaria and garden ponds (Holdich et al. 2009), so the probability of repeated introductions is likely.

**Contaminant on animals**

**Qu. 1.2c. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response: For this pathway, we are considering the possibility of repeated and independent introductions in the risk assessment area, as the species is already present in Europe. The species could be accidentally introduced through fish stocking (Collas et al. 2015).

**Qu. 1.3c. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: Source of these repeated introductions could be specimens from populations established in Europe. For introductions and entry, we can hypothesize few crayfish, as the species is introduced as contaminant. Likelihood of reinvasion could be moderately likely, it depends by the frequency of these stocking activities in the ponds, from where the species can easily escape (e.g., by over land migration).

**Qu. 1.4c. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: As testified by the presence of the species in France (Collas et al. 2015), it can survive during the transport along this pathway. There is no reproduction or increase during transport.

**Qu. 1.5c. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: It depends by the biosecurity measures targeting fish stocks, e.g. if stocks are inspected before the release.

**Qu. 1.6c. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: Its presence in France shows the possibility to be introduced and enter into the environments undetected (Colls et al. 2015). (

**Qu. 1.7c. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: Its repeated introductions could be widespread; also entry could be widespread, being linked to release into fish ponds that are numerous.

**Qu. 1.8b. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Even if the other two previous listed pathways are more common, we cannot completely discard the probability to be introduced as contaminant as probably happened in France (Collas et al. 2015).

**Qu. 1.9. Estimate the overall likelihood of introduction into the risk assessment area or entry into the environment based on all pathways and specify if different in relevant biogeographical regions in current conditions.**

Provide a thorough assessment of the risk of introduction in relevant biogeographical regions in current conditions: providing insight into the risk of introduction into the risk assessment area.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The species is already present in the Continental and Atlantic biogeographic regions in the EU (Kouba et al. 2014). Being a species present in Internet trade, it could be sold all across the risk assessment area, , in particular, according to the model developed on current climate, Black Sea, Continental. Mediterranean, Pannonian, and Steppic regions are (potentially) affected regarding introduction and entry.

**Qu. 1.10. Estimate the overall likelihood of introduction into the risk assessment area or entry into the environment based on all pathways in foreseeable climate change conditions?**

Thorough assessment of the risk of introduction in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of introduction (e.g. change in trade or user preferences)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely introduction within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: It is an adaptable species and, and we can expect that it could be still used in aquaria and urban ponds also in the future.

## 2 PROBABILITY OF ESTABLISHMENT

### Important instructions:

- For organisms which are already established in parts of the risk assessment area or have previously been eradicated, the likelihood of establishment should be scored as “very likely” by default.
- Discuss the risk also for those parts of the risk assessment area, where the species is not yet established.

**Qu. 2.1. How likely is it that the organism will be able to establish in the risk assessment area based on similarity of climatic and abiotic conditions in its distribution elsewhere in the world?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The species is already established in the risk assessment area (Kouba et al. 2014). According to the model developed on current climate, the species could find many suitable areas and water bodies in Black Sea, Continental, Mediterranean, Pannonian, and Steppic regions, being a high adaptable species. Further suitable areas, even if few, are predicted also for Alpine, Atlantic and Boreal regions.

**Qu. 2.2. How widespread are habitats or species necessary for the survival, development and multiplication of the organism in the risk assessment area? Consider if the organism specifically requires another species to complete its life cycle.**

<b>RESPONSE</b>	very isolated isolated moderately widespread <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: The species shows a high degree of plasticity in North America: it occurs in ponds, roadside ditches, flood plains, stagnant waters and sluggish streams with abundant aquatic plants and plant debris for cover; it has a preference for soft mud substrate (Maude & Williams 1983) and can tolerate high turbidity. It has a low potential to colonize highly fast flowing streams (Souty-Grosset et

al. 2006; Adams et al. 2010): when its ability to maintain itself in a current was tested, it started to slip downstream when flow exceeded 26 cm/sec (Maude & Williams 1983). It can tolerate water temperature up to 30 °C and low oxygen level (Tack 1941); egg development is faster at 25 °C than at 12 °C, but at 30 °C eggs die (Rach & Dawson 1991). It is able to construct deep burrows used during dry periods and in fall-winter when water temperatures are too low. As underlined by Chucholl (2012), this capability also allows it to inhabit shallow and temporary water bodies, a niche formerly not occupied by any native crayfish in Central Europe.

**Qu. 2.3. How likely is it that establishment will occur despite competition from existing species in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: In laboratory experiments, *F. immunis* was shown to be superior to the non-native *F. limosus* in direct aggressive interactions and competition for shelter (Chucholl et al. 2008). In the Upper Rhine, the abundance of *F. limosus* decreased after the colonization of *F. immunis* (Gelmar et al. 2006), probably because the latter is a strongly r-selected (i.e producing many eggs and offsprings) and burrowing species (Gelmar et al. 2006; Chucholl 2012). In the native range, *F. virilis* can outcompete *F. immunis* in streams because of greater aggressive behaviour (Bovbjerg 1970). This leads the latter to avoid the competition occupying temporary backwaters or pools. From laboratory experiments, there are contrasting results on interspecific pairs composed by the non-native marbled crayfish *Procambarus virginalis* and *F. immunis*: for Hossain et al. (2020), the former is competitively superior to *F. immunis*, while for Günter (2016) *F. immunis* is clearly superior in size-matched interspecific bouts. However, in natural conditions, the situation could be affected by other variables (e.g. predator pressure).

The possible competition with *Procambarus clarkii* and *Pacifastacus leniusculus*, the most widespread non-native species in Europe after *F. limosus*, has been experimentally tested only in the case of *P. leniusculus*. According to Wendler & Chucholl (2016). *F. immunis* is dominant over size- and sex-matched *P. leniusculus* in both direct interactions and competition for shelter. The inverse situation occurs, when *P. leniusculus* has a size advantage of 4 mm, which is closer to field conditions, since the latter grows considerably larger. The congeneric *F. limosus* outcompetes the native *Austropotamobius pallipes* (Kouba et al. 2014), so *F. immunis*, more aggressive than *F. limosus*, could outcompete the native one.

**Qu. 2.4. How likely is it that establishment will occur despite predators, parasites or pathogens already present in the risk assessment area?**

<b>RESPONSE</b>	N/A	<b>CONFIDENCE</b>	low
-----------------	-----	-------------------	-----

	very unlikely unlikely moderately likely likely <b>very likely</b>		medium <b>high</b>
--	--	--	-----------------------

Response: As with other crayfish, birds, fish and aquatic mammals can predate the species (Hamr 2002), but they do not have a major impact on the population, as they usually do not cause its extinction. *Faxonius immunis* can carry and transmit the crayfish plague (Schrimpf et al. 2013), but as other North American crayfish species *F. immunis* is not severely affected (Svoboda et al. 2017). Moreover, the already established populations of the species in Germany and France demonstrate that they can establish permanent populations despite resident fish and birds.

**Qu. 2.5. How likely is the organism to establish despite existing management practices in the risk assessment area? Explain if existing management practices could facilitate establishment.**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Management practices can be more effective at the early stage of invasion in a closed system, but not in an open system, such as a river. In USA calico crayfish has been demonstrated as highly sensitive to the insecticide permethrin (Thurston et al. 1985) but this cannot be used in every country and waterbodies. Early warning and rapid response processes for crayfish would not limit/prevent establishment in some cases (e.g. if the species results to be more diffused than expected). To prevent new introductions, a complete banning of the species from the trade plus an intensive educational campaign for citizens to avoid its further spread should be promoted. Management practices that promote the use of alien crayfish as a product, e.g. for bait or human consumption, may facilitate establishment (Kouba et al. 2014). Management practices in the environment, e.g. ecosystem restoration via creation of corridors and connections, can favour the spread and establishment of the species, as, for example, happened for the red swamp crayfish *Procambarus clarkii* in Italy (Mazza et al. 2018).

**Qu. 2.6. How likely is it that biological properties of the organism would allow it to survive eradication campaigns in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

	very likely		
--	-------------	--	--

Response: It depends on the invaded habitat and the applied eradication methodology. As with all crayfish species, eradication is very challenging: this species is difficult to detect at low densities, and it cannot be easily removed by only physical means. Moreover, the species digs deep burrows that can allow it to survive some physical and chemical management actions, and has a high reproductive rate that facilitates the recovery of the population in case of incomplete eradication. In addition, it readily moves over land, allowing it to potentially avoid adverse conditions during eradication attempts. Eradication from complex natural habitats, in particular streams and rivers, is currently considered not feasible due to a lack of effective targeted methods and prohibitive collateral damage of non-selective methods (e.g., biocides) (Gherardi et al. 2011).

**Qu. 2.7. How likely are the biological characteristics of the organism to facilitate its establishment in the risk assessment area?**

including the following elements:

- a list and description of the reproduction mechanisms of the species in relation to the environmental conditions in the risk assessment area
- an indication of the propagule pressure of the species (e.g. number of gametes, seeds, eggs or propagules, number of reproductive cycles per year) of each of those reproduction mechanisms in relation to the environmental conditions in the risk assessment area.
- If relevant, comment on the likelihood of establishment based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in establishment whereas for others high propagule pressure (many thousands of individuals) may not.
- If relevant, comment on the adaptability of the organism to facilitate its establishment and if low genetic diversity in the founder population would have an influence on establishment.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The species is omnivorous, with no ontogenetic shift in the diet observed in Europe (Chucholl 2012). It is a strongly r-selected species: it has a high growth rate, with early maturity occurring also at the end of first summer in young of the year; but its life span is short (estimated 2.5 years; Chucholl 2012). Laboratory experiments have showed that *F. immunis* juveniles were larger than *F. virilis* at the third instar and gained weight more rapidly (Wetzel & Brown 1993). In Europe, the species may reproduce two to three times during its life-time, depending on whether they attain sexual maturity at the end of their first summer, and a female can produce up to 500 eggs (Chucholl 2012). Contrary to other cambarids, mating occurs in autumn and female incubate the eggs during the winter in the burrows, releasing the offspring in early spring (Chucholl 2012). As in other *Faxonius* species, storage of spermatophores in the *annulus ventralis* could enable females to mate with a suitable mate even at low population densities (and this is very important when establishing in a new

environment; Buřič et al. 2013). Moreover, extended maternal care (especially present in cambarids and parastacids) allow a good survival of offspring (Mathews 2011). Low genetic diversity is not a problem for successful invasion in crayfish as reported for the congeneric *F. limosus* (Filipová et al. 2011b).

In the USA (but the species could follow the same patterns in Europe: C. Chucholl, pers. comm.), it can tolerate low oxygen levels and water temperature up to 30 °C (even 36 °C: Wiens & Armitage 1961) and low oxygen levels (Tack 1941); egg development is faster at 25°C than at 12°C, but at 30°C eggs die (Rach & Dawson 1991). When temperature preferences were tested, calico crayfish avoided temperature extremes (6 °C and 36 °C): they wandered freely through the intermediate, being most active at night when they tended to select a temperature around 22 °C while, during the day, they were inactive and selected areas with a temperature around 4 degrees cooler (Crawshaw 1974). The species has been reported also to have a high dispersal capability overland (Hermann et al. 2018).

**Qu. 2.8. If the organism does not establish, then how likely is it that casual populations will continue to occur?**

Consider, for example, a species which cannot reproduce in the risk assessment area, because of unsuitable climatic conditions or host plants, but is present because of recurring introduction, entry and release events. This may also apply for long-living organisms.

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
	unlikely		<b>medium</b>
	moderately likely		high
	<b>likely</b>		
	very likely		

Response: Continuous release of the species as unwanted pet (or bait) would likely occur.

**Qu. 2.9. Estimate the overall likelihood of establishment in the risk assessment area under current climatic conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under current climatic conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in current conditions: providing insight in the risk of establishment in (new areas in) the risk assessment area.

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
	unlikely		medium
	moderately likely		<b>high</b>
	likely		
	<b>very likely</b>		

Response: The species is already established in the Continental and Atlantic biogeographic regions of Europe (Kouba et al. 2014; Vermiert 2020). According to the model developed on current climate, the

species could find many suitable areas to establish permanent populations in Black Sea, Continental, Mediterranean, Pannonian, and Steppic regions, while very few suitable areas are present in Alpine, Atlantic and Boreal regions.

**Qu. 2.10. Estimate the overall likelihood of establishment in the risk assessment area under foreseeable climate change conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under foreseeable climate change conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of establishment (e.g. increase in average winter temperature, increase in drought periods)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely establishment within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Based on the SDM (Annex VIII), in the 2070s under climate change scenario RCP2.6/RCP 4.5, the areas suitable for the species will increase (except for a slight decrease in the Mediterranean region under RCP 4.5) in the future, particularly in the Alpine, Atlantic, Boreal and Continental regions.

### 3 PROBABILITY OF SPREAD

**Important instructions:**

- Spread is defined as the expansion of the geographical distribution of an alien species within the risk assessment area.
- Repeated releases at separate locations do not represent continuous spread and should be considered in the probability of introduction and entry section (Qu. 1.7).

**Qu. 3.1. How important is the expected spread of this organism within the risk assessment area by natural means? (List and comment on each of the mechanisms for natural spread.)**

including the following elements:

- a list and description of the natural spread mechanisms of the species in relation to the environmental conditions in the risk assessment area.
- an indication of the rate of spread discussed in relation to the species biology and the environmental conditions in the risk assessment area.

The description of spread patterns here refers to the CBD pathway category “Unaided (Natural Spread)”. It should include elements of the species life history and behavioural traits able to explain its ability to spread, including: reproduction or growth strategy, dispersal capacity, longevity, dietary requirements, environmental and climatic requirements, specialist or generalist characteristics.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: Currently, the species is colonizing new areas upstream and downstream by natural spread. Since its first report, it is currently reported in a stretch of more than 150 km, spreading through canals, ditches and streams, colonizing a variety of aquatic systems from the floodplain to the slope of the Black Forest and occupying different habitat types (Chucholl 2012; Ott 2017). In Germany, the species has been found to actively disperse overland, moving from pond to pond (no dispersal rate has been reported in the study), over the entire year, especially between March and May, during the spawning season of this species, and between September and November, when *F. immunis* is mating (Hermann et al. 2018).

**Qu. 3.2a. List and describe relevant pathways of spread other than "unaided". For each pathway answer questions 3.3 to 3.9 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 3.3a, 3.4a, etc. and then 3.3b, 3.4b etc. for the next pathway.**

including the following elements:

- a list and description of pathways of spread with an indication of their importance and associated risks (e.g. the likelihood of spread in the risk assessment area, based on these pathways; likelihood of survival, or reproduction, or increase during transport and storage;

ability and likelihood of transfer from the pathway to a suitable habitat or host) in relation to the environmental conditions in the risk assessment area.

- an indication of the rate of spread for each pathway discussed in relation to the species biology and the environmental conditions in the risk assessment area.
- All relevant pathways of spread (except “Unaided (Natural Spread)”, which is assessed in Qu. 4.1) should be considered. The classification of pathways developed by the Convention of Biological Diversity shall be used (see Annex IV).

**Pathway name: Corridor (interconnected waterways/basins/seas)**

**Qu. 3.3a. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional	<b>CONFIDENCE</b>	low
	<b>unintentional</b>		medium
			<b>high</b>

Response: The Rhine river is connected with other rivers by canals, so the species could spread using this pathway, as happened for other aquatic alien species (Leuven et al. 2009).

**Qu. 3.4a. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
	unlikely		<b>medium</b>
	moderately likely		high
	<b>likely</b>		
	very likely		

Response: There are no data on the propagule pressure, but, as shown by the natural spread of the species along the Rhine, the species could spread also through this pathway. Some traits mentioned above- successful reproduction, low genetic diversity, possible maternal care- could facilitate the spread. Reinvasion could happen, as the species actively disperses, even overland (Chucholl 2012;

Hermann et al. 2018). As rate, we can consider a similar rate to the reported natural spread: in around ten years it colonized a stretch of almost 100 km along the Rhine (Chucholl 2012).

**Qu. 3.5a. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
	unlikely		<b>medium</b>
	moderately likely		high
	likely		
	<b>very likely</b>		

Response: The species could survive along this pathway, as also showed by its active dispersal along the Rhine. It could even reproduce while spreading. This happened for other macroinvertebrates (Leuven et al. 2009).

**Qu. 3.6a. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	<b>low</b>
	unlikely		medium
	moderately likely		high
	<b>likely</b>		
	very likely		

Response: Some barriers along the interconnected water bodies could slow the spread of species, but they would not affect its survival.

**Qu. 3.7a. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
	unlikely		<b>medium</b>
	moderately likely		high
	likely		
	<b>very likely</b>		

Response: Interconnected canals and rivers allowed the undetected spread of many invasive species in Europe (Panov et al. 2007, 2009); this could happen also for *F. immunis*.

**Qu. 3.8a. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: During natural dispersal, the species usually arrives and settles in suitable habitats or moves on; the same could happen using this pathway.

**Qu. 3.9a. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area. (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly slowly moderately <b>rapidly</b> very rapidly	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: Considering that the Rhine is connected with other rivers and that the species could rapidly disperse unaided (almost 100 km within 10 years: Chucholl 2012), we could hypothesize a similar rapid spread along this pathway.

**Qu. 3.10. Within the risk assessment area, how difficult would it be to contain the organism in relation to these pathways of spread?**

<b>RESPONSE</b>	very easy easy with some difficulty <b>difficult</b> very difficult	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: Once in an aquatic system, particularly a well-connected one such as the Rhine basin, it is difficult to contain the species. Physical barriers have been tested on other alien crayfish, but they can also stop native species movement (Gherardi et al. 2011). Containment could be hypothesized for closed (or almost confined systems: e.g. ponds or areas that could be fenced).

**Qu. 3.11. Estimate the overall potential rate of spread in relevant biogeographical regions under current conditions for this organism in the risk assessment area (indicate any key issues and provide quantitative data where possible).**

Thorough assessment of the risk of spread in relevant biogeographical regions in current conditions, providing insight in the risk of spread into (new areas in) the risk assessment area.

<b>RESPONSE</b>	very slowly slowly moderately <b>rapidly</b> very rapidly	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: The species has colonized almost 100 km of river area within approx. 10 years (Chucholl 2012). We can expect that the species will continue to spread (unaided or using corridors) in the Continental and Atlantic region. The lower Rhine drainage is probably very prone to invasion by *F. immunis* (C. Chucholl, pers. comm.) , as evidenced by the recent reports in the Netherlands (Ottburg et al. 2019).

**Qu. 3.12. Estimate the overall potential rate of spread in relevant biogeographical regions in foreseeable climate change conditions (provide quantitative data where possible).**

Thorough assessment of the risk of spread in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk, specifically if rates of spread are likely slowed down or accelerated.

<b>RESPONSE</b>	very slowly slowly moderately <b>rapidly</b> very rapidly	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: It is likely that the species will be able to spread also in the future, as the availability of suitable areas will increase with climate change (Annex VIII). As climate change will favour the species, we can hypothesize that in the future at least a similar rate of spread to the current one could occur, considering that all the regions will almost become suitable.

## 4 MAGNITUDE OF IMPACT

Important instructions:

- Questions 4.1-4.5 relate to biodiversity and ecosystem impacts, 4.6-4.8 to impacts on ecosystem services, 4.9-4.13 to economic impact, 4.14-4.15 to social and human health impact, and 4.16-4.18 to other impacts. These impacts can be interlinked, for example, a disease may cause impacts on biodiversity and/or ecosystem functioning that leads to impacts on ecosystem services and finally economic impacts. In such cases the assessor should try to note the different impacts where most appropriate, cross-referencing between questions when needed.
- Each set of questions starts with the impact elsewhere in the world, then considers impacts in the risk assessment area (=EU27+UK excluding outermost regions) separating known impacts to date (i.e. past and current impacts) from potential future impacts (including foreseeable climate change).
- Only negative impacts are considered in this section (socio-economic benefits are considered in Qu. A.7)

### Biodiversity and ecosystem impacts

**Qu. 4.1. How important is the impact of the organism on biodiversity at all levels of organisation caused by the organism in its non-native range excluding the risk assessment area?**

including the following elements:

- Biodiversity means the variability among living organisms from all sources, including terrestrial, marine and other aquatic ecosystems and the ecological complexes of which they are part; this includes diversity within species, between species and of ecosystems
- impacted chemical, physical or structural characteristics and functioning of ecosystems

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: In the USA, the species has been hypothesized to have the potential to cause impacts in the introduced range (Jansen et al. 2009), being omnivorous and more aggressive than the congeneric *F. limosus*, but up to now there are no published data and details of impacts for this area.

**Qu. 4.2. How important is the current known impact of the organism on biodiversity at all levels of organisation (e.g. decline in native species, changes in native species communities, hybridisation) in the risk assessment area (include any past impact in your response)?**

Discuss impacts that are currently occurring or are likely occurring or have occurred in the past in the risk assessment area. Where there is no direct evidence of impact in the risk assessment area (for

example no studies have been conducted), evidence from outside of the risk assessment area can be used to infer impacts within the risk assessment area.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: In Europe, the species has been found to carry crayfish plague, lethal for European native crayfish (Schrimpf et al. 2013). The species is omnivorous: from the stomach content analyses, Chucholl (2012) showed that in Germany the main food item is detritus, followed by macroinvertebrates and macrophytes, with no ontogenetic shift in the diet clearly reported up to now. In the same study, the species was found to prey on a wide spectrum of macroinvertebrates, mainly Chironomidae larvae, Cladocera and Ephemeroptera larvae. Moreover, “The relatively high importance of Cladocera in its diet, along with the positive selection of *Dreissena*, indicates that *O. immunis* is able to access the plankton pool as an energy resource, in addition to benthic macroinvertebrates, macrophytes and detritus. The relatively high importance of energy-rich macroinvertebrate prey in its diet probably supports the sustained high growth rate of *O. immunis*” (Chucholl 2012). Chucholl (2012) noted that “in Lake Bärensee (the study lake in Germany), the decline of macrophyte species coincided with the first observations of *O. immunis* in the lake, suggesting that *O. immunis* might negatively affect macrophyte biomass, as was experimentally shown by Letson and Makarewicz (1994)”.

From studies carried out in USA, it results that plant material is often the dominant food item found in the stomachs, followed by zooplankton (*Daphnia*), insect remains, isopods (*Asellus*), midge larvae (*Chironomus*), rotifers and diatoms (Tack 1941), and that calico crayfish juveniles were found to filter feed whereas adults may do so opportunistically (Budd et al. 1978).

In Germany, Hermann et al. (2016) from laboratory experiments on juvenile growth in Europe inferred that juveniles could eat mainly macrozoobenthos, in accordance with findings in other crayfish species (juveniles usually are more carnivores), even if no other evidence on this issue has been reported. Ott (2016) reports negative impacts on amphibians, molluscs, caddisflies, and dragonflies in the river Rhine. Ott (2018) reports that “In the floodplain of the river Rhine in the two German federal states of Baden-Württemberg and Rhineland-Palatinate the calico crayfish (*Orconectes immunis*) increased its distribution area remarkably, which has a strong influence on the dragonfly fauna of the floodplain, also affecting several dragonfly species of the EC habitats directive (e.g. *Leucorrhinia caudalis*, *Ophiogomphus cecilia*).” In Germany, Herrmann et al. (2018c) and Martens et al. (2018) found a significant reduction in Coleoptera, Odonata, Mollusca and Trichoptera between the years 2015 and 2017 in a pond created for amphibian conservation, comparing the populations of these invertebrates before and after *F. immunis* has built up high population densities. They also found that that *F. immunis* can grow up to densities > 15 crayfish/m<sup>2</sup> in small conservation ponds leading to minimum levels of presence of odonates. In agreement with the major impact of *F. immunis* on macroinvertebrates in small ponds, Wendler (2018) demonstrated *F. immunis* to exhibit the highest *per capita* effect on gammarid prey among four invasive and one native crayfish species using comparative function response analysis. Finally, it is a burrowing species, so together with damages to

riverbank, increase in turbidity with cascade effects on native species (less oxygen and light for the species living under the water surface with their consequent reduction) can be expected, as recorded for other invasive alien crayfish intensively burrowing in Europe (e.g. *Procambarus clarkii*; Souty-Grosset et al. 2016).

A recent laboratory experiment on functional response of different alien crayfish present in Europe, *F. immunis* included, showed that this species, together with the signal crayfish *Pacifastacus leniusculus*, is one of the most impactful invaders, with the highest effects on macrobenthos and detritus (Chucholl & Chucholl 2021).

**Qu. 4.3. How important is the potential future impact of the organism on biodiversity at all levels of organisation likely to be in the risk assessment area?**  
 See comment above. The potential future impact shall be assessed only for the risk assessment area.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: According to the SDM (Annex VIII), the species will find more suitable climatic areas in Europe in the future, starting from the Continental and Atlantic regions already invaded. Being an omnivorous species, it can cause a decrease in macrophyte cover, macroinvertebrates abundance and diversity, changing trophic interaction and community composition.

**Qu. 4.4. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism currently in the risk assessment area?**  
 including the following elements:

- native species impacted, including red list species, endemic species and species listed in the Birds and Habitats directives
- protected sites impacted, in particular Natura 2000
- habitats impacted, in particular habitats listed in the Habitats Directive, or red list habitats
- the ecological status of water bodies according to the Water Framework Directive and environmental status of the marine environment according to the Marine Strategy Framework Directive

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: Impact on native crayfish species listed in the Habitat Directive, such as the white-clawed crayfish, *Austropotamobius pallipes*, the stone crayfish *A. torrentium* and the noble crayfish *Astacus astacus*, could be significant through disease (i.e. crayfish plague lethally affecting native species; Schrimpf et al. 2013). Impact could be significant also on native macroinvertebrates (e.g. odonates *Leucorrhinia caudalis*, *Ophiogomphus cecilia*, both species in the European Red List of Dragonflies and in the Habitat Directive) and amphibians (e.g. *Rana* spp: Ott 2016, 2017). All invaded habitats could be affected as a result of the species consumption of macroinvertebrates and macrophytes, in addition to burrowing and sediment mobilization (“milky water”). In this way, it can alter the ecological status of water bodies according to the Water Framework Directive. It has negative effects in protected areas (Francois et al. 2019) and has the potential to affect habitats and species listed in the Habitat Directive (e.g. 3150 Natural eutrophic lakes with *Magnopotamion* or *Hydrocharition*; 3270 Rivers with muddy banks with *Chenopodion rubri* pp and *Bidention* pp vegetation; abovementioned dragonflies and crayfish).

**Qu. 4.5. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism likely to be in the future in the risk assessment area?**

including the following elements:

- native species impacted, including red list species and species listed in the Birds and Habitats directives
- protected sites impacted, in particular Natura 2000
- habitats impacted, in particular habitats listed in the Habitats Directive, or red list habitats
- the ecological status of water bodies according to the Water Framework Directive and environmental status of the marine environment according to the Marine Strategy Framework Directive

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: According to the SDM (Annex VIII), the species will find more suitable climatic areas in Europe in the future, so we can expect a major impact on species and habitats of conservation concerns listed in the answer of Qu. 4.4. areas.

**Ecosystem Services impacts**

**Qu. 4.6. How important is the impact of the organism on provisioning, regulating, and cultural services in its non-native range excluding the risk assessment area?**

- For a list of services use the CICES classification V5.1 provided in Annex V.
- Impacts on ecosystem services build on the observed impacts on biodiversity (habitat, species, genetic, functional) but focus exclusively on reflecting these changes in relation to their links with socio-economic well-being.

- Quantitative data should be provided whenever available and references duly reported.
- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: In the USA introduced range, no information has been found. We cannot discard, however, that, being a burrowing species, together with damage to riverbanks, the increase in turbidity can have cascading effects on native species and ecosystem services (please see the response to the subsequent Qu 4.7 for details) (e.g. *Procambarus clarkii*; Souty-Grosset et al. 2016).

**Qu. 4.7. How important is the impact of the organism on provisioning, regulating, and cultural services currently in the different biogeographic regions or marine sub-regions where the species has established in the risk assessment area (include any past impact in your response)?**

- See guidance to Qu. 4.6.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: Increase in turbidity is reported in some ponds (Francois et al. 2019). Being a burrowing species, it can damage riverbanks leading to soil erosion and changes in sediments (regulating services: baseline flows and extreme event regulation; soil quality regulation), while the increase in turbidity can have a cascade effect on native species, primary production and trophic chains (provisioning services: wild plants and wild animals) and water quality (regulating services: water conditions, and provisioning services: water quality), as recorded for other invasive alien crayfish intensively burrowing in Europe (e.g. *Procambarus clarkii*; Souty-Grosset et al. 2016). Also cultural services can be impacted, because “milky water” ponds do not attract people (physical and experiential interactions with natural environment), and the species alters the pristine characteristics of the habitat (intellectual and representative interactions with natural environment).

**Qu. 4.8. How important is the impact of the organism on provisioning, regulating, and cultural services likely to be in the different biogeographic regions or marine sub-regions where the species can establish in the risk assessment area in the future?**

- See guidance to Qu. 4.6.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: According to the predictive climatic models, the species will find more suitable climatic areas in Europe in the future (see Annex VIII), so we can expect still major impacts on ecosystem services (provisioning: wild plants, wild animals, water quality; regulating services: baseline flows and extreme event regulation, soil quality regulation, water conditions; cultural services: physical and experiential interactions with natural environment, intellectual and representative interactions with natural environment).

## Economic impacts

**Qu. 4.9. How great is the overall economic cost caused by the organism within its current area of distribution (excluding the risk assessment area), including both costs of / loss due to damage and the cost of current management.**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the world these should be reported here. The assessment of the potential costs of / loss due to damage shall describe those costs quantitatively and/or qualitatively depending on what information is available. Cost of / loss due to damage within different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage. As far as possible, it would be useful to separate costs of / loss due to the organism from costs of current management.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: Souty-Grosset et al. (2006) report that the species in the USA is considered a pest in rice paddies, where it burrows extensively and causes damage to young rice plants. However, there is no quantification of this damage available. No information has been found for costs of damaged banks and their management.

**Qu. 4.10. How great is the economic cost of / loss due to damage (excluding costs of management) of the organism currently in the risk assessment area (include any past costs in your response)?**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the EU these should be reported here. Assessment of the potential costs of damage on human health, safety, and the economy, including the cost of non-action. A full economic assessment at EU scale might not be possible, but qualitative data or different case studies from across the EU (or third countries if relevant) may provide useful information to inform decision making. In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. Cost of / loss due to damage within different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: No information has been found on the issue in the risk assessment area. We can only hypothesize the response by considering the estimated costs caused by *Procambarus clarkii* for damaging banks (e.g. 1000 euro/m<sup>2</sup>, info provided by an Italian Land Reclamation Authority reported in Souty-Grosset et al. 2016), because also *F. immunis* is considered a highly burrowing species as *P. clarkii*.

**Qu. 4.11. How great is the economic cost of / loss due to damage (excluding costs of management) of the organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.10.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: This very much depends on the time elapsed between first introduction and when action is taken to control the species. If action is taken immediately to mitigate its spread, then costs could be relatively low (for example damage to banks would be limited), but if left to spread the costs would potentially be major (the costs linked to riverbanks could increase; increase of turbidity could also affect fish populations with a potential consequence on fishing activities).

**Qu. 4.12. How great are the economic costs / losses associated with managing this organism currently in the risk assessment area (include any past costs in your response)?**

- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: No published information has been found on the issue. Management actions are ongoing in some ponds in Germany, but no detailed information is available on costs. Considering the current extent of the species, we can only hypothesize the response, because the species could be managed only in certain areas (closed and/or confined water bodies).

**Qu. 4.13. How great are the economic costs / losses associated with managing this organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.12.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: This very much depends on when action is taken to control the species if it is introduced. If action is taken immediately to mitigate its spread, then costs could be relatively low, but if left to spread the costs would potentially be major. Intensive trapping an area of 10,000 m<sup>2</sup> with 120 traps for 171 trap days could cost approximately 30,000 euro to reduce species abundance by at least 70%. But intensive trapping should be permanently maintained through time. Eradication of crayfish from a water body of 19,000 m<sup>2</sup> could cost around 46,500 euro of biocides. Drainage at least once of a pond of approximately 400,000 m<sup>3</sup> could cost around 40-50,000 euro (E. Tricarico, pers. comm.). Costs are estimated on the basis of the experience with measures targeting other invasive crayfish present in the risk assessment area.

## Social and human health impacts

**Qu. 4.14. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism for the risk assessment area and for third countries, if relevant (e.g. with similar eco-climatic conditions).**

The description of the known impact and the assessment of potential future impact on human health, safety and the economy, shall, if relevant, include information on

- illnesses, allergies or other affections to humans that may derive directly or indirectly from a species;
- damages provoked directly or indirectly by a species with consequences for the safety of people, property or infrastructure;
- direct or indirect disruption of, or other consequences for, an economic or social activity due to the presence of a species.

Social and human health impacts can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>	minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: No human health impacts have been reported up to now. Risk of flooding might increase if dykes are destabilized by crayfish burrowing.

**Qu. 4.15. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism in the future for the risk assessment area.**

- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: As in the future, the suitable areas for the species will increase we can hypothesize that risk of flooding might increase for crayfish burrowing, because they actively dig and this could lead to instability/collapse of banks, as already happened for a similar burrowing species *Procambarus clarkii* (Haubrock et al. 2019).

## Other impacts

**Qu. 4.16. How important is the organism in facilitating other damaging organisms (e.g. diseases) as food source, a host, a symbiont or a vector etc.?**

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: The species carries the crayfish plague, lethal for European native crayfish (Filipová et al. 2013; Schrimpf et al. 2013). We cannot discard the possibility that the species could carry other pathogens and diseases as found for the congeneric *F. limosus*.

**Qu. 4.17. How important might other impacts not already covered by previous questions be resulting from introduction of the organism?**

<b>RESPONSE</b>	minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	--	-------------------	-----------------------

Response: NA

**Qu. 4.18. How important are the expected impacts of the organism despite any natural control by other organisms, such as predators, parasites or pathogens that may already be present in the risk assessment area?**

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: Even if fish and birds could predate on the species, they regulate the population to a low level of density but do not cause extinction. A recent study showed that the species, together with the signal crayfish *Pacifastacus leniusculus*, is one of the most impactful invaders (Chucholl & Chucholl 2021), thus overcoming also other notable invasive crayfish as *Faxonius limosus* and *Procambarus fallax* forma *virginalis*.

**Qu. 4.19. Estimate the overall impact in the risk assessment area under current climate conditions. In addition, details of overall impact in relevant biogeographical regions should be provided.**

Thorough assessment of the overall impact on biodiversity and ecosystem services, with impacts on economy as well as social and human health as aggravating factors, in current conditions.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: Some studies already demonstrated relevant ecological impacts (reduction of macroinvertebrate abundance; decline of macrophytes; vector of crayfish plague, lethal for native crayfish; highly burrowing activity with damages to banks) in the Continental region where the species is present (Chucholl 2012; Ott 2016, 2018; Herrmann et al., 2018c; Martens et al. 2018), but further studies are needed to better assess them, particularly in different habitats and through time, and to deeply investigate the effects of its intense burrowing activity. Studies to understand the ecosystem services impacts and quantify the economic impacts are also necessary.

**Qu. 4.20. Estimate the overall impact in the risk assessment area in foreseeable climate change conditions. In addition, details of overall impact in relevant biogeographical regions should be provided.**

Thorough assessment of the overall impact on biodiversity and ecosystem services, with impacts on economy as well as social and human health as aggravating factors, under future conditions.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: As the species will find more suitable areas for introduction, entry and establishment in the future (see Annex VIII), an increase of its impacts has to be expected. According to the SDM (Annex VIII), impacts might increase in the Alpine, Atlantic, Black Sea, Boreal, and Continental biogeographical regions (under both RCP 2.6 and RCP 4.5), but decrease in the Mediterranean and Steppic regions (under RCP 4.5).

<b>RISK SUMMARIES</b>			
	<b>RESPONSE</b>	<b>CONFIDENCE</b>	<b>COMMENT</b>
<b>Summarise Introduction and Entry*</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	low medium <b>high</b>	The species is already present in Europe (France and Germany) since 1993.
<b>Summarise Establishment*</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	low medium <b>high</b>	The species is already established in Europe (Germany from 1997, France from 2010).
<b>Summarise Spread*</b>	very slowly slowly moderately <b>rapidly</b> very rapidly	low medium <b>high</b>	After its first detection in 1993, the species is currently colonizing a riverine stretch of more than 150 km, and it is still spreading. Considering the favourable current and future climatic conditions and its capability to disperse also overland, the species will continue to spread rapidly.
<b>Summarise Impact*</b>	minimal minor moderate <b>major</b> massive	low medium <b>high</b>	The studies on the impacts are recent and still ongoing, but they have already demonstrated ecological impacts (reduction of macroinvertebrate abundance; decline of macrophytes; vector of crayfish plague; highly burrowing activity with damages to banks). Considering that the species is omnivorous, colonizes a wide range of habitats and extensively burrows, with favorable current and future climate conditions we can expect major impacts.
<b>Conclusion of the risk assessment (overall risk)</b>	low moderate <b>high</b>	low <b>medium</b> high	Based on the evidence from the recent literature, species and habitats protected under the EU Nature Directives are under threat and there is risk that this will increase in the future if the species spreads. The species can cause also moderate economic damages in the future.

\*in current climate conditions and in foreseeable future climate conditions

## Distribution Summary

Please answer as follows:

- Yes if recorded, established or invasive
- if not recorded, established or invasive
- ? Unknown; data deficient and/or?

The columns refer to the answers to Questions A5 to A12 under Section A.

For data on marine species at the Member State level, delete Member States that have no marine borders.

In all other cases, provide answers for all columns.

## ANNEX I Scoring of Likelihoods of Events

(taken from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

<b>Score</b>	<b>Description</b>	<b>Frequency</b>
Very unlikely	This sort of event is theoretically possible, but is never known to have occurred and is not expected to occur	1 in 10,000 years
Unlikely	This sort of event has occurred somewhere at least once in the last millenium	1 in 1,000 years
Moderately likely	This sort of event has occurred somewhere at least once in the last century	1 in 100 years
Likely	This sort of event has happened on several occasions elsewhere, or on at least once in the last decade	1 in 10 years
Very likely	This sort of event happens continually and would be expected to occur	Once a year

## ANNEX II Scoring of Magnitude of Impacts

(modified from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

Score	Biodiversity and ecosystem impact	Ecosystem Services impact	Economic impact (Monetary loss and response costs per year)	Social and human health impact, and other impacts
	<i>Question 5.1-5</i>	<i>Question 5.6-8</i>	<i>Question 5.9-13</i>	<i>Question 5.14-18</i>
Minimal	Local, short-term population loss, no significant ecosystem effect	No services affected <sup>5</sup>	Up to 10,000 Euro	No social disruption. Local, mild, short-term reversible effects to individuals.
Minor	Some ecosystem impact, reversible changes, localised	Local and temporary, reversible effects to one or few services	10,000-100,000 Euro	Significant concern expressed at local level. Mild short-term reversible effects to identifiable groups, localised.
Moderate	Measureable long-term damage to populations and ecosystem, but reversible; little spread, no extinction	Measureable, temporary, local and reversible effects on one or several services	100,000-1,000,000 Euro	Temporary changes to normal activities at local level. Minor irreversible effects and/or larger numbers covered by reversible effects, localised.
Major	Long-term irreversible ecosystem change, spreading beyond local area	Local and irreversible or widespread and reversible effects on one / several services	1,000,000-10,000,000 Euro	Some permanent change of activity locally, concern expressed over wider area. Significant irreversible effects locally or reversible effects over large area.
Massive	Widespread, long-term population loss or extinction, affecting several species with serious ecosystem effects	Widespread and irreversible effects on one / several services	Above 10,000,000 Euro	Long-term social change, significant loss of employment, migration from affected area. Widespread, severe, long-term, irreversible health effects.

<sup>5</sup> Not to be confused with “no impact”.

## ANNEX III Scoring of Confidence Levels

(modified from Bacher et al. 2017)

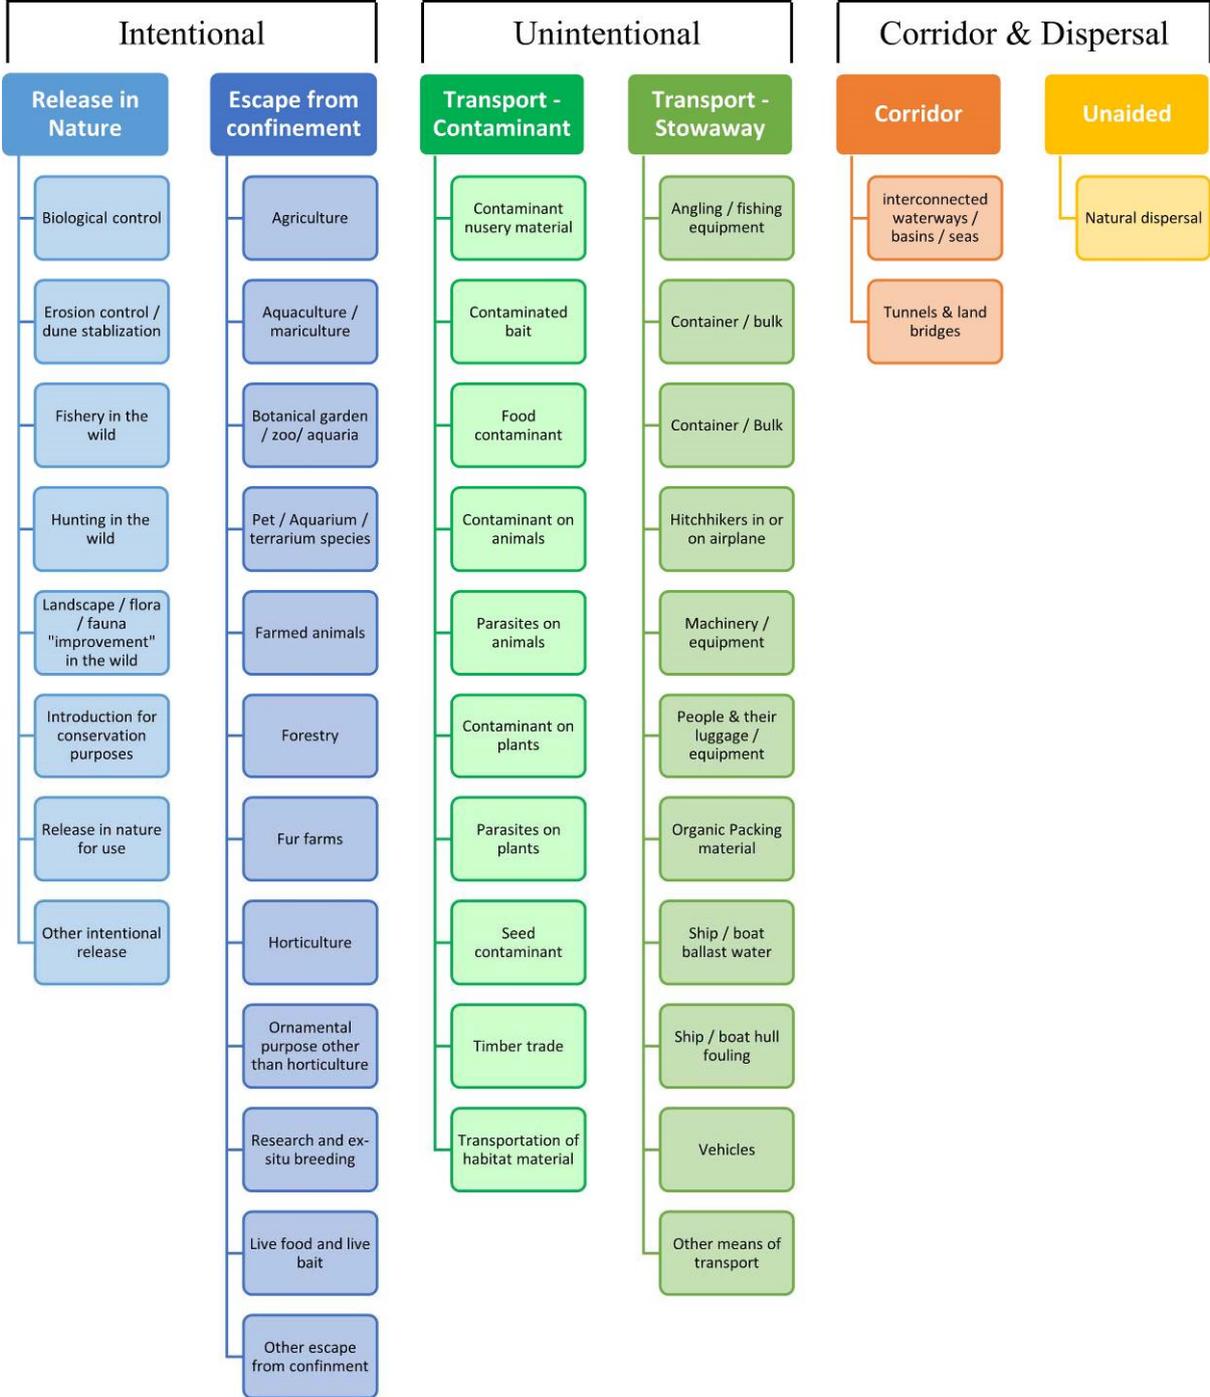

Each answer provided in the risk assessment must include an assessment of the level of confidence attached to that answer, reflecting the possibility that information needed for the answer is not available or is insufficient or available but conflicting.

The responses in the risk assessment should clearly support the choice of the confidence level.

<b>Confidence level</b>	<b>Description</b>
Low	There is no direct observational evidence to support the assessment, e.g. only inferred data have been used as supporting evidence <i>and/or</i> Impacts are recorded at a spatial scale which is unlikely to be relevant to the assessment area <i>and/or</i> Evidence is poor and difficult to interpret, e.g. because it is strongly ambiguous <i>and/or</i> The information sources are considered to be of low quality or contain information that is unreliable.
Medium	There is some direct observational evidence to support the assessment, but some information is inferred <i>and/or</i> Impacts are recorded at a small spatial scale, but rescaling of the data to relevant scales of the assessment area is considered reliable, or to embrace little uncertainty <i>and/or</i> The interpretation of the data is to some extent ambiguous or contradictory.
High	There is direct relevant observational evidence to support the assessment (including causality) <i>and</i> Impacts are recorded at a comparable scale <i>and/or</i> There are reliable/good quality data sources on impacts of the taxa <i>and</i> The interpretation of data/information is straightforward <i>and/or</i> Data/information are not controversial or contradictory.

# ANNEX IV CBD pathway categorisation scheme

Overview of CBD pathway categorisation scheme showing how the 44 pathways relate to the six main pathway categories. All of the pathways can be broadly classified into 1) those that involve intentional transport (blue), 2) those in which the taxa are unintentionally transported (green) and 3) those where taxa moved between regions without direct transportation by humans and/or via artificial corridors (orange and yellow). **Note that the pathways in the category “Escape from confinement” can be considered intentional for the introduction into the risk assessment area and unintentional for the entry into the environment.**

## ANNEX V Ecosystem services classification (CICES V5.1, simplified) and examples

For the purposes of this risk assessment, please feel free to use what seems as the most appropriate category / level / combination of impact (Section – Division – Group), reflecting information available.

Section	Division	Group	Examples (i.e. relevant CICES “classes”)
Provisioning	Biomass	<b>Cultivated <i>terrestrial</i> plants</b>	<p>Cultivated terrestrial plants (including fungi, algae) grown for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from cultivated plants, fungi, algae and bacteria for direct use or processing (excluding genetic materials);            Cultivated plants (including fungi, algae) grown as a <u>source of energy</u></p> <p><i>Example: negative impacts of non-native organisms to crops, orchards, timber etc.</i></p>
		<b>Cultivated <i>aquatic</i> plants</b>	<p>Plants cultivated by in- situ aquaculture grown for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from in-situ aquaculture for direct use or processing (excluding genetic materials);            Plants cultivated by in- situ aquaculture grown as an <u>energy source</u>.</p> <p><i>Example: negative impacts of non-native organisms to aquatic plants cultivated for nutrition, gardening etc. purposes.</i></p>
		<b>Reared animals</b>	<p>Animals reared for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from reared animals for direct use or processing (excluding genetic materials);            Animals reared to provide <u>energy</u> (including mechanical)</p> <p><i>Example: negative impacts of non-native organisms to livestock</i></p>
		<b>Reared <i>aquatic</i> animals</b>	<p>Animals reared by in-situ aquaculture for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from animals grown by in-situ aquaculture for direct use or processing (excluding genetic materials);            Animals reared by in-situ aquaculture as an <u>energy source</u></p> <p><i>Example: negative impacts of non-native organisms to fish farming</i></p>
		<b>Wild plants</b> (terrestrial and aquatic)	<p>Wild plants (terrestrial and aquatic, including fungi, algae) used for <u>nutrition</u>;  <u>Fibres and other materials</u> from wild plants for direct use or processing (excluding genetic materials);            Wild plants (terrestrial and aquatic, including fungi, algae) used as a <u>source of energy</u></p> <p><i>Example: reduction in the availability of wild plants (e.g. wild berries, ornamentals) due to non-native organisms (competition, spread of disease etc.)</i></p>
		<b>Wild animals</b> (terrestrial and aquatic)	<p>Wild animals (terrestrial and aquatic) used for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from wild animals for direct use or processing (excluding genetic materials);            Wild animals (terrestrial and aquatic) used as a <u>source of energy</u></p>

			<i>Example: reduction in the availability of wild animals (e.g. fish stocks, game) due to non-native organisms (competition, predations, spread of disease etc.)</i>
	<b>Genetic material</b> from all biota	<b>Genetic material</b> from plants, algae or fungi	<u>Seeds, spores and other plant materials</u> collected for maintaining or establishing a population; Higher and lower plants (whole organisms) used to <u>breed new strains or varieties</u> ; Individual genes extracted from higher and lower plants for the <u>design and construction of new biological entities</u>  <i>Example: negative impacts of non-native organisms due to interbreeding</i>
		<b>Genetic material</b> from animals	Animal material collected for the purposes of maintaining or establishing a population; Wild animals (whole organisms) used to breed new strains or varieties; Individual genes extracted from organisms for the design and construction of new biological entities  <i>Example: negative impacts of non-native organisms due to interbreeding</i>
	<b>Water</b> <sup>6</sup>	<b>Surface water</b> used for nutrition, materials or energy	Surface water for <u>drinking</u> ; Surface water used as a material ( <u>non-drinking purposes</u> ); Freshwater surface water, coastal and marine water used as an <u>energy source</u>  <i>Example: loss of access to surface water due to spread of non-native organisms</i>
		<b>Ground water</b> for used for nutrition, materials or energy	Ground (and subsurface) water for <u>drinking</u> ; Ground water (and subsurface) used as a material ( <u>non-drinking purposes</u> ); Ground water (and subsurface) used as an <u>energy source</u>  <i>Example: reduced availability of ground water due to spread of non-native organisms and associated increase of ground water consumption by vegetation.</i>
<b>Regulation &amp; Maintenance</b>	<b>Transformation</b> of biochemical or physical inputs to ecosystems	<b>Mediation of wastes or toxic substances</b> of anthropogenic origin by living processes	<u>Bio-remediation</u> by micro-organisms, algae, plants, and animals; <u>Filtration/sequestration/storage/accumulation</u> by micro-organisms, algae, plants, and animals  <i>Example: changes caused by non-native organisms to ecosystem functioning and ability to filtrate etc. waste or toxics</i>
		<b>Mediation of nuisances</b> of anthropogenic origin	<u>Smell reduction</u> ; <u>noise attenuation</u> ; <u>visual screening</u> (e.g. by means of green infrastructure)  <i>Example: changes caused by non-native organisms to ecosystem structure, leading to reduced ability to mediate nuisances.</i>
	<b>Regulation</b> of physical, chemical, biological conditions	<b>Baseline flows and extreme event</b> regulation	Control of <u>erosion</u> rates; Buffering and attenuation of <u>mass movement</u> ; <u>Hydrological cycle and water flow regulation</u> (Including flood control, and coastal protection); <u>Wind</u> protection; <u>Fire</u> protection

<sup>6</sup> Note: in the CICES classification provisioning of water is considered as an abiotic service whereas the rest of ecosystem services listed here are considered biotic.

			<p><i>Example: changes caused by non-native organisms to ecosystem functioning or structure leading to, for example, destabilisation of soil, increased risk or intensity of wild fires etc.</i></p>
		<p><b>Lifecycle maintenance, habitat and gene pool protection</b></p>	<p>Pollination (or 'gamete' dispersal in a marine context); <u>Seed dispersal</u>; Maintaining <u>nursery populations and habitats</u> (Including gene pool protection)</p> <p><i>Example: changes caused by non-native organisms to the abundance and/or distribution of wild pollinators; changes to the availability / quality of nursery habitats for fisheries</i></p>
		<p><b>Pest and disease control</b></p>	<p>Pest control; Disease control</p> <p><i>Example: changes caused by non-native organisms to the abundance and/or distribution of pests</i></p>
		<p><b>Soil quality regulation</b></p>	<p><u>Weathering processes</u> and their effect on soil quality; <u>Decomposition and fixing processes</u> and their effect on soil quality</p> <p><i>Example: changes caused by non-native organisms to vegetation structure and/or soil fauna leading to reduced soil quality</i></p>
		<p><b>Water conditions</b></p>	<p>Regulation of the <u>chemical condition</u> of freshwaters by living processes; Regulation of the chemical condition of salt waters by living processes</p> <p><i>Example: changes caused by non-native organisms to buffer strips along water courses that remove nutrients in runoff and/or fish communities that regulate the resilience and resistance of water bodies to eutrophication</i></p>
		<p><b>Atmospheric composition and conditions</b></p>	<p>Regulation of <u>chemical composition</u> of atmosphere and oceans; Regulation of <u>temperature and humidity</u>, including ventilation and transpiration</p> <p><i>Example: changes caused by non-native organisms to ecosystems' ability to sequester carbon and/or evaporative cooling (e.g. by urban trees)</i></p>
<b>Cultural</b>	<b>Direct, in-situ and outdoor interactions</b> with living systems that depend on presence in the environmental setting	<p><b>Physical and experiential</b> interactions with natural environment</p>	<p>Characteristics of living systems that that enable activities promoting health, recuperation or enjoyment through <u>active or immersive interactions</u>;</p> <p>Characteristics of living systems that enable activities promoting health, recuperation or enjoyment through <u>passive or observational interactions</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that make it attractive for recreation, wild life watching etc.</i></p>
		<p><b>Intellectual and representative</b> interactions with natural environment</p>	<p>Characteristics of living systems that enable <u>scientific investigation</u> or the creation of traditional ecological knowledge;</p> <p>Characteristics of living systems that enable <u>education and training</u>;</p> <p>Characteristics of living systems that are resonant in terms of <u>culture or heritage</u>;</p> <p>Characteristics of living systems that enable <u>aesthetic experiences</u></p>

			<i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have cultural importance</i>
	<b>Indirect, remote, often indoor interactions</b> with living systems that do not require presence in the environmental setting	<b>Spiritual, symbolic</b> and other interactions with natural environment	<p>Elements of living systems that have <u>symbolic meaning</u>;</p> <p>Elements of living systems that have <u>sacred or religious meaning</u>;</p> <p>Elements of living systems used for <u>entertainment or representation</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have sacred or religious meaning</i></p>
		Other biotic characteristics that have a <b>non-use value</b>	<p>Characteristics or features of living systems that have an <u>existence value</u>;</p> <p>Characteristics or features of living systems that have an <u>option or bequest value</u></p> <p><i>Example: changes caused by non-native organisms to ecosystems designated as wilderness areas, habitats of endangered species etc.</i></p>

## **ANNEX VIII Species Distribution Model**

### **Projection of environmental suitability for *Faxonius immunis* establishment in Europe**

Björn Beckmann, Elena Tricarico, Frances Lucy and Dan Chapman

10 October 2020

#### **Aim**

To project the suitability for potential establishment of *Faxonius immunis* in Europe, under current and predicted future climatic conditions.

#### **Data for modelling**

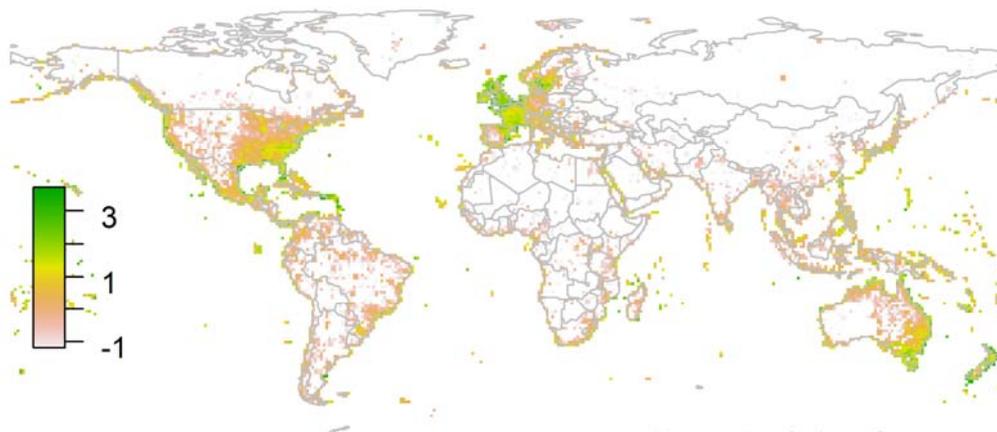

Species occurrence data were obtained from the Integrated Digitized Biocollections (iDigBio) (1038 records), the Global Biodiversity Information Facility (GBIF) (371 records), the Biodiversity Information Serving Our Nation database (BISON) (247 records), iNaturalist (82 records), and additional records from the risk assessment team. We scrutinised occurrence records from regions where the species is not known to be established and removed any dubious records (e.g. fossils) or where the georeferencing was too imprecise (e.g. records referenced to a country or island centroid) or outside of the coverage of the predictor layers (e.g. small island or coastal occurrences). The remaining records were gridded at a 0.25 x 0.25 degree resolution for modelling, yielding 550 grid cells with occurrences (Figure 1a). As a proxy for recording effort, the density of Decapoda records held by GBIF was also compiled on the same grid (Figure 1b).

**Figure 1.** (a) Occurrence records obtained for *Faxonius immunis* and used in the modelling, showing native and invaded distributions. (b) The recording density of Decapoda on GBIF, which was used as a proxy for recording effort.

(a) Species distribution used in modelling

(b) Estimated recording effort (log10-scaled)

Climate data were selected from the 'Bioclim' variables contained within the WorldClim database (Hijmans et al. 2005), originally at 5 arcminute resolution (0.083 x 0.083 degrees of longitude/latitude) and aggregated to a 0.25 x 0.25 degree grid for use in the model.

Based on the biology of *Faxonius immunis*, the following climate variables were used in the modelling:

- Temperature seasonality (Bio4)
- Maximum temperature of the warmest month (Bio5)
- Minimum temperature of the coldest month (Bio6)
- Mean temperature of the wettest quarter (Bio8)
- Annual precipitation (Bio12)
- Precipitation of the wettest month (Bio13)

- Precipitation seasonality (Bio15)

To estimate the effect of climate change on the potential distribution, equivalent modelled future climate conditions for the 2070s under the Representative Concentration Pathways (RCP) 2.6 and 4.5 were also obtained. These represent low and medium emissions scenarios, respectively. The above variables were obtained as averages of outputs of eight Global Climate Models (BCC-CSM1-1, CCSM4, GISS-E2-R, HadGEM2-AO, IPSL-CM5A-LR, MIROC-ESM, MRI-CGCM3, NorESM1-M), downscaled and calibrated against the WorldClim baseline (see [http://www.worldclim.org/cmip5\\_5m](http://www.worldclim.org/cmip5_5m)).

### Species distribution model

A presence-background (presence-only) ensemble modelling strategy was employed using the BIOMOD2 R package version 3.4.6 (Thuiller et al. 2009; Thuiller et al. 2020). These models contrast the environment at the species' occurrence locations against a random sample of the global background environmental conditions (often termed 'pseudo-absences') in order to characterise and project suitability for occurrence. This approach has been developed for distributions that are in equilibrium with the environment. Because invasive species' distributions are not at equilibrium and subject to dispersal constraints at a global scale, we took care to minimise the inclusion of locations suitable for the species but where it has not been able to disperse to (Chapman et al. 2019). Therefore the background sampling region included:

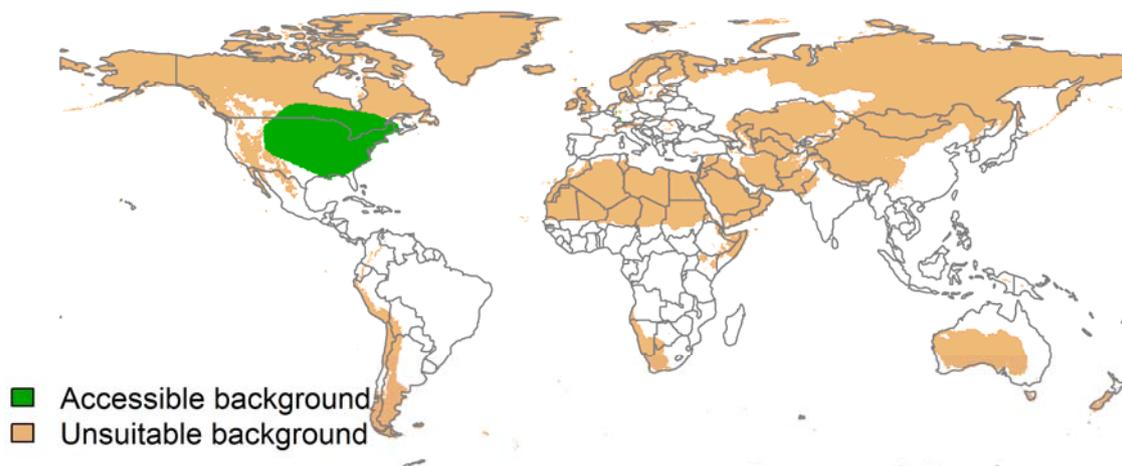

- The area accessible by native *Faxonius immunis* populations, in which the species is likely to have had sufficient time to disperse to all locations. Based on presumed maximum dispersal distances, the accessible region was defined as a 400km buffer around the native range occurrences; AND
- A 30km buffer around the non-native occurrences, encompassing regions likely to have had high propagule pressure for introduction by humans and/or dispersal of the species; AND
- Regions where we have an *a priori* expectation of high unsuitability for the species so that absence is assumed irrespective of dispersal constraints (see Figure 2). The following rules were applied to define a region expected to be highly unsuitable for *Faxonius immunis* at the spatial scale of the model:
  - Minimum temperature of the coldest month (Bio6) < -24°C
  - Maximum temperature of the warmest month (Bio5) < 21°C
  - Annual precipitation (Bio12) < 350mm

Altogether, only 0.7% of occurrence grid cells were located in the unsuitable background region.

Within the unsuitable background region, 10 samples of 5000 randomly sampled grid cells were obtained. In the accessible background (comprising the accessible areas around native and non-native occurrences as detailed above), the same number of pseudo-absence samples were drawn as there were presence records (550), weighting the sampling by a proxy for recording effort (Figure 2).

**Figure 2.** The background from which pseudo-absence samples were taken in the modelling of *Faxonius immunis*. Samples were taken from a 400km buffer around the native range and a 30km buffer around non-native occurrences (together forming the accessible background), and from areas

expected to be highly unsuitable for the species (the unsuitable background region). Samples from the accessible background were weighted by a proxy for recording effort (Figure 1(b)).

Each dataset (i.e. combination of the presences and the individual background samples) was randomly split into 80% for model training and 20% for model evaluation. With each training dataset, five statistical algorithms were fitted with the default BIOMOD2 settings and rescaled using logistic regression, except where specified below:

- Generalised linear model (GLM)
- Generalised boosting model (GBM)
- Generalised additive model (GAM) with a maximum of four degrees of freedom per smoothing spline
- Random forest (RF)
- Maxent

Since the total background sample was larger than the number of occurrences, prevalence fitting weights were applied to give equal overall importance to the occurrences and the background. Normalised variable importance was assessed and variable response functions were produced using BIOMOD2's default procedure.

Model predictive performance was assessed by the following three measures:

- AUC, the area under the receiver operating characteristic curve (Fielding & Bell 1997). Predictions of presence-absence models can be compared with a subset of records set aside for model evaluation (here 20%) by constructing a confusion matrix with the number of true positive, false positive, false negative and true negative cases. For models generating non-dichotomous scores (as here) a threshold can be applied to transform the scores into a dichotomous set of presence-absence predictions. Two measures that can be derived from the confusion matrix are sensitivity (the proportion of observed presences that are predicted as such, quantifying omission errors), and specificity (the proportion of observed absences that are predicted as such, quantifying commission errors). A receiver operating characteristic (ROC) curve can be constructed by using

all possible thresholds to classify the scores into confusion matrices, obtaining sensitivity and specificity for each matrix, and plotting sensitivity against the corresponding proportion of false positives (equal to  $1 - \text{specificity}$ ). The use of all possible thresholds avoids the need for a selection of a single threshold, which is often arbitrary, and allows appreciation of the trade-off between sensitivity and specificity. The area under the ROC curve (AUC) is often used as a single threshold-independent measure for model performance (Manel et al. 2001). AUC is the probability that a randomly selected presence has a higher model-predicted suitability than a randomly selected absence (Allouche et al. 2006).

- Cohen's Kappa (Cohen 1960). This measure corrects the overall accuracy of model predictions (ratio of the sum of true presences plus true absences to the total number of records) by the accuracy expected to occur by chance. The kappa statistic ranges from -1 to +1, where +1 indicates perfect agreement and values of zero or less indicate a performance no better than random. Advantages of kappa are its simplicity, the fact that both commission and omission errors are accounted for in one parameter, and its relative tolerance to zero values in the confusion matrix (Manel et al. 2001). However, Kappa has been criticised for being sensitive to prevalence (the proportion of sites in which the species was recorded as present) and may therefore be inappropriate for comparisons of model accuracy between species or regions (McPherson et al. 2004; Allouche et al. 2006).
- TSS, the true skill statistic (Allouche et al. 2006). TSS is defined as  $\text{sensitivity} + \text{specificity} - 1$ , and corrects for Kappa's dependency on prevalence. TSS compares the number of correct forecasts, minus those attributable to random guessing, to that of a hypothetical set of perfect forecasts. Like kappa, TSS takes into account both omission and commission errors, and success as a result of random guessing, and ranges from -1 to +1, where +1 indicates perfect agreement and values of zero or less indicate a performance no better than random (Allouche et al. 2006).

An ensemble model was created by first rejecting poorly performing algorithms with relatively extreme low AUC values and then averaging the predictions of the remaining algorithms, weighted by their AUC. To identify poorly performing algorithms, AUC values were converted into modified z-scores based on their difference to the median and the median absolute deviation across all algorithms (Iglewicz & Hoaglin 1993). Algorithms with  $z < -2$  were rejected. In this way, ensemble projections were made for each dataset and then averaged to give an overall suitability, as well as its standard deviation. The projections were then classified into suitable and unsuitable regions using the 'minROCDist' method, which minimizes the distance between the ROC plot and the upper left corner of the plot (point (0,1)).

We also produced limiting factor maps for Europe following Elith et al. (2010). For this, projections were made separately with each individual variable fixed at a near-optimal value. These were chosen as the median values at the occurrence grid cells. Then, the most strongly limiting factors were identified as the one resulting in the highest increase in suitability in each grid cell.

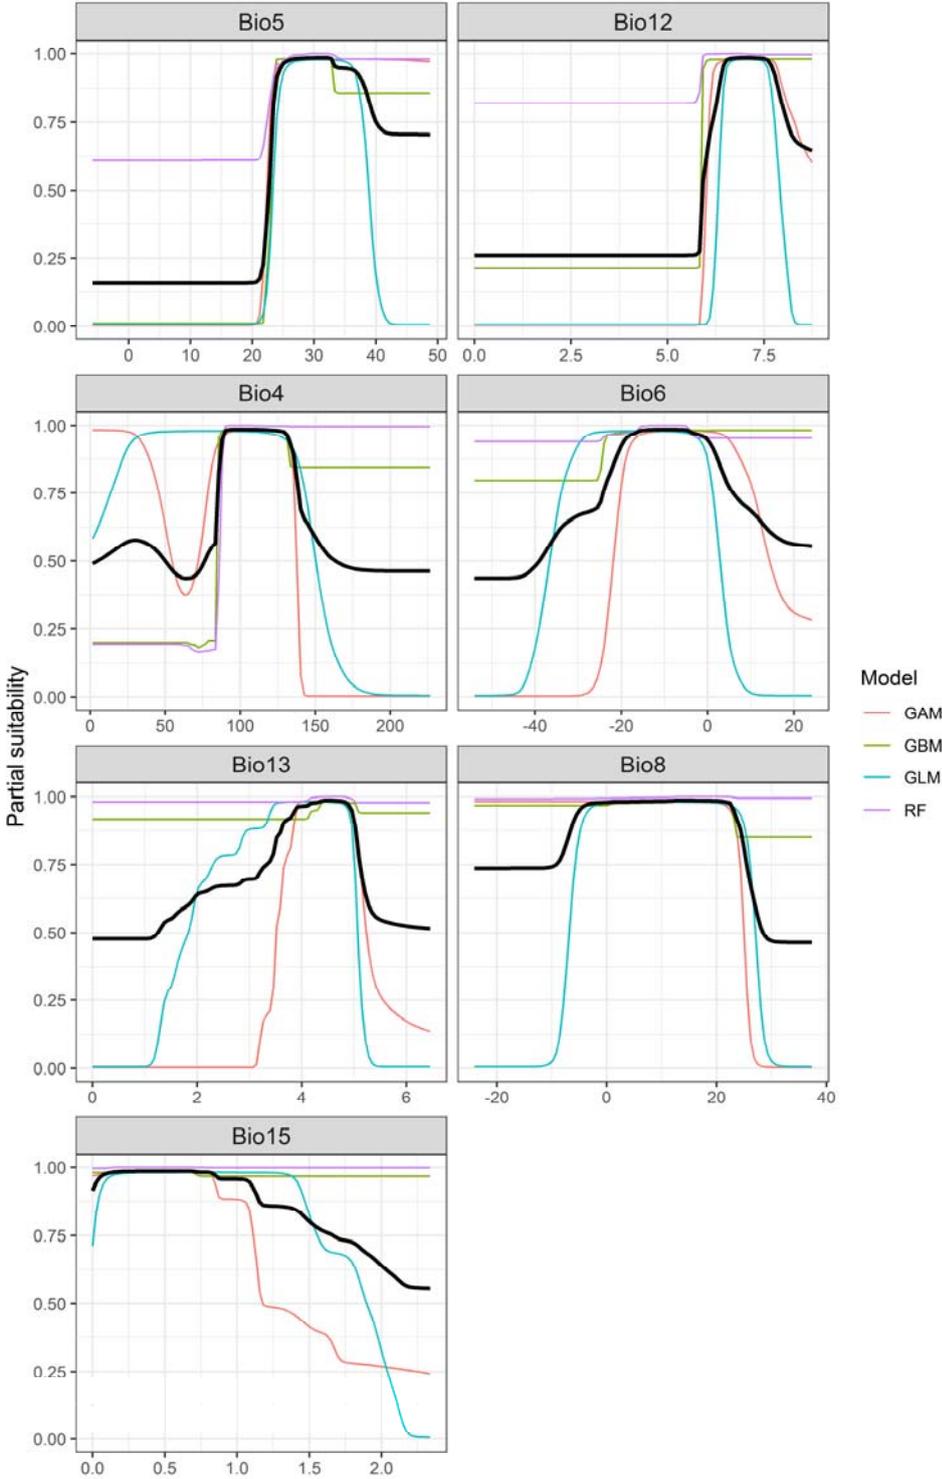

## Results

The ensemble model suggested that suitability for *Faxonius immunis* was most strongly determined by Maximum temperature of the warmest month (Bio5), accounting for 30.6% of variation explained, followed by Annual precipitation (Bio12) (28.5%), Temperature seasonality (Bio4) (18.5%), Minimum temperature of the coldest month (Bio6) (7.9%), Precipitation of the wettest month (Bio13) (7.5%), Mean temperature of the wettest quarter (Bio8) (4.3%) and Precipitation seasonality (Bio15) (2.5%) (Table 1, Figure 3).

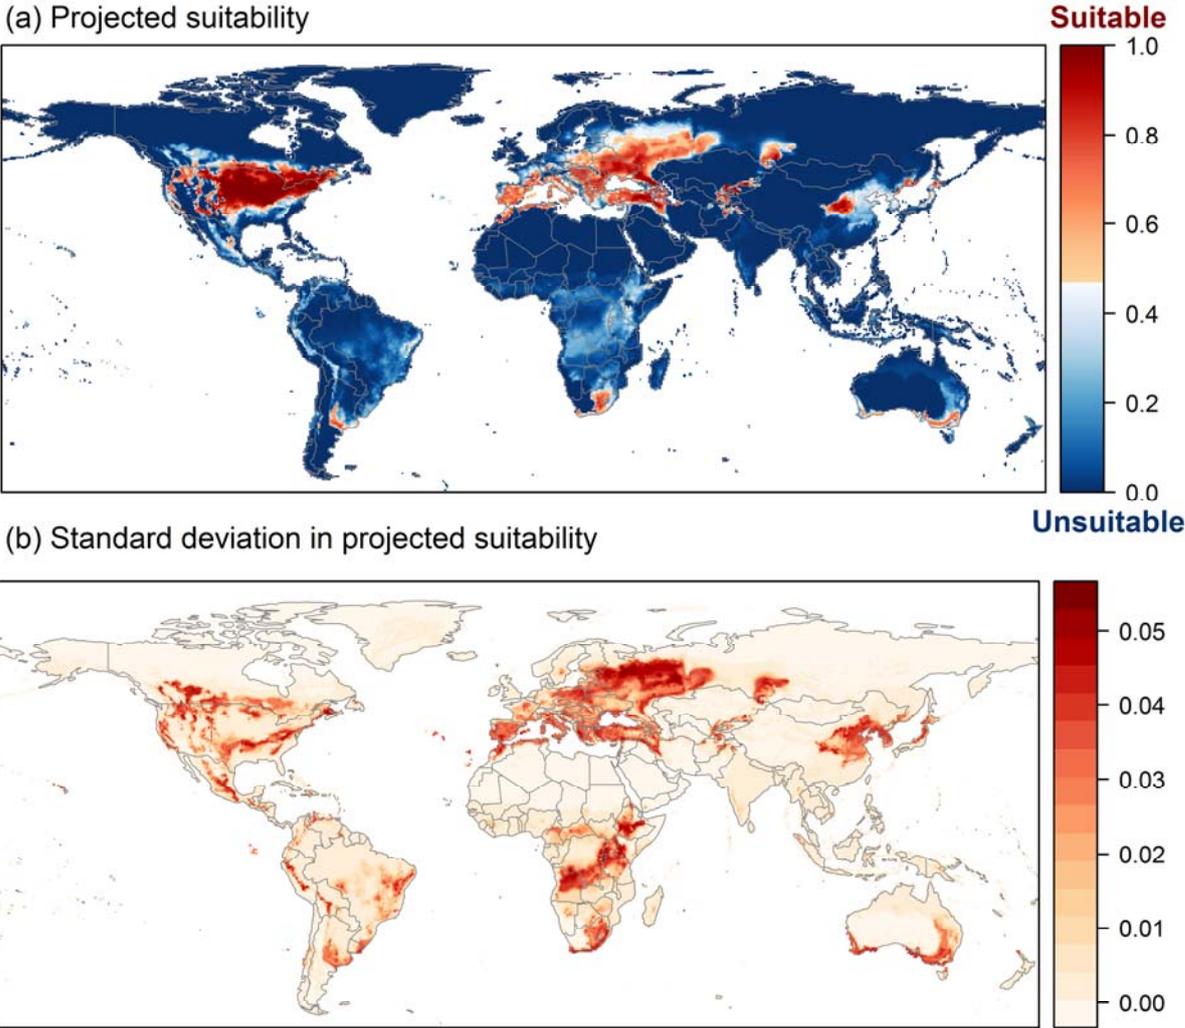

**Table 1.** Summary of the cross-validation predictive performance (AUC, Kappa, TSS) and variable importance of the fitted model algorithms and the ensemble (AUC-weighted average of the best performing algorithms). Results are the average from models fitted to 10 different background samples of the data.

Algorithm	AUC	Kappa	TSS	Used in the ensemble	Variable importance (%)						
					Maximum temperature of the warmest month (Bio5)	Annual precipitation (Bio12)	Temperature seasonality (Bio4)	Minimum temperature of the coldest month (Bio6)	Precipitation of the wettest month (Bio13)	Mean temperature of the wettest quarter (Bio8)	Precipitation seasonality (Bio15)
GLM	0.986	0.820	0.936	yes	28	33	7	11	10	6	5
GAM	0.987	0.835	0.945	yes	26	24	13	16	11	6	3
GBM	0.988	0.831	0.948	yes	40	35	19	1	3	1	0
RF	0.990	0.862	0.950	yes	28	22	35	4	6	4	1
Maxent	0.945	0.800	0.857	no	35	20	15	12	9	4	5
<b>Ensemble</b>	<b>0.990</b>	<b>0.856</b>	<b>0.946</b>		<b>31</b>	<b>29</b>	<b>19</b>	<b>8</b>	<b>7</b>	<b>4</b>	<b>3</b>

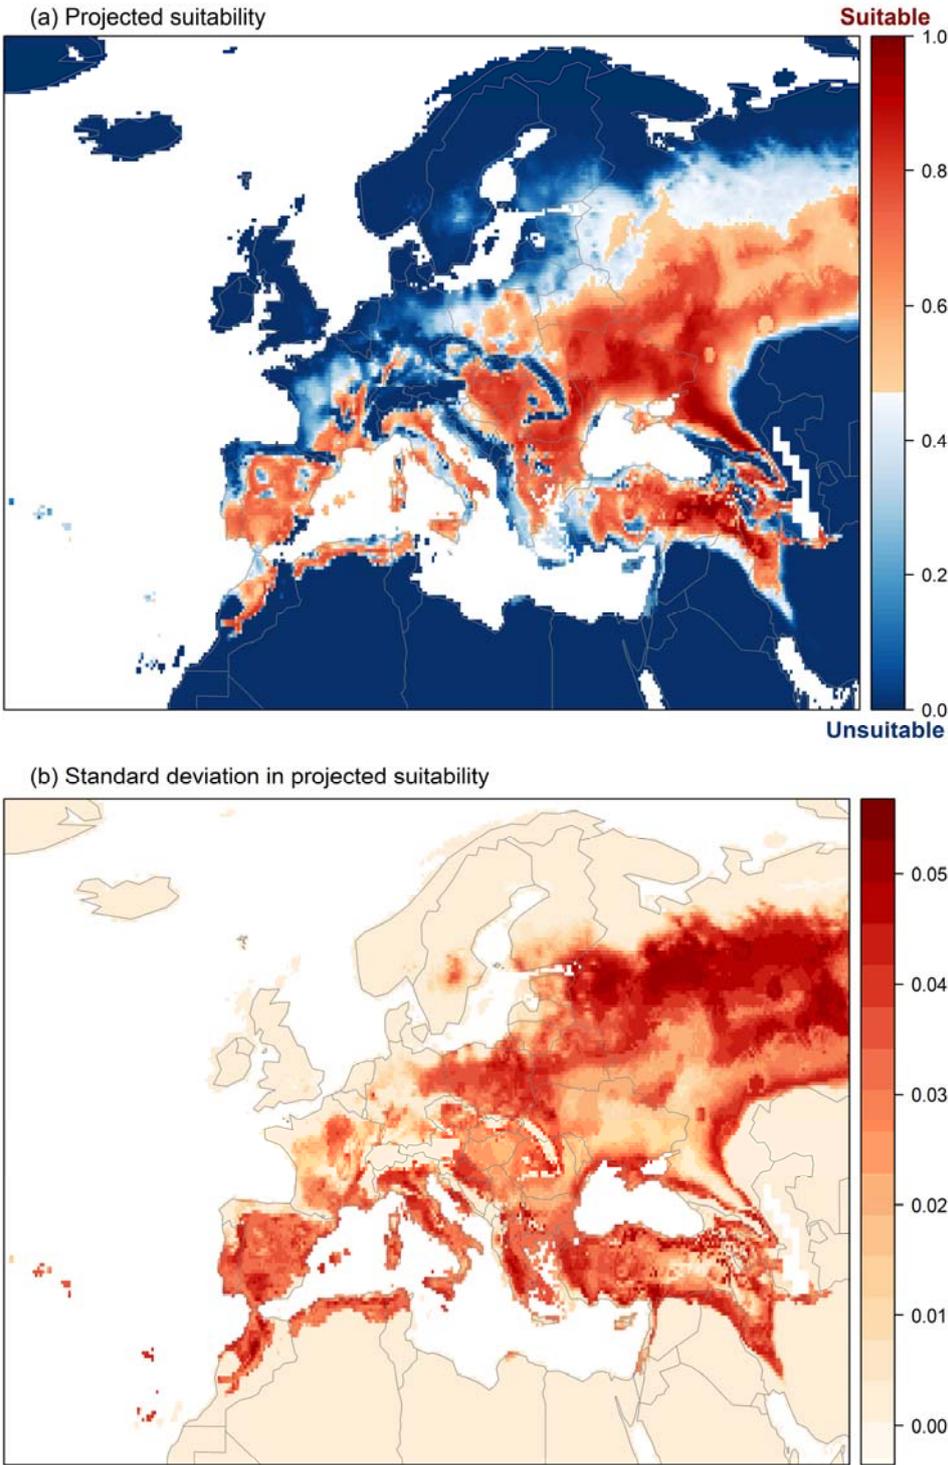

**Figure 3.** Partial response plots from the fitted models. Thin coloured lines show responses from the algorithms in the ensemble, while the thick black line is their ensemble. In each plot, other model variables are held at their median value in the training data. Some of the divergence among algorithms is because of their different treatment of interactions among variables.

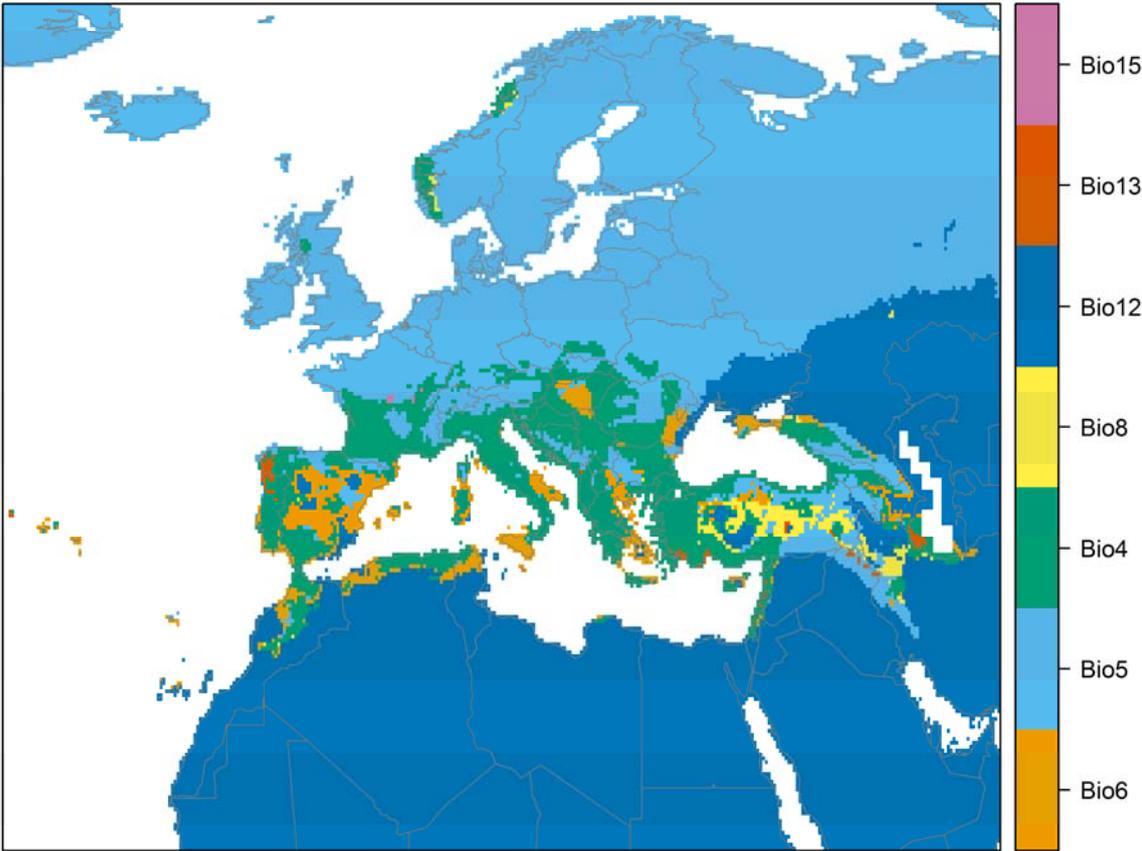

**Figure 4.** (a) Projected global suitability for *Faxonius immunis* establishment in the current climate. For visualisation, the projection has been aggregated to a 0.5 x 0.5 degree resolution, by taking the maximum suitability of constituent higher resolution grid cells. Values > 0.47 may be suitable for the species. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

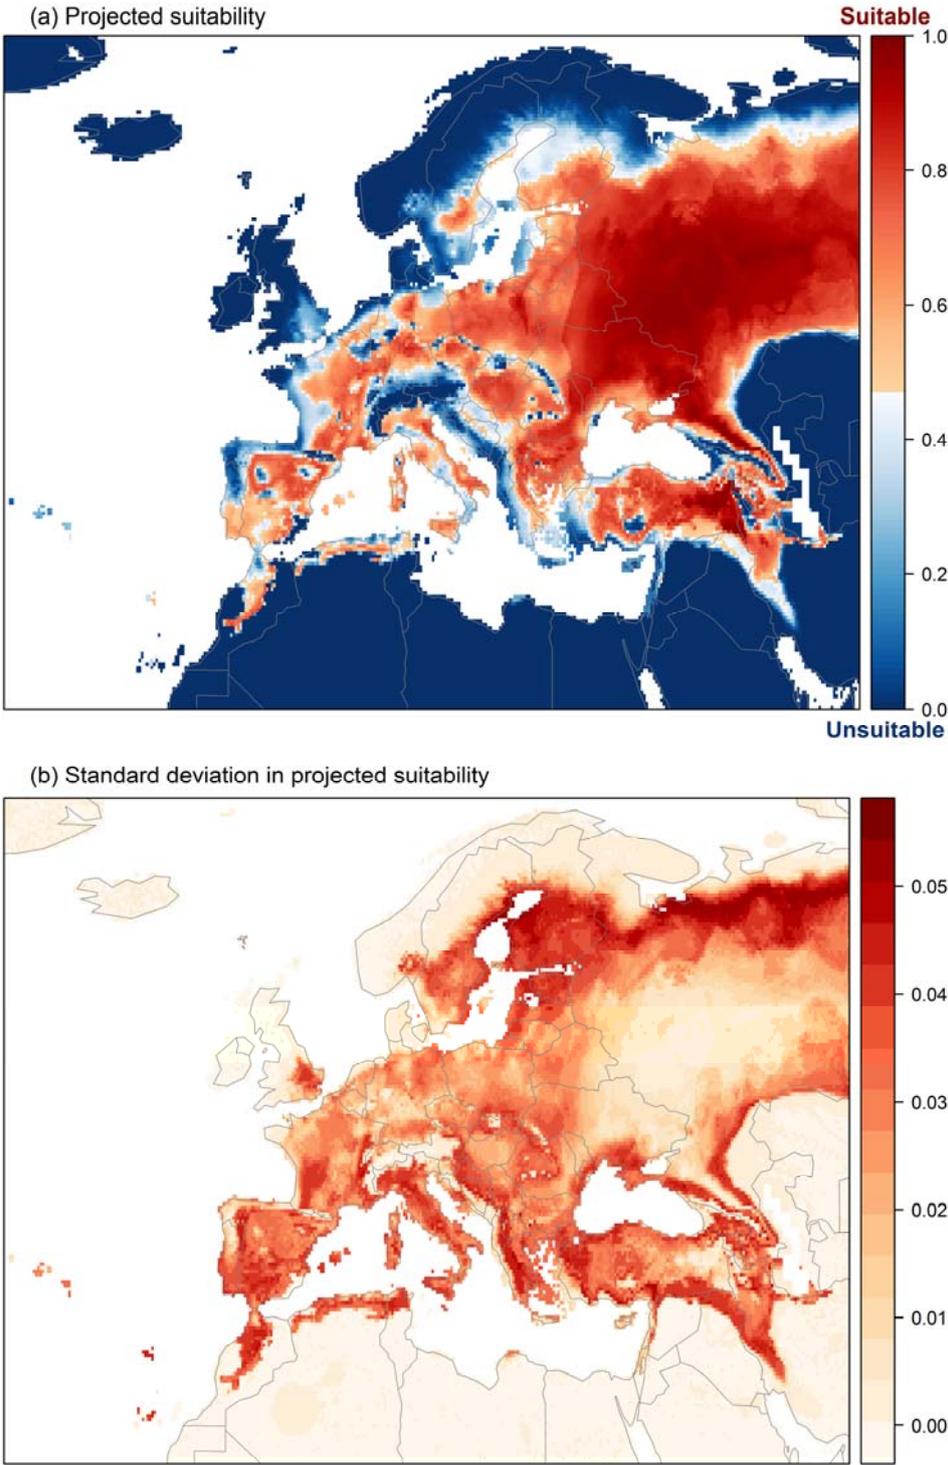

**Figure 5.** (a) Projected current suitability for *Faxonius immunis* establishment in Europe and the Mediterranean region. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

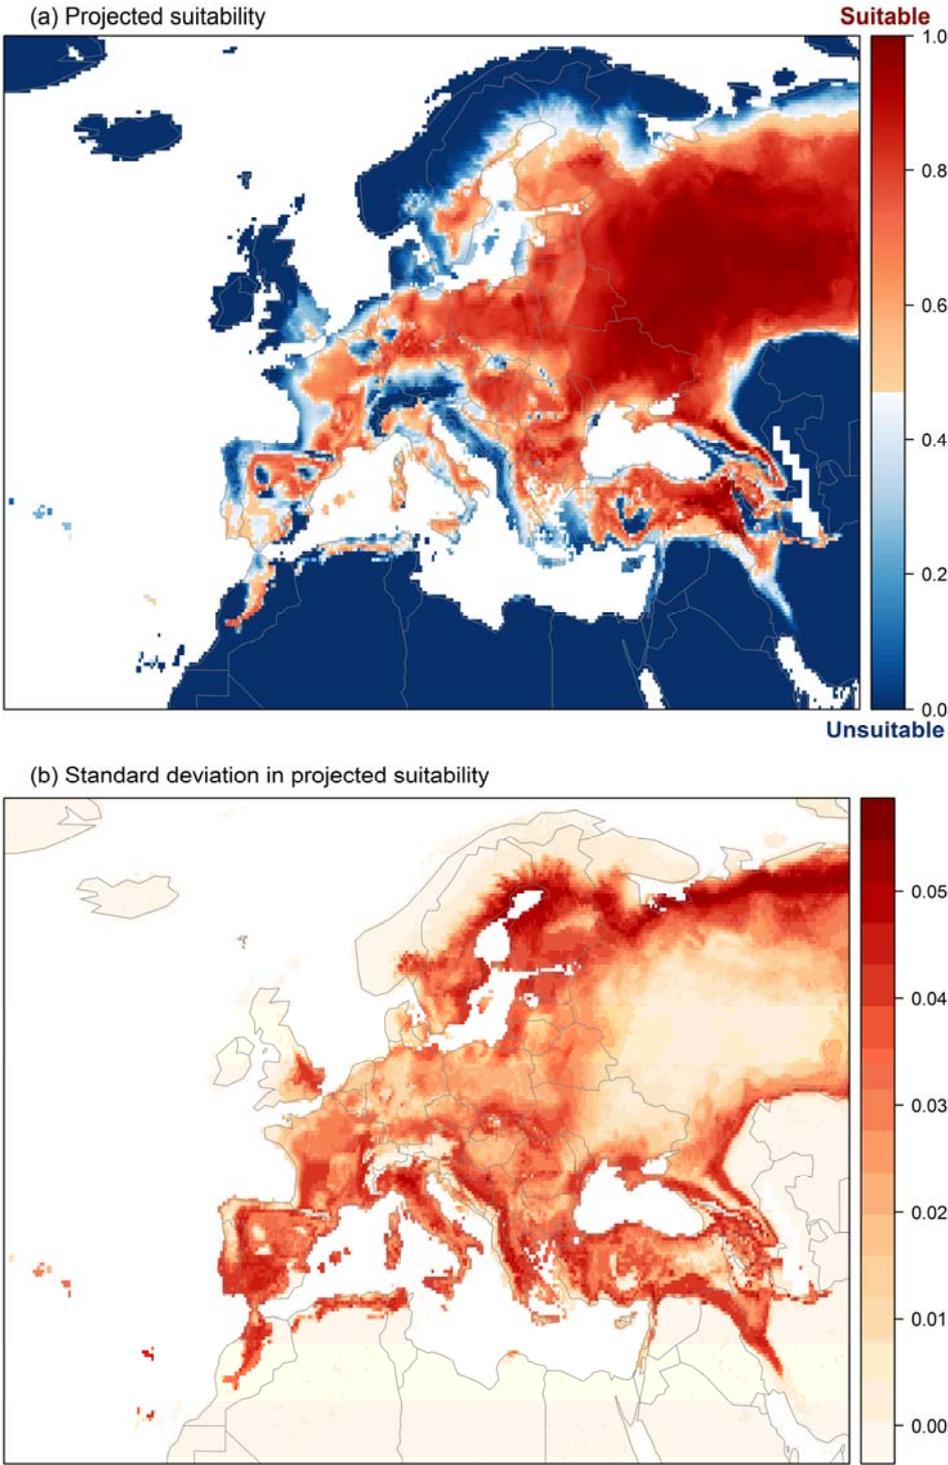

**Figure 6.** The most strongly limiting factors for *Faxonius immunis* establishment estimated by the model in Europe and the Mediterranean region in current climatic conditions.

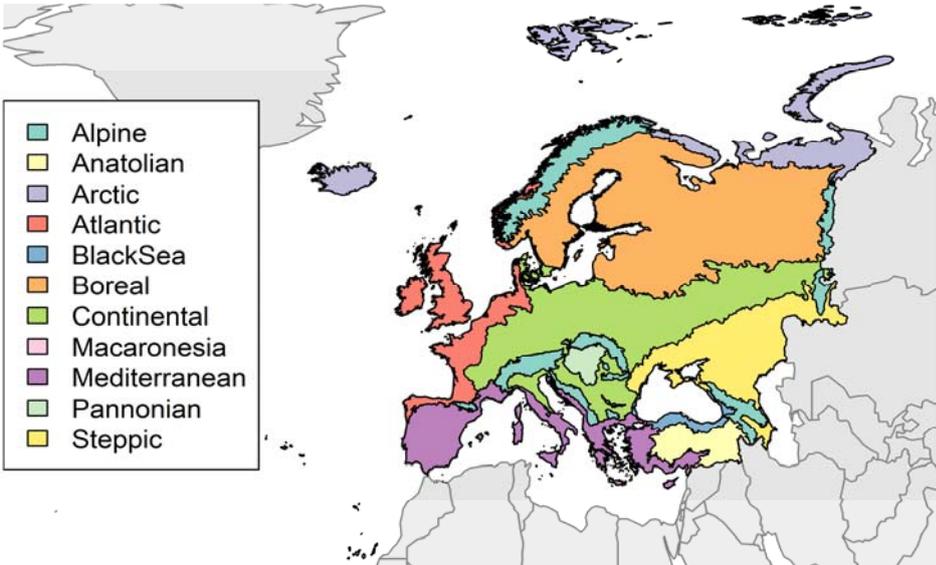

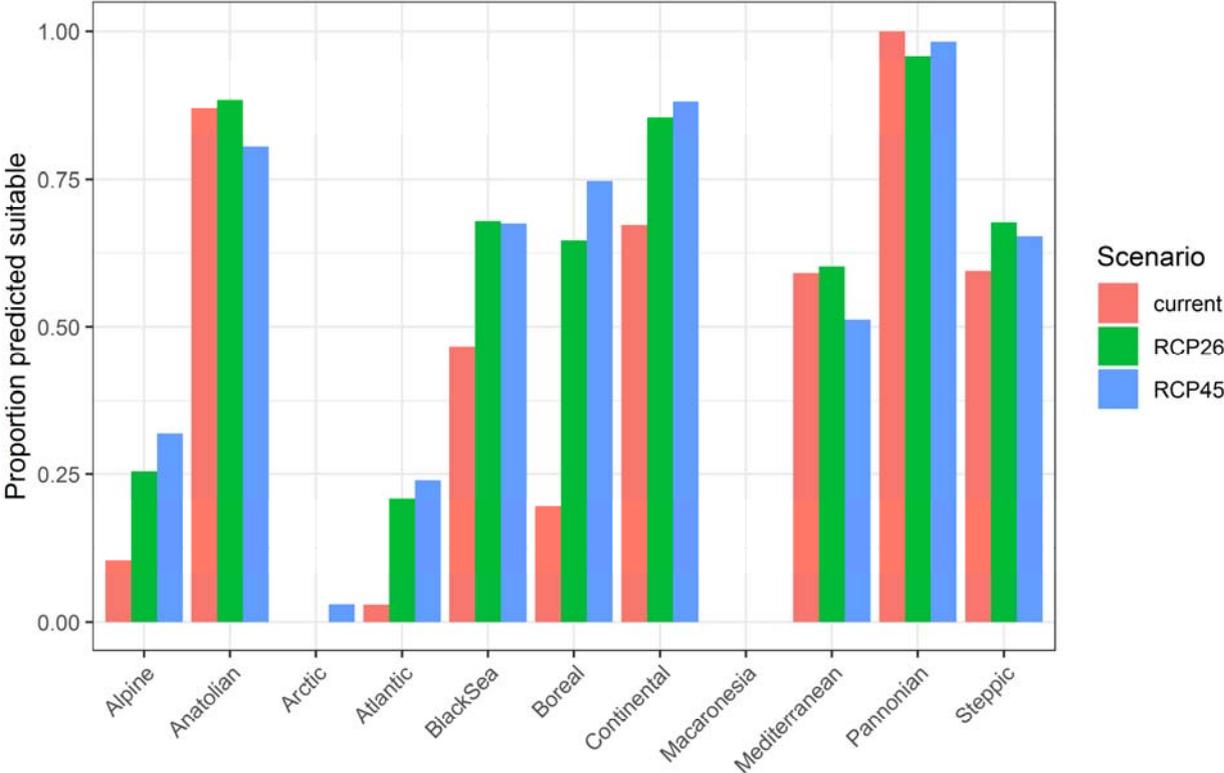

**Figure 7.** (a) Projected suitability for *Faxonius immunis* establishment in Europe and the Mediterranean region in the 2070s under climate change scenario RCP2.6, equivalent to Figure 5. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

**Figure 8.** (a) Projected suitability for *Faxonius immunis* establishment in Europe and the Mediterranean region in the 2070s under climate change scenario RCP4.5, equivalent to Figure 5. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

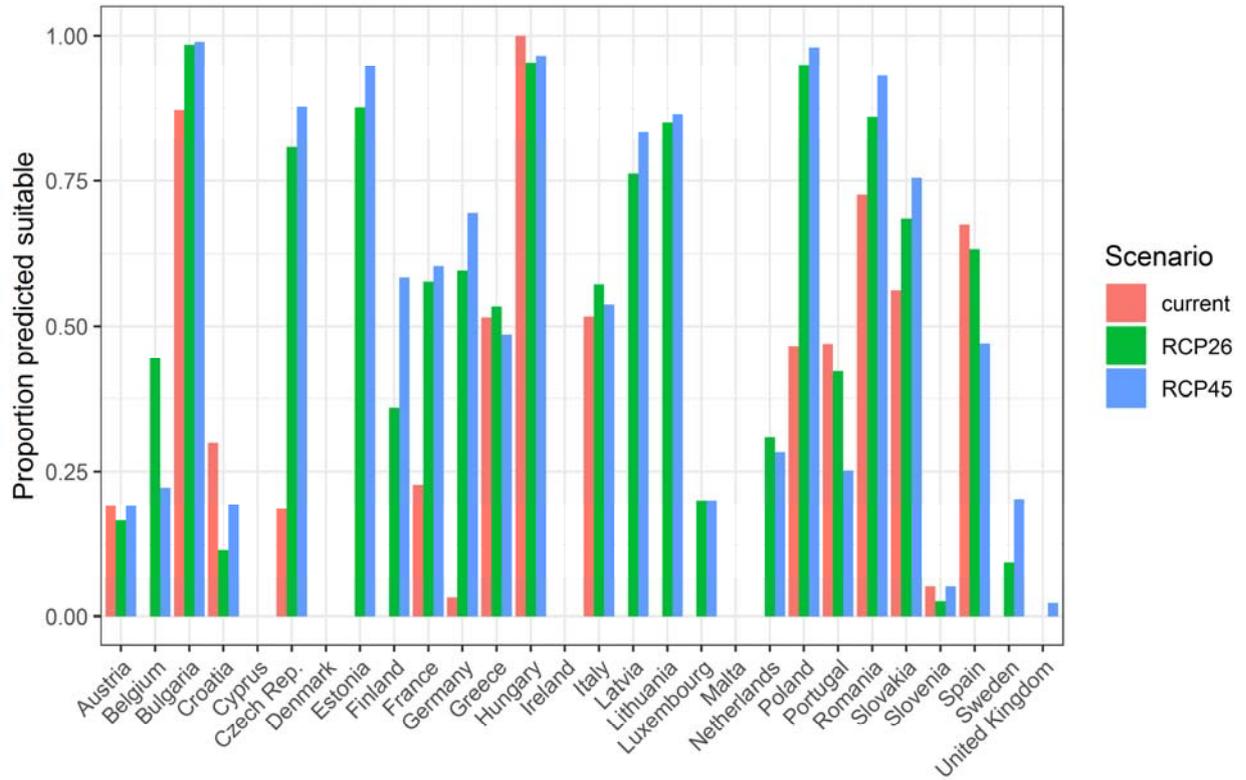

**Figure 9.** Variation in projected suitability for *Faxonius immunis* establishment among Biogeographical Regions of Europe (<https://www.eea.europa.eu/data-and-maps/data/biogeographical-regions-europe-3>). The bar plots show the proportion of grid cells in each region classified as suitable in the current climate and projected climate for the 2070s under two RCP emissions scenarios. The location of each region is also shown. The Arctic and Macaronesian biogeographical regions are not part of the study area, but are included for completeness.

**Table 2.** Variation in projected suitability for *Faxonius immunis* establishment among Biogeographical regions of Europe (numerical values of Figure 9 above). The numbers are the proportion of grid cells in each region classified as suitable in the current climate and projected climate for the 2070s under two RCP emissions scenarios. The Arctic and Macaronesian biogeographical regions are not part of the study area, but are included for completeness.

<b>Biogeographical region</b>	<b>Current climate</b>	<b>RCP26</b>	<b>RCP45</b>

### **Caveats to the modelling**

To remove spatial recording biases, the selection of the background sample from the accessible background was weighted by the density of terrestrial Decapoda records on the Global Biodiversity Information Facility (GBIF). While this is preferable to not accounting for recording bias at all, it may not provide the perfect measure of recording bias.

There was substantial variation among modelling algorithms in the partial response plots (Figure 3). In part this will reflect their different treatment of interactions among variables. Since partial plots are made with other variables held at their median, there may be values of a particular variable at which this does not provide a realistic combination of variables to predict from.

Other variables potentially affecting the distribution of the species, such as types of land cover were not included in the model.

Finally, Filipová et al. (2011) suggested that calico crayfish might represent a cryptic species complex, “making the forecasting of ecological properties of European *F. immunis* populations based on data from populations in its indigenous North American range difficult because the latter might comprise different cryptic species” (Chucholl 2012).

## SECTION A – Organism Information and Screening

### A1. Identify the organism. Is it clearly a single taxonomic entity and can it be adequately distinguished from other entities of the same rank?

including the following elements:

- the taxonomic family, order and class to which the species belongs;
- the scientific name and author of the species, as well as a list of the most common synonym names;
- names used in commerce (if any)
- a list of the most common subspecies, lower taxa, varieties, breeds or hybrids

As a general rule, one risk assessment should be developed for a single species. However, there may be cases where it may be justified to develop one risk assessment covering more than one species (e.g. species belonging to the same genus with comparable or identical features and impact). It shall be clearly stated if the risk assessment covers more than one species, or if it excludes or only includes certain subspecies, lower taxa, hybrids, varieties or breeds (and if so, which subspecies, lower taxa, hybrids, varieties or breeds). Any such choice must be properly justified.

Response: The present risk assessment covers one species (no lower taxa or hybrids): *Misgurnus anguillicaudatus* (Cantor, 1842). It belongs to the genus *Misgurnus* Lacepède 1803, which is part of the Cobitidae (loaches or weatherfishes) (Froese and Pauly 2019).

Actinopterygii > Cypriniformes (Carps) > Cobitidae (Loaches or weatherfishes) > Cobitinae > *Misgurnus* Lacepède 1803 > *Misgurnus anguillicaudatus* (Cantor, 1842)

Kingdom: Animalia

Phylum: Chordata

Class: Actinopterygii (ray-finned fishes)

Order: Cypriniformes (Carps)

Family: Cobitidae (Loaches)

Genus: *Misgurnus* Lacepède 1803

Cobitidae consists of 28 genera and 262 species (Froese and Pauly 2019); in the closely related genera *Misgurnus* and *Paramisgurnus* the taxonomy is not clear and the number of recognised species differs from study to study and database to database.

According to the Integrated Taxonomic Information System ([www.itis.org](http://www.itis.org)) *Misgurnus* spp. comprises of the following species:

*Misgurnus anguillicaudatus* (Cantor, 1842) – valid – oriental weatherfish, dojo, Japanese weatherfish

( *Misgurnus bipartitus* (Sauvage and Dabry de Thiersant, 1874) – **invalid**)

*Misgurnus buphoensis* Kim and Park, 1995 – valid

( *Misgurnus erikssoni* Rendahl, 1922 – **invalid**)

*Misgurnus fossilis* (Linnaeus, 1758) – valid – weatherfish

*Misgurnus mizolepis* Günther, 1888 – valid

*Misgurnus mohoity* (Dybowski, 1869) – valid

*Misgurnus nikolskyi* Vasil'eva, 2001 – valid

*Misgurnus tonkinensis* Rendahl, 1937 – valid

For the genus *Paramisgurnus*, only one valid species *Paramisgurnus dabryanus* Dabry de Thiersant, 1872 is recognised.

Other views on the taxonomy of the genera *Misgurnus* and *Paramisgurnus* can be found (e.g. Eschmeyer's Catalog of Fishes) but recently it has become clear that the taxonomic understanding of the weatherfish genera is still poor and there are many challenges associated with accurate species assignment in this group (Belle et al. 2021).

Also FishBase (Froese and Pauly 2019) mentions *M. bipartitus* as an invalid name and considers it as a synonym for *M. mohoity*; this was based on a study by Bogutskaya and Naseka (2004). A recent study by Zangl et al. (2020), however, keeps *M. bipartitus* and *M. mohoity* as separate species. They consider eight valid species in the genus *Misgurnus* and one in *Paramisgurnus*. Furthermore, this last study also states that the specimens of *M. anguillicaudatus* in Austria (and parts of Germany) were misidentified and should be *M. bipartitus* (based on morphology and genetics) instead. Genetic data from INBO (Brys et al. 2020) point in the same direction and conclude that the non-native weatherfish occurring in Belgium (and the Netherlands) is not *M. anguillicaudatus* but indeed *M. bipartitus*.

According to Kottelat and Freyhof (2007), only two non-native 'oriental' weatherfish were recorded in the risk assessment (RA) area (*M. anguillicaudatus* and *Paramisgurnus dabryanus*). However, Zięba et al. (2010) report that a fish imported under the name *Misgurnus anguillicaudatus* in the UK was found to be *M. mizolepis*. This reproducing loach population in a pond in Essex is since eradicated (Zięba et al. 2010).

The preferred common name in English is oriental weatherfish, but also dojo, Japanese weatherfish, pond loach and Asian weather loach are used as common names. Scientific (non-valid) synonyms for *M. anguillicaudatus* following FishBase (Froese and Pauly 2019) are *Cobitis anguillicaudata*, *Misgurnus anguillicaudatus anguillicaudatus*, *Misgurnus fossilis anguillicaudatus*, *Misgurnus aguillcadatus*, *Nemachilus lividus*, *Misgurnus lividus*, *Nemacheilus lividus*, *Misgurnus crossochilus*, *Ussuria leptcephala*, *Misgurnus mizolepis grangeri*, *Misgurnus mohoity leopardus*, *Misgurnus mohoity yunnan*, *Misgurnus punctatus*, *Misgurnus mizolepis punctatus*, *Misgurnus mizolepis unicolor*, *Misgurnus elongatus*, *Misgurnus mizolepis elongatus*, *Cobitis fossilis*, *Cobitis fossilis mohoity*, *Misgurnus mohoity*, *Misgurnus mizolepis*, *Misgurnus mizolepis multimaculatus*.

In the RA area, *M. anguillicaudatus* (oriental weatherfish) is currently established in four countries. Populations are reported from The Netherlands (van Kessel et al. 2013a; Niemeijer and van Kessel 2016), Germany (Freyhof and Korte 2005), Spain (Franch et al. 2008), and Italy (Razzetti et al. 2001). Possibly some of these populations are misidentified and are in fact *M. bipartitus* (see Zangl et al. 2020); confirmed populations of *M. bipartitus* exist in Austria and Germany (Zangl et al. 2020), Belgium and The Netherlands (Brys et al. 2020). In France, two records of *M. anguillicaudatus* are known from the Seine basin (N. Poulet, pers. com.) but the species is not established in this Member State. Other, non-established Asian weatherfish species are reported from Switzerland and Germany, namely *P. dabryanus* (large-scale loach) (Freyhof and Brooks 2011; Stoeckle et al. 2019) and from the UK, *M. mizolepis* (Zięba et al. 2010).

*Misgurnus anguillicaudatus* is known to hybridise naturally with *P. dabryanus* (You et al. 2009). In aquaculture, Fujimoto et al. (2008a) were able to produce hybrids of *M. anguillicaudatus* and *M. mizolepis*. Artificial reproduction was also used to successfully crossbreed *M. anguillicaudatus* with the native *M. fossilis* (J. Wanzenböck, pers. comm.).

The known common names of *M. anguillicaudatus* in European languages other than English are the following: FR: loche asiatique, IT: cobite di stagno orientale, DK: kinesisk smerling, DE: Ostasiatischer Schlammpeitzger, NL: Aziatische modderkruiper, SLO: azijska činklja.

**A2. Provide information on the existence of other species that look very similar [that may be detected in the risk assessment area, either in the environment, in confinement or associated with a pathway of introduction]**

Include both native and non-native species that could be confused with the species being assessed, including the following elements:

- other alien species with similar invasive characteristics, to be avoided as substitute species (in this case preparing a risk assessment for more than one species together may be considered);
- other alien species without similar invasive characteristics, potential substitute species;
- native species, potential misidentification and mis-targeting

Response: Loaches and weatherfishes from the genus *Misgurnus* have a long eel-like body and ten chin barbels. The Global Invasive Species Database (GISD; <http://www.iucngisd.org/gisd/species.php?sc=1537>) describes *Misgurnus anguillicaudatus* as “brown to yellow with greenish, gray-brown to black marbling, with a paler ventral. Its eel-like body is long, laterally compressed, commonly measuring around 15 cm, but reaching a maximum size near 30 cm. It has a small, narrow mouth and subinferior with 10 barbels, 4 of them, clearly smaller than the other, placed below the lower lip. Its lips are thick and fleshy. Its lateral line is short and does not exceed the length of the pectoral fin. Its pectoral fins are triangular with a stout spine. The dorsal fin originates above the pelvic fin origin and is single and short-based. It bears conspicuous adipose crests along the ventral and dorsal mid-lines of the caudal peduncle. It also has a characteristic dark spot in the upper half of the base of the caudal fin. It has 9 dorsal rays, 6-7 pelvic rays, and 7-8 anal rays. Generally males have larger pectoral fins and females fuller abdomens”. Males can be distinguished from females (sexual dimorphism) by the enlarged second ray of the pectoral fin and the presence (vs. absence in females) of the lamina circularis (Urquhart and Koetsier 2011).

Kottelat and Freyhof (2007) state the *M. anguillicaudatus* can be distinguished from other species of *Misgurnus* in Europe by (1) dark, irregular spots on the body and no stripes, (2) the caudal peduncle has low adipose crests, (3) lamina circularis (i.e. ventral base of the second pectoral ray broadens into a rounded plate and covers the bases of the other pectoral rays) is present in males and (4) there is a dark spot on the upper caudal base.

In the RA area, only one species of the genus *Misgurnus* is native (*Misgurnus fossilis*). Its native range encompasses Europe north of the Alps, from the Meuse eastward to the Neva drainages and Lake Ladoga, the northern Black Sea basin from the Danube eastward to Kuban and the Caspian basin in the Volga and Ural drainages (Kottelat and Freyhof 2007). It is not native in Great Britain, Scandinavia and Iberia. The European weatherfish *M. fossilis* also has an anguilliform body shape

and ten barbels but has a broad midlateral line from eye to caudal base and a narrow stripe from opercle at least to pelvic origin instead of irregular spots on the body for *M. anguillicaudatus*. A lamina circularis is absent in males while it is present in *M. anguillicaudatus* (Kottelat and Freyhof 2007). Other native loaches belong to separate genera (*Cobitis* and *Sabanejewia*) and can be readily distinguished from *Misgurnus* because the suborbital spine is externally visible (*versus* hidden under muscles in *Misgurnus*) and the lower lip has 0-2 short, barbel-like mental lobes (*vs.* 4 long, barbel-like mental lobes in *Misgurnus*) (Kottelat and Freyhof, 2007).

Discussed below are other non-native *Misgurnus* and *Paramisgurnus* species that can be potential substitute species.

*Misgurnus bipartitus* is morphologically very similar to *M. anguillicaudatus*, but good identification keys are not available (Frable 2008). Nichols (1943) provides a dichotomous key for identifying *M. anguillicaudatus* from other *Misgurnus* species, but does not mention *M. bipartitus* and separates *M. mohoity* from other Chinese *Misgurnus* species by the fact that the skin is not thickened and the scales of *M. mohoity* are regular and fully exposed where for other *Misgurnus* species the skin is more or less thickened and the scales are more or less embedded. Yi et al. (2017) provide a morphological comparison of four Chinese *Misgurnus* species (*P. dabryanus*, *M. anguillicaudatus*, *M. bipartitus*, *M. mohoity*) and conclude that morphometric measurements can be used to distinguish between these species but also warn that “efficient delimitation of these four closely species based on one or several morphological characters seems to be difficult and limited”.

Zangl et al. (2020) based their morphological identification of *M. bipartitus* on characters given in the key by Vasil’eva (2001 and the translated Chinese key therein) namely the caudal peduncle depth 2.4–2.5 times in caudal peduncle length *vs.* 1.3–1.8 times in *M. anguillicaudatus* and the maximum body depth 8.2–8.6 times in standard length (SL) *vs.* < 7.5 times in *M. anguillicaudatus*. The latter species is more elongated (Nichols 1943).

The Chinese fine-scaled loach *M. mizolepis* is closely related to *M. anguillicaudatus*. This species can be readily distinguished from the oriental weatherfish because it has a greater number of fine surface scales covering its body rather than irregularly embedded scales (Frable 2008). Moreover the peduncular keels (adipose crests near caudal peduncle) are greatly developed in *M. mizolepis* while they are low in *M. anguillicaudatus* (Nichols 1943; Kottelat and Freyhof 2007). This is contrary to what the CABI datasheet on this species states “It has conspicuous adipose crests along the ventral and dorsal mid-lines of the caudal peduncle” (CABI 2020).

As with *M. mizolepis* the adipose crests near the caudal peduncle are greatly developed in the large-scale loach *P. dabryanus*. This species can be distinguished from *M. anguillicaudatus* because the dark dot on the upper caudal base is missing and from *M. fossilis* by the absence of a broad midlateral stripe from eye to caudal base, and the absence of the narrow stripe from opercle to the pelvic origin (Stoeckle et al. 2019).

Correct identification of *Misgurnus* and *Paramisgurnus* species remains difficult, morphologically as well as genetically, even when DNA sequence data are available, as systematics and taxonomy are still not fully resolved (Zangl et al. 2020). Belle et al. (2021) highlight this problem and conclude that their analysis of genetic weatherfish identification using mtDNA barcodes confirms the still incomplete and unresolved classical and molecular taxonomy of *Misgurnus* and *Paramisgurnus* genera. Nonetheless, they found distinct existing phylogenetic clusters for the genera *Misgurnus* and *Paramisgurnus* and they suggest DNA barcoding and genotyping of detected non-native or traded weatherfish specimens to assign a specimen to the right species.

**A3. Does a relevant earlier risk assessment exist? Give details of any previous risk assessment, including the final scores and its validity in relation to the risk assessment area.**

Response: A risk assessment was performed for South Australia in 2014 (Fredberg et al. 2014). The authors used FISK and NAPRA tools to assess, rank and score the environmental, economic and social impacts and costs of *M. anguillicaudatus* and found that the species has a high risk of establishment and several potential impacts were suggested, including competition for spawning sites and for food and shelter, disturbance and/or predation of fish and frog eggs, alteration of habitat and decreased water quality. Fredberg et al. (2014), however, concluded that these impacts were largely speculative and further research is needed to fill several knowledge gaps.

For the USA, an Ecological Risk Screening Summary was written by The U.S. Fish and Wildlife Service in 2012. *Misgurnus anguillicaudatus* is established in the US and they concluded that there is a high risk of additional introductions, establishment, and impacts in other areas because this species is highly adaptable, quick to reproduce, and is extremely popular in the aquaculture and aquarium industry. The climate match with the native range is high and multiple impacts are expected (reductions in macroinvertebrate populations, altered aquatic habitats, and the fish are vectors for certain fish parasites). Their overall risk was estimated as high but with a medium certainty of the assessment.

Interesova et al. (2020) assessed a number of non-native fishes in the River Ob Basin (Russia) and rated *M. anguillicaudatus* as having a high risk of becoming invasive. The species was also assessed for state of New York and the New York Invasiveness Rank was High ([http://nyis.info/wp-content/uploads/2017/10/1ae76\\_Misgurnus-anguillicaudatus-Ecological.pdf](http://nyis.info/wp-content/uploads/2017/10/1ae76_Misgurnus-anguillicaudatus-Ecological.pdf)).

In the Netherlands, Spikmans et al. (2010) made a pest risk analysis for ten non-native fish species based on literature and climate match. For oriental weatherfish they found a high current climate match with most of the Dutch rivers suitable for establishment of this fish. They do not assess the invasiveness of this species but only summarise the literature on possible impacts (predation, competition and disease transmission).

Almeida et al. (2013), using FISK for the Iberian Peninsula, and Radočaj et al. (2021), using AS-ISK for Croatia and Slovenia, both report high scores for the invasiveness of *M. anguillicaudatus*.

All the above risk assessments are valid for the RA area because of a reasonable to good climate match and the high adaptability of the oriental weatherloach.

**A4. Where is the organism native?**

including the following elements:

- an indication of the continent or part of a continent, climatic zone and habitat where the species is naturally occurring
- if applicable, indicate whether the species could naturally spread into the risk assessment area

Response: The oriental weatherfish is native to the East Asian temperate regions, including Cambodia, China, India, Japan, Korea, Laos, Taiwan, Thailand, Vietnam and the Tugur and Amur River catchments in Siberia (Kottelat and Freyhof 2007). In its native habitat, *M. anguillicaudatus* is found in mangrove swamps along rivers and lakes. In addition, the species is found in ponds, marshes and rice fields (Spikmans et al. 2010). In general, the species prefers stagnant or weakly flowing water (Froese and Pauly 2019). The oriental weatherfish is mainly found in waters with a muddy bottom. The species burrows in sediment or leaf litter, with only its head protruding (Simon et al. 2006, Froese and Pauly 2019). Natural spread from its native area into the risk assessment area is not possible.

**A5. What is the global non-native distribution of the organism outside the risk assessment area?**

Response: Outside the RA area, oriental weatherfish was introduced to Australia (Koster et al. 2002 (extensive overview of Australian populations), Keller and Lake 2007, Fredberg et al. 2014), North America (several authors, e.g. Tabor et al. 2001, Simon et al. 2006), South America (Abilhoa et al. 2013) and Asia outside of their natural range (Belle et al. 2017).

**A6. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species been recorded and where is it established? The information needs to be given separately for recorded (including casual or transient occurrences) and established occurrences. “Established” means the process of an alien species successfully producing viable offspring with the likelihood of continued survival<sup>2</sup>.**

**A6a. Recorded: List regions**

**A6b. Established: List regions**

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

- Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea.

Comment on the sources of information on which the response is based and discuss any uncertainty in the response.

For delimitation of EU biogeographical regions please refer to <https://www.eea.europa.eu/data-and-maps/figures/biogeographical-regions-in-europe-2> (see also Annex VI).

For delimitation of EU marine regions and subregions consider the Marine Strategy Framework Directive areas; please refer to <https://www.eea.europa.eu/data-and-maps/data/msfd-regions-and->

<sup>2</sup> Convention on Biological Diversity, Decision VI/23

subregions/technical-document/pdf (see also Annex VI).

Response (6a): **Continental** (Freyhof and Korte 2005; Belle et al. 2017), **Mediterranean** (Franch et al. 2008; Razzetti et al. 2001). All references are very trustworthy and report the first records first hand. Although van Kessel et al. (2013a) report *M. anguillicaudatus* from the **Atlantic** region, this species turned out to be *M. bipartitus* after a genetic screening (Brys et al. 2020).

Response (6b): **Continental** (Freyhof and Korte (2005) report adults and juveniles and suggest that a successfully reproducing population has been established in Germany), **Mediterranean** (Franch et al. (2008) state that oriental weatherfish has an established population in the Ebro, northeastern Iberian Peninsula). All references are very trustworthy and report the first records first hand. Natural reproduction and presence of young fishes was reported for The Netherlands (Atlantic region) by Binnendijk et al. (2017), however, this species turned out to be *M. bipartitus* after a genetic screening (Brys et al. 2020).

**A7. In which biogeographic region(s) or marine subregion(s) in the risk assessment area could the species establish in the future under current climate and under foreseeable climate change? The information needs be given separately for current climate and under foreseeable climate change conditions.**

**A7a. Current climate: List regions**

**A7b. Future climate: List regions**

With regard to EU biogeographic and marine (sub)regions, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

Response (7a): The species could currently establish in all EU biogeographic regions (Annex VIII). The highest suitability is in the Black Sea, Continental, Mediterranean and Pannonian regions followed from high to low by the Steppic, Boreal, Atlantic and Alpine regions (see figure 1).

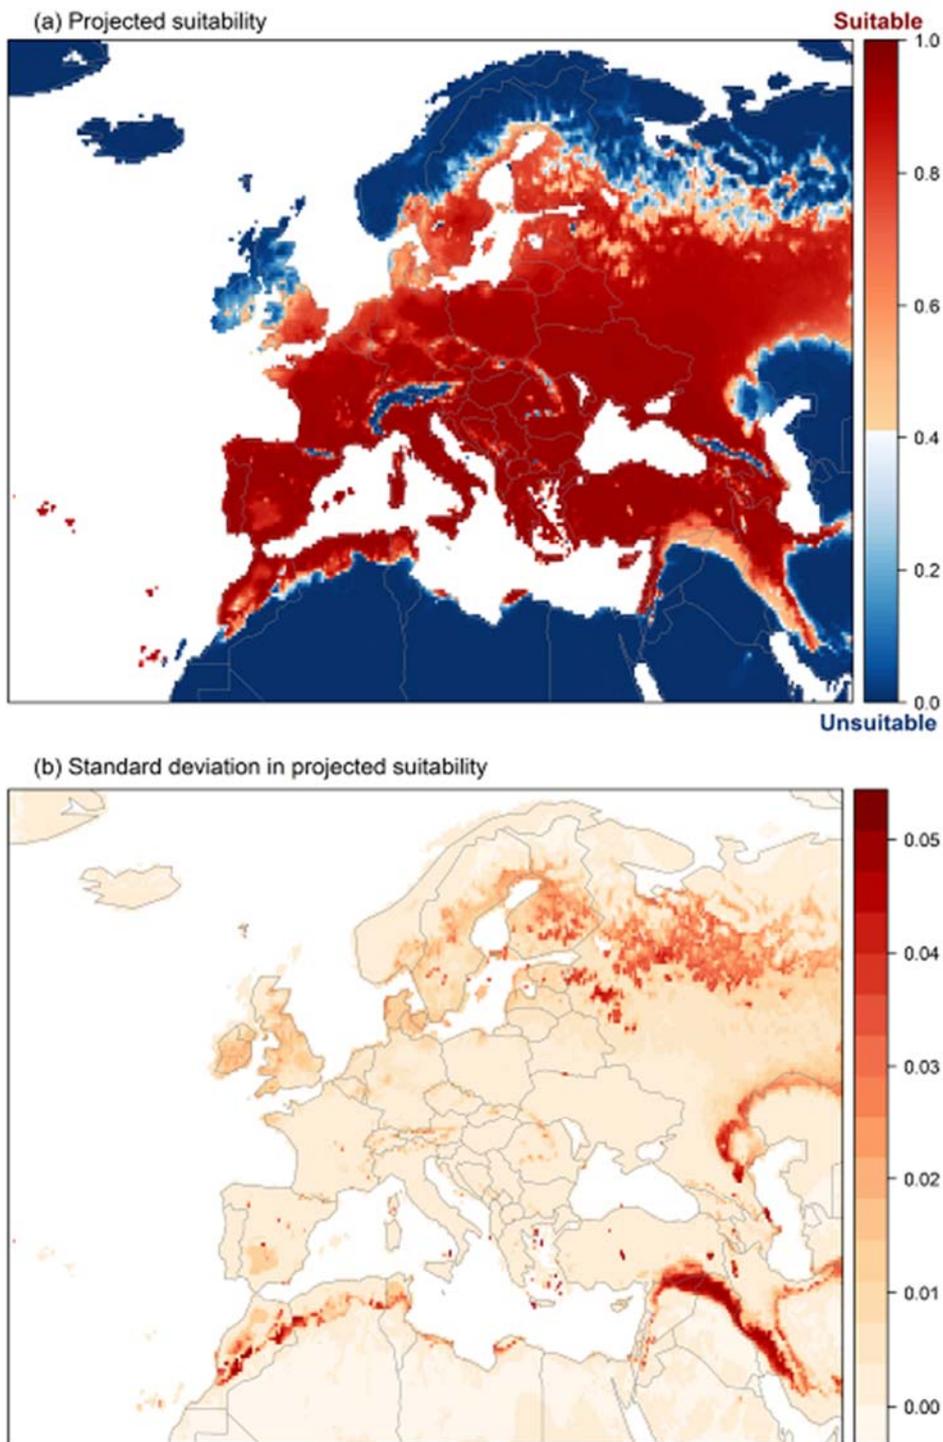

Figure 1: (a) Projected current suitability for *Misgurnus anguillicaudatus* establishment in Europe and the Mediterranean region. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

Response (7b): The species could establish in the 2070s under climate change scenario RCP2.6 and scenario RCP4.5 in all EU biogeographic regions (Annex VIII). The highest suitability is in the Black

Sea, Continental, Mediterranean and Pannonian regions followed from high to low by the Steppic, Atlantic, Boreal and Alpine regions (see figure 2 for scenario RCP2.6).

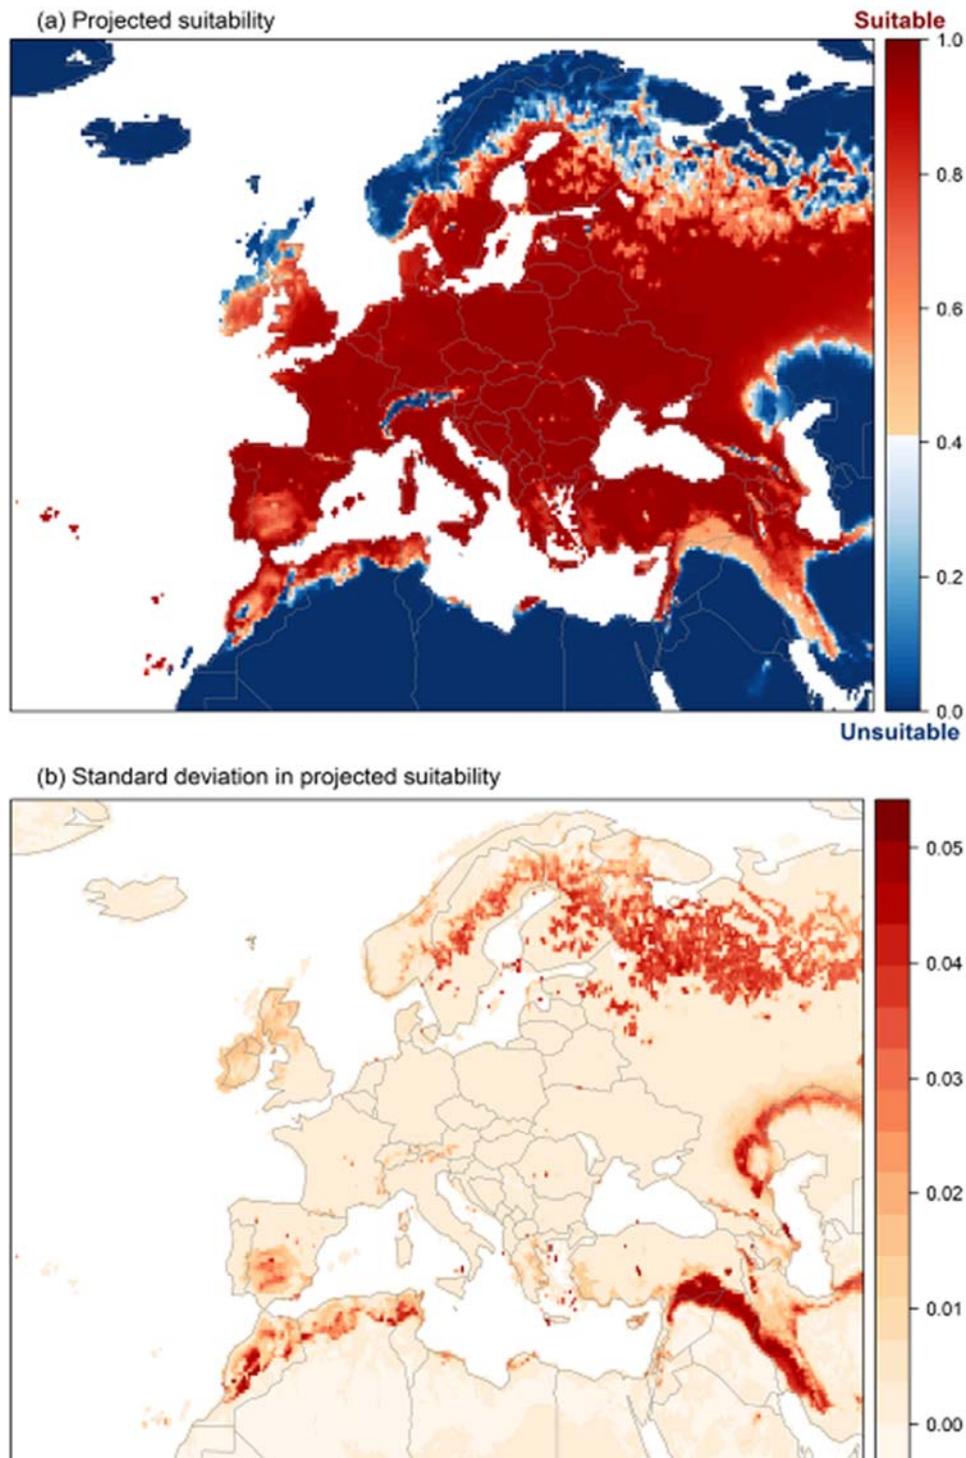

Figure 2: (a) Projected suitability for *Misgurnus anguillicaudatus* establishment in Europe and the Mediterranean region in the 2070s under climate change scenario RCP2.6, equivalent to Figure 1. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

It is not totally clear which aspects of climate change are most likely to affect the risk assessment but the SDM (Annex VIII) suggested that suitability for *Misgurnus anguillicaudatus* was strongly determined by the maximum temperature of the warmest month (27.1%) and by annual precipitation (23.8%). In both climate change scenarios, the suitable area will increase in the colder parts of the RA area e.g. UK, Ireland, Finland and Sweden.

**A8. In which EU Member States has the species been recorded and in which EU Member States has it established? List them with an indication of the timeline of observations. The information needs be given separately for recorded and established occurrences.**

**A8a. Recorded: List Member States**

**A8b. Established: List Member States**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden

The description of the invasion history of the species shall include information on countries invaded and an indication of the timeline of the first observations, establishment and spread.

Response (8a): The oriental weatherfish was first recorded in Germany in 1990 (Freyhof and Korte 2005). Subsequently first records came from Italy in 1997 (Razzetti et al. 2001), Spain in 2001 (Franch et al. 2008) and the Netherlands in 2012 (van Kessel et al. 2013a).

It must be noted that possibly some of these populations are misidentified and in fact are other *Misgurnus* species. Recently it became clear, after genetic screening, that confirmed populations of *M. bipartitus* exist in Austria and Germany (Zangl et al. 2020), and Belgium and the Netherlands (Brys et al. 2020). It is, however, impossible to check all the reported *M. anguillicaudatus* specimens on their correct identification.

Response (8b): After the first record in 1990 in Germany (Freyhof and Korte 2005), in 2002, 43 specimens were caught ranging from 5.5 to 20.0 cm standard length; these specimens included adults and juveniles, suggesting a successfully reproducing, established population. Some specimens were caught in 2016 in the River Inn (South Germany), but establishment is not confirmed (Belle et al. 2017).

Razzetti et al. (2001) reported the first record for Italy in 1997, more individuals were caught in 1998 and the presence of dozens of adults and young fish of both sexes (total length between 9 and 21 cm) in 2000 confirmed the establishment of this species there.

Since the first Spanish record in 2001, the population of oriental weatherfish is expanding (Franch et al. 2008). The capture of over 1,000 weatherfish shows that its population is composed of both juvenile and adult individuals suggesting an established population.

**A9. In which EU Member States could the species establish in the future under current climate and under foreseeable climate change? The information needs be given separately for current**

**climate and under foreseeable climate change conditions.**

**A9a. Current climate: List Member States**

**A9b. Future climate: List Member States**

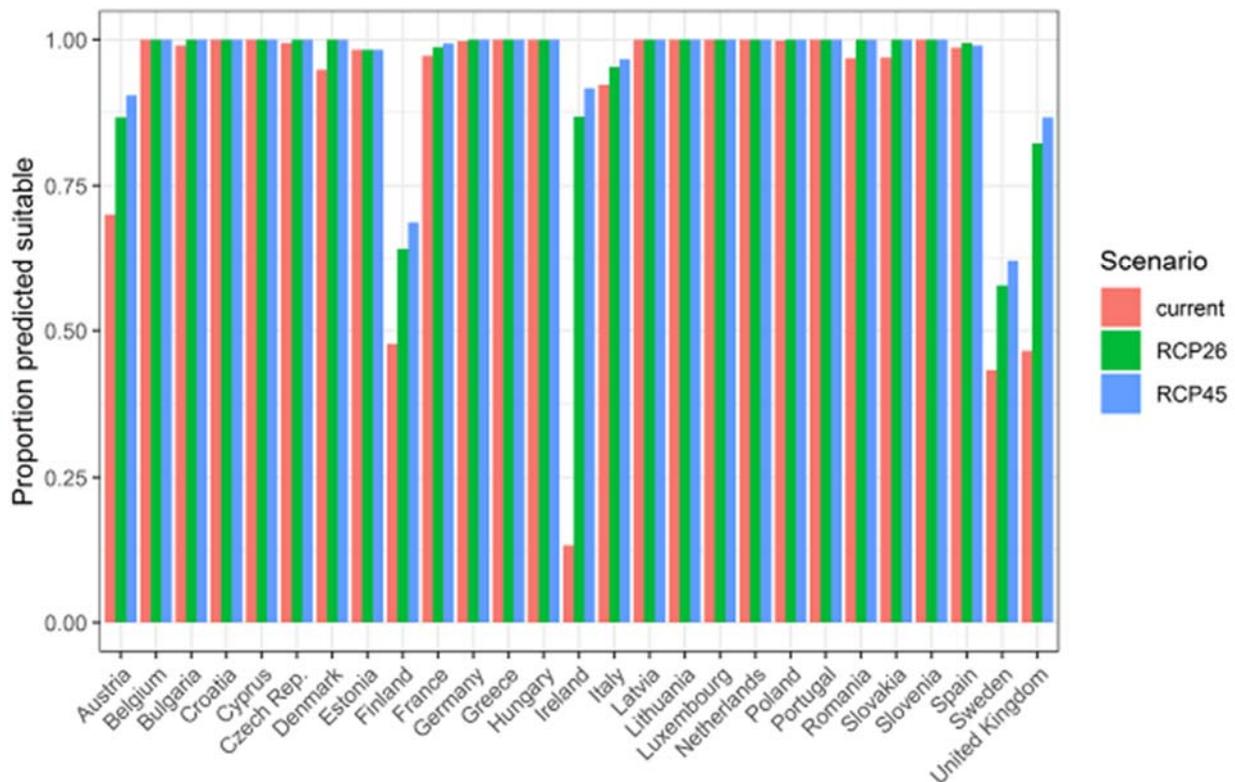

With regard to EU Member States, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

Response (9a): Under current climate conditions *M. anguillicaudatus* could establish in all EU MS and the UK; there seems to be a high establishment potential for most MS but less so for Ireland, UK, Sweden, Finland and Austria (see figure 3).

Response (9b): In the 2070s, under climate change scenario RCP2.6 and scenario RCP4.5 *M. anguillicaudatus* could establish in all EU MS and the UK: there seems to be a high establishment

potential for most MS with increased potential (compared to current conditions) for Ireland, UK, Sweden, Finland and Austria (see Figure 3).

It is not totally clear which aspects of climate change are most likely to affect the risk assessment but the SDM (Annex VIII) suggested that suitability for *Misgurnus anguillicaudatus* was strongly determined by the maximum temperature of the warmest month (27.1%) and by annual precipitation (23.8%). In both climate change scenarios, the suitable area for establishment will increase in the colder parts of the RA area e.g. UK, Ireland, Finland and Sweden.

**A10. Is the organism known to be invasive (i.e. to threaten or adversely impact upon biodiversity and related ecosystem services) anywhere outside the risk assessment area?**

Response: Several authors reported adverse impacts but most of these impacts are anecdotal. For instance, Nobile et al. (2017) sum up possible impacts of established oriental weatherfishes for Brazil as follows: niche overlap, competition for resources and space, introduction of parasites, predation on eggs of fishes and restructuring of the aquatic ecosystem.

Keller and Lake (2007) report the potential impacts for Australia. In a mesocosm experiment, they found that oriental weatherfish caused significant reductions in macroinvertebrate numbers and biomass and that this fish was also associated with elevated ammonia, nitrate/nitrite (NO<sub>x</sub>), and turbidity levels. However, the authors conclude: “We are not able to conclusively determine that oriental weatherfish are having large impacts in natural systems”.

In Asia, the species is known to hybridize with other species of *Misgurnus* and *Paramisgurnus* (You et al. 2009; Fujimoto et al. 2008a), but it is not clear what the impact of this phenomenon will be.

Schmidt and Schmidt (2014) conclude that *M. anguillicaudatus* does not seem to affect other vertebrates in the Hudson River Valley (New York) but that attention should be paid on the potential negative interactions (competition for food) with the native eastern mudminnow *Umbra pygmaea*. Similarly, López et al. (2012) suggest potential competition for food resources with benthic species such as river blenny (*Salaria fluviatilis*), European eel (*Anguilla anguilla*) and Iberian loach (*Cobitis paludica*). Also, Radočaj et al. (2021) state that in Croatia and Slovenia, *M. anguillicaudatus* can produce hybrids with congeneric the native *M. fossilis* with impacts on their genetic diversity

*Misgurnus anguillicaudatus* has been responsible for the establishment of the parasitic flatworm *Gyrodactylus macracanthus* (Dove and Ernst 1998) in Australia. Ogawa (1994) names this loach as host of the gill parasite *Ancyrocephalus cruciatus*, fin parasite *Gyrodactylus micracanthus*, and other unidentified fin and gill parasites of the genus *Gyrodactylus*. *Misgurnus anguillicaudatus* can also host the parasite *Acanthocephalus opsariichthydis* (Amin et al. 2007). In addition, the gill parasites *Trichodina lechriodontata* and *Trichodina modesta* were found in oriental weatherfish (Zhao and Tang 2007). Also Reyda et al. (2019) report the introduction of at least three *Gyrodactylus* species in the USA through oriental weatherfish. These parasites can potentially infect indigenous fish species and can cause mortalities in aquaculture as was the case with another *Gyrodactylus* parasite (*G. salaris*) in Norway (Salte et al. 2010).

**A11. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species shown signs of invasiveness? Indicate the area endangered by the organism as**

**detailed as possible.**

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea

Response: Established populations in the RA area are reported in the Continental (Freyhof and Korte 2005) and Mediterranean biogeographic regions (Ebro delta (Franch et al. 2008) and the province of Pavia (Razzetti et al. 2001)). López et al. (2012) state densities of up to 100 individuals m<sup>-2</sup> of sampled area. Although it is not always explicitly stated in the papers that report the establishment of self-sustaining populations, most authors mention potential negative impacts that imply invasiveness (because of growing numbers and expanding populations).

**A12. In which EU Member States has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden

Response: Invasiveness is not explicitly stated in the papers that report established, self-sustaining populations in the RA area. Most impacts mentioned are anecdotal but imply invasiveness. In the future, invasiveness may be expected (because of growing numbers and expanding populations) in Germany (central east near Frankfurt am Main), Italy (Po river basin), and Spain (northeast, Ebro delta). Regarding, the Ebro population (northeastern Iberia) this population is highly abundant and its control is no longer possible. According with López et al. (2012) this species has already spread to other drainages within the northeastern part of Iberia. In the Netherlands (southeastern part near Weert) and Belgium (northeastern part near Bocholt), the congener *M. bipartitus* is showing an explosive population growth in just a few years (author's own observation).

**A13. Describe any known socio-economic benefits of the organism.**

including the following elements:

- Description of known uses for the species, including a list and description of known uses in the risk assessment area and third countries, if relevant.
- Description of social and economic benefits deriving from those uses, including a description of the environmental, social and economic relevance of each of those uses and an indication of

associated beneficiaries, quantitatively and/or qualitatively depending on what information is available.

If the information available is not sufficient to provide a description of those benefits for the entire risk assessment area, qualitative data or different case studies from across the risk assessment area or third countries shall be used, if available.

Response: *Misgurnus anguillicaudatus* is sold as an ornamental fish in the aquarium trade in the RA area as well as in the rest of the world (Strecker et al. 2011; Chang et al. 2009; Franch et al. 2008; Tabor et al. 2001), as a food source (Park et al. 2006) and as live bait (Franch et al. 2008). However, no published figures on quantities and costs were found.

In China (and other Asian countries), oriental weatherfish is a highly valued food fish and also used in traditional Chinese medicine. Since the 1990s the entire life cycle of this fish can be produced in aquaculture facilities and as of 2010 more than 204.552 tons were produced in aquaculture in China (Milton et al. 2018).

## SECTION B – Detailed assessment

### Important instructions:

- In the case of lack of information the assessors are requested to use a standardized answer: “No information has been found.”
- With regard to the scoring of the likelihood of events or the magnitude of impacts see Annexes I and II.
- With regard to the confidence levels, see Annex III.
- Highlight the selected response score and confidence level in **bold** but keep the other scores in normal text (so that the selected score is evident in the final document).

## 1 PROBABILITY OF INTRODUCTION AND ENTRY

### Important instructions:

- **Introduction** is the movement of the species into the risk assessment area (it may be either in captive conditions and/or in the environment, depending on the relevant pathways).
- **Entry** is the release/escape/arrival in the environment, i.e. occurrence in the wild
- Introduction and entry may coincide for species entering through pathways such as “corridor” or “unaided”, but it also may differ. If different, please consider all relevant pathways, both for the introduction into the risk assessment area and the entry in the environment.
- The classification of pathways developed by the Convention of Biological Diversity (CBD) should be used (see Annex IV). For detailed explanations of the CBD pathway classification scheme consult the IUCN/CEH guidance document<sup>3</sup> and the provided key to pathways<sup>4</sup>.
- For organisms which are already present (recorded or established) in the risk assessment area, the likelihood of introduction and entry should be scored as “very likely” by default.
- Repeated (independent) introductions and entries at separate locations in the risk assessment area should be considered here (see Qu. 1.7).

**Qu. 1.1. List relevant pathways through which the organism could be introduced into the risk assessment area and/or enter into the environment. Where possible give details about the specific origins and end points of the pathways as well as a description of any associated commodities.**

For each pathway answer questions 1.2 to 1.7 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 1.2a, 1.3a, etc. and then 1.2b, 1.3b etc. for the next pathway.

In this context a pathway is the route or mechanism of introduction and/or entry of the species.

The description of commodities with which the introduction of the species is generally associated shall include a list and description of commodities with an indication of associated risks (e.g. the

<sup>3</sup> <https://circabc.europa.eu/sd/a/738e82a8-f0a6-47c6-8f3b-aeddb535b83b/TSSR-2016-010%20CBD%20categories%20on%20pathways%20Final.pdf>

<sup>4</sup> <https://circabc.europa.eu/sd/a/Oaeba7f1-c8c2-45a1-9ba3-bcb91a9f039d/TSSR-2016-010%20CBD%20pathways%20key%20full%20only.pdf>

volume of trade; the likelihood of a commodity being contaminated or acting as vector).

If there are no active pathways or potential future pathways this should be stated explicitly here, and there is no need to answer the questions 1.2-1.9.

Two main pathways are identified:

Pathway name: Escape from confinement – Pet/Aquarium/Terrarium species

This pathway is estimated to be the most important for introduction and entry of the oriental weatherfish in the RA area, with the species being available for sale on the internet<sup>5</sup> and in shops. Disposal of aquarium fishes and escape into the wild from ponds happens frequently (Chan et al. 2019).

Pathway name: Escape from confinement – Live food and live bait

Although no data are available on the use of oriental weatherfish as live food or live bait in the RA area; it is an important food source in its native range, especially in China. So it can be assumed that this fish is intentionally imported to e.g. Chinatowns in Europe. The use of this species as live bait in the RA area is unclear and only mentioned as a possible introduction route by Franch et al. (2008). In Australia as well as in the USA and Japan, Koster et al. (2002) confirmed the use of this species as live bait.

**Pathway: Escape from confinement – Pet/Aquarium/Terrarium species**

**Qu. 1.2a. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	<b>intentional</b> unintentional	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response: *Misgurnus anguillicaudatus* has been imported into the RA area as an aquarium and garden pond species, it still is sold in many fish shops and on the internet. Entry into the wild was probably both intentional (release of unwanted specimens) and unintentional (flooding of garden ponds).

**Qu. 1.3a. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.

<sup>5</sup> <https://www.justcichlids.com/index.php/pages/Dojo-loach-for-sale.html>;  
<https://verduijncichlids.com/product/misgurnus-anguillicaudatus/>

- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: The aquarium trade is responsible for the worldwide movement of over 2 billion live freshwater fish per year (Chan et al. 2019). In Australia ornamental trade has become the leading vector for non-native fish introductions since the 1970s with species established in Australian drainages including oriental weatherfish. Oriental weatherfish were imported to Australia by the aquarium industry at a rate of up to 50,000 per year until the sale was banned in 1986 (Keller and Lake 2007). For the RA area, no exact data are available but several authors (e.g. van Kessel et al. 2013a, Zangl et al. 2020) mention this pathway (“aquarium trade”) as the most likely for some Member States. Although the propagule pressure of introductions into the RA area may be high, the entry of the introduced fishes into the wild will be much lower. Still, releases of aquarium fish occur frequently (Chan et al. 2019). No information has been found on the percentage of introduced fishes for ornamental purposes in the risk assessment area or entering the natural environment.

**Qu. 1.4a. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: Live transport of aquarium species is well organised, the survival during the passage would be high as with other fish transports. Moreover, oriental weatherfish is a hardy fish that can withstand reduced dissolved oxygen conditions (Koetsien and Urquhart 2012) and low temperatures (Urquhart and Koetsier 2014). Reproduction during transport is unlikely but not impossible because reproduction as well as fertilization of the eggs happens in the water column. Eggs hatch within 30 hours and larvae remain in the water column for a short period before settling on the bottom (Frable 2008). Survival of specimens that get released in the wild (dumped from aquaria or escaped after flooding) is bound to be high because of the hardiness of oriental weatherfish and its ability to survive several days out of the water (Koster et al. 2002).

**Qu. 1.5a. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Intentional fish transport is meant to keep the fish alive, so no management practices to imperil the survival would be in place. Aquarium holders will do their best to keep their fish alive under the best conditions and no management practices would be in place to prevent entry and survival in the wild.

**Qu. 1.6a. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: *Misgurnus* species can be difficult to distinguish from each other for non-trained people, e.g. *M. anguillicaudatus* imported for the aquarium trade in Great Britain turned out to be *M. mizolepis* instead (Zięba et al. 2010), the same can happen the other way round. Escape into the wild of aquarium and pond fishes happens frequently and may be noticed only years later (Chan et al. 2019). *M. anguillicaudatus* can be detected during regular monitoring for e.g. the Water Framework Directive but there may be several years between first occurrence and first detection. Also, this species has a benthic lifestyle and often lives in marshlike habitats which are difficult to sample. New detection methods, e.g. environmental DNA (eDNA) may be used for better and quicker detection of this cryptic species (Brys et al. 2020).

**Qu. 1.7a. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: Introductions via the aquarium trade can happen in any place, especially since *M. anguillicaudatus* is also for sale through the internet<sup>6</sup>. Intentional as well as unintentional entry into the wild can also occur in most places but propagule pressure is bound to be higher in a neighbourhood with dense human populations (Copp et al. 2005).

**Qu. 1.8a. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The oriental weatherfish is already established in several Member States (MS) of the RA area as a consequence of releases/escapes connected to the aquarium trade (Zangl et al. 2020). Additional introductions are still possible and probably ongoing since this species is readily available via the aquarium trade and the internet. Entry into the wild has already been encountered for several decades now, with natural populations in at least six MS (NL, BE, DE, AT, ES, IT).

**Pathway: Escape from confinement – Live food and live bait**

**Qu. 1.2b. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	intentional unintentional	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	------------------------------	-------------------	------------------------------

Response: As this fish is highly valued as a food source (especially in China), intentional import of this species to e.g. Chinatowns in the RA area cannot be excluded. The import of oriental weatherfish for use as live bait is not documented for the RA area but was for Australia, the USA and Japan (Koster et al. 2002).

**Qu. 1.3b. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one**

<sup>6</sup> <https://verduijncichlids.com/product/misgurnus-anguillicaudatus/>  
<https://www.gdaquarium.nl/a-28161018/tropische-vissen-database/misgurnus-anguillicaudatus-gold-weeraal-goud/#description>

**year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: Although no information has been found on organised imports of live weatherfish for food or as baits into the RA area, it is still possible that this species, farmed in large numbers in Asia, is intentionally imported to e.g. Chinatowns in Europe. Several authors (Franch et al. 2008, Milton et al. 2018) report that *M. anguillicaudatus* is important as a food source, especially in China (and some other East Asian countries). The use of this species in the RA area as live bait is unclear and only mentioned as a possible introduction route by Franch et al. (2008) but was confirmed for Australia, the USA and Japan (Koster et al. 2002).

**Qu. 1.4b. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Live transport of food species is well organised, the survival during the passage would be high as with other fish transports. Moreover, oriental weatherfish is a hardy fish that can withstand reduced dissolved oxygen conditions (Koetsien and Urquhart 2012) and low temperatures (Urquhart and Koetsier 2014). Reproduction during the transport is unlikely but not impossible because reproduction as well as fertilization of the eggs happens in the water column. Eggs hatch within 30 hours and larvae remain in water column for a short period before settling on the bottom (Frale 2008). Survival of specimens that get released in the wild (e.g. release of excess live bait) is expected

to be high because of the hardiness of oriental weatherfish and its ability to survive several days out of the water (Koster et al. 2002).

**Qu. 1.5b. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Intentional fish transport is meant to keep the fish alive, so no management practices to imperil the survival would be in place. Neither would management practices be in place to prevent survival of escaped fish in the wild.

**Qu. 1.6b. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: *Misgurnus* species can be difficult to distinguish from each other for non-trained people, e.g. *M. anguillicaudatus* imported for the aquarium trade in Great Britain turned out to be *M. mizolepis* instead (Zięba et al. 2010), the same can happen the other way round. Escape into the wild of live food fishes happens frequently and may be noticed only years later (Rixon et al. 2005).

**Qu. 1.7b. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: Introductions for the live food trade or as live bait can happen in any place, especially since *M. anguillicaudatus* is also for sale through the internet. Although no information has been found on

organised import of live weatherfish for food into the RA area, it is possible that this species is imported in Asian neighbourhoods of cities in Europe. Intentional as well as unintentional entry into wild can occur in these places where propagule pressure is higher near the neighbourhood of live food markets, but these live food markets are probably not widespread in the RA area.

**Qu. 1.8b. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response: Importation of live fishes is known as an important pathway for the introduction of invasive, non-native fishes in some regions in the world (Rixon et al. 2005), but probably less so in the RA area. However no specific information has been found on this subject.

**Qu. 1.9. Estimate the overall likelihood of introduction into the risk assessment area or entry into the environment based on all pathways and specify if different in relevant biogeographical regions in current conditions.**

Provide a thorough assessment of the risk of introduction in relevant biogeographical regions in current conditions: providing insight in to the risk of introduction into the risk assessment area.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The oriental weatherfish is already established in several Member States of the RA area. Additional introductions are still possible and probably ongoing since this species is readily available via the aquarium trade and the internet. It is also farmed in high numbers in China for the food industry. Several MS have already reported established populations in the wild as a consequence of deliberate introductions from aquaria or unintentional escapes from garden ponds.

**Qu. 1.10. Estimate the overall likelihood of introduction into the risk assessment area or entry into the environment based on all pathways in foreseeable climate change conditions?**

Thorough assessment of the risk of introduction in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this

risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of introduction (e.g. change in trade or user preferences)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely introduction within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: The species is established from NW Europe, over Central Europe to the south in Spain and Italy. The risk of introduction and/or entry is very likely and will probably not change much in foreseeable climate change conditions. Possibly northern MS will be at higher risk of invasion in the future because the temperature range of *M. anguillicaudatus* is very broad, this can be assumed from its broad native habitat. It is not clear which aspects of climate change are most likely to affect the risk assessment but an increase in average winter temperature will increase the suitable area in the colder parts of the RA area e.g. Great Britain, Ireland, Finland and Sweden (Annex VIII).

## 2 PROBABILITY OF ESTABLISHMENT

### Important instructions:

- For organisms which are already established in parts of the risk assessment area or have previously been eradicated, the likelihood of establishment should be scored as “very likely” by default.
- Discuss the risk also for those parts of the risk assessment area, where the species is not yet established.

**Qu. 2.1. How likely is it that the organism will be able to establish in the risk assessment area based on similarity of climatic and abiotic conditions in its distribution elsewhere in the world?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: Oriental weatherfish is a fish native mainly to the temperate climate region of east Asia (Köppen-Geiger climate classification) (Kottelat and Freyhof 2007). All temperate regions in the world (e.g. USA, Australia, Europe) have reported established populations of this species. In the RA area, the species is established from Central Europe (Germany) to the south in Spain and Italy. Probably all MS can contain established populations of *M. anguillicaudatus*, because it is a very hardy species that can tolerate harsh conditions like reduced dissolved oxygen conditions (Koetsien and Urquhart 2012) and low temperatures (Urquhart and Koetsier 2014). Specimens of this fish or its congener *M. bipartitus* have already been found in a cold alpine stretch of the River Inn in Germany and Austria (Zangl et al. 2020) but it is not known whether they are established there. Figure 1 (at page 11) shows a high (projected) suitability for establishment in most of the EU MS.

**Qu. 2.2. How widespread are habitats or species necessary for the survival, development and multiplication of the organism in the risk assessment area? Consider if the organism specifically requires another species to complete its life cycle.**

<b>RESPONSE</b>	very isolated isolated moderately widespread <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: *M. anguillicaudatus* occurs in rivers, lakes and ponds (Froese and Pauly 2019) and also in swamps and ricefields (You et al. 2009). It prefers muddy bottoms, where they hide in the muck and

leaf litter with only their heads sticking out. This species is very hardy and can survive a wide range of temperatures and environmental conditions. It is typically found in slow or still waters with muddy or silty bottoms abundant with aquatic plants (Froese and Pauly 2019). However, Schmidt and Schmidt (2014) noticed that their sample sites in the Hudson Valley (NY, USA) were mostly devoid of aquatic plants. Several authors (e.g. Franch et al. 2008; Zangl et al. 2020) mention also rivers as suitable habitat for the oriental weatherfish. The oriental weatherfish can breathe atmospheric oxygen by using its intestine as an accessory respiratory organ, allowing it to live in oxygen-poor waters and to bury itself in soft substrates to survive long droughts (Koetsier and Urquhart 2012). All these suitable habitats are widely available in the RA area.

**Qu. 2.3. How likely is it that establishment will occur despite competition from existing species in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: *Misgurnus anguillicaudatus* is established in the RA area in a wide range of habitats and climate conditions (see Q 2.1) where also other species occur. The congener species, *M. bipartitus*, for instance co-exists, in very high densities, with *M. fossilis* and *Cobitis taenia* (spined loach), two species with a similar habitat use and food items in its Dutch and Belgian non-native range (Brys et al. 2020). and *M. bipartitus* occurs there . In the Dutch population, top predators like pike *Esox lucius* and perch *Perca fluviatilis* were present in the fish community (Binnendijk et al. 2017) and not limiting establishment of *M. bipartitus*. Similar situations can be expected for the close relative *M. anguillicaudatus*.

**Qu. 2.4. How likely is it that establishment will occur despite predators, parasites or pathogens already present in the risk assessment area?**

<b>RESPONSE</b>	N/A very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: As in other parts of the world (USA, Australia, Brazil), *M. anguillicaudatus* became established in several regions in the RA area despite the presence of native predators (e.g. northern pike *Esox lucius* and Eurasian perch *Perca fluviatilis*), parasites or pathogens (Koster et al. 2002, Binnendijk et al. 2017).

**Qu. 2.5. How likely is the organism to establish despite existing management practices in the risk assessment area? Explain if existing management practices could facilitate establishment.**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Currently, no management practices seem to be ongoing in the RA area, no information has been found on this subject. Previous efforts to eradicate (or at least manage) the Dutch population (Binnendijk et al. 2017) failed. Over several years and multiple times per year Binnendijk et al. (2017) tried to catch (with dipnets and electrofishing) as many loaches as possible and removed them from the infested site. Although many specimens were captured (n= 763), eradication efforts were stopped because the numbers kept increasing with new and smaller (i.e. natural reproduction) caught each year. Other eradication methods were deemed unfeasible on the basis of financial, practical, ecological or legal reasons (Binnendijk et al. 2017). The Dutch management effort is the only management practice reported for the RA area.

In the context of European, national and regional legislations (e.g. Decision on the free migration of fish species in the hydrographic catchment areas of the Benelux countries<sup>7</sup>) several actions are undertaken to remove fish migration barriers from rivers and streams. These management practices to restore the natural connections may actually facilitate spread and enhance establishment of non-native species to new areas (Krieg and Zenker 2020). However, in the case of the oriental weatherfish, weirs and dams may have been less of a barrier for dispersal because Lintermans et al. (1990) reported observations of this species moving overland.

**Qu. 2.6. How likely is it that biological properties of the organism would allow it to survive eradication campaigns in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: The oriental weatherfish can breathe atmospheric oxygen by using its intestine as an accessory respiratory organ, allowing it to live in oxygen-poor waters and to bury itself in soft substrates to survive long droughts (Koetsier and Urquhart 2012). Eradication campaigns for fish often use the principle of water removal (e.g. drying of ponds) or oxygen depletion (e.g. use of piscicides) to

<sup>7</sup> [https://www.vmm.be/wetgeving/M\\_2009\\_1\\_NL.pdf](https://www.vmm.be/wetgeving/M_2009_1_NL.pdf)

kill unwanted fish species. Because of its unique feature to breathe atmospheric oxygen, oriental weatherfish is able to survive oxygen deprived conditions for many days. In experimental circumstances in the USA, some individuals survived for over 81 days in desiccated conditions with soil moisture content less than 3% (Koetsier and Urquhart 2014). An effort to eradicate (or at least manage) the Dutch *M. bipartitus* population, by using multiple catches and removals of individuals with electrofishing apparatus, fykes and dipnets failed (Binnendijk et al. 2017). On the other hand, a reproducing population of *M. mizolepis* in a small, plastic-lined garden pond in Essex has been eradicated (Zięba et al. 2010).

**Qu. 2.7. How likely are the biological characteristics of the organism to facilitate its establishment in the risk assessment area?**

including the following elements:

- a list and description of the reproduction mechanisms of the species in relation to the environmental conditions in the risk assessment area
- an indication of the propagule pressure of the species (e.g. number of gametes, seeds, eggs or propagules, number of reproductive cycles per year) of each of those reproduction mechanisms in relation to the environmental conditions in the risk assessment area.
- If relevant, comment on the likelihood of establishment based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in establishment whereas for others high propagule pressure (many thousands of individuals) may not.
- If relevant, comment on the adaptability of the organism to facilitate its establishment and if low genetic diversity in the founder population would have an influence on establishment.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: *Misgurnus anguillicaudatus* matures quickly, can reproduce multiple times in a season, and produces a great number of offspring (Nico et al. 2020). The male wraps his body around the female and stimulates her to release a cloud of eggs, which he simultaneously fertilizes. These fish are nonguarders and release their eggs in open water as well as on substratum (Breder and Rosen 1966). This indicates broad environmental conditions for reproduction. Yamamoto and Tagawa (2000) reported 2000 eggs per female for introduced weatherfish in Hawaii. However, Urquhart (2013) found an estimated number of mature ova in female fish ranged from zero up to 46,18 for a self-sustaining population in Idaho (USA). Within this study area, oriental weatherfish lived 5–7 years, reaching sexual maturity within the first year of life. Females remained fecund throughout their lifetime, and spawned twice per year, with young produced in the late spring (May) and early autumn (October) seasons.

The oriental weatherfish is also a very hardy species with broad temperature tolerances (Urquhart and Koetsier 2014) and can withstand low dissolved oxygen conditions and dessication (Koetsier and Urquhart 2012).

No data are available about the genetic diversity of the oriental weatherfish populations in the RA area. Belcik (2017) investigated the population genetics of introduced oriental weatherfish populations in the Chicago Area Waterways and concluded that the results from his study suggest a single introduction to these waterways before 1987, with a subsequent range expansion. This author also suggests that the population is genetically identical to the weatherfish introduced into Australia before 1984, and that these populations were derived from the same native population in Asia. Therefore, it seems fair to conclude that low genetic diversity of this species probably will not inhibit its ability to establish in new areas. Binnendijk et al. (2017) also assume a single introduction in the southeast of the Netherlands was responsible for the establishment for a large population of *M. bipartitus*.

**Qu. 2.8. If the organism does not establish, then how likely is it that casual populations will continue to occur?**

Consider, for example, a species which cannot reproduce in the risk assessment area, because of unsuitable climatic conditions or host plants, but is present because of recurring introduction, entry and release events. This may also apply for long-living organisms.

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Most MS contain suitable habitat for oriental weatherfish to survive and inhabit, even if establishment would not be possible, there is a continued chance of e.g. aquarium specimens being dumped (Chan et al. 2019) as there is a continued sale of this species for the aquarium trade throughout the RA area and they will survive because of their broad tolerance for physiological variables, a flexible diet and a high reproductive potential (Koetsier and Urquhart 2012).

**Qu. 2.9. Estimate the overall likelihood of establishment in the risk assessment area under current climatic conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under current climatic conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in current conditions: providing insight in the risk of establishment in (new areas in) the risk assessment area.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: *M. anguillicaudatus* is established in several MS in the RA area (the Netherlands, Belgium, Germany, Spain, Italy). The SDM (Annex VIII) pointed out that most MS and most biogeographical regions have favourable conditions for establishment. Suitable habitats are available all over the RA area and because of its flexibility and broad tolerance for physiological variables, new introductions of oriental weatherfish will almost certainly lead to new established populations. Moreover, indications exist that oriental weatherfish can reproduce by gynogenesis (Morishima et al. 2002), a form of asexual reproduction in which growth and development of embryos occur without fertilization and where the egg are stimulated to develop simply by the presence of sperm: in the case of *M. anguillicaudatus* the sperm of a cyprinid species e.g. gibel carp *Carassius gibelio* is sufficient. This means that even the escape into the wild of one mature female can be enough to start a population. Also, there may be several years between first occurrence and first detection as *M. anguillicaudatus* has a benthic lifestyle and often lives in marshlike habitats which are difficult to sample with traditional methods like electrofishing and fykes. New detection methods, e.g. environmental DNA (eDNA) may be used for better and quicker detection of this cryptic species (Brys et al. 2020).

**Qu. 2.10. Estimate the overall likelihood of establishment in the risk assessment area under foreseeable climate change conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under foreseeable climate change conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of establishment (e.g. increase in average winter temperature, increase in drought periods)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely establishment within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: The species could establish in the 2070s under climate change scenario RCP2.6 in all EU biogeographic regions (Annex VIII). The highest calculated suitability is in the Black Sea, Continental, Mediterranean and Pannonian regions followed from high to low by the Steppic, Atlantic,

Boreal and Alpine regions (see figure 2). Under scenario RCP4.5, conditions get better for most ecoregions in the RA area (figure 4). The SDM (Annex VIII) suggested that suitability for *Misgurnus anguillicaudatus* was strongly determined by the maximum temperature of the warmest month (27.1%), followed by annual precipitation (23.8%) while minimum temperature of the coldest month only accounted for 8.8% of the variation.

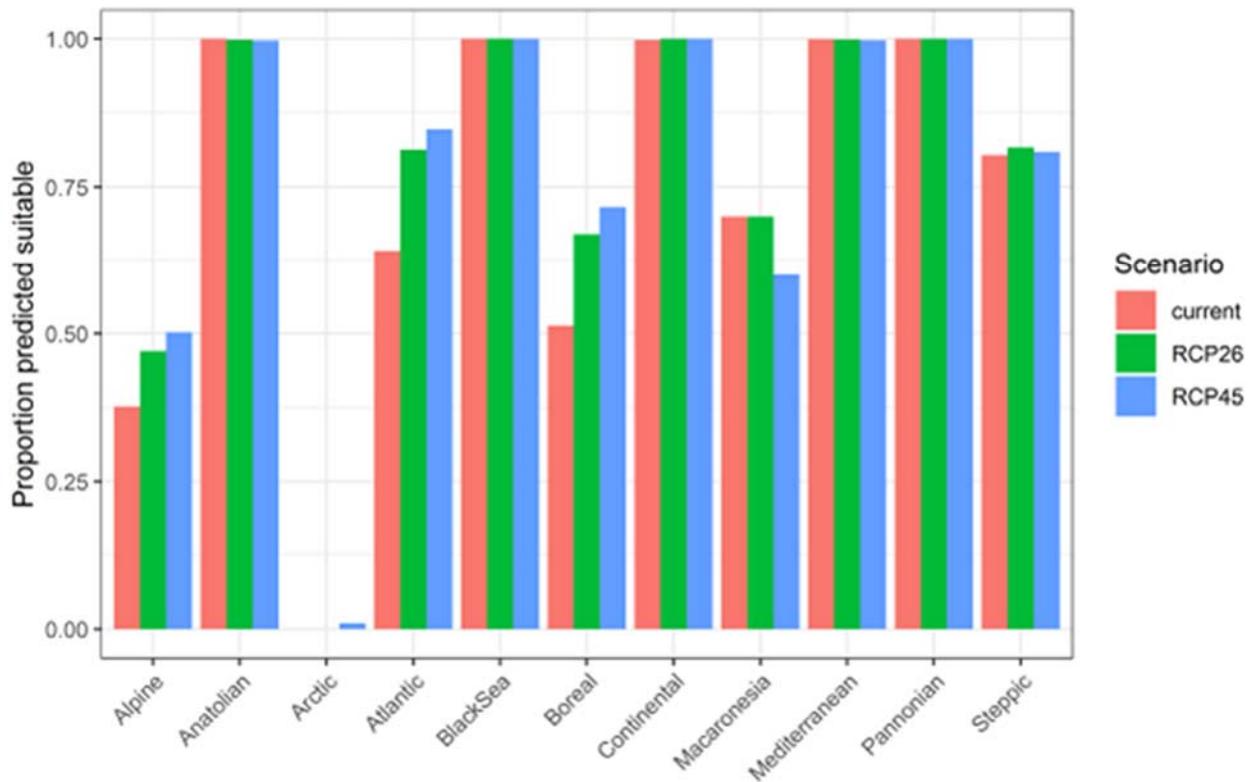

Figure 4: Variation in projected suitability for *Misgurnus anguillicaudatus* establishment among biogeographical regions of Europe. The bar plots show the proportion of grid cells in each region classified as suitable in the current climate and projected climate for the 2070s under two RCP emissions scenarios. The Anatolian, Arctic and Macaronesian biogeographical regions are not part of the study area, but are included for completeness.

### 3 PROBABILITY OF SPREAD

**Important instructions:**

- Spread is defined as the expansion of the geographical distribution of an alien species within the risk assessment area.
- Repeated releases at separate locations do not represent continuous spread and should be considered in the probability of introduction and entry section (Qu. 1.7).

**Qu. 3.1. How important is the expected spread of this organism within the risk assessment area by natural means? (List and comment on each of the mechanisms for natural spread.)**

including the following elements:

- a list and description of the natural spread mechanisms of the species in relation to the environmental conditions in the risk assessment area.
- an indication of the rate of spread discussed in relation to the species biology and the environmental conditions in the risk assessment area.

The description of spread patterns here refers to the CBD pathway category “Unaided (Natural Spread)”. It should include elements of the species life history and behavioural traits able to explain its ability to spread, including: reproduction or growth strategy, dispersal capacity, longevity, dietary requirements, environmental and climatic requirements, specialist or generalist characteristics.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: Natural spread can occur between connecting waters. Although overland movements are theoretically possible because of its air breathing capacity, Koetsier and Urquhart (2012) concluded that even in worsening environmental conditions (dessication experiments) oriental weatherfish rather bury themselves in the mud than trying to move away. However, Koster et al. (2002) reported the find of a specimen of oriental weatherfish moving overland during a wet day a short distance outside of a garden pond in Australia. Schmidt and Schmidt (2014) report that oriental weatherfish had colonized at least 20 km of the Dwaar Kill mainstem (plus several tributaries) and it is present in at least 8.5 km of the Wallkill River; this spread was probably realised over the last 20-30 years.

In the RA area, in the Ebro delta, oriental weatherfish was first detected in 2001 and by 2007 the species had spread over 31 1 x 1 km UTM quadrates (Franch et al. 2008). López et al. (2012) state that this species has large capacity to disperse from the established populations, finally colonizing all the Ebro delta.

In the Netherlands, natural spread of the congener *M. bipartitus* was also relatively high; from the discovery in 2012 to the end of 2016, this oriental weatherfish had moved twelve kilometers downstream and one kilometer (and possibly more) upstream (Binnendijk et al. 2017). In the downstream direction it looks like the spread was stopped by a (temporary) barrier. The Belgian population originated from natural spread from the neighbouring Dutch population, through a natural connection, with seven years between first records in the Netherlands and Belgium (Brys et al. 2020).

**Qu. 3.2a. List and describe relevant pathways of spread other than "unaided". For each pathway answer questions 3.3 to 3.9 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 3.3a, 3.4a, etc. and then 3.3b, 3.4b etc. for the next pathway.**

including the following elements:

- a list and description of pathways of spread with an indication of their importance and associated risks (e.g. the likelihood of spread in the risk assessment area, based on these pathways; likelihood of survival, or reproduction, or increase during transport and storage; ability and likelihood of transfer from the pathway to a suitable habitat or host) in relation to the environmental conditions in the risk assessment area.
- an indication of the rate of spread for each pathway discussed in relation to the species biology and the environmental conditions in the risk assessment area.
- All relevant pathways of spread (except “Unaided (Natural Spread)”, which is assessed in Qu. 3.1) should be considered. The classification of pathways developed by the Convention of Biological Diversity shall be used (see Annex IV).

Only one pathway for spread was identified: Corridor – Interconnected waterways / basins / seas. All over the introduced range, secondary spread was noticed from initial infection sources. In the RA area most river catchments are connected by man-made canals, which act as corridors for the spread of invasive aquatic species (Leuven et al. 2009), however, it is unclear how important this pathway is for *M. anguillicaudatus* in the RA area.

**Pathway name: Corridor – Interconnected waterways / basins / seas**

**Qu. 3.3a. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response: In the RA area most river catchments are connected by man-made canals, which act as corridors for the spread of invasive aquatic species (Leuven et al. 2009). Although the canals are intentionally built to connect water basins to allow boat traffic between them, the spread through these systems is unintentional.

**Qu. 3.4a. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Range expansion of the oriental weatherfish through man-made channels and canals was not investigated in the RA area. However, in the USA, oriental weatherfish used the North Shore Channel and the Chicago Sanitary and Ship Canal to move from the Lake Michigan Basin side toward the rivers and tributaries of the Mississippi River Basin (Belcik 2017). In Australia, these fish have also been collected from concrete flood control channels, and rock-filled wire cages used as soil conservation structures (Koster et al. 2002). In the native range, oriental weatherfish are known to inhabit irrigation channels for rice fields (Fujimoto et al. 2008b). The above indicates that channels and canals are valid corridors for the dispersal of the oriental weatherfish.

No numbers are available to give an indication of the propagule pressure through this pathway. However, a few specimens are enough to start a new population (e.g. Dutch and German population: van Kessel et al. 2013a, Freyhof and Korte 2005). On top of this, indications exist that oriental weatherfish can reproduce by gynogenesis (Morishima et al. 2002).

**Qu. 3.5a. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: NA

**Qu. 3.6a. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: Currently, no management practices seem to be ongoing in the RA area, no information has been found on this subject. Previous efforts to eradicate (or at least manage) the Dutch population (Binnendijk et al. 2017) failed. Over several years and multiple times per year Binnendijk et al. (2017) tried to catch (with dipnets and electrofishing) as many loaches as possible and removed them from the infested site. Although many specimens were captured (n= 763), eradication efforts were stopped because the numbers kept increasing with new and smaller young-of-the-year individuals (i.e. natural reproduction) caught each year. Other eradication methods were deemed unfeasible on the basis of financial, practical, ecological or legal reasons (Binnendijk et al. 2017). Chemicals (e.g. rotenone) can be used to eradicate fish in small, closed waters but are very difficult to apply in large, open water systems like canals. Also are these chemicals not species-specific and cause high collateral damage among non-target species. The use of these chemicals is also legally restricted (Koster et al. 2002).

**Qu. 3.7a. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response: No information has been found on dedicated monitoring of oriental weatherfish in the RA area. *M. anguillicaudatus* can be detected during regular monitoring for e.g. the Water Framework Directive but there may be several years between first occurrence and first detection. Also, this species has a benthic lifestyle and often lives in marshlike habitats which are difficult to sample. New detection methods, e.g. environmental DNA (eDNA) may be used for better and quicker detection of this cryptic species (Brys et al. 2020).

**Qu. 3.8a. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response: Much of the RA area offers suitable habitat for oriental weatherfish. The corridors provide a perfect pathway between the suitable habitats in different river catchments. There are no data about the presence of oriental weatherfish in canals in the RA area. In other introduced areas e.g. Belcik (2017) reported that the oriental weatherfish used the North Shore Channel and the Chicago Sanitary and Ship Canal to move from the Lake Michigan Basin side toward the rivers and tributaries of the Mississippi River Basin.

**Qu. 3.9a. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area. (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: No information has been found on the spread potential through this pathway in the RA area, but considering the moderate expected spread by natural means and the estimated relatively low number of existing populations of oriental weatherfish in the RA area, the rate of spread based on this pathway is thought to be moderate even though environmental conditions are favourable in most MS of the RA area.

**Qu. 3.10. Within the risk assessment area, how difficult would it be to contain the organism in relation to these pathways of spread?**

<b>RESPONSE</b>	very easy easy with some difficulty difficult <b>very difficult</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: Natural spread is very difficult to contain. In the RA area most river catchments are connected by artificial canals. Once oriental weatherfish is introduced, it will spread almost unnoticed, until one or a few specimens are coincidentally detected. Containment of this species in large river and other natural water systems is almost impossible, in common with most fish species. In smaller systems oriental weatherfish may be contained using piscicides (e.g. rotenone) but with high collateral damage. Also, piscicides may have legal restrictions of its use in several Member States of the RA area.

**Qu. 3.11. Estimate the overall potential rate of spread in relevant biogeographical regions under current conditions for this organism in the risk assessment area (indicate any key issues and provide quantitative data where possible).**

Thorough assessment of the risk of spread in relevant biogeographical regions in current conditions, providing insight in the risk of spread into (new areas in) the risk assessment area.

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: Oriental weatherloach do not appear to undertake migrations over long distances as part of their life-cycle (Lucas and Barras 2001). However, little appears to be known about their general movement patterns (Koster et al. 2002). As indicated in Q 3.1, the rate of spread in most countries and continents is not very fast (probably less than 10 km per year). A study by Schultz (1960) determined that in the Shiawassee River in Michigan, their expansion was slow, around 0.8 km per year but a study conducted in Australia concluded that oriental weatherfish can expand their range more quickly at about 7.2 km per year (Lintermans et al. 1990). Frable (2008) states that within just two years, oriental weatherfish populations had spread more than 35km in Washington. Koster et al. (2002) report that oriental weatherfish may be restricted in their ability to colonise in an upstream direction.

Currently there are only a few known established populations of oriental weatherfish in the RA area and, despite the high availability of suitable habitat, it is estimated that the overall potential rate of spread under current conditions is rather slow. The spread via corridors (e.g. canals) and through natural waterways is probably only of importance for Member States/regions with neighbouring existing populations in the RA area.

**Qu. 3.12. Estimate the overall potential rate of spread in relevant biogeographical regions in foreseeable climate change conditions (provide quantitative data where possible).**

Thorough assessment of the risk of spread in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk, specifically if rates of spread are likely slowed down or accelerated.

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: Although the establishment potential is expected to increase in the foreseeable climate change conditions (see Qs A7 and A9), the rate of spread rate is not expected to change compared to current conditions.

## 4 MAGNITUDE OF IMPACT

Important instructions:

- Questions 4.1-4.5 relate to biodiversity and ecosystem impacts, 4.6-4.8 to impacts on ecosystem services, 4.9-4.13 to economic impact, 4.14-4.15 to social and human health impact, and 4.16-4.18 to other impacts. These impacts can be interlinked, for example, a disease may cause impacts on biodiversity and/or ecosystem functioning that leads to impacts on ecosystem services and finally economic impacts. In such cases the assessor should try to note the different impacts where most appropriate, cross-referencing between questions when needed.
- Each set of questions starts with the impact elsewhere in the world, then considers impacts in the risk assessment area (=EU+UK, excluding outermost regions) separating known impacts to date (i.e. past and current impacts) from potential future impacts (including foreseeable climate change).
- Only negative impacts are considered in this section (socio-economic benefits are considered in Qu. A.7)
- ##

### Biodiversity and ecosystem impacts

**Qu. 4.1. How important is the impact of the organism on biodiversity at all levels of organisation caused by the organism in its non-native range excluding the risk assessment area?**

including the following elements:

- Biodiversity means the variability among living organisms from all sources, including terrestrial, marine and other aquatic ecosystems and the ecological complexes of which they are part; this includes diversity within species, between species and of ecosystems
- impacted chemical, physical or structural characteristics and functioning of ecosystems

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: Fredberg et al. (2014) suggest several potential impacts of oriental weatherfish in Australia including competition for spawning sites and for food and shelter, disturbance and/or predation of fish and frog eggs, alteration of habitat and decreased water quality. They, however, concluded that these impacts were largely speculative and further research is needed to fill several knowledge gaps.

For the USA, the U.S. Fish and Wildlife Service (2012) reported that there is a high risk of impacts because this species is highly adaptable, quick to reproduce, and is extremely popular in the aquaculture and aquarium industry. The climate match with the native range is high and multiple impacts are expected (reductions in macroinvertebrate populations, altered aquatic habitats, and the fish are vectors for certain fish parasites).

Several authors reported adverse impacts but most of these impacts are anecdotal. For instance, Nobile et al. (2017) sum up possible impacts of established oriental weatherfishes for Brazil as follows: niche overlap, competition for resources and space, introduction of parasites, predation on eggs of fishes and restructuration of the aquatic ecosystem.

Keller and Lake (2007) report the potential impacts for Australia. In a mesocosm experiment, they found that oriental weatherfish caused significant reductions in macroinvertebrate numbers and biomass and that this fish was also associated with elevated ammonia, nitrate/nitrite (NOx), and turbidity levels. However, the authors conclude: “We are not able to conclusively determine that oriental weatherfish are having large impacts in natural systems”.

In Asia, the species is known to hybridize with other species of *Misgurnus* and *Paramisgurnus* (You et al. 2009; Fujimoto et al. 2008a) but it is not clear what the impact of this phenomenon will be. *Misgurnus anguillicaudatus* is known to hybridise naturally with *P. dabryanus* (You et al. 2009). In aquaculture, Fujimoto et al. (2008a) were able to produce hybrids of *M. anguillicaudatus* and *M. mizolepis*.

Schmidt and Schmidt (2014) conclude that *M. anguillicaudatus* does not seem to affect other vertebrates in the Hudson River Valley (New York) but that attention should be paid on the potential negative interactions with the native eastern mudminnow *Umbra pygmaea*.

*M. anguillicaudatus* has been responsible for the establishment of the parasitic flatworm *Gyrodactylus macracanthus* (Dove and Ernst 1998) in Australia. Ogawa (1994) names this loach as host of the gill parasite *Ancyrocephalus cruciatus*, fin parasite *Gyrodactylus micracanthus*, and other unidentified fin and gill parasites of the genus *Gyrodactylus*. *Gyrodactylus* species can potentially infect indigenous fish species and can cause mortalities in aquaculture as was the case with another *Gyrodactylus* parasite (*G. salaris*) in Norway (Salte et al. 2010). *M. anguillicaudatus* can also host the parasite *Acanthocephalus opsariichthydis* (Amin et al. 2007). In addition, the gill parasites *Trichodina lechriodentata* and *Trichodina modesta* were found in oriental weatherfish (Zhao and Tang 2007). Also Reyda et al. (2019) report the introduction of at least three *Gyrodactylus* species in the USA through oriental weatherfish.

**Qu. 4.2. How important is the current known impact of the organism on biodiversity at all levels of organisation (e.g. decline in native species, changes in native species communities, hybridisation) in the risk assessment area (include any past impact in your response)?**

Discuss impacts that are currently occurring or are likely occurring or have occurred in the past in the risk assessment area. Where there is no direct evidence of impact in the risk assessment area (for example no studies have been conducted), evidence from outside of the risk assessment area can be used to infer impacts within the risk assessment area.

<b>RESPONSE</b>	minimal	<b>CONFIDENCE</b>	low
	minor		<b>medium</b>
	moderate		high
	<b>major</b>		
	massive		

Response: No studies were found that explicitly investigate the impact in the RA area. Within the RA area, the same biodiversity impacts as in Qu 4.1., however, can be assumed. Of major concern is the fact that *M. anguillicaudatus* is known to hybridise naturally with other weatherfishes e.g. with *P. dabryanus* (You et al. 2009). Artificial reproduction was used to successfully crossbreed *M. anguillicaudatus* with the native *M. fossilis* (J. Wanzenböck, pers. comm.). The European weatherfish *M. fossilis* is highly endangered in parts of its native territory, e.g. Belgium (Verreycken et al. 2014) with populations declining everywhere in the EU (Freyhof and Brooks 2011). Co-occurrence of a close relative of the oriental weatherfish, *M. bipartitus*, with European weatherfish was found in sites in the Netherlands and in Belgium and because *M. bipartitus* occurs in much larger numbers than the rare European weatherfish, the latter is automatically exposed to a much greater hybridization pressure (Brys et al. 2020).

**Qu. 4.3. How important is the potential future impact of the organism on biodiversity at all levels of organisation likely to be in the risk assessment area?**

See comment above. The potential future impact shall be assessed only for the risk assessment area.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: Probably the current potential impact will not change much in the near future. However, if *M. anguillicaudatus* spreads further and more oriental weatherfish populations would establish then the potential impact might increase. Especially in areas where *M. fossilis* populations are declining, the relative pressure of *M. anguillicaudatus* on this native species will be higher in the future. Also when higher densities of oriental weatherfish occur, there could be other impacts, for example alteration of macroinvertebrate communities and decline of water quality in lakes and streams (Keller and Lake 2007).

**Qu. 4.4. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism currently in the risk assessment area?**

including the following elements:

- native species impacted, including red list species, endemic species and species listed in the Birds and Habitats directives
- protected sites impacted, in particular Natura 2000
- habitats impacted, in particular habitats listed in the Habitats Directive, or red list habitats
- the ecological status of water bodies according to the Water Framework Directive and environmental status of the marine environment according to the Marine Strategy Framework Directive

<b>RESPONSE</b>	minimal minor	<b>CONFIDENCE</b>	low <b>medium</b>
-----------------	------------------	-------------------	----------------------

	moderate <b>major</b> massive		high
--	-------------------------------------	--	------

Response: The European weatherfish is protected by EU law (Habitats Directive Annex II and Bern Convention Annex III). It is listed as a species of least concern but as declining everywhere in the native range on the IUCN Red List of Threatened Species (Freyhof and Brooks 2011). Hartvich et al. (2010) report the conservation status of *M. fossilis* as follows: Endangered on the Red List in the Czech Republic; Danger of extinction, category 1 in Austria; Vulnerable in Croatia, Near Threatened in Slovakia and Vulnerable in Poland. The species is also listed as Endangered on the Red List of Flanders (Belgium) (Verreycken et al. 2014) and as Vulnerable on the Red List of The Netherlands (Spikmans and Kranenbarg 2016). The goal to preserve and improve populations of *M. fossilis* in the EU can be seriously hampered by the presence of oriental weatherfish through possible competition and hybridization. Probably no other native species are impacted directly by the oriental weatherfish as there are no closely related species present in the RA area.

The impact of oriental weatherfish on protected sites in the RA area (e.g. Natura 2000 habitats or particular habitats listed in the Habitats Directive) is not clear. However, as oriental weatherfish was associated with elevated ammonia, nitrate/nitrite (NO<sub>x</sub>), and turbidity levels in mesocosm experiments in Australia (Keller and Lake 2007), the impact on these protected habitats may become moderate to major should high densities of oriental weatherfish establish there.

Also the ecological status of water bodies according to the Water Framework Directive (WFD) can be lower due to the presence of non-native species. Some groups (e.g. habitat-sensitive) fish species are of great importance for the WFD assessment of certain water types. Water managers assess the ecological status of waters, among other things, on the relative share of "habitat sensitive" species in the WFD assessment. The negative effects on these species as a result of competition with non-native species may have a negative effect on the results of WFD assessments (van Kessel et al. 2013b).

**Qu. 4.5. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.4.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: No major changes are expected for the future. However, should *M. anguillicaudatus* further expand its spread and establish in more sites and at higher densities, then slightly higher impacts as mentioned in Qu. 4.4. can be expected.

## Ecosystem Services impacts

**Qu. 4.6. How important is the impact of the organism on provisioning, regulating, and cultural services in its non-native range excluding the risk assessment area?**

- For a list of services use the CICES classification V5.1 provided in Annex V.
- Impacts on ecosystem services build on the observed impacts on biodiversity (habitat, species, genetic, functional) but focus exclusively on reflecting these changes in relation to their links with socio-economic well-being.
- Quantitative data should be provided whenever available and references duly reported.
- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: No information has been found on the issue but two ecosystem services impacts can be possible in a minor form (1) Provisioning/Genetic material/ Genetic material from animals i.e. possible loss of local genetic material of *M. fossilis* as a consequence of hybridisation with oriental weatherfish (Brys et al. 2020) and (2) Regulations and Maintenance/Regulation of physical/chemical/biological condition/Water condition through elevated ammonia, nitrate/nitrite (NOx), and turbidity levels (Keller and Lake 2007).

**Qu. 4.7. How important is the impact of the organism on provisioning, regulating, and cultural services currently in the different biogeographic regions or marine sub-regions where the species has established in the risk assessment area (include any past impact in your response)?**

- See guidance to Qu. 4.6.

<b>RESPONSE</b>	N/A minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: No information has been found on the issue.

**Qu. 4.8. How important is the impact of the organism on provisioning, regulating, and cultural services likely to be in the different biogeographic regions or marine sub-regions where the**

**species can establish in the risk assessment area in the future?**

- See guidance to Qu. 4.6.

<b>RESPONSE</b>	N/A minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response: No information has been found on the issue.

## Economic impacts

**Qu. 4.9. How great is the overall economic cost caused by the organism within its current area of distribution (excluding the risk assessment area), including both costs of / loss due to damage and the cost of current management.**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the world these should be reported here. The assessment of the potential costs of / loss due to damage shall describe those costs quantitatively and/or qualitatively depending on what information is available. Cost of / loss due to damage within different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage. As far as possible, it would be useful to separate costs of / loss due to the organism from costs of current management.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: No economic costs (e.g. management) of this species are mentioned. Established populations of oriental weatherfish are not actively managed in any state or territory in Australia, nor at a national level (Koster et al. 2002) but eradication with rotenone was trialled in the Wingecarribee River system and was unsuccessful. Eradication campaigns with rotenone are known to be costly. In the USA, rotenone treatments of large areas to remove (but not completely eradicate) common carps and ictalurid catfishes were reported to cost between US\$25,000 for 31 ha ( $\approx$  €730/ha) and US\$40,000 for 492 ha ( $\approx$ €74/ha) (U.S. Fish and Wildlife Service - Environmental Conservation Online System, 2020). In Hawaii, the control of tilapia with rotenone (CFT Legumine) was estimated to cost US\$5000 for 81 ha (€56/ha) (only product was counted, not personnel and equipment) (Tavares 2009).

**Qu. 4.10. How great is the economic cost of / loss due to damage (excluding costs of**

**management) of the organism currently in the risk assessment area (include any past costs in your response)?**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the EU these should be reported here. Assessment of the potential costs of damage on human health, safety, and the economy, including the cost of non-action. A full economic assessment at EU scale might not be possible, but qualitative data or different case studies from across the EU (or third countries if relevant) may provide useful information to inform decision making. In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. Cost of / loss due to damage within different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: No economic costs of this species are known.

**Qu. 4.11. How great is the economic cost of / loss due to damage (excluding costs of management) of the organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.10.

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: No economic costs of this species are known for the current nor future situation.

**Qu. 4.12. How great are the economic costs / losses associated with managing this organism currently in the risk assessment area (include any past costs in your response)?**

- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”.

<b>RESPONSE</b>	minimal minor	<b>CONFIDENCE</b>	<b>low</b> medium
-----------------	------------------	-------------------	----------------------

	<b>moderate</b> major massive		high
--	-------------------------------------	--	------

Response: The only reported management programme of oriental weatherfish in the RA area is for the Netherlands. Efforts to eradicate (or at least manage) the Dutch population (Binnendijk et al. 2017) failed. Over several years and multiple times per year Binnendijk et al. (2017) tried to catch (with dipnets and electrofishing) as many loaches as possible and removed them from the infested site. Although many specimens were captured (n= 763), eradication efforts were stopped because the numbers kept increasing with new and smaller young-of-the-year individuals (i.e. natural reproduction) caught each year. The costs of these management efforts were not reported. Other eradication methods were deemed unfeasible on the basis of financial, practical, ecological or legal reasons (Binnendijk et al. 2017).

**Qu. 4.13. How great are the economic costs / losses associated with managing this organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.12.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: Currently no targeted management schemes exist for oriental weatherfish in the RA area. In the past, only one management programme of oriental weatherfish in the RA area was reported (i.e. for the Netherlands (Binnendijk et al. 2017)). However, if *M. anguillicaudatus* were to further spread and establish large populations, then management costs would increase with expanding populations.

## Social and human health impacts

**Qu. 4.14. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism for the risk assessment area and for third countries, if relevant (e.g. with similar eco-climatic conditions).**

The description of the known impact and the assessment of potential future impact on human health, safety and the economy, shall, if relevant, include information on

- illnesses, allergies or other affections to humans that may derive directly or indirectly from a species;
- damages provoked directly or indirectly by a species with consequences for the safety of people, property or infrastructure;
- direct or indirect disruption of, or other consequences for, an economic or social activity due to the presence of a species.

Social and human health impacts can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>	<b>minimal</b> minor moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: No information has been found on the issue and although no information on social and human health impacts is available for the RA area, it can be assumed that this is only minimal since reports from other (longer) invaded areas (e.g. Australia and the USA) do not explicitly mention these impacts either (Frable 2008, Koster et al. 2002).

**Qu. 4.15. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism in the future for the risk assessment area.**

- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”.

<b>RESPONSE</b>	<b>minimal</b> minor moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: No information has been found on the issue but see previous answer.

## Other impacts

**Qu. 4.16. How important is the organism in facilitating other damaging organisms (e.g. diseases) as food source, a host, a symbiont or a vector etc.?**

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response: *Misgurnus anguillicaudatus* has been responsible for the establishment of the parasitic flatworm *Gyrodactylus macracanthus* (Dove and Ernst 1998) in Australia. Ogawa (1994) names this

loach as host of the gill parasite *Ancyrocephalus cruciatus*, fin parasite *Gyrodactylus micracanthus*, and other unidentified fin and gill parasites of the genus *Gyrodactylus*. *Misgurnus anguillicaudatus* can also host the parasite *Acanthocephalus opsariichthydis* (Amin et al. 2007). In addition, also the gill parasites *Trichodina lechriodontata* and *Trichodina modesta* were found in oriental weatherfish (Zhao and Tang 2007). Reyda et al. (2019) report the introduction of at least three *Gyrodactylus* species in the USA through oriental weatherfish. These parasites can potentially infect indigenous fish species and can cause mortalities in aquaculture as was the case with another *Gyrodactylus* parasite (*G. salaris*) in Norway (Salte et al. 2010).

**Qu. 4.17. How important might other impacts not already covered by previous questions be resulting from introduction of the organism?**

RESPONSE	N/A	CONFIDENCE	
	minimal		low
	minor		medium
	moderate		high
	major		
	massive		

Response: No information has been found on the issue.

**Qu. 4.18. How important are the expected impacts of the organism despite any natural control by other organisms, such as predators, parasites or pathogens that may already be present in the risk assessment area?**

RESPONSE		CONFIDENCE	
	minimal		low
	minor		<b>medium</b>
	<b>moderate</b>		high
	major		
	massive		

Response: The main impact of oriental weatherfish could be the possible hybridisation with the native, endangered European weatherfish *M. fossilis* (Brys et al. 2020). However, it can also indirectly affect native species through competition (e.g. for food (Schmidt and Schmidt 2014) and may affect the aquatic environment by modifying conditions such as altering water quality (Keller and Lake 2007). The natural control of the populations of oriental weatherfish by other organisms may be limited but their role is mostly unknown. Though there have been occasional reports of oriental weatherfish being eaten by redbfin perch and brown trout, they often occur in shallow degraded habitats which large native predators may avoid (Koster et al. 2002). In the Dutch population of *M. bipartitus*, top predators like pike *Esox lucius* and perch *Perca fluviatilis* were present in the fish community (Binnendijk et al. 2017) and not limiting the establishment of this invasive species.

**Qu. 4.19. Estimate the overall impact in the risk assessment area under current climate conditions. In addition, details of overall impact in relevant biogeographical regions should be provided.**

Thorough assessment of the overall impact on biodiversity and ecosystem services, with impacts on economy as well as social and human health as aggravating factors, in current conditions.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response: The major concern of *M. anguillicaudatus* is the potential hybridisation with the native *M. fossilis*. The European weatherfish is highly endangered in parts of its native territory with populations declining everywhere in the EU (Freyhof and Brooks 2013). Co-occurrence of oriental weatherfish with European weatherfish can expose a great hybridization pressure on the latter (Brys et al. 2020). Oriental weatherfish can also indirectly affect native species through competition and may affect the aquatic environment by modifying conditions such as altering water quality and uprooting plants (Keller and Lake 2007). *Misgurnus anguillicaudatus* is also identified as carrier of several parasites and some of these (e.g. *Gyrodactylus* species) may be harmful to wild populations of native fish and to the aquaculture industry.

**Qu. 4.20. Estimate the overall impact in the risk assessment area in foreseeable climate change conditions. In addition, details of overall impact in relevant biogeographical regions should be provided.**

Thorough assessment of the overall impact on biodiversity and ecosystem services, with impacts on economy as well as social and human health as aggravating factors, under future conditions.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response: No large changes in impact are to be expected in future climate conditions although some biogeographical regions (see Qu. A7) may have a higher establishment suitability. Little is known about the overall impact in the risk assessment area in the current situation (see Qu. 4.19), however, in the future, the overall impact may increase if more oriental weatherfish populations become established.

<b>RISK SUMMARIES</b>			
	<b>RESPONSE</b>	<b>CONFIDENCE</b>	<b>COMMENT</b>
<b>Summarise Introduction and Entry*</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	low medium <b>high</b>	The oriental weatherfish is present in several member states (MS) of the RA area. Additional introductions are possible and probably ongoing since this species is available via the aquarium trade and the internet. It is also farmed in high numbers in China for the food industry.
<b>Summarise Establishment*</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	low medium <b>high</b>	Several MS have established populations in the wild as a consequence of deliberate introductions and unintentional escapes. The species could currently establish in all EU biogeographic regions and conditions improve for most regions under climate change.
<b>Summarise Spread*</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	low <b>medium</b> high	The rate of spread is not very fast (probably less than 10 km per year). Currently there are only a few known established populations in the RA area and despite the high availability of suitable habitat it is estimated that the overall potential rate of spread under current and future conditions is only moderate.
<b>Summarise Impact*</b>	minimal minor <b>moderate</b> major massive	low <b>medium</b> high	The major concern of <i>M. anguillicaudatus</i> is the potential hybridisation with the endangered native <i>M. fossilis</i> . Oriental weatherfish can also indirectly affect native species through competition and may affect the aquatic environment by modifying conditions such as altering water quality and uprooting plants and carry several parasites which may be harmful to wild populations of native fish and to the aquaculture industry. Future impacts are mostly unknown but may increase if more populations of oriental weatherfish were to establish.
<b>Conclusion of the risk assessment (overall risk)</b>	low moderate <b>high</b>	low <b>medium</b> high	Since the risks of introduction and entry and of establishment are high (with high confidence) and impacts are moderate (with

			medium confidence), the overall risk is high. Specifically, the threat to the endangered native European weatherfish <i>M. fossilis</i> is of great concern.
--	--	--	--

\*in current climate conditions and in foreseeable future climate conditions

## Distribution Summary

Please answer as follows:

- Yes if recorded, established or invasive
- if not recorded, established or invasive
- ? Unknown; data deficient

The columns refer to the answers to Questions A5 to A12 under Section A.

For data on marine species at the Member State level, delete Member States that have no marine borders. In all other cases, provide answers for all columns.

### Member States and the United Kingdom

	Recorded	Established (currently)	Possible establishment (under current climate)	Possible establishment (under foreseeable climate)	Invasive (currently)

## ANNEX I Scoring of Likelihoods of Events

(taken from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

<b>Score</b>	<b>Description</b>	<b>Frequency</b>
Very unlikely	This sort of event is theoretically possible, but is never known to have occurred and is not expected to occur	1 in 10,000 years
Unlikely	This sort of event has occurred somewhere at least once in the last millenium	1 in 1,000 years
Moderately likely	This sort of event has occurred somewhere at least once in the last century	1 in 100 years
Likely	This sort of event has happened on several occasions elsewhere, or on at least once in the last decade	1 in 10 years
Very likely	This sort of event happens continually and would be expected to occur	Once a year

## ANNEX II Scoring of Magnitude of Impacts

(modified from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

Score	Biodiversity and ecosystem impact	Ecosystem Services impact	Economic impact (Monetary loss and response costs per year)	Social and human health impact, and other impacts
	<i>Question 5.1-5</i>	<i>Question 5.6-8</i>	<i>Question 5.9-13</i>	<i>Question 5.14-18</i>
Minimal	Local, short-term population loss, no significant ecosystem effect	No services affected <sup>8</sup>	Up to 10,000 Euro	No social disruption. Local, mild, short-term reversible effects to individuals.
Minor	Some ecosystem impact, reversible changes, localised	Local and temporary, reversible effects to one or few services	10,000-100,000 Euro	Significant concern expressed at local level. Mild short-term reversible effects to identifiable groups, localised.
Moderate	Measureable long-term damage to populations and ecosystem, but reversible; little spread, no extinction	Measureable, temporary, local and reversible effects on one or several services	100,000-1,000,000 Euro	Temporary changes to normal activities at local level. Minor irreversible effects and/or larger numbers covered by reversible effects, localised.
Major	Long-term irreversible ecosystem change, spreading beyond local area	Local and irreversible or widespread and reversible effects on one / several services	1,000,000-10,000,000 Euro	Some permanent change of activity locally, concern expressed over wider area. Significant irreversible effects locally or reversible effects over large area.
Massive	Widespread, long-term population loss or extinction, affecting several species with serious ecosystem effects	Widespread and irreversible effects on one / several services	Above 10,000,000 Euro	Long-term social change, significant loss of employment, migration from affected area. Widespread, severe, long-term, irreversible health effects.

<sup>8</sup> Not to be confused with “no impact”.

## ANNEX III Scoring of Confidence Levels

(modified from Bacher et al. 2017)

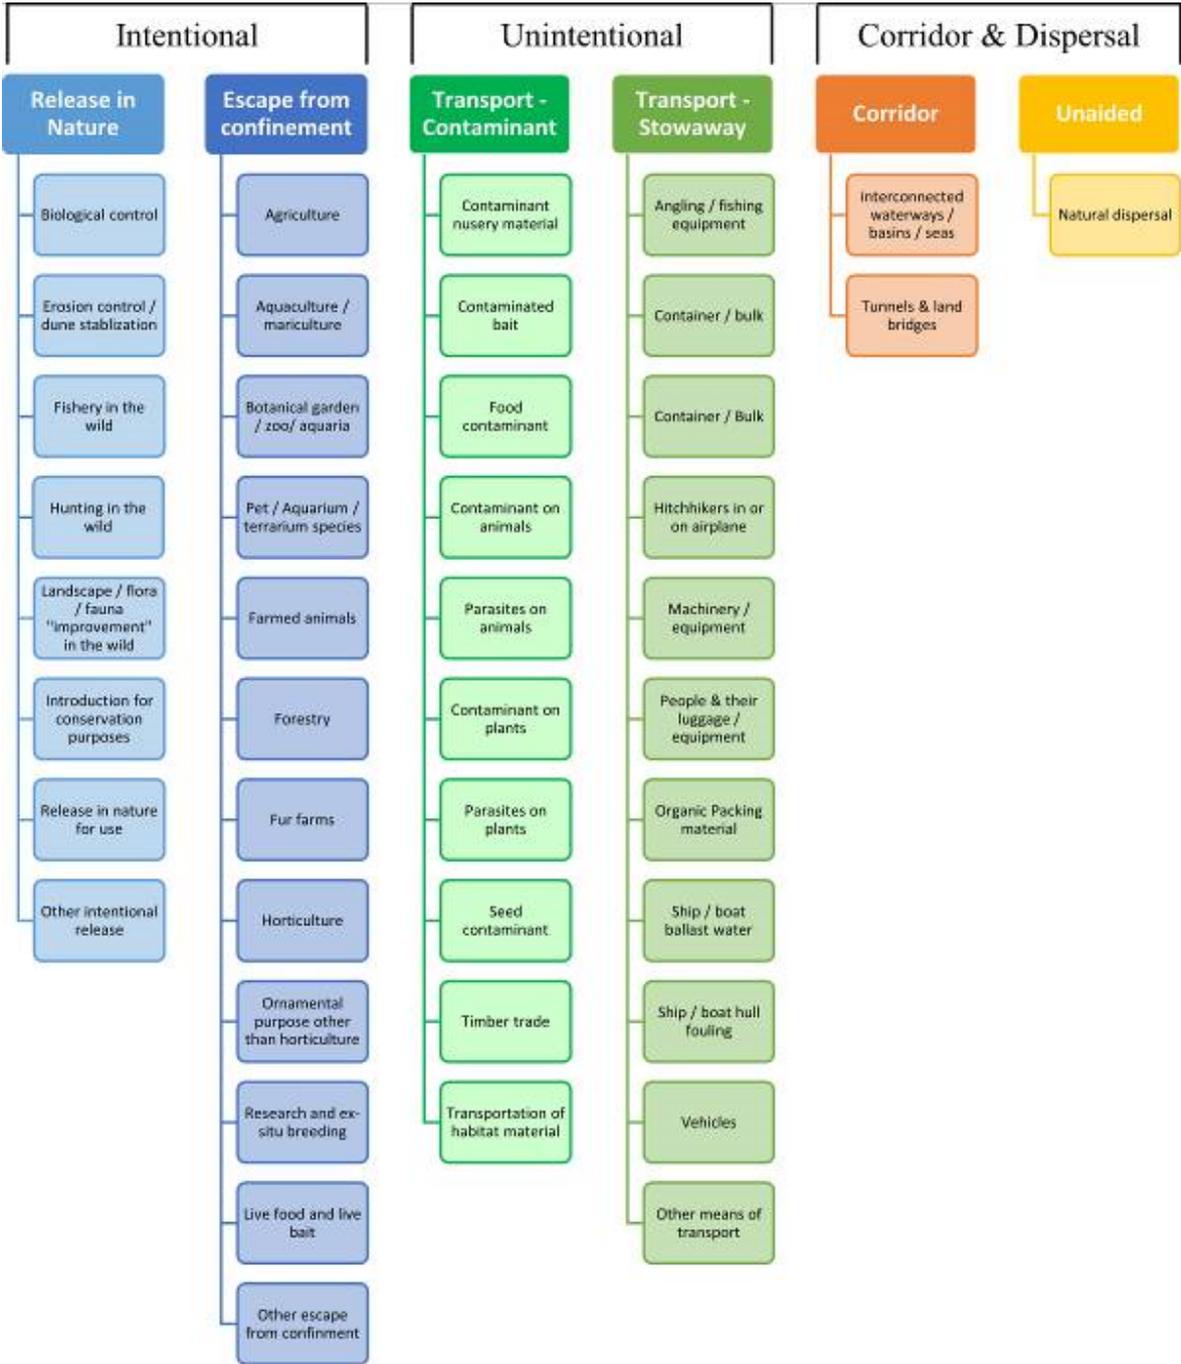

Each answer provided in the risk assessment must include an assessment of the level of confidence attached to that answer, reflecting the possibility that information needed for the answer is not available or is insufficient or available but conflicting.

The responses in the risk assessment should clearly support the choice of the confidence level.

Confidence level	Description
Low	There is no direct observational evidence to support the assessment, e.g. only inferred data have been used as supporting evidence <i>and/or</i> Impacts are recorded at a spatial scale which is unlikely to be relevant to the assessment area <i>and/or</i> Evidence is poor and difficult to interpret, e.g. because it is strongly ambiguous <i>and/or</i> The information sources are considered to be of low quality or contain information that is unreliable.
Medium	There is some direct observational evidence to support the assessment, but some information is inferred <i>and/or</i> Impacts are recorded at a small spatial scale, but rescaling of the data to relevant scales of the assessment area is considered reliable, or to embrace little uncertainty <i>and/or</i> The interpretation of the data is to some extent ambiguous or contradictory.
High	There is direct relevant observational evidence to support the assessment (including causality) <i>and</i> Impacts are recorded at a comparable scale <i>and/or</i> There are reliable/good quality data sources on impacts of the taxa <i>and</i> The interpretation of data/information is straightforward <i>and/or</i> Data/information are not controversial or contradictory.

# ANNEX IV CBD pathway categorisation scheme

Overview of CBD pathway categorisation scheme showing how the 44 pathways relate to the six main pathway categories. All of the pathways can be broadly classified into 1) those that involve intentional transport (blue), 2) those in which the taxa are unintentionally transported (green) and 3) those where taxa moved between regions without direct transportation by humans and/or via artificial corridors (orange and yellow). **Note that the pathways in the category “Escape from confinement” can be considered intentional for the introduction into the risk assessment area and unintentional for the entry into the environment.**

## ANNEX V Ecosystem services classification (CICES V5.1, simplified) and examples

For the purposes of this risk assessment, please feel free to use what seems as the most appropriate category / level / combination of impact (Section – Division – Group), reflecting information available.

Section	Division	Group	Examples (i.e. relevant CICES “classes”)
Provisioning	Biomass	<b>Cultivated <i>terrestrial</i> plants</b>	<p>Cultivated terrestrial plants (including fungi, algae) grown for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from cultivated plants, fungi, algae and bacteria for direct use or processing (excluding genetic materials);            Cultivated plants (including fungi, algae) grown as a <u>source of energy</u></p> <p><i>Example: negative impacts of non-native organisms to crops, orchards, timber etc.</i></p>
		<b>Cultivated <i>aquatic</i> plants</b>	<p>Plants cultivated by in- situ aquaculture grown for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from in-situ aquaculture for direct use or processing (excluding genetic materials);            Plants cultivated by in- situ aquaculture grown as an <u>energy source</u>.</p> <p><i>Example: negative impacts of non-native organisms to aquatic plants cultivated for nutrition, gardening etc. purposes.</i></p>
		<b>Reared animals</b>	<p>Animals reared for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from reared animals for direct use or processing (excluding genetic materials);            Animals reared to provide <u>energy</u> (including mechanical)</p> <p><i>Example: negative impacts of non-native organisms to livestock</i></p>
		<b>Reared <i>aquatic</i> animals</b>	<p>Animals reared by in-situ aquaculture for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from animals grown by in-situ aquaculture for direct use or processing (excluding genetic materials);            Animals reared by in-situ aquaculture as an <u>energy source</u></p> <p><i>Example: negative impacts of non-native organisms to fish farming</i></p>
		<b>Wild plants</b> (terrestrial and aquatic)	<p>Wild plants (terrestrial and aquatic, including fungi, algae) used for <u>nutrition</u>;  <u>Fibres and other materials</u> from wild plants for direct use or processing (excluding genetic materials);            Wild plants (terrestrial and aquatic, including fungi, algae) used as a <u>source of energy</u></p> <p><i>Example: reduction in the availability of wild plants (e.g. wild berries, ornamentals) due to non-native organisms (competition, spread of disease etc.)</i></p>
		<b>Wild animals</b> (terrestrial and aquatic)	<p>Wild animals (terrestrial and aquatic) used for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from wild animals for direct use or processing (excluding genetic materials);            Wild animals (terrestrial and aquatic) used as a <u>source of energy</u></p> <p><i>Example: reduction in the availability of wild animals (e.g. fish stocks, game) due to non-native organisms (competition,</i></p>

			<i>predations, spread of disease etc.)</i>
	<b>Genetic material</b> from all biota	<b>Genetic material</b> from plants, algae or fungi	<p><u>Seeds, spores and other plant materials</u> collected for maintaining or establishing a population; Higher and lower plants (whole organisms) used to <u>breed new strains or varieties</u>; Individual genes extracted from higher and lower plants for the <u>design and construction of new biological entities</u></p> <p><i>Example: negative impacts of non-native organisms due to interbreeding</i></p>
		<b>Genetic material</b> from animals	<p>Animal material collected for the purposes of maintaining or establishing a population; Wild animals (whole organisms) used to breed new strains or varieties; Individual genes extracted from organisms for the design and construction of new biological entities</p> <p><i>Example: negative impacts of non-native organisms due to interbreeding</i></p>
	<b>Water<sup>9</sup></b>	<b>Surface water</b> used for nutrition, materials or energy	<p>Surface water for <u>drinking</u>; Surface water used as a material (<u>non-drinking purposes</u>); Freshwater surface water, coastal and marine water used as an <u>energy source</u></p> <p><i>Example: loss of access to surface water due to spread of non-native organisms</i></p>
		<b>Ground water</b> for used for nutrition, materials or energy	<p>Ground (and subsurface) water for <u>drinking</u>; Ground water (and subsurface) used as a material (<u>non-drinking purposes</u>); Ground water (and subsurface) used as an <u>energy source</u></p> <p><i>Example: reduced availability of ground water due to spread of non-native organisms and associated increase of ground water consumption by vegetation.</i></p>
<b>Regulation &amp; Maintenance</b>	Transformation of biochemical or physical inputs to ecosystems	<b>Mediation of wastes or toxic substances</b> of anthropogenic origin by living processes	<p><u>Bio-remediation</u> by micro-organisms, algae, plants, and animals; <u>Filtration/sequestration/storage/accumulation</u> by micro-organisms, algae, plants, and animals</p> <p><i>Example: changes caused by non-native organisms to ecosystem functioning and ability to filtrate etc. waste or toxics</i></p>
		<b>Mediation of nuisances</b> of anthropogenic origin	<p><u>Smell reduction</u>; <u>noise attenuation</u>; <u>visual screening</u> (e.g. by means of green infrastructure)</p> <p><i>Example: changes caused by non-native organisms to ecosystem structure, leading to reduced ability to mediate nuisances.</i></p>
	Regulation of physical, chemical, biological conditions	<b>Baseline flows and extreme event</b> regulation	<p>Control of <u>erosion</u> rates; Buffering and attenuation of <u>mass movement</u>; <u>Hydrological cycle and water flow regulation</u> (Including flood control, and coastal protection); <u>Wind</u> protection; <u>Fire</u> protection</p> <p><i>Example: changes caused by non-native organisms to ecosystem functioning or structure leading to, for example, destabilisation of soil, increased risk or intensity of wild fires etc.</i></p>

<sup>9</sup> Note: in the CICES classification provisioning of water is considered as an abiotic service whereas the rest of ecosystem services listed here are considered biotic.

		<p><b>Lifecycle maintenance, habitat and gene pool protection</b></p>	<p><u>Pollination</u> (or 'gamete' dispersal in a marine context); <u>Seed dispersal</u>; Maintaining <u>nursery populations and habitats</u> (Including gene pool protection)</p> <p><i>Example: changes caused by non-native organisms to the abundance and/or distribution of wild pollinators; changes to the availability / quality of nursery habitats for fisheries</i></p>
		<p><b>Pest and disease control</b></p>	<p>Pest control; Disease control</p> <p><i>Example: changes caused by non-native organisms to the abundance and/or distribution of pests</i></p>
		<p><b>Soil quality regulation</b></p>	<p><u>Weathering processes</u> and their effect on soil quality; <u>Decomposition and fixing processes</u> and their effect on soil quality</p> <p><i>Example: changes caused by non-native organisms to vegetation structure and/or soil fauna leading to reduced soil quality</i></p>
		<p><b>Water conditions</b></p>	<p>Regulation of the <u>chemical condition</u> of freshwaters by living processes; Regulation of the chemical condition of salt waters by living processes</p> <p><i>Example: changes caused by non-native organisms to buffer strips along water courses that remove nutrients in runoff and/or fish communities that regulate the resilience and resistance of water bodies to eutrophication</i></p>
		<p><b>Atmospheric composition and conditions</b></p>	<p>Regulation of <u>chemical composition</u> of atmosphere and oceans; Regulation of <u>temperature and humidity</u>, including ventilation and transpiration</p> <p><i>Example: changes caused by non-native organisms to ecosystems' ability to sequester carbon and/or evaporative cooling (e.g. by urban trees)</i></p>
Cultural	Direct, in-situ and outdoor interactions with living systems that depend on presence in the environmental setting	<p><b>Physical and experiential interactions with natural environment</b></p>	<p>Characteristics of living systems that that enable activities promoting health, recuperation or enjoyment through <u>active or immersive interactions</u>;</p> <p>Characteristics of living systems that enable activities promoting health, recuperation or enjoyment through <u>passive or observational interactions</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that make it attractive for recreation, wild life watching etc.</i></p>
		<p><b>Intellectual and representative interactions with natural environment</b></p>	<p>Characteristics of living systems that enable <u>scientific investigation</u> or the creation of traditional ecological knowledge;</p> <p>Characteristics of living systems that enable <u>education and training</u>;</p> <p>Characteristics of living systems that are resonant in terms of <u>culture or heritage</u>;</p> <p>Characteristics of living systems that enable <u>aesthetic experiences</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have cultural importance</i></p>

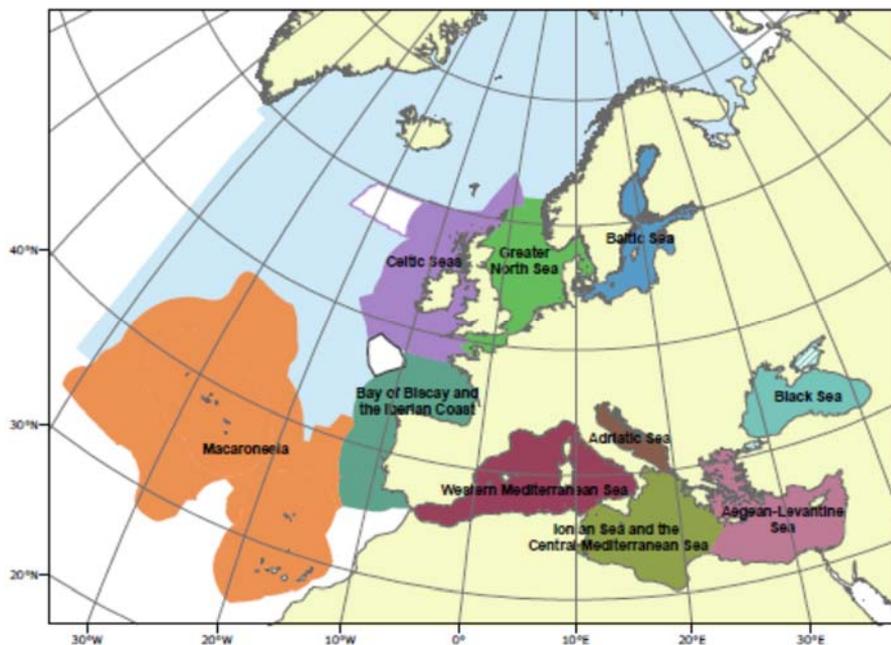

<p><b>Indirect, remote, often indoor interactions</b> with living systems that do not require presence in the environmental setting</p>	<p><b>Spiritual, symbolic</b> and other interactions with natural environment</p>	<p>Elements of living systems that have <u>symbolic meaning</u>;  Elements of living systems that have <u>sacred or religious meaning</u>;  Elements of living systems used for <u>entertainment or representation</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have sacred or religious meaning</i></p>
	<p>Other biotic characteristics that have a <b>non-use value</b></p>	<p>Characteristics or features of living systems that have an <u>existence value</u>;  Characteristics or features of living systems that have an <u>option or bequest value</u></p> <p><i>Example: changes caused by non-native organisms to ecosystems designated as wilderness areas, habitats of endangered species etc.</i></p>

## ANNEX VI EU Biogeographic Regions and MSFD Subregions

See <https://www.eea.europa.eu/data-and-maps/figures/biogeographical-regions-in-europe-2>,

## ANNEX VIII Species Distribution Model

### Projection of environmental suitability for *Misgurnus anguillicaudatus* establishment in Europe

Björn Beckmann, Hugo Verreycken and Dan Chapman

08 October 2020

#### Aim

To project the suitability for potential establishment of *Misgurnus anguillicaudatus* in Europe, under current and predicted future climatic conditions.

#### Data for modelling

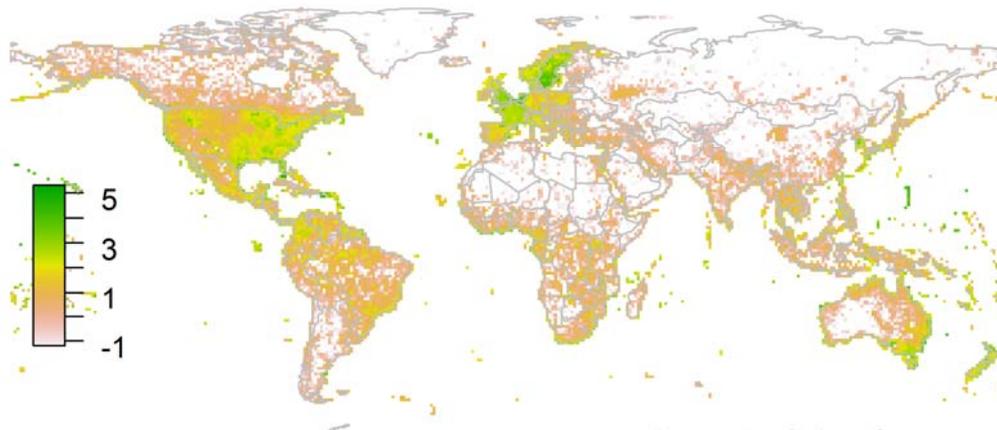

Species occurrence data were obtained from the Global Biodiversity Information Facility (GBIF) (8448 records), the Atlas of Living Australia (979 records), the Integrated Digitized Biocollections (iDigBio) (219 records), iNaturalist (181 records), the Biodiversity Information Serving Our Nation database (BISON) (109 records), the Berkeley Ecoinformatics Engine database (1 records), and 18 additional records from the risk assessment team which were not included in the above and taken from individual publications. We scrutinised occurrence records from regions where the species is not known to be established and removed any dubious records (e.g. fossils) or where the georeferencing was too imprecise (e.g. records referenced to a country or island centroid) or outside of the coverage of the predictor layers (e.g. small island or coastal occurrences). The remaining records were gridded at a 0.25 x 0.25 degree resolution for modelling, yielding 494 grid cells with occurrences (Figure 1a). As a proxy for recording effort, the density of Actinopterygii records held by GBIF was also compiled on the same grid (Figure 1b).

**Figure 1.** (a) Occurrence records obtained for *Misgurnus anguillicaudatus* and used in the modelling, showing native and invaded distributions. (b) The recording density of Actinopterygii on GBIF, which was used as a proxy for recording effort.

(a) Species distribution used in modelling

(b) Estimated recording effort (log10-scaled)

Climate data were selected from the 'Bioclim' variables contained within the WorldClim database (Hijmans et al., 2005), originally at 5 arcminute resolution (0.083 x 0.083 degrees of longitude/latitude) and aggregated to a 0.25 x 0.25 degree grid for use in the model.

Based on the biology of *Misgurnus anguillicaudatus*, the following climate variables were used in the modelling:

- Temperature seasonality (Bio4)
- Maximum temperature of the warmest month (Bio5)
- Minimum temperature of the coldest month (Bio6)
- Annual precipitation (Bio12)
- Precipitation seasonality (Bio15)

To estimate the effect of climate change on the potential distribution, equivalent modelled future climate conditions for the 2070s under the Representative Concentration Pathways (RCP) 2.6 and 4.5 were also obtained. These represent low and medium emissions scenarios, respectively. The above variables were obtained as averages of outputs of eight Global Climate Models (BCC-CSM1-1, CCSM4, GISS-E2-R, HadGEM2-AO, IPSL-CM5A-LR, MIROC-ESM, MRI-CGCM3, NorESM1-M), downscaled and calibrated against the WorldClim baseline (see [http://www.worldclim.org/cmip5\\_5m](http://www.worldclim.org/cmip5_5m)).

The following habitat layers were also used:

- Human influence index (HII): As many non-native invasive species associate with anthropogenically disturbed habitats. We used the Global Human Influence Index Dataset of the Last of the Wild Project (Wildlife Conservation Society - WCS & Center for International Earth Science Information Network - CIESIN - Columbia University, 2005), which is developed from nine global data layers covering human population pressure (population density), human land use and infrastructure (built-up areas, nighttime lights, land use/land cover) and human access (coastlines, roads, railroads, navigable rivers). The index ranges between 0 and 1 and was  $\ln+1$  transformed for the modelling to improve normality.

### Species distribution model

A presence-background (presence-only) ensemble modelling strategy was employed using the BIOMOD2 R package version 3.4.6 (Thuiller et al., 2020, Thuiller et al., 2009). These models contrast the environment at the species' occurrence locations against a random sample of the global background environmental conditions (often termed 'pseudo-absences') in order to characterise and project suitability for occurrence. This approach has been developed for distributions that are in equilibrium with the environment. Because invasive species' distributions are not at equilibrium and subject to dispersal constraints at a global scale, we took care to minimise the inclusion of locations suitable for the species but where it has not been able to disperse to (Chapman et al. 2019).

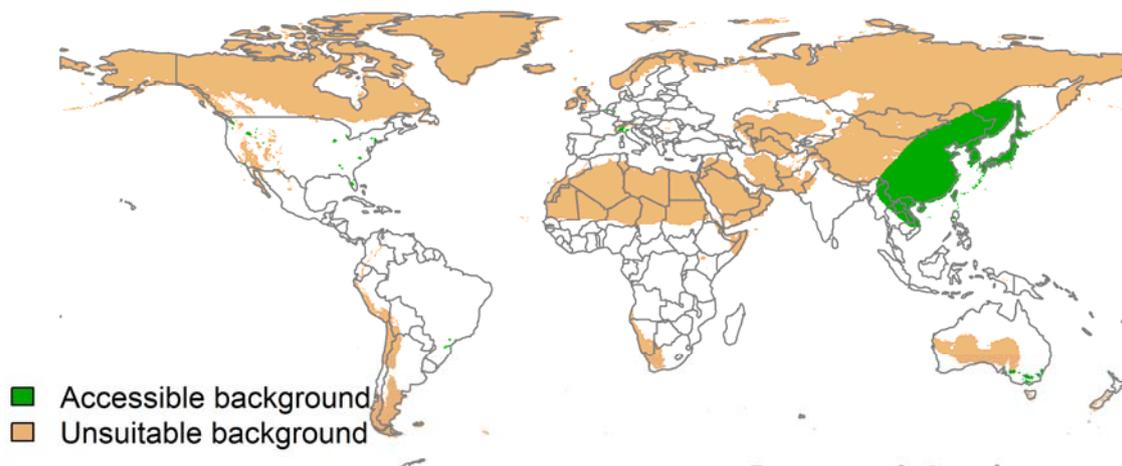

Therefore the background sampling region included:

- The area accessible by native *Misgurnus anguillicaudatus* populations, in which the species is likely to have had sufficient time to disperse to all locations. Based on presumed maximum dispersal distances, the accessible region was defined as a 400km buffer around the native range occurrences; AND
- A 30km buffer around the non-native occurrences, encompassing regions likely to have had high propagule pressure for introduction by humans and/or dispersal of the species; AND
- Regions where we have an *a priori* expectation of high unsuitability for the species so that absence is assumed irrespective of dispersal constraints (see Figure 2). The following rules were applied to define a region expected to be highly unsuitable for *Misgurnus anguillicaudatus* at the spatial scale of the model:
  - Minimum temperature of the coldest month (Bio6) < -23°C
  - Maximum temperature of the warmest month (Bio5) < 19°C
  - Annual precipitation (Bio12) < 250mm

Altogether, only 1% of occurrence grid cells were located in the unsuitable background region.

Within the unsuitable background region, 10 samples of 5000 randomly sampled grid cells were obtained. In the accessible background (comprising the accessible areas around native and non-native occurrences as detailed above), the same number of pseudo-absence samples were drawn as there were presence records (494), weighting the sampling by a proxy for recording effort (Figure 2).

**Figure 2.** The background from which pseudo-absence samples were taken in the modelling of *Misgurnus anguillicaudatus*. Samples were taken from a 400km buffer around the native range and a 30km buffer around non-native occurrences (together forming the accessible background), and from areas expected to be highly unsuitable for the species (the unsuitable background region). Samples from the accessible background were weighted by a proxy for recording effort (Figure 1(b)).

Each dataset (i.e. combination of the presences and the individual background samples) was randomly split into 80% for model training and 20% for model evaluation. With each training dataset, five statistical algorithms were fitted with the default BIOMOD2 settings and rescaled using logistic regression, except where specified below:

- Generalised linear model (GLM)
- Generalised boosting model (GBM)
- Generalised additive model (GAM) with a maximum of four degrees of freedom per smoothing spline
- Random forest (RF)
- Maxent

Since the total background sample was larger than the number of occurrences, prevalence fitting weights were applied to give equal overall importance to the occurrences and the background. Normalised variable importance was assessed and variable response functions were produced using BIOMOD2's default procedure.

Model predictive performance was assessed by the following three measures:

- AUC, the area under the receiver operating characteristic curve (Fielding & Bell 1997). Predictions of presence-absence models can be compared with a subset of records set aside for model evaluation (here 20%) by constructing a confusion matrix with the number of true positive, false positive, false negative and true negative cases. For models generating non-dichotomous scores (as here) a threshold can be applied to transform the scores into a dichotomous set of presence-absence predictions. Two measures that can be derived from the confusion matrix are sensitivity (the proportion of observed presences that are predicted as such, quantifying omission errors), and specificity (the proportion of observed absences that are predicted as such, quantifying commission errors). A receiver operating characteristic (ROC) curve can be constructed by using all possible thresholds to classify the scores into confusion matrices, obtaining sensitivity and specificity for each matrix, and plotting sensitivity against the corresponding proportion of false positives (equal to  $1 - \text{specificity}$ ). The use of all possible thresholds avoids the need for a selection of a single threshold, which is often arbitrary, and allows appreciation of the trade-off between sensitivity and specificity. The area under the ROC curve (AUC) is often used as a single threshold-independent measure for model performance (Manel, Williams & Ormerod 2001). AUC is the probability that a randomly selected presence has a higher model-predicted suitability than a randomly selected absence (Allouche et al. 2006).
- Cohen's Kappa (Cohen 1960). This measure corrects the overall accuracy of model predictions (ratio of the sum of true presences plus true absences to the total number of records) by the accuracy expected to occur by chance. The kappa statistic ranges from -1 to +1, where +1 indicates perfect agreement and values of zero or less indicate a performance no better than random. Advantages of kappa are its simplicity, the fact that both commission and omission errors are accounted for in one parameter, and its relative tolerance to zero values in the confusion matrix (Manel, Williams & Ormerod 2001). However, Kappa has been criticised for being sensitive to prevalence (the proportion of sites in which the species was recorded as present) and may therefore be inappropriate for comparisons of model accuracy between species or regions (McPherson, Jetz & Rogers 2004, Allouche et al. 2006).
- TSS, the true skill statistic (Allouche et al. 2006). TSS is defined as sensitivity + specificity - 1, and corrects for Kappa's dependency on prevalence. TSS compares the number of correct forecasts, minus those attributable to random guessing, to that of a hypothetical set of perfect forecasts. Like kappa, TSS takes into account both omission and commission errors, and success as a result of random guessing, and ranges from -1 to +1, where +1 indicates perfect agreement and values of zero or less indicate a performance no better than random (Allouche et al. 2006).

An ensemble model was created by first rejecting poorly performing algorithms with relatively extreme low AUC values and then averaging the predictions of the remaining algorithms, weighted by their AUC. To identify poorly performing algorithms, AUC values were converted into modified z-scores based on their difference to the median and the median absolute deviation across all algorithms (Iglewicz & Hoaglin, 1993). Algorithms with  $z < -2$  were rejected. In this way, ensemble projections were made for each dataset and then averaged to give an overall suitability, as well as its standard deviation. The projections were then classified into suitable and unsuitable regions using the 'minROCDist' method, which minimizes the distance between the ROC plot and the upper left corner of the plot (point (0,1)).

We also produced limiting factor maps for Europe following Elith et al. (2010). For this, projections were made separately with each individual variable fixed at a near-optimal value. These were chosen as the median values at the occurrence grid cells. Then, the most strongly limiting factors were identified as the one resulting in the highest increase in suitability in each grid cell.

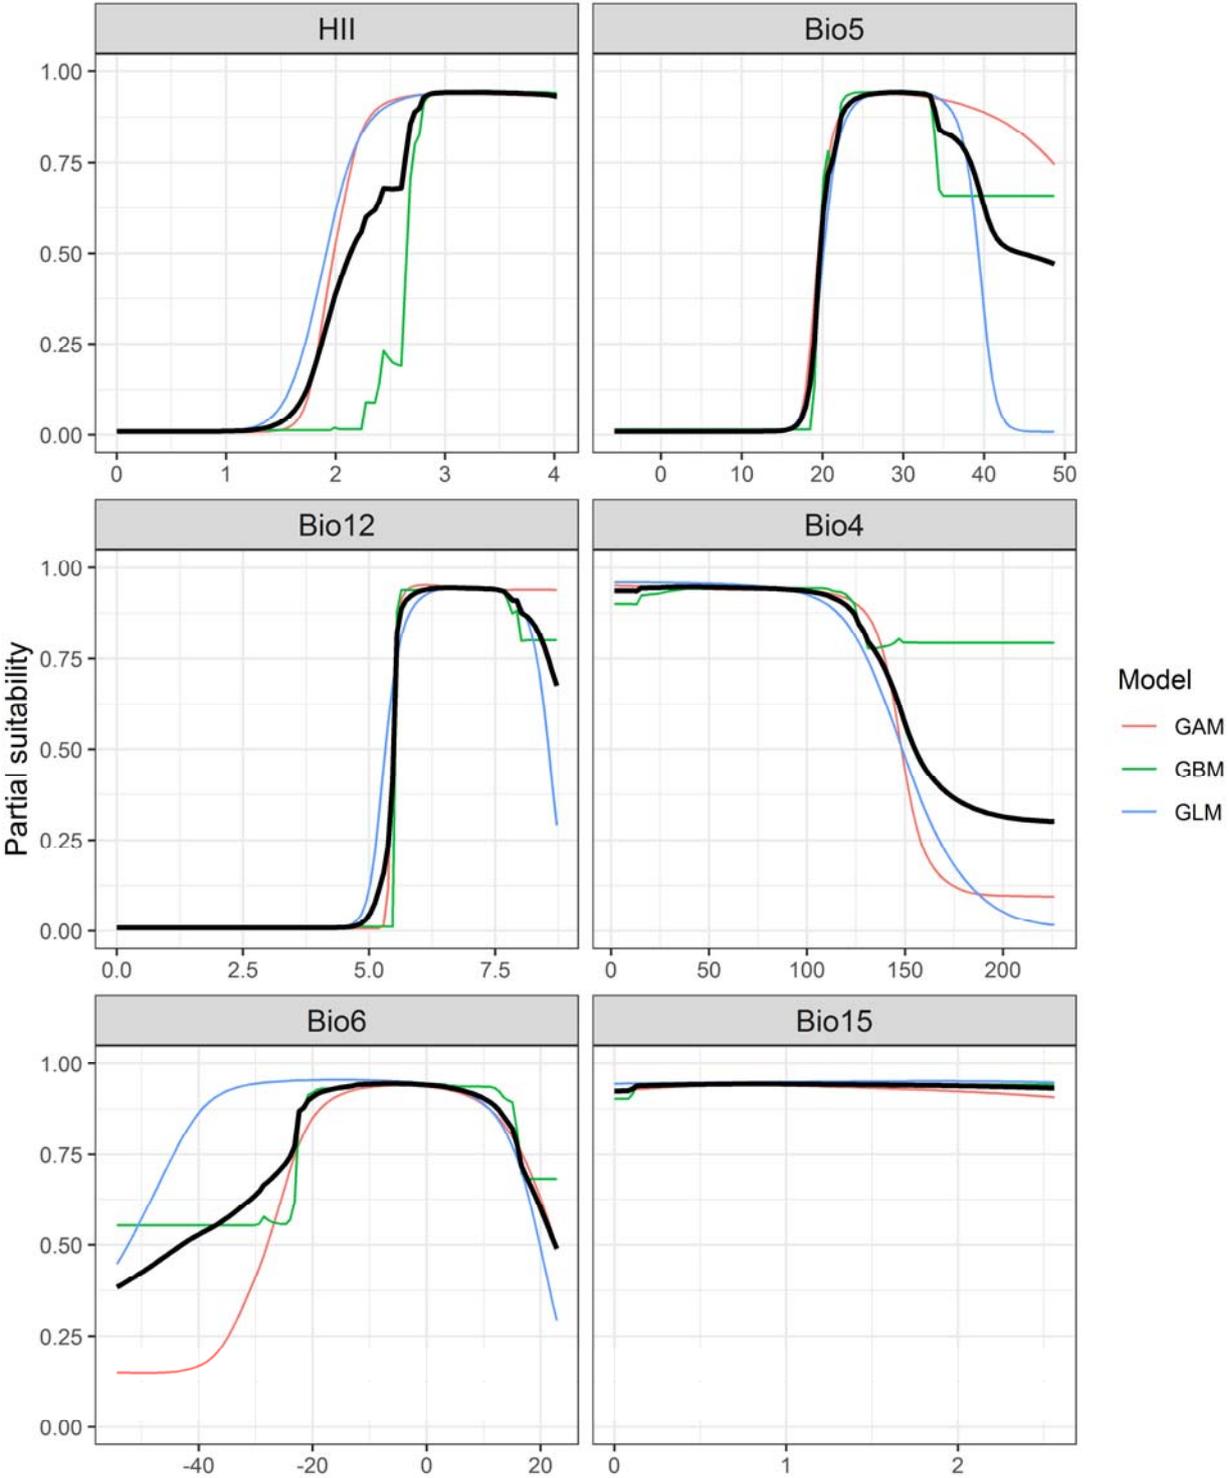

## Results

The ensemble model suggested that suitability for *Misgurnus anguillicaudatus* was most strongly determined by Human influence index (HII), accounting for 34.3% of variation explained, followed by Maximum temperature of the warmest month (Bio5) (27.4%), Annual precipitation (Bio12) (23.7%), Temperature seasonality (Bio4) (7.5%), Minimum temperature of the coldest month (Bio6) (6.9%) and Precipitation seasonality (Bio15) (0.1%) (Table 1, Figure 3).

**Table 1.** Summary of the cross-validation predictive performance (AUC, Kappa, TSS) and variable importance of the fitted model algorithms and the ensemble (AUC-weighted average of the best performing algorithms). Results are the average from models fitted to 10 different background samples of the data.

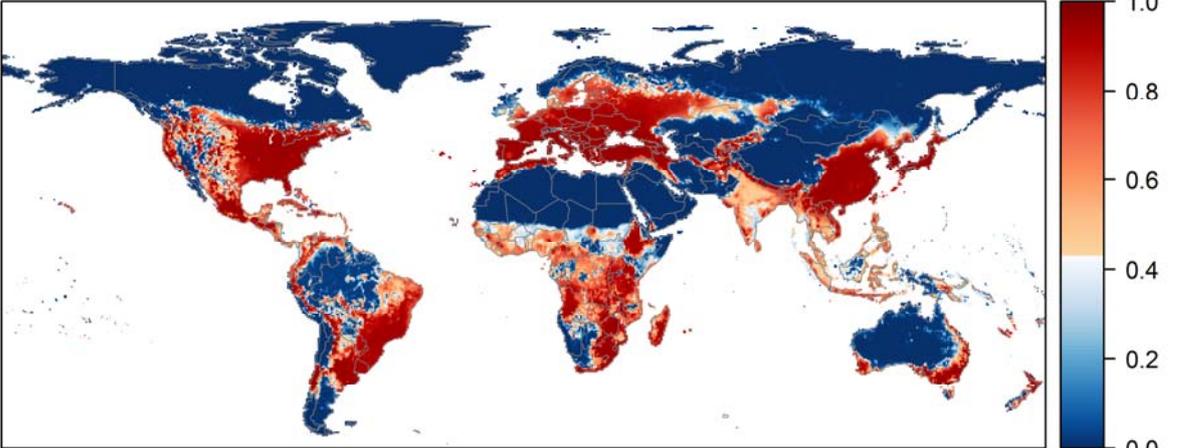

Algorithm	AUC	Kappa	TSS	Used in the ensemble	Variable importance (%)					
					Human influence index (HII)	Maximum temperature of the warmest month (Bio5)	Annual precipitation (Bio12)	Temperature seasonality (Bio4)	Minimum temperature of the coldest month (Bio6)	Precipitation seasonality (Bio15)
GLM	0.962	0.632	0.892	yes	31	32	20	14	2	0
GAM	0.963	0.630	0.894	yes	30	24	27	7	13	0

RF	0.944	0.607	0.883	no	24	22	35	8	7	5
Maxent	0.957	0.634	0.891	no	18	22	27	5	24	4
<b>Ensemble</b>	<b>0.964</b>	<b>0.633</b>	<b>0.893</b>		<b>34</b>	<b>27</b>	<b>24</b>	<b>8</b>	<b>7</b>	<b>0</b>

**Figure 3.** Partial response plots from the fitted models. Thin coloured lines show responses from the algorithms in the ensemble, while the thick black line is their ensemble. In each plot, other model variables are held at their median value in the training data. Some of the divergence among algorithms is because of their different treatment of interactions among variables.

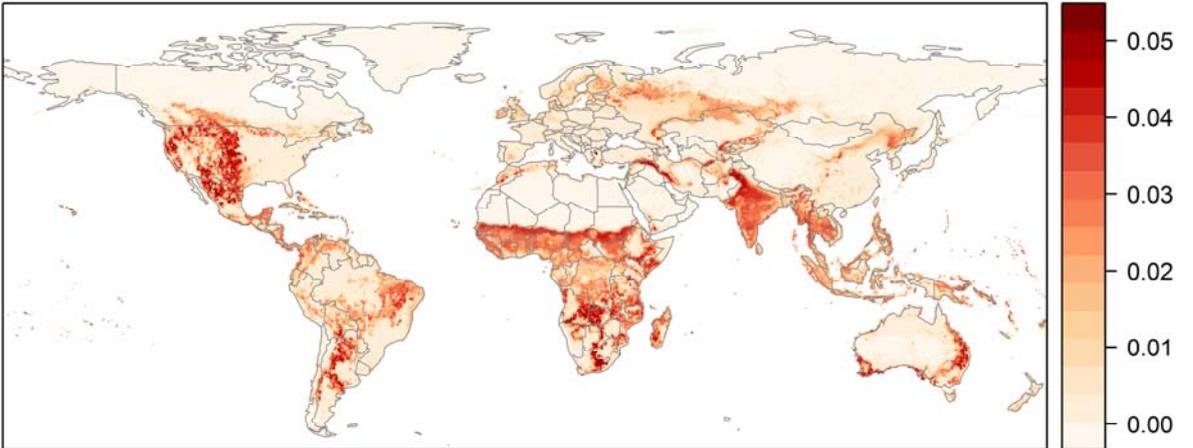

**Figure 4.** (a) Projected global suitability for *Misgurnus anguillicaudatus* establishment in the current climate. For visualisation, the projection has been aggregated to a 0.5 x 0.5 degree resolution, by taking the maximum suitability of constituent higher resolution grid cells. Values > 0.43 may be suitable for the species. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

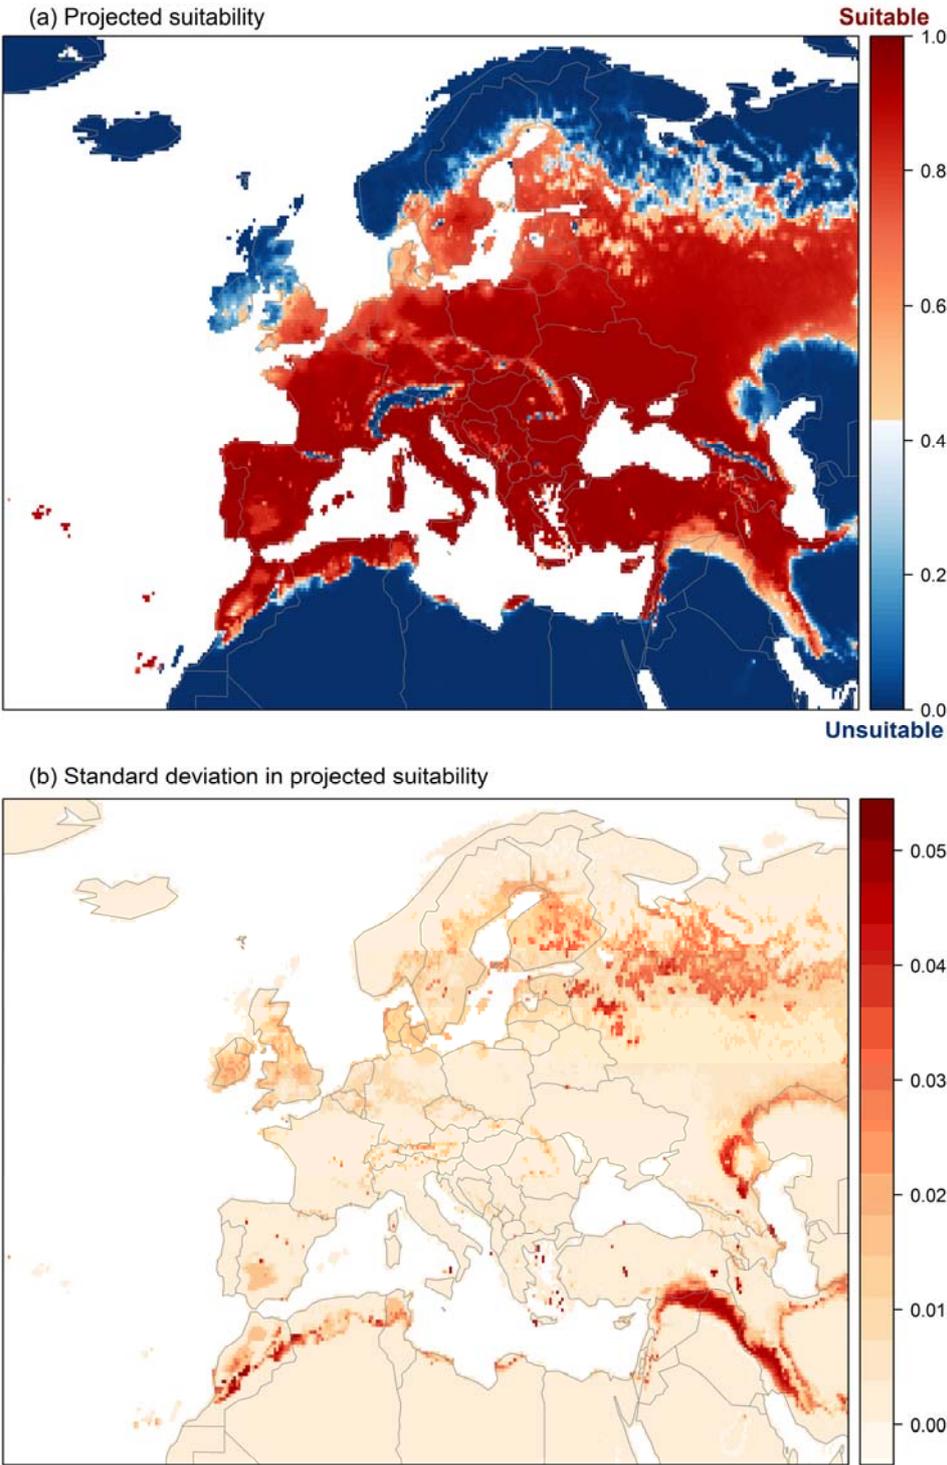

(a) Projected suitability

(b) Standard deviation in projected suitability

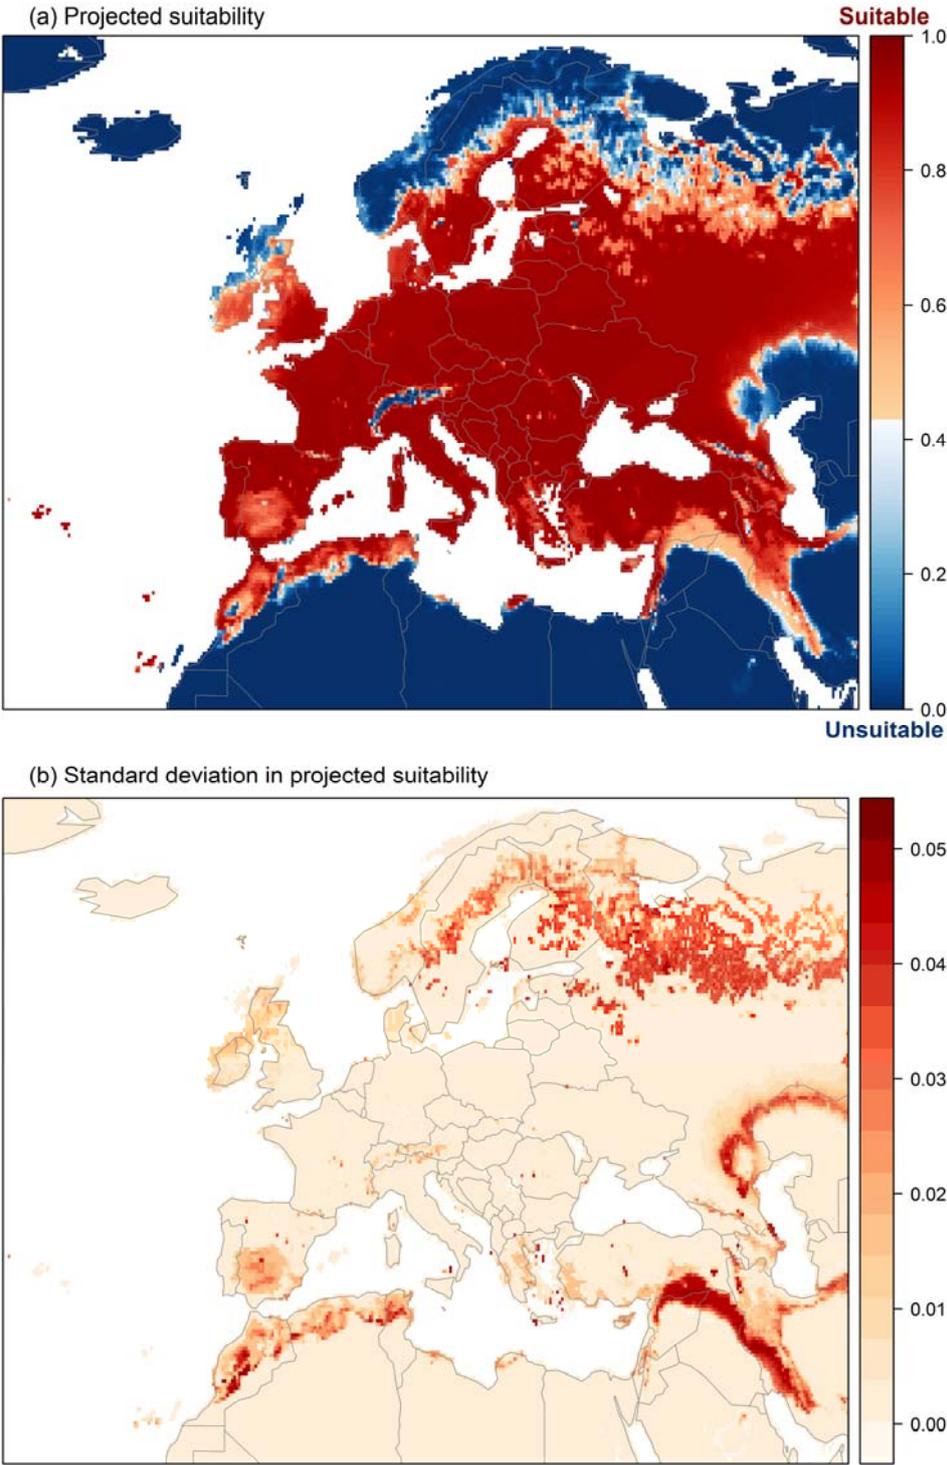

**Figure 5.** (a) Projected current suitability for *Misgurnus anguillicaudatus* establishment in Europe and the Mediterranean region. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

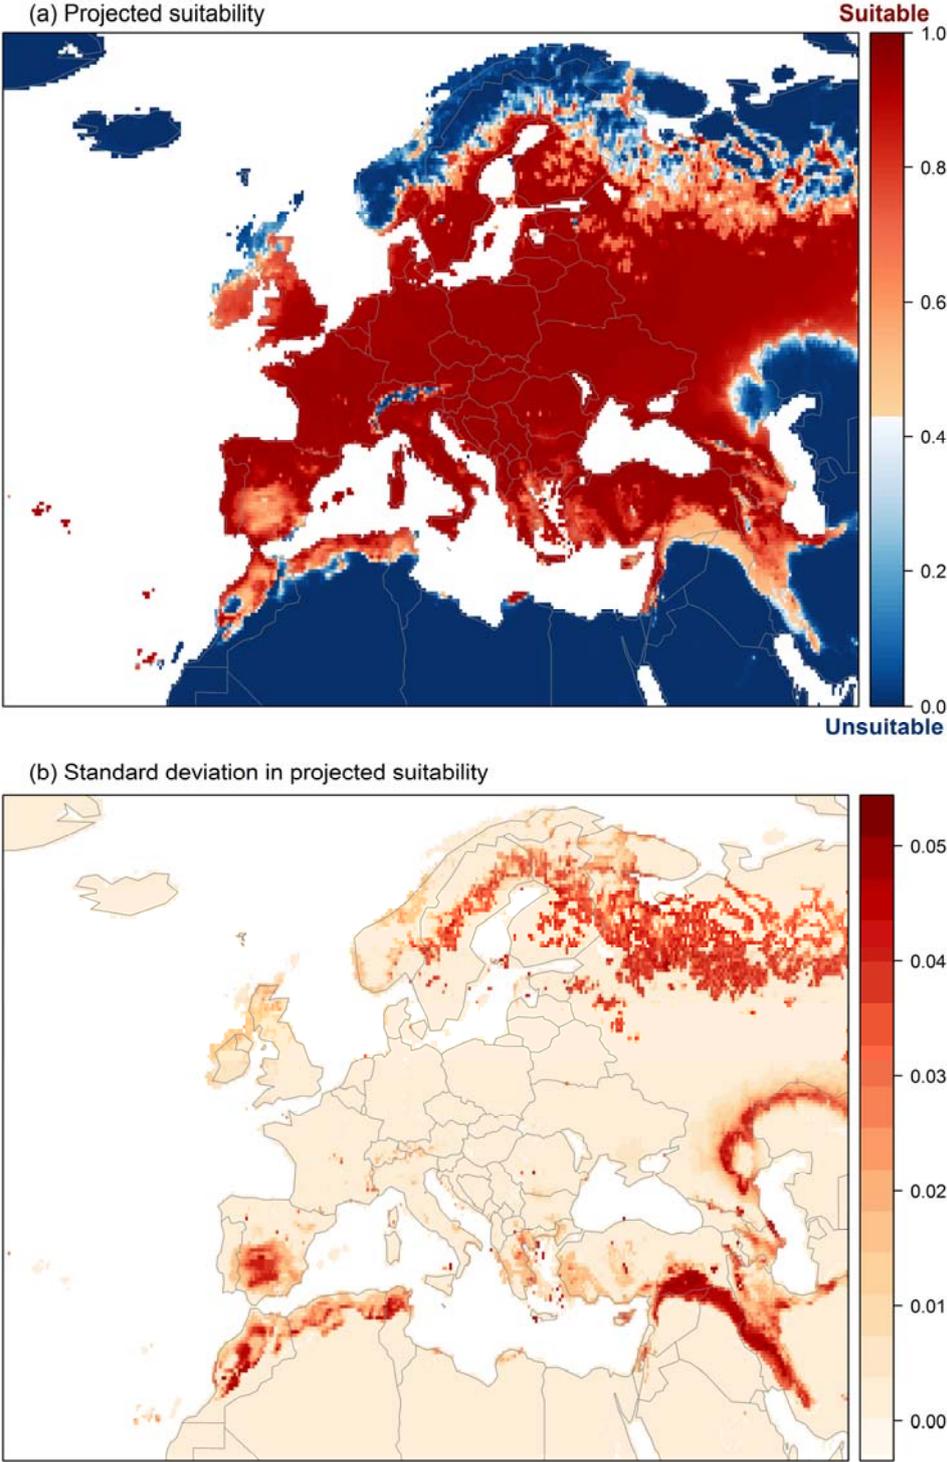

**Figure 6.** The most strongly limiting factors for *Misgurnus anguillicaudatus* establishment estimated by the model in Europe and the Mediterranean region in current climatic conditions.

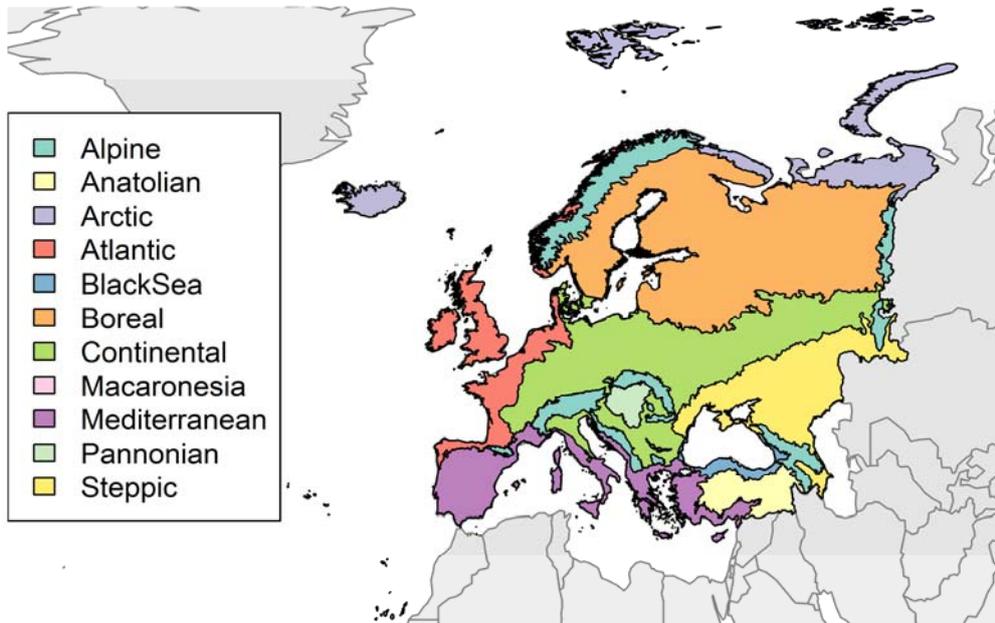

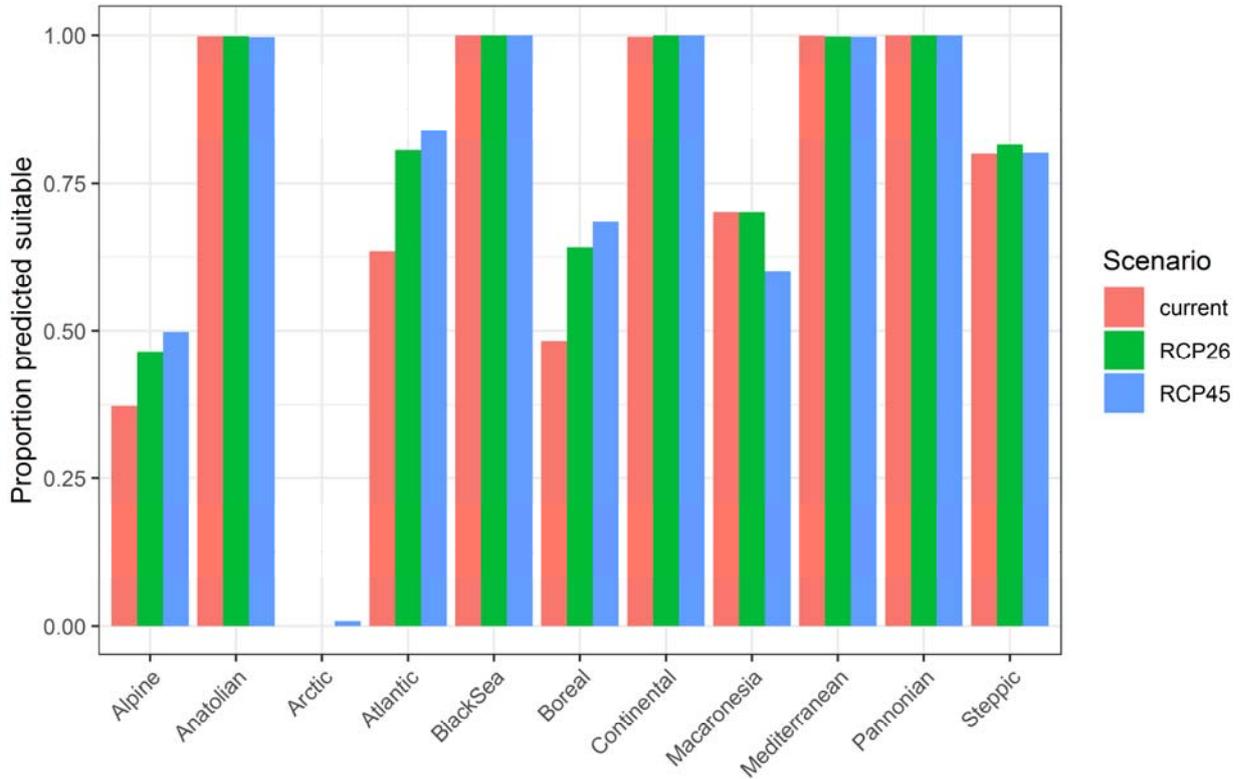

**Figure 7.** (a) Projected suitability for *Misgurnus anguillicaudatus* establishment in Europe and the Mediterranean region in the 2070s under climate change scenario RCP2.6, equivalent to Figure 5. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

**Figure 8.** (a) Projected suitability for *Misgurnus anguillicaudatus* establishment in Europe and the Mediterranean region in the 2070s under climate change scenario RCP4.5, equivalent to Figure 5. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

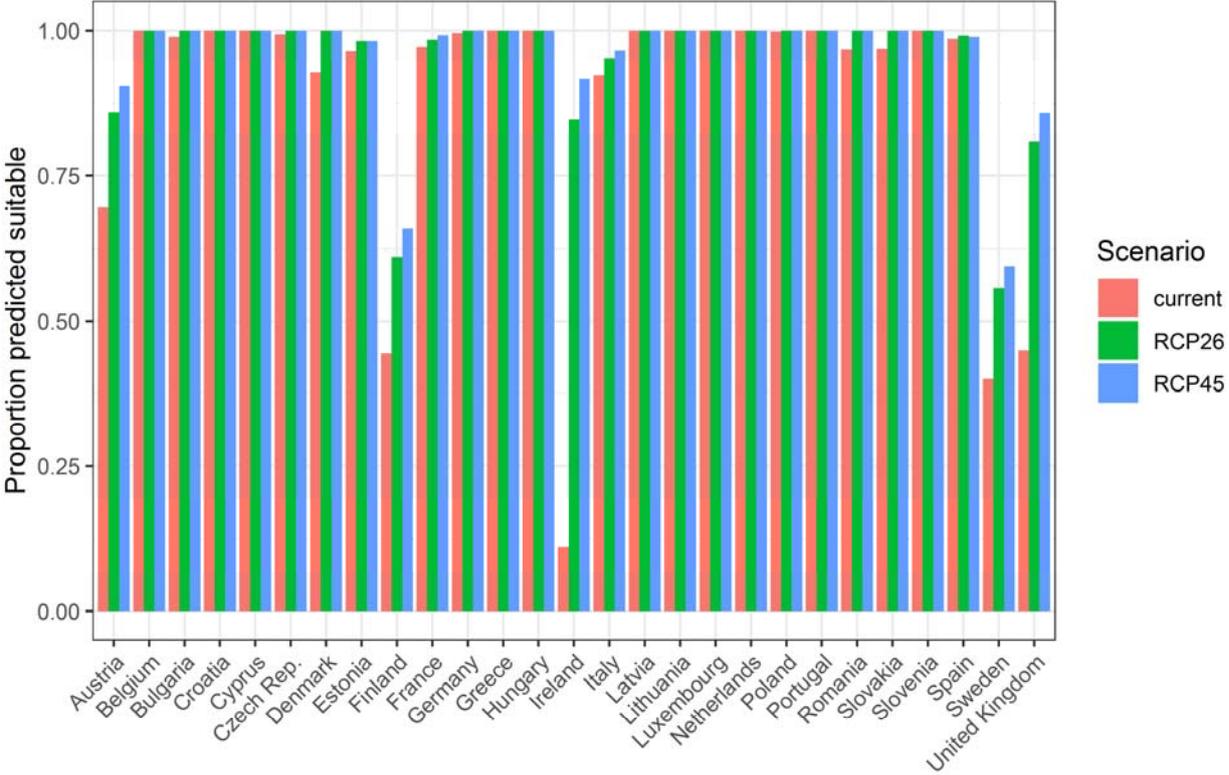

**Figure 9.** Variation in projected suitability for *Misgurnus anguillicaudatus* establishment among Biogeographical Regions of Europe (<https://www.eea.europa.eu/data-and-maps/data/biogeographical-regions-europe-3>). The bar plots show the proportion of grid cells in each region classified as suitable in the current climate and projected climate for the 2070s under two RCP emissions scenarios. The location of each region is also shown. The Arctic and Macaronesian biogeographical regions are not part of the study area, but are included for completeness.

**Table 2.** Variation in projected suitability for *Misgurnus anguillicaudatus* establishment among Biogeographical regions of Europe (numerical values of Figure 9 above). The numbers are the proportion of grid cells in each region classified as suitable in the current climate and projected climate for the 2070s under two RCP emissions scenarios. The Arctic and Macaronesian biogeographical regions are not part of the study area, but are included for completeness.

<b>Region</b>	<b>current climate</b>	<b>RCP26</b>	<b>RCP45</b>

### **Caveats to the modelling**

To remove spatial recording biases, the selection of the background sample from the accessible background was weighted by the density of Actinopterygii records on the Global Biodiversity Information Facility (GBIF). While this is preferable to not accounting for recording bias at all, it may not provide the perfect measure of recording bias.

There was substantial variation among modelling algorithms in the partial response plots (Figure 3). In part this will reflect their different treatment of interactions among variables. Since partial plots are made with other variables held at their median, there may be values of a particular variable at which this does not provide a realistic combination of variables to predict from.

Other variables potentially affecting the distribution of the species, such as types of land cover were not included in the model.

## SECTION A – Organism Information and Screening

### A1. Identify the organism. Is it clearly a single taxonomic entity and can it be adequately distinguished from other entities of the same rank?

including the following elements:

- the taxonomic family, order and class to which the species belongs;
- the scientific name and author of the species, as well as a list of the most common synonym names;
- names used in commerce (if any)
- a list of the most common subspecies, lower taxa, varieties, breeds or hybrids

As a general rule, one risk assessment should be developed for a single species. However, there may be cases where it may be justified to develop one risk assessment covering more than one species (e.g. species belonging to the same genus with comparable or identical features and impact). It shall be clearly stated if the risk assessment covers more than one species, or if it excludes or only includes certain subspecies, lower taxa, hybrids, varieties or breeds (and if so, which subspecies, lower taxa, hybrids, varieties or breeds). Any such choice must be properly justified.

Response:

The red-vented bulbul belongs to the class Aves, order Passeriformes, family Pycnonotidae. The scientific name for the red-vented bulbul is *Pycnonotus cafer*, and the author is Linnaeus, 1766. Earlier names include *Turdus cafer* (Linnaeus, 1766), *Molpastes haemorrhous* (J.F. Gmelin, 1789), *Pycnonotus pygaeus* (Sharpe, 1881) and *Molpastes cafer* (Baker, 1930). Other names for the species in English and in other languages include common bulbul or sooty-headed bulbul (Thibault, 2018a), bulbul ventirrojo (ES), Bulbul à ventre rouge (FR), Rußbülbül (DE), Kala buulbuul (NL), roodbuikbuulbuul (NL) and Bilbil czerwonoplamy (PL).

The genus *Pycnonotus* comprises 49 species (Delacour, 1943; Dickinson and Dekker, 2002; Gill et al., 2021).

*Pycnonotus cafer* comprises eight subspecies (Dickinson et al., 2002):

- Central Indian red-vented bulbul (*P. c. humayuni* Deignan, 1951), found in south-eastern Pakistan, north-western and north-central India;
- Punjab red-vented bulbul (*P. c. intermedius* Blyth, 1846), in Kashmir, Kohat down to the Salt Range and along the western Himalayas to Kumaon, originally described as a separate species;
- *P. c. bengalensis* (Blyth, 1845), in central and eastern Himalayas from Nepal to Assam, north-eastern India and Bangladesh, originally described as a separate species;
- *P. c. stanfordi* (Deignan, 1949), in northern Burma and south-western China;
- *P. c. melanchimus* (Deignan, 1949), in south-central Burma and northern Thailand;
- *P. c. wetmorei* (Deignan, 1960), in eastern India;
- *P. c. cafer* (Linnaeus, 1766), in southern India;
- *P. c. haemorrhousus* (Gmelin, 1789), in Sri Lanka (Dickinson et al., 2002).

In its native range, *P. c. humayuni* is known to hybridize with *Pycnonotus leucogenys* (Gray, 1835). These hybrids were once described as subspecies *magrathi* (Sibley & Short, 1959). Hybridisation with

*Pycnonotus leucogenys* has also been observed in the United Arab Emirates (Khan, 1993) and Bahrain (Khamis, 2010). The offspring of hybrids in Bahrain is believed to be sterile (Khamis, 2010). In Myanmar, there is some natural hybridization with *Pycnonotus aurigaster* (Sharpe, 1909; Rasmussen & Anderton, 2005), with hybrids formerly considered as the subspecies *P. c. burmanicus* and *P. c. nigropileus* (Dickinson et al. 2002; Dickinson & Dekker 2002). Hybridisation with *Pycnonotus leucotis* (Gould, 1836) has been observed in Kuwait (Gregory, 2005), Qatar (Nation et al., 1997) and Iran (Azin et al., 2008). Hybridisation with *Pycnonotus xanthopygos* (Hemprich & Ehrenberg, 1833) has been observed in the United Arab Emirates (Khan, 1993).

**A2. Provide information on the existence of other species that look very similar [that may be detected in the risk assessment area, either in the environment, in confinement or associated with a pathway of introduction]**

Include both native and non-native species that could be confused with the species being assessed, including the following elements:

- other alien species with similar invasive characteristics, to be avoided as substitute species (in this case preparing a risk assessment for more than one species together may be considered);
- other alien species without similar invasive characteristics, potential substitute species;
- native species, potential misidentification and mis-targeting

Response:

*Pycnonotus cafer* has brown feathering and a black crest on its head, neck and throat (Thibault, 2018a; Pratt et al., 1987). Its sub-caudal feathers have a bright crimson colour, hence the species' name (Berger, 1981; Zia et al., 2014). It has a pale greyish white lower belly and rump which is highly visible in flight, and a long tail with a white tip (Zia et al., 2014). The tips of the back and breast feathers are white and this light edging gives them a scaly appearance (Thibault, 2018a). The tail is black with a narrow white tip (Thibault, 2018a). The red-vented bulbul measures about 21 cm in length (Berger, 1972) and its weight can vary from 26 to 45 grams (Long, 1981). Males can measure up to 23 cm in length, slightly larger than females, which is the only sexual dimorphism in the red-vented bulbul (Stuart & Stuart, 1999). Juveniles look like adults but with paler feathering and brownish edging on the feathers (Thibault, 2018a). It may live for up to 11 years in captivity (Walker, 2008).

The red-whiskered bulbul (*P. jocosus*) or crested bulbul, has been introduced to many regions of the world, including in Europe (Spain). The red-whiskered bulbul has an erect black/dark brown crest, a dark brown/black head with prominent white cheek patches and red whiskers below each eye. It is widely kept as a cage bird, escaped and established in many places, including Australia, Madagascar, Hawaii, Japan, the Seychelles, the USA and Spain. It is a pest of agriculture and gardens, feeding on fruits, vegetables, flower buds and insects. Furthermore, it is known to have environmental impacts through the dispersal of seeds of invasive plants, interspecific competition and predation on geckos and invertebrates (Hawaii Invasive Species Council, 2017; Cottrell, 2017).

In Europe, both the red-vented bulbul and the red-whiskered bulbul are established sympatrically in Valencia, Spain (Lever, 2015; Dyer et al., 2017), so it is possible that one species could be confused for the other in this region. Another alien species physically resembling the red-vented bulbul is the sooty-headed bulbul (*P. aurigaster*), mostly because of its red vent and black head. However, the breast and belly of *P. aurigaster* is lighter and only birds of the *chrysorrhoides* group have a red vent (Fishpool & Tobias, 2019). The sooty-headed bulbul is one of the most abundant and widespread native bulbuls on Java and Bali. It has been introduced to Sumatra, Singapore and Borneo where its alien populations have been expanding since the 1980s. It is suggested that this spread can be attributed to escaped birds from captivity (Phillipps & Phillipps, 2011). However, the species currently has no known alien populations in Europe. Hybrids between red-vented and sooty-headed bulbul do occur and can be difficult to identify (see A1). The only other bulbul with a known alien population is the yellow-vented bulbul (*P. goiavier*), which is native to the Malay Peninsula, Borneo, Thailand and the Philippines, and has an alien population on Sulawesi (Lever, 2005). However, the yellow-vented bulbul does not possess similar physical characteristics to the red-vented bulbul.

The only native species that somewhat resembles the red-vented bulbul and that therefore could be misidentified as such is the common bulbul (*P. barbatus*). This species is one of the commonest birds in Africa but is very rare in the wild in the risk assessment area. In recent years, common bulbul has bred in Tarifa (Cádiz, Andalusia, Spain) in an area that is potentially suitable for the red-vented bulbul as well. Birds are still present in the area, but only one pair has been known to breed and its status in Europe is currently tenuous (personal communication K. Bensusan, 22/10/2019). In 2013, two adult common bulbuls were observed feeding a young, which represented the first breeding record for the species in Europe (van den Berg & Haas, 2013).

**A3. Does a relevant earlier risk assessment exist? Give details of any previous risk assessment, including the final scores and its validity in relation to the risk assessment area.**

Response:

No other risk assessments for the species were found. However, as a well-known invader listed on the IUCN/ISSG list of 100th of the worst invasive species (Lowe et al., 2004), the species was included in several scoring exercises of invasive bird impacts globally. The results of these exercises are discussed in Qu. 5.1. An assessment of the impacts of the red-vented bulbul, undertaken using the Environmental Impact Classification for Alien Taxa (EICAT) classified the species as having Moderate (MO) impacts<sup>2</sup> through competition with native birds and by spreading the seeds of alien plants (Evans et al., 2016). The red-vented bulbul is also listed in the DAISIE database, however without any specific assessment.

**A4. Where is the organism native?**

including the following elements:

<sup>2</sup> EICAT categories are, from low to high impact: Minimal Concern (MC), Minor (MN), Moderate (MO), Major (MR), Massive (MV). MO impacts cause declines in populations of native species but do not cause native species extinctions.

- an indication of the continent or part of a continent, climatic zone and habitat where the species is naturally occurring
- if applicable, indicate whether the species could naturally spread into the risk assessment area

Response:

*Pycnonotus cafer* is native to the Indian Subcontinent, Southeast Asia, and Malay Peninsula (Long, 1981). It occurs naturally from Eastern Pakistan to southern China and Vietnam, and from Northern India to Sri Lanka. The species is linked to an equatorial climate according to the Kopper-Geigen classification (Kottek et al., 2006) and can live in diverse habitat types. The species is found in open areas, dry scrub, plains, cropland, natural forests, forest edges as well as plantations and prefers anthropogenic environments (urban areas, gardens, parks, farms) (Vander Velde, 2002). In India, the species is used for bulbul fighting, a traditional yet recently prohibited custom at harvest festivals (Ratnagar, 2015).

**A5. What is the global non-native distribution of the organism outside the risk assessment area?**

Response:

According to Thibault et al. (2018c), *Pycnonotus cafer* was introduced into 18 countries and established in 17 of them. The species is now present on at least 37 islands and seven continental locations (Thibault et al., 2018c). In order of first detection the countries where red-vented bulbul was introduced are: Fiji, Australia (extinct), Tonga, the Independent State of Samoa, New Zealand (eradicated), American Samoa, USA (Hawaii, Texas), Qatar, United Arab Emirates, French Polynesia, Saudi Arabia, Kuwait, New Caledonia, Bahrain, Oman, Spain (mainland Spain and Fuerteventura - Canary Islands), the Marshall Islands and Iran (Thibault et al., 2018c).

The first record of the red-vented bulbul outside of its native range was in Fiji in 1903 (Parham, 1955) where the species established and colonised several islands (Thibault et al., 2018c). It was probably brought there by Indian immigrants in the early 1900s (Watling, 1978), as it was widely used in bird fights in India because of its aggressive behaviour (Ali & Ripley, 1971). The bird has been recorded 6100 times in eight Pacific archipelagos since this first detection (Thibault 2018a).

The red-vented bulbul was detected in Melbourne and Sydney, Australia in 1918 and again in Melbourne in 1942 (Lendon, 1952; Watling, 1978; Dyer et al., 2017). Although a small population persisted for some time in the suburbs of Melbourne since 1918 (Watling 1978), it did however not successfully establish in Australia (Thibault et al., 2018c). The subspecies *P. c. bengalensis* was found in Melbourne in 1982 (Dyer et al., 2017). There are no records of the species since then. It is considered to be eradicated in Australia (<http://www.issg.org/database>).

The red-vented bulbul was deliberately introduced in the 1940s in Tonga to control unwanted insects (Watling, 1978). The red-vented bulbul probably reached the Independent State of Samoa in the early 1950's, and has since spread to several islands in the archipelago (Dhondt, 1977). The first observation of red-vented bulbul in Auckland, New Zealand was in 1952, but the species was eradicated in 1955

(Turbott, 1956; Watling, 1978). The red-vented bulbul was introduced in American Samoa in the late 1950s and quickly became established (Clapp & Sibley 1966; Freifeld, 1999). First observations for Hawaii (USA) date from 1966. In French Polynesia, the red-vented bulbul was first noticed in the residential area of Papeete in 1979. They are now common on Tahiti on elevations of up to 1000 m, possibly having negative interactions with the Tahiti monarch (*Pomarea nigra*) (Blanvillain et al., 2003). The species was intentionally released in Nouméa (New Caledonia) around 1983 by bird dealers to avoid prosecution (Thibault et al., 2018c). The red-vented bulbul was first sighted on the Marshall Islands in 2000, near the major commercial dock of Majuro, and was known to hitchhike on ships to other areas of the archipelago. In 2002, there were already several breeding populations (Vander Velde, 2002). Several individuals were seen by Christina Sylvester on the Kwajalein Atoll in November 2018 (<http://www.underwaterkwaj.com/land/bird-kwaj/bird-kwaj.htm>, visited on 07/06/2019).

In the Middle East, the red-vented bulbul was first detected in Qatar in 1971 (Nation et al., 1997). It has been reported 3080 times in five countries around the Persian Gulf since this first detection. The red-vented bulbul was first detected in the United Arab Emirates in 1974 where it is now common and expanding (Pedersen & Aspinall, 2010), and was first detected in Saudi Arabia in the 1980s (personal communication J. Babington). In Kuwait, the red-vented bulbul was first observed in 1981, and it is currently scarce, with a declining range (Gregory, 2005). According to Khamis (2010), the red-vented bulbul was first recorded in Bahrain in 1986, likely following an escape. At present, the bird maintains a self-sustaining population here. The first observation in Oman dates from 1987 and the red-vented bulbul is now a common bird there (Thibault et al., 2018a). In Iran, the red-vented bulbul was first recorded in 2007 when 10-12 individuals were observed in the east of Kish Island, Hormozgan Province (Azin et al., 2008).

The red-vented bulbul was first observed in Houston (Texas, USA) near the end of the 1990's. At least 14 sightings were reported between May 1999 and March 2004. These sightings have been estimated to represent 32 birds at 10 sites in Houston (Eubanks et al., 2006).

A population is also established on Fuerteventura (Canary Islands, Spain) with the first sightings in the late 1990s. By 2017, the species had spread over the entire island (SEO/Birdlife 2017; Nowakowski and Dulisz 2019).

**A6. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species been recorded and where is it established? The information needs to be given separately for recorded and established occurrences.**

**A6a. Recorded: List regions**

**A6b. Established: List regions**

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

- Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea.

Comment on the sources of information on which the response is based and discuss any uncertainty in the response.

For delimitation of EU biogeographical regions please refer to <https://www.eea.europa.eu/data-and-maps/figures/biogeographical-regions-in-europe-2> (see also Annex V).

For delimitation of EU marine regions and subregions consider the Marine Strategy Framework Directive areas; please refer to <https://www.eea.europa.eu/data-and-maps/data/msfd-regions-and-subregions/technical-document/pdf> (see also Annex V).

Response (6a): Mediterranean, Atlantic

In the Netherlands, there have been multiple sightings of individual birds in the wild since 1999 (Avifauna Groningen, 2000; waarneming.nl). A number of these birds were sighted in the middle of urban areas suggesting an escaped origin. In Belgium, there was one observation of an escape in a natural area in a military Domain in 2005 (Brecht, Antwerp province). There are probably many more unreported incidental records of escaped birds across the risk assessment area. In Spain, there are some observations in Málaga and Torremolinos (personal communication A. Paterson).

Response (6b): Mediterranean

In Valencia (Spain), the species seems to be established, but no research has targeted this species yet. Breeding was observed in 2017 in gardens of urbanized areas surrounding the city. The range is not big, but they seem to be fairly common. There, the species is sympatric with the well-established red-whiskered bulbul (*P. jocosus*). (<https://www.miteco.gob.es/es/biodiversidad/temas/inventarios-nacionales/>; personal communication C. Gutiérrez-Expósito, 12/12/2018).

**A7. In which biogeographic region(s) or marine subregion(s) in the risk assessment area could the species establish in the future under current climate and under foreseeable climate change? The information needs to be given separately for current climate and under foreseeable climate change conditions.**

**A7a. Current climate: List regions**

**A7b. Future climate: List regions**

With regard to EU biogeographic and marine (sub)regions, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

Response (7a): Mediterranean

According to the species distribution model (SDM, Annex VII), the red-vented bulbul could potentially establish in the Mediterranean biogeographical region. However, only around 2% of this bioregion is predicted to be suitable under current climatic conditions.

Response (7b): Mediterranean.

Under climate change scenarios RCP 2.6 and RCP 4.5, only the Mediterranean biogeographical region is deemed suitable for the establishment of *P. cafer*. The proportion of the region predicted to be suitable increases under both RCP scenarios, to 4% under RCP 2.6 and 6% under RCP 4.5.

**A8. In which EU Member States has the species been recorded and in which EU Member States has it established? List them with an indication of the timeline of observations. The information needs be given separately for recorded and established occurrences.**

**A8a. Recorded: List Member States**

**A8b. Established: List Member States**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, the Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden

The description of the invasion history of the species shall include information on countries invaded and an indication of the timeline of the first observations, establishment and spread.

Response (8a): Spain, Belgium, The Netherlands

In the province of Málaga (Spain), breeding was observed in 2001 and 2002, however, it seems that the red-vented bulbul is not established there anymore. The last documented sighting of red-vented bulbul in Málaga province dates back to 2007. In Torremolinos (Málaga), a group of birds was observed in 1998, 2001 and 2002 (personal communication A. Paterson). On November 9, 2000, three individuals were observed singing and on May 27, 2001, a couple copulating. On 7 July 2002, four specimens were observed, of which two were juveniles. On September 9, 2002, a second clutch was confirmed, and the pair was observed with a chick, indicating the species successfully established in this area. However, there are no indications red-vented bulbul is currently still established around Torremolinos (<https://www.miteco.gob.es/es/biodiversidad/temas/inventarios-nacionales/>).

In Belgium, the red-vented bulbul was observed in August 2005 in the province of Antwerp (<http://waarnemingen.be/waarneming/view/41885488>). This is the only known observation for Belgium.

In the Netherlands, the red-vented bulbul was observed on five occasions, in September and October of 2006, and in July 2009 (<https://data.biodiversitydata.nl/obsint/observation/OBS.44081179>).

Response (8b): Spain

In Valencia (Valencia, Spain), the species seems to be established, as breeding was observed in 2017 when a family group of bulbuls were seen in urban gardens surrounding the city (personal communication C. Gutiérrez-Expósito, 12/12/2018). Their range is small, but they are not uncommon. The species is sympatric with a well-established red-whiskered bulbul (*P. jocosus*) population. Successful breeding of red-vented bulbul was reported in 2002 around Torremolinos but there, the last sighting was performed in 2007 (see above).

**A9. In which EU Member States could the species establish in the future under current climate and under foreseeable climate change? The information needs to be given separately for current climate and under foreseeable climate change conditions.**

**A9a. Current climate: List Member States**

**A9b. Future climate: List Member States**

With regard to EU Member States, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

Response (9a): Cyprus, Spain, Greece, France and potentially other Mediterranean member states with islands (Italy, Portugal, Malta) for which the confidence on the SDM is lower. Under current climate, these countries have suitable areas for the establishment of the red-vented bulbul. Yet the suitable area represents only 2% of the Mediterranean bioregion (see 7a, Annex VII, figure 9).

Overall, the main limiting factor in most of the risk assessment area is annual mean temperature (Bio1). Since *P. cafer* is a species of subtropical climate, it is reasonable to assume that most of Europe will be too cold for successful reproduction. Second, precipitation of the wettest month

(Bio13) is the main limiting factor in some parts of southern Europe. The red-vented bulbul indeed avoids deserts and needs trees/shrubs for nesting (Zia et al., 2014), and a low precipitation of the wettest month indicates this. The ensemble model suggested that suitability for red-vented bulbul was most strongly determined by Annual mean temperature (Bio1), accounting for 43.5% of variation explained, followed by Mean temperature of the warmest quarter (Bio10) (24.7%), Precipitation of the wettest month (Bio13) (8.8%), Minimum temperature of the coldest month (Bio6) (8.3%), Annual precipitation (Bio12) (5.9%), Human influence index (HII) (5.6%), Precipitation of the driest month (Bio14) (2.3%) and Global tree cover (Tree) (0.9%). For more details, see Annex VII.

Response (9b):

RCP 2.6: Cyprus, France, Greece, Spain and potentially other Mediterranean member states with islands (Italy, Portugal, Malta) for which the confidence on the SDM is lower.

RCP 4.5: Cyprus, France, Greece, Spain and potentially other Mediterranean member states with islands (Italy, Portugal, Malta) for which the confidence on the SDM is lower.

For more details, see Annex VII.

<b>A10. Is the organism known to be invasive (i.e. to threaten or adversely impact upon biodiversity and related ecosystem services) anywhere outside the risk assessment area?</b>
---

Response:

Yes. The red-vented bulbul impacts native biodiversity outside of the risk assessment area in three ways:

1/ Frugivory: most damage relates to its diverse diet that comprises fruits and berries (Islam & Williams, 2000; Brooks, 2013), flowers, buds, insects and small reptiles (Vander Velde, 2002). It feeds on cultivated (food and ornamental) plants and is considered a problematic seed disperser of invasive alien plants, such as *Lantana camara* (Spotswood et al, 2013).

2/ Competition: its aggressive behaviour towards other birds has been reported to lead to niche contraction of some native birds (e.g. Tahiti flycatcher (*Pomarea nigra*)) in the Pacific (Blanvillain et al., 2003). Its numerical abundance was inversely correlated with the abundance of nine bird species in New Caledonia (Thibault et al., 2018d).

3/ Hybridisation: in the Middle East, crossbreeding with native bulbul species (*P. leucogenys*, *P. leucotis*, *P. xanthopygos*) threatens the genetic integrity of these native bird populations (Khan, 1993; Nation et al., 1997; Gregory, 2005; Azin et al., 2008; Khamis, 2010).

On the semi-arid island of Fuerteventura (Canary Islands, Macaronesia, Spain but outside the risk assessment area) the species was first observed in Corralejo in 2003 and expanded its range in the period 2013–2018 to cover the entire island (1.658 km<sup>2</sup>) (SEO/Birdlife 2017; Nowakowski and Dulisz 2019). There is not a lot of habitat available to the birds on the island, and they are limited to towns and holiday resorts with gardens and parks, but also inhabit agricultural plantations. The first breeding was confirmed in 2018 around Costa Calma. The birds were observed in stands of trees in gardens of a

holiday resort composed of various palm trees, fig trees, oleanders, yuccas, acacias and shrubs, and often visited the dry shrubs, typical for semi-arid vegetation of the open landscape of the island, located outside the resort's gardens (Nowakowski & Dulisz 2019).

**A11. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea

Response:

The red-vented bulbul is currently only present in the Mediterranean biogeographic region (Spain) within the risk assessment area (see Qu. A6b), but has not shown signs of invasiveness (see Qu. A8b).

**A12. In which EU Member States has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, the Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden

Response:

The red-vented bulbul has only recently established locally in Spain and has not shown signs of invasiveness (see Qu. A.8b).

**A13. Describe any known socio-economic benefits of the organism.**

including the following elements:

- Description of known uses for the species, including a list and description of known uses in the Union and third countries, if relevant.
- Description of social and economic benefits deriving from those uses, including a description of

the environmental, social and economic relevance of each of those uses and an indication of associated beneficiaries, quantitatively and/or qualitatively depending on what information is available.

If the information available is not sufficient to provide a description of those benefits for the entire risk assessment area, qualitative data or different case studies from across the Union or third countries shall be used, if available.

Response:

In its native Indian range, the red-vented bulbul has been reported to feed on the cotton bollworm (*Helicoverpa armigera*), a moth that is globally considered as a major pest species because its larvae feed on a wide range of plants, including many important cultivated crops such as cotton (Rana et al., 2014, 2017).

In a cost-benefit analysis done by Daigneault & Brown (2013) on Fiji, 47% of surveyed village focus groups reported benefits of the red-vented bulbul for their community. 18% responded that it is effective at insect control, 12% noted that the red-vented bulbul sends out alarms calls when a mongoose is about to attack chickens, thereby reducing the attacks on chickens and another 12% stated that the bulbul is occasionally eaten by villagers. In addition, in the north-east of India, red-vented bulbul fights were part of a traditional and religious annual celebration, until this practice was banned in January 2016 (Shalet, 2016).

As the species is widely kept as a caged bird within and outside the risk assessment area (see A.2), it represents ornamental, sentimental and aesthetic value as a companion animal. There are no official records on trade volumes, but there are plenty of advertisements for birds online, often sold in pairs. Prices found online vary from € 165 – 250 per bird or € 250 per pair.

## SECTION B – Detailed assessment

### Important instructions:

- In the case of lack of information the assessors are requested to use a standardized answer: “No information has been found.”
- With regard to the scoring of the likelihood of events or the magnitude of impacts see Annexes I and II.
- With regard to the confidence levels, see Annex III.
- Highlight the selected response score and confidence level in **bold** but keep the other scores in normal text (so that the selected score is evident in the final document).

## 1 PROBABILITY OF INTRODUCTION

### Important instructions:

- **Introduction** is the movement of the species into the risk assessment area (it may be either in captive conditions and/or in the environment, depending on the relevant pathways).
- **Entry** is the release/escape/arrival in the environment, i.e. occurrence in the wild and is treated in the next section (N.B. introduction and entry may coincide for species entering through pathways such as “corridor” or “unaided”).
- The classification of pathways developed by the Convention of Biological Diversity (CBD) should be used. For detailed explanations of the CBD pathway classification scheme consult the IUCN/CEH guidance document<sup>3</sup> and the provided key to pathways<sup>4</sup>.
- For organisms which are already present in the risk assessment area, only complete this section for current active pathways and, if relevant, potential future pathways.

### Qu. 1.1. List relevant pathways through which the organism could be introduced. Where possible give details about the specific origins and end points of pathways as well as a description of any associated commodities.

For each pathway answer questions 1.2 to 1.7 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 1.2a, 1.3a, etc. and then 1.2b, 1.3b etc. for the next pathway.

In this context a pathway is the route or mechanism of introduction of the species.

The description of commodities with which the introduction of the species is generally associated shall include a list and description of commodities with an indication of associated risks (e.g. the volume of trade; the likelihood of a commodity being contaminated or acting as vector).

If there are no active pathways or potential future pathways this should be stated explicitly here, and there is no need to answer the questions

1.2-1.9

<sup>3</sup> <https://circabc.europa.eu/sd/a/738e82a8-f0a6-47c6-8f3b-aeddb535b83b/TSSR-2016-010%20CBD%20categories%20on%20pathways%20Final.pdf>

<sup>4</sup> <https://circabc.europa.eu/sd/a/0aeba7f1-c8c2-45a1-9ba3-bcb91a9f039d/TSSR-2016-010%20CBD%20pathways%20key%20full%20only.pdf>

Pathway name:

- a. ESCAPE from confinement: Botanical garden/zoo/aquaria (excluding domestic aquaria)
- b. ESCAPE from confinement: Pet/aquarium/terrarium species (including live food for such species)
- c. TRANSPORT stowaway: Hitchhikers on ship/boat (excluding ballast water and hull fouling)

Deliberate releases of red-vented bulbul for biocontrol of insect pests have also been documented in the Indo-Pacific (Watling, 1978) but these pathways of introduction are rare and considered irrelevant for the risk assessment area. Therefore they are not dealt with here (see also Qu. 2.1).

**Qu. 1.2a. ESCAPE from confinement: Botanical garden/zoo/aquaria (excluding domestic aquaria)**

**Is introduction along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	intentional unintentional	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	------------------------------	-------------------	------------------------------

Response:

Intentional because zoological gardens will intentionally buy or acquire one or more red-vented bulbul individuals to put on display.

**Qu. 1.3a. How likely is it that large numbers of the organism will be introduced through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in introduction whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response:

Whilst there is no data available on the total captive red-vented bulbul population within all zoological collections within the EU, information was provided by EAZA (European Association of Zoos and Aquaria) on populations kept at approximately 300 of their Member zoos and aquariums in 25 EU Member States (with the exception of Cyprus and Malta), and the United Kingdom. The information provided by EAZA (EAZA datafile 3/10/2019) indicates that the species is kept in low numbers by EAZA Member zoos in Germany, Poland, and the United Kingdom. This data comes from the animal care and management software provided by Species360 Zoological Information Management System (ZIMS) (zims.Species360.org, 2018) whose usage is widespread throughout the EAZA Membership. It must be noted that the actual situation might slightly differ if the species has been recorded under a different/older taxonomic name.

The red-vented bulbul is on display in at least the following EAZA zoos in the risk assessment area: Warsaw Zoological Garden (Poland), Köln Zoologischer Garten (Germany), Plzen Zoo (Czech Republic), Graested Nordsjællands Fuglepark (Denmark), Helsingborg Djurparken / ex. Fågelparken (Sweden), Farnham Birdworld & Underwater World (UK), Thrigby Hall Wildlife Gardens (UK) ([www.zootierliste.de](http://www.zootierliste.de)). EAZA is the European Association of Zoos and Aquaria and has 300 full members, 21 candidates for membership, 40 corporate members and 38 associate members as of May 2018 ([www.eaza.net](http://www.eaza.net)). This list comprises just a quarter of all zoological gardens and animal parks in Europe ([www.zoos.media](http://www.zoos.media)). Therefore, it is difficult to assess to what extent the species is kept in captivity within the risk assessment area.

Although the import of wild birds into the EU has been illegal since 2005, zoological gardens with a special zoo license can still import them. Indeed, the red-vented bulbul is present in several zoos, but it is only moderately likely that large numbers will be introduced in the zoos within the risk assessment area over the course of one year. However, no information is available as to the total number of zoos that keep red-vented bulbul, the size of the captive population nor how often these are introduced into a new zoo, so the confidence level is low.

**Qu. 1.4a. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

If a zoo intentionally buys or acquires one or more red-vented bulbul individuals, it is very likely that these animals will survive their transport and storage along this pathway, since they are meant to stay alive. Reproduction however, is very unlikely.

**Qu. 1.5a. How likely is the organism to survive existing management practices during transport**

**and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

When imported legally by a zoological garden with a license, there is no reason why existing management practices would target this species. In the case of illegal import, there are no known existing management practices that target the red-vented bulbul.

**Qu. 1.6a. How likely is the organism to be introduced into the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response:

The receiving zoo will always know that they are introducing the red-vented bulbul. Additionally, when on display, visitors will also detect this bird.

**Qu. 1.7a. Estimate the overall likelihood of introduction into the risk assessment area based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

The red-vented bulbul is already introduced in the risk assessment area, as it is present in several zoological gardens. Since zoological gardens can acquire a license to import wild birds and this species is not considered threatened, we can say with high confidence that it is very likely that the red-vented bulbul will be introduced into the risk assessment area through this pathway.

*End of pathway assessment, repeat Qu. 1.3 to 1.7 as necessary using separate identifier.*

**Qu. 1.2b. ESCAPE from confinement: Pet/aquarium/terrarium species (including live food for such species)**

**Is introduction along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	intentional unintentional	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	------------------------------	-------------------	------------------------------

Response:

Intentional because a person will intentionally buy the red-vented bulbul to keep as a pet even if the subsequent escape would be accidental (following IUCN 2017).

**Qu. 1.3b. How likely is it that large numbers of the organism will be introduced through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in introduction whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response:

On several hobbyist websites, it is stated that the red-vented bulbul is among the most easily-kept of the softbills, which is a term applied to non-typical cage birds, such as bulbuls. The species has a confident and inquisitive nature, with a “friendly” personality towards humans, making them popular as pets. As stated in Qu. A13, there are no official records on trade volumes, but there are plenty of advertisements for birds online, often sold in pairs. Prices found online vary from € 165–250 per bird or € 250 per pair. For example, in France, red-vented bulbuls are advertised for sale online at € 250 per pair ([www.leboncoin.fr](http://www.leboncoin.fr)). Captive breeding in outdoor aviaries occurs as French regulations do not require a declaration of detention up to 50 individuals (personal communication J.-F. Maillard, June 2020). Wild caught bird trade (as opposed to captive bred) has been suspended in the EU since 2005, when a temporary ban on wild bird imports was installed to prevent the spread of avian influenza (Reino et al., 2017). The ban was made permanent in 2007 and considers all wild caught bird imports regardless of species’ conservation status. This ban has been effective in reducing propagule pressure (Cardador et al., 2019). We did not find any records of illegal trade into the EU from non-EU countries. At the moment, there are no documented records of illegally imported red-vented bulbuls in the risk assessment area. It is however possible that releases could happen, for instance by activists or pet owners wanting to free their birds, not being able to take care of them, releasing excess birds after overly successful breeding or because of panic releases (cf. Hulme, 2015). However, we know the red-vented bulbul is exchanged/traded between hobbyists within Europe. We did not find information on the number of the red-vented bulbul present in the risk assessment area, which makes it impossible to assess propagule pressure. Neither do we know how many birds are exchanged/traded between hobbyists, so we also have no idea of the market for animals bred in captivity. Our confidence is therefore low.

**Qu. 1.4b. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response:

As stated in Qu. 1.3b, we do not know if the red-vented bulbul is imported into the EU illegally, making it very difficult to assess if many birds die during transport. We can assume though that the intention is to bring live animals with the aim to keep them and make them reproduce in captivity. Likewise, in the case of exchange/trade between hobbyists, their intention is to keep the birds alive and well during transport to deliver them so survival is likely. Since we have no official records on this matter, confidence is low.

**Qu. 1.5b. How likely is the organism to survive existing management practices during transport**

**and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

In the case of trade between hobbyists, this is a legal trade pathway with the intention to keep the birds alive and well during transport to deliver them to the buyer. As stated above, we do not know if the red-vented bulbul is imported into the EU illegally. We also do not know of any existing management practices that could possibly kill the red-vented bulbul during transport and storage along this pathway. According to the IUCN, the red-vented bulbul is not subjected to any international management or trade controls (IUCN, 2019). Because of this, we think it is very likely that the red-vented bulbul will survive existing management practices, with medium confidence.

**Qu. 1.6b. How likely is the organism to be introduced into the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

The red-vented bulbul has been introduced without being detected at first in several parts of its invasive range in the Pacific and the Middle East (Watling, 1978; Vander Velde, 2002). However, we could not find evidence on any undetected introductions of the red-vented bulbul into the risk assessment area, so confidence is only medium.

**Qu. 1.7b. Estimate the overall likelihood of introduction into the risk assessment area based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b>	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

	likely very likely		
--	-----------------------	--	--

Response:

This species is already present as a pet in private collections in several (if not all) countries within the risk assessment area. Several hobbyist websites currently have the species on offer, suggesting it is very likely to be introduced repeatedly in the future within the risk assessment area. However, information on introduction from outside the risk assessment area is lacking, therefore our response is moderately likely with low confidence.

*End of pathway assessment, repeat Qu. 1.3 to 1.7 as necessary using separate identifier.*

**Qu. 1.2c. TRANSPORT stowaway: Hitchhikers on ship/boat (excluding ballast water and hull fouling)**

**Is introduction along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response:

If the red-vented bulbul were to hitchhike on cargo ships or fishing boats, then this would be unintentional transport.

**Qu. 1.3c. How likely is it that large numbers of the organism will be introduced through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in introduction whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	<b>low</b>
-----------------	---------------	-------------------	------------

	unlikely <b>moderately likely</b> likely very likely		medium high
--	---	--	----------------

Response:

Some of the introductions of red-vented bulbul on the Marshall Islands could possibly be stowaways on container ships or fishing boats (Vander Velde, 2002; Brochier et al., 2010). Locations of first sightings in Majuro were all in close proximity to its major commercial port. Here, containers enter from Hawaii and Asia, where there are resident populations of red-vented bulbul. There are also speculations that introductions in Hawaii and New Zealand (Auckland in the 1950s) could have been assisted by barge or boat (Islam & Williams, 2000; Heather & Robertson, 1996).

Red-vented bulbuls are known to nest in some unusual places, including the motor of a ceiling fan and the end of a curtain rod, both within buildings (Islam & Williams, 2000). Hence, the possibility exists that a few birds stowed away among some heavy equipment or in crevices on board of a ship (Vander Velde, 2002). However, there are no confirmed stowaways so the confidence level of our answer is low.

This type of introductory event is considered to be moderately likely, since it possibly already happened outside of the risk assessment area. However, there are no official records of this, so confidence level is low.

**Qu. 1.4c. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response:

see Qu. 1.3c.

In the past, some birds were stowaways and survived on a ship from Hawaii to Majuro (Marshall Islands), a journey of around 3700 km (Vander Velde et al., 2002). Birds from the population on the Arabian Peninsula could possibly hitchhike to Europe through this pathway (the distance from Dubai to Cyprus is around 6000 km). There is also a population on Fuerteventura, one of the Canary Islands (Spain) (Nowakowski and Dulisz 2019). The journey from Fuerteventura to Cádiz (Spain) is just over 1100 km, which probably is perfectly manageable for the red-vented bulbul.

When it comes to food supply for survival, if a couple of red-vented bulbuls have been able to survive a journey of 3700 km (Vander Velde, 2002), they probably found food or were fed along the way, indicating this could also be possible for journeys of 6000 km or more.

**Qu. 1.5c. How likely is the organism to survive existing management practices during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response:

There are no known management practices for these birds on ships, hence it is likely to survive transport and storage along the pathway.

**Qu. 1.6c. How likely is the organism to be introduced into the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response:

It is unlikely stowaway red-vented bulbul on cargo ships or fishing boats would remain undetected during the journey. These birds are noisy, active and curious (Vander Velde, 2002). Nonetheless, even if the birds would be detected, there is no certainty that this sighting would ever be reported by the sailors. Since there are no official records of this happening, the confidence is low.

**Qu. 1.7c. Estimate the overall likelihood of introduction into the risk assessment area based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely	<b>CONFIDENCE</b>	<b>low</b> medium
-----------------	---------------------------	-------------------	----------------------

	<b>moderately likely</b> likely very likely		high
--	---	--	------

Response:

This has possibly happened in the past in the Pacific Ocean, not in the risk assessment area. There are no official records so the confidence is low.

*End of pathway assessment, repeat Qu. 1.3 to 1.7 as necessary using separate identifier.*

**Qu. 1.8. Estimate the overall likelihood of introduction into the risk assessment area based on all pathways and specify if different in relevant biogeographical regions in current conditions.**

Provide a thorough assessment of the risk of introduction in relevant biogeographical regions in current conditions: providing insight in to the risk of introduction into the Union.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

This species is already present in zoological gardens and private collections in multiple countries within the risk assessment area. We did not find any quantitative data though. Since there is a ban on the introduction of wild birds into the EU, from which only zoological gardens with a license are exempted, it is most likely that the red-vented bulbul will be introduced through the first pathway. Introductions into private collections are less likely, and introductions as stowaways will be the least likely. There are no indications of differences between biogeographical regions.

**Qu. 1.9. Estimate the overall likelihood of introduction into the risk assessment area based on all pathways in foreseeable climate change conditions?**

Thorough assessment of the risk of introduction in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)

- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of introduction (e.g. change in trade or user preferences)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely introduction within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

The likelihood of introduction will not change in any climate change scenario since none of the pathways will be affected by any of these scenarios.

## 2 PROBABILITY OF ENTRY

### Important instructions:

- Entry is the release/escape/arrival in the environment, i.e. occurrence in the wild. Entry is not to be confused with spread, the movement of an organism within the risk assessment area.
- The classification of pathways developed by the Convention of Biological Diversity (CBD) should be used. For detailed explanations of the CBD pathway classification scheme consult the IUCN/CEH guidance document<sup>5</sup> and the provided key to pathways<sup>6</sup>.
- For organisms which are already present in the risk assessment area, only complete this section for current active or if relevant potential future pathways. This section need not be completed for organisms which have entered in the past and have no current pathway of entry.

### Qu. 2.1. List relevant pathways through which the organism could enter into the environment.

For each pathway answer questions 2.2 to 2.7 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 2.2a, 2.3a, etc. and then 2.2b, 2.3b etc. for the next pathway.

In this context a pathway is the route or mechanism of entry of the species into the environment.

If there are no active pathways or potential future pathways this should be stated explicitly here, and there is no need to answer the questions 2.2-2.8

Pathway name:

- a) ESCAPE from confinement: Botanical garden/zoo/aquaria (excluding domestic aquaria)
- b) ESCAPE from confinement: Pet/aquarium/terrarium species (including live food for such species)
- c) TRANSPORT stowaway: Hitchhikers on ship/boat (excluding ballast water and hull fouling)

Deliberate releases of red-vented bulbul for biocontrol of insect pests have also been documented in the Indo-Pacific (Watling, 1978). As this is not an active pathway in the risk assessment area we do not consider it here. Furthermore, outside the risk assessment area, red-vented bulbul was introduced through other intentional release. For example, the initial introduction in 1903 on the Fiji islands was attributed to Indian immigrants bringing the species for bulbul fighting and releasing them to avoid persecution (Parham, 1955; Watling, 1978; Gill et al., 1995). Since 2016 this practice is however banned (Ratnagar, 2015). Also, in several Asian countries (China, Vietnam, Malaysia, Thailand, Korea, Cambodia, possibly more), people “make merit” by releasing captive animals for religious reasons (McNeely, 2001). Although these prayer releases do occur in Asia (McNeely, 2001; Severinghaus & Chi, 1999), we consider them less relevant for Europe and therefore this pathway is not dealt with here.

<sup>5</sup> <https://circabc.europa.eu/sd/a/738e82a8-f0a6-47c6-8f3b-aeddb535b83b/TSSR-2016-010%20CBD%20categories%20on%20pathways%20Final.pdf>

<sup>6</sup> <https://circabc.europa.eu/sd/a/0aeba7f1-c8c2-45a1-9ba3-bcb91a9f039d/TSSR-2016-010%20CBD%20pathways%20key%20full%20only.pdf>

**Qu. 2.2a. ESCAPE from confinement: Botanical garden/zoo/aquaria (excluding domestic aquaria)**

**Is entry into the environment intentional (e.g. the organism is released for a specific purpose) or unintentional (e.g. the organism escapes from confinement)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response:

Escape, so entry into the environment is unintentional with high confidence.

**Qu. 2.3a. How likely is it that large numbers of the organism will enter into the environment along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of entry into the environment based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in entry whereas for others high propagule pressure (many thousands of individuals) may not).

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

The red-vented bulbul is present in several EAZA zoological gardens throughout Europe (see Qu. 1.3a). These are all located in Northern or Central Europe, not in Southern Europe, where we expect more suitable habitat and climate for red-vented bulbul. However, as stated above, EAZA only represents a quarter of all European zoological gardens, so there might be some in zoological gardens in Southern Europe.

There is a record of a zoo escape on Fuerteventura (Canary Islands), outside of the risk assessment area. Here, birds escaped from the zoological garden of La Lajita in 2013 (together with common

myna *Acridotheres tristis*), settled and started to breed in the surroundings a few years later (Nowakowski and Dulisz 2019). The myna was eradicated from the surroundings of the zoo, yet the bulbuls were left unattended and spread to the rest of the island (Nowakowski and Dulisz 2019). Considering the potential impact on biodiversity of the Canary Islands ecosystems, including by predation on native and endemic species, there are calls for its eradication (SEO/Birdlife 2017).

**Qu. 2.4a. How likely is the organism to enter into the environment within the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response:

It is very unlikely that the red-vented bulbul would be able to escape from a zoological garden without this being noticed. In the event of an escape, the zoo will most likely take measures to recapture the animal. However, a study by Cassey & Hogg (2015) in Australia stated that, compared with mammals and reptiles, bird escapes were significantly less likely to be retrieved, and more likely to remain undetected.

**Qu. 2.5a. How likely is the organism to enter into the environment during the months of the year most appropriate for establishment?**

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response:

Mean annual temperature is the limiting factor for most of the risk assessment area. If the red-vented bulbul would escape in northern Europe, then it would likely enter a habitat which is too cold in autumn, winter and spring. The bird could possibly survive if it would enter into the environment during summer.

For more information on climate suitability see Qu. A7.

**Qu. 2.6a. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host in the environment?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response:

Zoological gardens are often located in urbanized areas, meaning that if the red-vented bulbul would escape, it would easily find an urban garden or park in which to establish. As mentioned in Qu. 2.5a, if the zoological garden is located too northerly in Europe, the climate will be too cold during autumn, winter and spring.

**Qu. 2.7a. Estimate the overall likelihood of entry into the environment within the risk assessment area based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response:

If the red-vented bulbul is present in zoological gardens within its predicted suitable habitat, then it is moderately likely that the species would enter into the environment within the risk assessment area. Given that we do not have information on the presence of the red-vented bulbul in zoological gardens within these suitable areas, the confidence level is low.

*End of pathway assessment, repeat Qu. 2.2 to 2.7. as necessary using separate identifier.*

**Qu. 2.2b. ESCAPE from confinement: Pet/aquarium/terrarium species (including live food for such species)**

**Is entry into the environment intentional (e.g. the organism is released for a specific purpose) or unintentional (e.g. the organism escapes from confinement)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response:

Escape, so entry into the environment is unintentional, with a high confidence level.

**Qu. 2.3b. How likely is it that large numbers of the organism will enter into the environment along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of entry into the environment based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in entry whereas for others high propagule pressure (many thousands of individuals) may not).

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

The red-vented bulbul is probably kept as a pet in most (if not all) countries within the risk assessment area (see Qu. 1.7b) and the species can easily be found on display for sale online, often under the name “Kala buulbuul” (e.g. [www.vogelspecialclub.nl](http://www.vogelspecialclub.nl)). For example, in the Netherlands, the species is kept and bred by members of a bird breeders association specialized in insect and fruit-eating species who adopted a code of best practice for keeping of red-vented bulbul (NBvB, 2014). It is known as a hardy species to keep in aviaries, which is easy to breed on a variety of mealworms and insects when they have young. Several hobby-keeper websites indicate that red-vented bulbul wings should not be clipped, since they exercise by flying, not by climbing. Some websites indicate the species should be kept in a large walk-in aviary, preferably outdoors, implying a higher chance of escape compared to birds kept inside in small cages. Additionally, red-vented bulbuls are often sold and kept in pairs, which implies that there is a high chance of breeding when they would escape. Shieh et al. (2006) reported that Pycnonotidae (with Sturnidae, Timaliidae and Cacatuidae) have significantly higher probabilities of escaping from captivity in Asia, in comparison to other birds families.

Considering the locations where birds were observed in the Netherlands and Belgium (see Qu. A6) and the fact that the species is kept in captivity, it can be assumed escapes have happened here in the past.

**Qu. 2.4b. How likely is the organism to enter into the environment within the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

If the red-vented bulbul would escape, it is likely that the keeper will alarm neighbours and maybe even animal rescue centres nearby.

**Qu. 2.5b. How likely is the organism to enter into the environment during the months of the year most appropriate for establishment?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

The red-vented bulbul is a species of equatorial climate, and will most likely only be able to establish in the Mediterranean biogeographical region within the risk assessment area. For more information on climate suitability see Qu. A7 and the SDM.

If this species would escape from its confinement in the south of Europe, then any moment of the year will probably be appropriate for establishment. The species is known to settle in urban areas, where temperatures are higher and food is more readily available, increasing its chances of establishment (Vander Velde, 2002).

In fact, there have been two successful entry events for the red-vented bulbul in the risk assessment area: in Málaga and in Valencia. In Valencia, there has been establishment following the entry of the species. It is possible that these birds escaped, but this has not been recorded.

Confidence level is medium because of the lack of official reports on the matter within the risk assessment area.

**Qu. 2.6b. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host in the environment?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:  
 See Qu. 2.6a.

**Qu. 2.7b. Estimate the overall likelihood of entry into the environment within the risk assessment area based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

This sort of event has happened (and was recorded) multiple times in the past outside the risk assessment area. Moreover, this has happened inside the risk assessment area too, but records of this are scarce and not official. The confidence level of our response is still high because of the records outside of the risk assessment area.

*End of pathway assessment, repeat Qu. 2.2 to 2.7. as necessary using separate identifier.*

**Qu. 2.2c. TRANSPORT stowaway: Hitchhikers on ship/boat (excluding ballast water and hull fouling)**

**Is entry into the environment intentional (e.g. the organism is released for a specific purpose) or unintentional (e.g. the organism escapes from confinement)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response:

Birds that hitchhike on a ship/boat would enter unintentionally.

**Qu. 2.3c. How likely is it that large numbers of the organism will enter into the environment along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of entry into the environment based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in entry whereas for others high propagule pressure (many thousands of individuals) may not).

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response:

This sort of event has allegedly happened before in the Pacific (Vander Velde, 2002). However, the number of birds that would actually be able to enter the environment through this pathway over the course of one year will be very low, therefore we score unlikely. Since we have no official records of this happening, our confidence is low.

For more information, see Qu. 1.3c.

**Qu. 2.4c. How likely is the organism to enter into the environment within the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	low
-----------------	---------------	-------------------	-----

	unlikely moderately likely likely very likely		medium <b>high</b>
--	--	--	-----------------------

Response:

See response Qu. 1.6b.

**Qu. 2.5c. How likely is the organism to enter into the environment during the months of the year most appropriate for establishment?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

The red-vented bulbul is a species of equatorial climate, and will most likely only be able to establish in the Mediterranean biogeographical region within the risk assessment area. For more information on climate suitability see Qu. A7 and the SDM (Annex VII).

There are populations of the red-vented bulbul on Fuerteventura (Canary Islands) and on the Arabian Peninsula, which are in fact closest to the areas within the risk assessment area where it is most likely that the red-vented bulbul could establish. For additional information regarding months of the year most appropriate for establishment, see response Qu. 2.5b.

**Qu. 2.6c. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host in the environment?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

See response to Qu. 2.6a.

**Qu. 2.7c. Estimate the overall likelihood of entry into the environment within the risk assessment area based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low medium high
-----------------	--	-------------------	-----------------------

Response:

This sort of event has probably happened in the past (not in the RA area), but has not been recorded very well, hence the low confidence.

*End of pathway assessment, repeat Qu. 2.2 to 2.7. as necessary using separate identifier.*

**Qu. 2.8. Estimate the overall likelihood of entry into the environment within the risk assessment area based on all pathways in current conditions and specify if different in relevant biogeographical regions.**

Provide a thorough assessment of the risk of entry into the environment in relevant biogeographical regions in current conditions.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

Entry has happened in several locations within the risk assessment area (at least in the Netherlands, Belgium, Spain, see Qu. A8). Since the red-vented bulbul is kept as a pet and is on display in zoological gardens, escape and release events are bound to occur in the future. Additionally, it is possible that some individuals or pairs will hitchhike with boats coming from areas with a red-vented bulbul population. Entry could happen in all biogeographical regions within the risk assessment area, but establishment will only be possible in the Mediterranean region. For additional information, see Qu. A7 and the SDM.

**Qu. 2.9. Estimate the overall likelihood of entry into the environment within the risk assessment area based on all pathways in foreseeable climate change conditions and specify if different in relevant biogeographical regions.**

Thorough assessment of the risk of entry in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk, specifically if likelihood of entry is likely to increase or decrease for specific pathways.

<b>RESPONSE</b>		<b>CONFIDENCE</b>	
	very unlikely unlikely moderately likely likely <b>very likely</b>		low <b>medium</b> high

Response:

Climate change will not alter the possibility of entry into the environment, so we score this question the same as we scored the question under current climate. For additional information, see Qu. A7 and SDM (Annex VII).

### 3 PROBABILITY OF ESTABLISHMENT

**Important instructions:**

- For organisms which are already established in parts of the risk assessment area, answer the questions with regard to those areas, where the species is not yet established.

**Qu. 3.1. How likely is it that the organism will be able to establish in the risk assessment area based on the history of invasion by this organism elsewhere in the world (including similarity between other abiotic conditions within it and the organism’s current distribution)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

The red-vented bulbul is a species of an equatorial climate but is also established in cooler and drier climate regions (including the Mediterranean biogeographical region), both in and outside of the risk assessment area. It has so far primarily established in urban areas, of which there is no shortage within the risk assessment area.

**Qu. 3.2. How widespread are habitats or species necessary for the survival, development and multiplication of the organism in the risk assessment area?**

<b>RESPONSE</b>	very isolated isolated <b>moderately widespread</b> widespread ubiquitous	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response:

The climatic niche of the red-vented bulbul corresponds to an equatorial climate according to the Koppen-Geiger classification (Kottek et al., 2006). In the Mediterranean biogeographical region, suitable habitat for the red-vented bulbul is moderately widespread. Under current climate the area predicted suitable represents only 2% of the entire Mediterranean bioregion but is likely to increase under future climatic conditions (see 7a,b; Annex VII, figure 9). Especially Cyprus, the southern

islands of Greece, Southern Andalucia (Spain) and the area around Gibraltar, and a small part of France are at risk. With a non-native range that is still expanding, there is a possibility that the potential climatic niche hence the predicted potential distribution is underestimated.

The red-vented bulbul feeds on a variety of fruits, berries, flowers, buds, insects and small vertebrate prey (Bhatt & Kumar 2001). This broad diet that includes cultivated plants allows the red-vented bulbul to find food easily. Red-vented bulbul builds its nest in trees and bushes at different heights, either on the forks of trees, in the middle or at the top (Vijayan, 1980; Zia et al., 2014). According to several studies, preferred nest height varies from 1 - 4 metres and preferred trees are thorny and very close to each other (Vijayan, 1980; Watling, 1983; Zia et al., 2014). The study done by Zia et al. (2014) in the native range in India found that the percentage of failed nests was highest for treetop nests, with most nests being destroyed due to heavy wind, rain or predators. Such thorny trees are omnipresent in the Mediterranean, not the least on the Greek islands, therefore red-vented bulbul has plenty of suitable breeding habitat available in the Mediterranean biogeographical region.

It is unlikely that the red-vented bulbul would be able to establish in the northern Atlantic, Boreal, Pannonian, Steppe, Black Sea, Alpine or Continental biogeographical regions, due to the cold winter (Annex VII). This is corroborated by reports from a keeper in The Netherlands who says that several young died when kept outside due to the cold weather during the night (<http://www.buulbuul.nl/Mijn%20Kala%20buulbuul.html>).

**Qu. 3.3. If the organism requires another species for critical stages in its life cycle then how likely is the organism to become associated with such species in the risk assessment area?**

<b>RESPONSE</b>	N/A very unlikely unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

The red-vented bulbul does not require another species for any critical stage of its life cycle.

**Qu. 3.4. How likely is it that establishment will occur despite competition from existing species in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

	very likely		
--	-------------	--	--

Response:

Potentially, the red-vented bulbul could compete for food and space (e.g. for nesting) with other bird species. However, as establishment often occurs in (sub)urban areas with gardens, parks and artificial habitat (see A8, A10), usually depleted in local fauna, very low levels of competition with native species can be expected and it is very likely establishment will occur despite this. In the risk assessment area, competition with highly successful native species such as corvids, gulls and starlings could impact establishment in some cases, but there have been no studies that have assessed this so far hence medium confidence.

It should be noted that the red-whiskered bulbul (*P. jocosus*) established around Valencia shortly after the first observation was made in 2003 in the lower Rio Turia basin area (Santos 2015). The red-whiskered bulbul has been reproducing for more than a decade here and was estimated at 100-150 individuals in 2016 (Santos 2015). Detailed impact studies for Spain are equally lacking for this species. However, as the two species of bulbul are now sympatric, there is the possibility of cumulated impact of an entire invasive bird community. Introduced species may act in concert, facilitating one another's invasion, and increasing the likelihood of successful establishment, spread and impact. Such positive interactions among introduced species are relatively common (e.g. between birds/mammals and plants), but few have been studied in detail (Traveset & Richardson 2014). No information on such mechanisms is available for bulbuls.

The red-vented bulbul is known to be aggressive towards other birds in its preferred forage trees, especially during the breeding season (Sherman & Fall, 2010; Blanvillain et al., 2003; Gorman 1972). Competition with other (native) bird species is in fact one of the three serious impact categories associated with red-vented bulbul, so it is unlikely that competition will be limiting for this bird (Thibault et al., 2018d). For example, in Tahiti, red-vented bulbuls compete with the Tahiti monarch (*Pomarea nigra*), an endemic and critically endangered passerine (Blanvillain et al., 2003). Another study, done by Thibault et al. (2018d) in New-Caledonia found that nine out of ten native bird species monitored in man-modified habitats were less abundant when the red-vented bulbul was present. The impact of the red-vented bulbul appears to be restricted to niche contraction of the native species (Thibault et al., 2018d).

A study in New Caledonia (Thibault et al., 2018d) states that there are no indications for interspecific competition with other invasive species present on the island, such as common myna (*Acridotheres tristis*) and red-whiskered bulbul. It is possible that these species show some sort of niche segregation in their invaded range, as shown for red-vented bulbul and common myna in French Polynesia by Bates et al. (2014).

**Qu. 3.5. How likely is it that establishment will occur despite predators, parasites or pathogens already present in the risk assessment area?**

<b>RESPONSE</b>	N/A	<b>CONFIDENCE</b>	low
-----------------	-----	-------------------	-----

	very unlikely unlikely moderately likely <b>likely</b> very likely		medium <b>high</b>
--	--	--	-----------------------

Response:

Predators

The red-vented bulbul is not particularly vulnerable to predation. In its native range, a study carried out by Zia et al. (2017) found that predation rate on red-vented bulbul was only 6% in eggs and 9% in nestlings. Predators in the study area included bird species such as crested eagle (*Morphnus guianensis*) and barn owl (*Tyto alba*), and rodents such as the black rat (*Rattus rattus*). Breeding success in the study was 82% and 86% for eggs and fledglings, respectively. The red-vented bulbul has specific behavioural adaptations to avoid predatory impact during nesting, notably through broken-wing display, that one or both parents would perform when a predator is seen near the nest (Kumar 2004, 2010).

Parasites

In its native range, the red-vented bulbul is known to host the internal parasite *Isospora* spp. known to cause isosporiasis in passerine birds (Boughton et al., 1938), lice species such as *Menacanthus eurysternus* (Price 1975), *Bruelia guldum*, *Sturnidoecus guldum* (Ansari 1957), the mite *Pteroherpis pycnonoti* (Constantinescu et al., unpublished) as well as disease carrying ticks (Islam & Williams, 2000; Vander Velde & Vander Velde 2013; Thibault et al., 2018c). Vander Velde and Vander Velde (2013) considered the constant influx of red-vented bulbuls on Micronesia a potential risk for the spread of tick-borne diseases.

Pathogens

In 1996, Jarvi et al. (2003) detected no avian malaria (*Plasmodium* spp.) in blood smears, and Atkinson et al. (2006) found no evidence of *Plasmodium*, *Trypanosoma*, *Atoxoplasma* or microfilaria. Red-vented bulbuls in Tahiti, however, have been found to carry the zoonotic disease *Chlamydia* sp. (Blanvillain et al., 2013). Grewal (1964) experimentally infected red-vented bulbuls with *Plasmodium praecox* (= *relictum*), the most widespread malaria parasite of birds. The birds developed typical infections about a week after inoculation and survived without apparent. The species may therefore be a carrier in nature (Grewal 1964).

**Qu. 3.6. How likely is the organism to establish despite existing management practices in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

	<b>very likely</b>		
--	--------------------	--	--

Response:

There are no known existing management practices against this species in the risk assessment area.

**Qu. 3.7. How likely are existing management practices in the risk assessment area to facilitate establishment?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response:

There are no known existing management practices against this species in the risk assessment area.

**Qu. 3.8. How likely is it that biological properties of the organism would allow it to survive eradication campaigns in the risk assessment area?**

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

As stated before, the red-vented bulbul is a loud species and it is thus unlikely to stay undetected. It is in fact this biological property that will make it more susceptible to eradication campaigns.

The most suitable habitat for the red-vented bulbul are Cyprus and the Greek islands. Invasive alien species control tends to be more achievable on islands than on the continent (Myers et al., 2000; McGeoch et al., 2016).

For more information, see the Annex with control measures.

**Qu. 3.9. How likely are the biological characteristics of the organism to facilitate its establishment in the risk assessment area?**

including the following elements:

- a list and description of the reproduction mechanisms of the species in relation to the environmental conditions in the Union
- an indication of the propagule pressure of the species (e.g. number of gametes, seeds, eggs or propagules, number of reproductive cycles per year) of each of those reproduction mechanisms in relation to the environmental conditions in the Union.

If relevant, comment on the likelihood of establishment based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

The red-vented bulbul lives in anthropogenic landscapes in all of its alien range in the Pacific, Houston, Fuerteventura, Málaga and Valencia, so it can be assumed that the highly fragmented and anthropogenic landscape in southern Europe will not hamper its establishment.

If a pair escapes or is released from confinement, a population could establish from just this pair given that genetic diversity is sufficiently high. This is allegedly what happened in the Republic of the Marshall Islands, when a pair may have hitchhiked on a ship and established a population (Vander Velde, 2002).

The red-vented bulbul often has two to three broods per year, that consist of two to five eggs (Long, 1981; Vander Velde, 2002), with an incubation period of about 14 days (Berger, 1972). Consequently, population size is likely to increase fast, leading to establishment.

**Qu. 3.10. How likely is the adaptability of the organism to facilitate its establishment?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

The red-vented bulbul is a species that thrives in urban and suburban gardens and parks, indicating that it is an adaptable species (Brooks, 2013; Thibault, 2018a). Thibault (2018a) showed that densities in suburban areas vary along an urbanization gradient, but can go up to 120 individuals/km<sup>2</sup>. In their native range, bulbuls are found from 0 to 2,000m, along forest edges, as well as in gardens and cultivated areas. These habitats have plenty of exotic plant species available to red-vented bulbul, usually not or little consumed by local wildlife, a resource that can easily be exploited by these adaptable birds and offering some advantage over native passerines. Virtually all of the bulbuls in Houston are found in residential gardens at sea level, with the only other cases being fragments of secondary habitat in edge situations.

**Qu. 3.11. How likely is it that the organism could establish despite low genetic diversity in the founder population?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

No genetic diversity studies have been done on the red-vented bulbul, but several studies on singular breeding species (i.e., species that breed in pairs on a defended territory) show that these do not avoid random mating (Van Tienderen & van Noordwijk, 1988; Keller & Arcese, 1998; Hansson et al., 2007). However, Kruuk et al. (2002) noticed severe inbreeding depression in collared flycatchers, indicating species-specific differences in inbreeding tolerance.

Even with a small founder population, the red-vented bulbul has established in several parts of the world where it is thriving (also see Qu. A5).

**Qu. 3.12. If the organism does not establish, then how likely is it that casual populations will continue to occur?**

Consider, for example, a species which cannot reproduce in the risk assessment area, because of unsuitable climatic conditions or host plants, but is present because of recurring introduction, entry and release events. This may also apply for long-living organisms.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

Since the red-vented bulbul is a popular pet bird and is present in zoological gardens, there is a continuous risk of release and escape in the future. Actual recurring introduction, entry and release events without establishment will happen in areas with unsuitable climatic conditions, e.g. in many colder parts of Europe, where it is too cold for the red-vented bulbul to reproduce successfully.

**Qu. 3.13. Estimate the overall likelihood of establishment in the risk assessment area based on the similarity between climatic conditions within it and the organism’s current distribution under current climatic conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under current climatic conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in current conditions: providing insight in the risk of establishment in (new areas in) the Union.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

As stated in Qu. A7 and the SDM (Annex VII), establishment is most likely in the Mediterranean biogeographical region but only a small proportion of the area is predicted suitable. Indeed, establishment has already happened in Valencia (Spain). The ensemble model (Annex VII) suggested that the suitable distribution area for red-vented bulbul was most strongly determined by Annual mean temperature (Bio1), accounting for 43.5% of variation explained, followed by Mean temperature of the warmest quarter (Bio10) (24.7%). Annual mean temperature (Bio1) was also the most strongly limiting factors for establishment of red-vented bulbul in most of Europe and the Mediterranean region in current climatic conditions. In some Mediterranean areas (southern Iberia, Balearic islands, Sicily and Sardinia, Greece and Aegean islands, Cyprus), Precipitation of the wettest month (Bio13) was the most limiting factor. Other climatic variables such as Precipitation of the wettest month (Bio13) (8.8%), Minimum temperature of the coldest month (Bio6) (8.3%), Annual precipitation (Bio12) (5.9%) and Precipitation of the driest month (Bio14) (2.3%) explained much less of the variation in the species distribution model. The considered Non-climatic factors Human influence index (HII) (5.6%) and Global tree cover (Tree) (0.9%) explained only little of the observed variation. For information about important non-climatic variables, see Qu. 3.14.

**Qu. 3.14 Estimate the overall likelihood of establishment in the risk assessment area under foreseeable climate change conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under foreseeable climate change conditions should be**

**provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of establishment (e.g. increase in average winter temperature, increase in drought periods)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely establishment within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

As stated in Qu. A7 and the SDM (Annex VII), establishment is estimated to be possible in the Mediterranean biogeographical regions under both RCP 2.6 and RCP 4.5. The Mediterranean will remain the most vulnerable region under climate change. The proportion of the area suitable for establishment in the Mediterranean biogeographical region is predicted to double under RCP 2.6 and to triple under RCP 4.5 by 2070. Therefore, we scored very likely.

## 4 PROBABILITY OF SPREAD

### Important instructions:

- Spread is defined as the expansion of the geographical distribution of an alien species within the risk assessment area.
- Repeated releases at separate locations do not represent continuous spread and should be considered in the probability of entry section. In other words, intentional anthropogenic “spread” via release or escape (“jump-dispersal”), should be dealt within the entry section. However, as repeated releases contribute to the spread of the target organism in the risk assessment area, the relevant pathway(s) should be briefly discussed here too, with an explicit reference to the entry section for additional details.

### Qu. 4.1. How important is the expected spread of this organism within the risk assessment area by natural means? (List and comment on each of the mechanisms for natural spread.)

including the following elements:

- a list and description of the natural spread mechanisms of the species in relation to the environmental conditions in the risk assessment area.
- an indication of the rate of each of those spread mechanisms in relation to the environmental conditions in the Union.

The description of spread patterns should include elements of the species life history and behavioural traits able to explain its ability to spread, including: reproduction or growth strategy, dispersal capacity, longevity, dietary requirements, environmental and climatic requirements, specialist or generalist characteristics.

RESPONSE		CONFIDENCE	
	minimal		low
	minor		<b>medium</b>
	<b>moderate</b>		high
	major		
	massive		

Response:

For information on spread outside of the risk assessment area, see Qu. A5. For information on spread inside of the risk assessment area, see Qu. A8(b). There is a discrepancy between spread rate inside and outside of the risk assessment area, the rate being higher outside than inside. The rate of spread will be dependent on propagule pressure and the size of the population that has established.

Life history traits important for spread: the breeding season in the red-vented bulbul starts in February and lasts till September (Zia et al., 2014). Nest construction period is only 2 - 5 days, which is notably faster than other Pycnonotids like yellow-throated bulbul and grey-headed bulbul for which nest building takes 3 - 8 days (Balakrishnan, 2010). According to a study performed by Zia et al. (2014), preferred nest-building vegetation of the red-vented bulbul was beri (*Zizyphus nummularia*) (31%) followed by guava (*Psidium guajava*) (22%), sheesham (*Dalbergia sissoo*) (18%), snatha (*Dodonea viscosa*) (16%) and date palm (*Phoenix dactylifera*) (13%). Clutch size in general in Pycnonotids is two and rarely three (Ali & Ripley, 1987). Clutch size of the red-vented bulbul varies from 1 - 4, and

there are indications that this varies between regions, as studies from different regions of the species' range have partially different results (Zia et al., 2017; Prajapati et al., 2011; Rao et al., 2013).

The study done by Zia et al. (2014) also recorded the predators of the red-vented bulbul nests. Mostly, rodents and raptors were responsible for failed nests, e.g. brown rat (*Rattus rattus*), barn owl (*Tyto alba*) and crested eagle (*Morphnus guianensis*). Another interesting found in the study was that nests made in beri plants were more likely to fail which could be connected to their location near residential areas, where human disturbance and urban pollution could have an effect on red-vented bulbul reproductive success.

**Qu. 4.2. How important is the expected spread of this organism within the risk assessment area by human assistance? (List and comment on each of the mechanisms for human-assisted spread and provide a description of the associated commodities.)**

including the following elements:

- a list and description of the anthropogenic spread mechanisms of the species in relation to the environmental conditions in the Union.
- an indication of the rate of each of those spread mechanisms in relation to the environmental conditions in the Union.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response:

The red-vented bulbul is known to nest in unusual sites (see Qu. 1.3b), and it could therefore spread by human assistance on cargo ships or fishing boats within the risk assessment area. It appears that this species preferentially spreads through urban corridors, possibly facilitating its spread in most European countries.

**Qu. 4.2a. List and describe relevant pathways of spread. Where possible give detail about the specific origins and end points of the pathways. For each pathway answer questions 4.3 to 4.9 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 4.3a, 4.4a, etc. and then 4.3b, 4.4b etc. for the next pathway.**

including the following elements:

- a list and description of pathways with an indication of their importance and associated risks (e.g. the likelihood of spread in the Union, based on these pathways; likelihood of survival, or reproduction, or increase during transport and storage; ability and likelihood of transfer from the pathway to a suitable habitat or host). Where possible details about the specific origins and end points of the pathways shall be included.

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication.
- All relevant pathways should be considered. The classification of pathways developed by the Convention of Biological Diversity shall be used.

Pathway name:

TRANSPORT (stowaway) - Hitchhikers on ship/boat (excluding ballast water and hull fouling)

**Qu. 4.3a. Is spread along this pathway intentional or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response:

Unintentional.

**Qu. 4.4a. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response:

Introduction, establishment and spread of the red-vented bulbul has allegedly happened through this pathway in the Pacific, suggesting that this could happen in the risk assessment area as well (Vander Velde et al., 2002). The red-vented bulbul was first sighted on the Marshall Islands in 2000 near the major commercial dock of Majuro and in 2002, there were already several breeding populations (Vander Velde, 2002).

The Mediterranean region and the Greek islands in particular are vulnerable given the large amount of islands and boat (commercial and leisure) traffic between them.

Also see response to Qu 1.3c and 1.4c.

**Qu. 4.5a. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

This sort of event has allegedly already happened in the Pacific (Vander Velde et al., 2002), but evidence is scarce, hence the low level of confidence. See Qu. 1.3c & 1.4c.

**Qu. 4.6a. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

There are no known existing management practices on ships that would target the red-vented bulbul.

**Qu. 4.7a. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response:

Also see Qu. 2.4a.

**Qu. 4.8a. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread? (including, where possible, details about the specific origins and end points of the pathway)**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response:

If the organism would spread through the Mediterranean by boat transport, it would enter new areas through harbours, which are often close to urbanisation. This would enhance its chances of spread, since the species is known to settle in urban areas (Vander Velde, 2002), where temperatures are higher and food is more readily available, increasing its chances of establishment.

**Qu. 4.9a. Estimate the overall potential rate of spread within the Union based on this pathway? (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly <b>slowly</b> moderately rapidly very rapidly	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response:

Spread through this pathway has possibly happened in the Pacific, and could happen in the risk assessment area, especially in the Mediterranean region. However, there are no official records of this so confidence is low.

*End of pathway assessment, repeat Qu. 4.3 to 4.9. as necessary using separate identifiers.*

**Qu. 4.10. Within the risk assessment area, how difficult would it be to contain the organism in relation to these pathways of spread?**

<b>RESPONSE</b>	very easy easy <b>with some difficulty</b> difficult very difficult	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response:

The species is easily recognisable and will probably be detected when present on a ship. However, even if conspicuous, the species does have a track-record as a stowaway (Vander Velde et al., 2002). Should the red-vented bulbul get more firmly established in the risk assessment area, it would take considerable effort to implement biosecurity procedures preventing stowaways, for example through controls on shipping routes between Mediterranean islands. We found no information on standard measures that sailors take to prevent the birds from escaping the ship. We did find some recommendations from the Australian government for sailors that encounter a stowaway animal on a ship: closing container or vessel doors, creating barriers; isolating the affected cargo in an area away from other goods; using blankets to restrict animal movement; taking photos of the animal or try to catch it. As these sets of measures are complex, we assume this would be implemented with some difficulty at least.

**Qu. 4.11. Estimate the overall potential rate of spread in relevant biogeographical regions under current conditions for this organism in the risk assessment area (indicate any key issues and provide quantitative data where possible).**

Thorough assessment of the risk of spread in relevant biogeographical regions in current conditions, providing insight in the risk of spread into (new areas in) the Union.

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response:

Groups and families of the red-vented bulbul can be seen in Valencia, but their range is small (Carlos Gutiérrez-Expósito, personal communication 2018), suggesting that (mainland) spread is slow. For additional information, see Qu. A8. The relatively slow spread could however be context dependent (e.g. environmental conditions, lack of suitable dispersal corridors, food availability) and therefore it is difficult to generalize the Valencia case to the whole risk assessment area. Invasion histories elsewhere in the world illustrate the species is certainly able to spread in insular contexts where highly attractive habitat is linked by boats.

**Qu. 4.12. Estimate the overall potential rate of spread in relevant biogeographical regions in foreseeable climate change conditions (provide quantitative data where possible).**

Thorough assessment of the risk of spread in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk, specifically if rates of spread are likely slowed down or accelerated.

<b>RESPONSE</b>		<b>CONFIDENCE</b>	
	very slowly		low
	slowly		<b>medium</b>
	<b>moderately</b>		high
	rapidly		
	very rapidly		

Response:

The species is classified as a rather sedentary species, showing possible movements depending on environmental conditions (del Hoyo et al., 2005). The invasion on Fuerteventura, where the species invaded the entire island in a few decades and has shown important range expansion in the period 2013–2018 (Nowakowski and Dulisz 2019) indeed shows spread could be very context-dependent and the species is certainly able to spread moderately rapidly or rapidly in insular contexts.

## 5 MAGNITUDE OF IMPACT

Important instructions:

- Questions 5.1-5.5 relate to biodiversity and ecosystem impacts, 5.6-5.8 to impacts on ecosystem services, 5.9-5.13 to economic impact, 5.14-5.15 to social and human health impact, and 5.16-5.18 to other impacts. These impacts can be interlinked, for example a disease may cause impacts on biodiversity and/or ecosystem functioning that leads to impacts on ecosystem services and finally economic impacts. In such cases the assessor should try to note the different impacts where most appropriate, cross-referencing between questions when needed.
- Each set of questions starts with the impact elsewhere in the world, then considers impacts in the risk assessment area (=EU excluding outermost regions, and the United Kingdom) separating known impacts to date (i.e. past and current impacts) from potential future impacts (including foreseeable climate change).
- Only negative impacts are considered in this section (socio-economic benefits are considered in Qu. A.7)

### Biodiversity and ecosystem impacts

**Qu. 5.1. How important is the impact of the organism on biodiversity at all levels of organisation caused by the organism in its non-native range excluding the risk assessment area?**

including the following elements:

- Biodiversity means the variability among living organisms from all sources, including terrestrial, marine and other aquatic ecosystems and the ecological complexes of which they are part; this includes diversity within species, between species and of ecosystems
- impacted chemical, physical or structural characteristics and functioning of ecosystems

RESPONSE		CONFIDENCE	
	minimal		low
	minor		medium
	<b>moderate</b>		<b>high</b>
	major		
	massive		

Comment:

Impacts on biodiversity were comprehensively reviewed by Thibault et al. (2018a) and include impact on native fauna through competition and community changes due to dispersal of invasive alien plant seeds. The authors note the lack of quantified impact studies and based on this, challenge the inclusion of red-vented bulbul on the list of the world's worst invasive species (Lowe et al., 2004). Evans et al. (2016), in their EICAT assessment of 415 bird species, scored impact of the red-vented bulbul as Moderate (MO) (i.e. *it causes declines in the population size of native species, but no changes to the structure of communities or to the abiotic or biotic composition of ecosystems*) with high confidence and list competition and interaction with other alien species (spreading the seeds of alien plants and thereby mediating alien plant invasions) as the impact mechanisms causing the most severe impacts. Martin-Albarracin et al. (2015) and Baker et al. (2014), in a global analysis of alien bird impact, note

competition and interactions with other non-native species as impact mechanisms. According to their scoring system used (an adapted scheme based on Kumschick and Nentwig (2010) and Blackburn et al. (2014), where 0 indicates no impact detected and 5 massive impact), the red-vented bulbul scores 2 on competition (i.e. *competition with several native species by exploitation competition, without large impact on affected species or decline of their populations*) and 4 on interactions with other species (i.e. *dispersal of seeds of non-native plants facilitates local or population extinction of at least one native species, and produces changes in community composition that are reversible but would not have occurred in the absence of the species*).

Impact mechanisms:

### 1: Frugivory (spreading the fruit/seeds of alien plants)

Thibault et al. (2018c) compiled lists of 110 plant species consumed and 33 plant species dispersed by red-vented bulbul. In the literature there are at least 56 mentions of problematic seed dispersal by the species from eight locations (six countries) (Thibault et al., 2018c). Red-vented bulbul is considered a major vector of some notoriously problematic invasive alien plant species on islands, such as the invasive tree miconia (*Miconia calvescens*) and lantana (*Lantana camara*) in French Polynesia (Meyer, 1996; Spotswood et al., 2012; 2013), lantana (*Lantana camara*), prickly solanum (*Solanum torvum*) and cape gooseberry (*Physalis angulata*) on Fiji (Fox, 2011), ivy gourd (*Coccinia grandis*) on Oahu and Brazilian peppertree (*Schinus terebinthifolius*) in New Caledonia (Spotswood et al., 2012; Thouzeau-Fonseca, 2013). Watling (1978) described the early invasion in the Indo-Pacific region and noted that the distribution of the red-vented bulbul on islands could be determined by the presence of three weed species the species used as principal food: spiked pepper (*Piper aduncum*), turkey berry (*Solanum torvum*) and Cape gooseberry (*Physalis peruviana*). All of these introduced, weedy species subsequently spread on islands with bulbuls present (Watling 1978).

### 2: Competition

Blanvillain et al. (2003) provide evidence of competition with Tahiti monarch (*Pomarea nigra*), a forest bird endemic to Tahiti (French Polynesia). They noted aggressive interactions (e.g. alarm calls and chasing) between flycatchers and red-vented bulbuls during and outside reproductive activity and suggest this interspecific competition for nest sites and territories might be in part responsible for low breeding success of the Tahiti flycatchers. In contrast, interactions with common myna (*Acridotheres tristis*) were more common when the birds had chicks and eggs in the nest and therefore mynas had a more important direct impact as nest predators of the monarchs (Blanvillain et al., 2003). Competition between red-vented bulbul and other remaining native birds in Fiji forests was also suspected based on reported interspecific aggressive interactions towards at least four native species mostly during the bulbul's breeding season. This caused habitat shifts in native birds (Watling 1978, 1983). Thibault et al. (2018d) provide evidence for competition in man-modified habitats in New Caledonia showing a negative relationship between red-vented bulbul and the abundance of nine native (including endemic) species with which its distribution range overlaps, hence red-vented bulbul is believed to drive reassembly of native species toward sub-optimal locations along an urban-rural gradient, by its aggressive behaviour enabling it to out-compete native species and dominate access to food (Thibault et al., 2018d). Interestingly, the abundance of other introduced alien species (*Acridotheres tristis*, *Passer domesticus*, *Spilopelia chinensis*) was not affected.

### 3: Hybridisation

Also, some studies report the presence of hybrids due to cross-breeding with native related bulbuls, such as white-cheeked bulbul (*Pycnonotus leucogenys*), white-eared bulbul (*P. leucotis*) and yellow-

vented bulbul (*P. xanthopygos*) in the Middle East (Khamis, 2010; Thibault et al., 2018ab). In Bahrain, two local bird ringers (Brendan Kavanagh and Abdulla Al-Khaabi) recorded a cross-breeding incident between the red-vented bulbul and the white-cheeked bulbul (*P. leucogenys*), where they observed hybrid chicks in a nest. A culturally important species, the local population of the white-cheeked bulbul is under the continuous threat of habitat degradation and poaching. Hence, cross-breeding, which leads to sterile offspring, forms an additional threat to this already vulnerable species and should be considered seriously (Khamis, 2010). Hybridisation of red-vented bulbul with common bulbul (*P. barbatus*), which is one of the commonest birds in Africa that only recently started breeding in southern Spain around Tarifa, has not been reported. Common bulbul is however known to hybridize with four other species, from Africa (*P. capensis*, *P. nigricans*, *P. tricolor*) and the Middle East (*P. xanthopygos*) (<https://avibase.bsc-eoc.org/>).

#### 4: Predation

Other impacts include predation on invertebrates such as Hemiptera, Coleoptera, Odonata, Lepidoptera (Fox, 2011), Hymenoptera and Diptera, as well as small reptiles including geckos and skinks (Brooks et al., 2013; Thibault et al., 2019). On Hawaii, predation by red-vented bulbul and red-whiskered bulbul on larvae and adults of the iconic monarch butterfly *Danaus plexippus* (Lepidoptera: Nymphalidae) led to changes in the proportions of colour morphs in the population (Stimson and Kasuya 2000). Clearly, bulbuls are not deterred by the cardiac glycosides in the monarchs' tissues and can exert heavy predation on larvae feeding on their host plant milkweed (Stimson and Berman 1990). However, we could find no evidence of population level impacts on these species.

Based on and in line with these assessments of alien birds and with species-specific studies we consider the current impact of red-vented bulbul outside the risk assessment area as moderate. Although it is noted that its harmful effects on agricultural systems and native fauna could be highly context-dependent (Thibault, 2018a), there is good evidence of the species altering ecosystems through the spread of seeds of other alien and invasive plant species, and for competition with other bird species, but there is no evidence of red-vented bulbul causing extinctions. This is in line with Thibault et al. (2018d) who suggest that red-vented bulbul causes niche contractions rather than mortality in native species, especially in human-modified landscapes where native birds are already under pressure. No documented cases of recovery of native species after *Pycnonotus* eradication was found, but presumably, as native species are rather displaced and pushed out of optimal habitat, this process is also reversible. Hence a moderate impact score but with high confidence as there are a good number of reliable impact studies on red-vented bulbul from several populations in its invasive range.

**Qu. 5.2. How important is the current known impact of the organism on biodiversity at all levels of organisation (e.g. decline in native species, changes in native species communities, hybridisation) in the risk assessment area (include any past impact in your response)?**

Discuss impacts that are currently occurring or are likely occurring or have occurred in the past in the risk assessment area. Where there is no direct evidence of impact in the risk assessment area (for example no studies have been conducted), evidence from outside of the risk assessment area can be used to infer impacts within the risk assessment area.

<b>RESPONSE</b>	minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	--	-------------------	-----------------------

Comment:

No direct evidence is available on impact of red-vented bulbul in the risk assessment area. Since the only established population in Spain is presumably still small, impact can be assumed to be minimal but with low confidence due to the lack of impact studies in the RA area.

**Qu. 5.3. How important is the potential future impact of the organism on biodiversity at all levels of organisation likely to be in the risk assessment area?**

See comment above. The potential future impact shall be assessed only for the risk assessment area.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Comment:

The species could have impacts on native biodiversity at places where it becomes more widely established and numerous, such as in peri-urban habitats, but also more natural vegetation types such as maquis, open dry scrubland, and forest edge habitat. Here, following the same categorisation of impact mechanisms as in the alien range (see Qu. 5.1), we identified a number of potentially sensitive receptors (species, habitats, protected areas) within the risk assessment area which could be impacted upon, considering the areas where the species is already established or areas predicted suitable for establishment (Iberia, Mediterranean, Mediterranean islands).

1: Frugivory (spreading the fruit/seeds of alien plants)

Because of its frugivorous diet, the red-vented bulbul is a possible disperser of invasive alien plant seeds (see Q5.1), and could thus facilitate invasions of invasive plants (Traveset, 2006; Traveset and Richardson 2014; MacFarlane et al., 2016). It is well known that island ecosystems are especially sensitive to the impacts of invasive alien species and because of high levels of endemism (e.g. Tershy et al., 2015; Bellard et al., 2016). The Mediterranean basin is particularly vulnerable to invasive alien plant invasions because its climatic conditions potentially allow the establishment of sub-tropical and tropical species (Lambdon et al., 2008; Brunel et al., 2010; Brundu 2015). Mediterranean islands are especially vulnerable (Lloret et al., 2005; Vila et al., 2006, 2008; Hulme et al., 2008). A number of established and emerging invasive alien plants for Mediterranean countries produce fleshy fruits and could therefore potentially be spread by birds such as the red-vented bulbul in the risk assessment area

(cf. Gosper et al., 2005; Spotswood et al., 2012, 2013). American pokeweed (*Phytolacca americana*) and Indian pokeweed (*P. acinosa*) produce fleshy purple berries that are spread by birds (McDonnell et al., 1984). Other examples of (potentially) invasive alien plants that might be spread by red-vented bulbuls in the risk assessment area include Brazilian peppertree (*Schinus terebinthifolius*), a commonly planted ornamental in the Mediterranean which is reported to be spread by the species (Thibault et al., 2018c), silver-leaved nightshade (*Solanum elaeagnifolium*), a common agricultural weed (Brunel et al., 2010), sticky nightshade (*S. sisymbriifolium*), a weed of pastures and irrigated crops, roseleaf bramble (*Rubus rosifolius*), Chinese privet (*Ligustrum sinense*) and garden privet (*L. ovalifolium*) (Tanner 2017). Some of these species typically occur in human-modified areas such as parks, gardens and ruderal terrains. By comparison, also red-whiskered bulbuls (*P. jocosus*), a species with comparable ecology, are notorious for spreading invasive weeds including *Lantana* spp., *Rubus* spp., *Phytolacca* spp., *Chrysanthemoides* spp. and *Ligustrum* spp. in Mediterranean parts of Australia and this is considered their biggest impact on ecosystems (Mo 2015). In Spain, red-whiskered bulbuls have been reported feeding on seeds and fruits of native as well as non-native plant species e.g. kurrajong (*Brachychiton populneus*), fig (*Ficus carica*), strawberry tree (*Arbutus unedo*), loquat (*Eriobotrya japonica*), privet (*Ligustrum vulgare*), chinaberry tree (*Melia azedarach*), pomegranate (*Punica granatum*), Peruvian pepper (*Schinus molle*), date palm (*Phoenix dactylifera*), oleander (*Nerium oleander*) flowers, feijoa (*Acca sellowiana*) and yucca (*Yucca* sp.). On Mauritius, red-whiskered bulbuls also have similar species in their diets e.g. *Ligustrum robustum*, *Rubus rosifolius*, *Rubus alceifolius* (Linnebjerg et al., 2010). Spread of typical garden ornamentals by red-vented bulbul could be an issue in the Mediterranean considering the habitat preference of the species for gardens and man-made habitat, for example *Trachycarpus fortunei*, *Mahonia aquifolium*, non-native *Ribes* sp., *Parthenocissus* sp., *Cotoneaster* sp., *Rosa* sp., *Elaeagnus* sp., *Ziziphus jujuba*, *Morus* sp., *Pittosporum* sp., *Myoporum* sp., *Mirabilis jalapa*, *Opuntia* sp., *Lycium* sp., *Lonicera* sp., *Aralia* sp. and *Hedera* sp. With regards to IAS of Union concern (Union list as it stands in 2019), *Persicaria perfoliata* is the only species that produces berry-like fruits (personal communication G. Brundu, 23/10/2019).

## 2: Competition

Impact on native bird species will mostly occur through competition for food or space including harassment of native birds by (groups of) red-vented bulbul, being chased away or on the nest through territorial interactions (see Qu. 5.1). However, as the species mostly occurs in urban, human influenced landscapes, most of the passerine species it would compete with are relatively common (e.g. blackcap *Sylvia atricapilla*, Sardinian warbler *S. melanocephala*, common blackbird *Turdus merula*, house sparrow *Passer domesticus*) and the presence of the bulbul is expected to lead mostly to niche contraction rather than declines or extinctions (cf. the reported impact of the species on Tahiti monarch, Blanvillain et al., 2003) hence a score of moderate. Other potentially impacted species could include the Iberian magpie (*Cyanopica cooki*), Iberian grey shrike (*Lanius meridionalis*) and ortolan bunting (*Emberiza hortulana*). Iberian magpies are a typical element of Iberian avifauna and have been split from their Asian conspecific based on genetic evidence (Kryukov et al., 2004). The species is highly valued by birdwatchers as a flagship species for Mediterranean agrosilvopastoral systems (e.g. dehesas) (see Q 5.7). Iberian magpies roam in groups in open woodland with grassy clearings, including orchards and olive groves. Their diet consists mainly of acorns and pine nuts, supplemented by invertebrates, soft fruits and berries, and also human-provided scraps in parks and towns. They are in the same feeding niche as red-vented bulbul.

## 3: Hybridisation

Hybridisation with common bulbul (*P. barbatus*) could potentially occur in the risk assessment area. However, hybrids have not yet been reported. Also, common bulbul is one of the commonest birds in Africa but it only recently expanded its range and started breeding in southern Spain around Tarifa so this risk of hybridisation is currently limited.

#### 4: Predation

Red-vented bulbul is known to be a predator of insects and smaller (or juvenile) vertebrate prey like geckos and lizards (Thibault et al., 2018c). Using Speybroeck et al. (2016) and data compiled on native reptiles on Mediterranean islands Ficetola et al. (2014) we compiled a list of lizards and geckos that could potentially be predated upon. A lot of those have restricted, endemic ranges within Mediterranean islands. These include: Greek Algyroides (*Algyroides moreoticus*) (endemic), Dalmatian Algyroides (*A. nigropunctatus*) and Peloponnese slow worm (*Anguis cephallonica*) on Ionian islands; Sicilian wall lizard (*Podarcis waglerianus*) (endemic) on Sicily and the threatened Aeolian wall lizard (*Podarcis raffoneae*) (endemic) on some smaller Aeolian islets; Milos wall lizard (*Podarcis milensis*) (endemic), Balkan green lizard (*Lacerta trilineata hansschweizeri*) (endemic subspecies), Skyros wall lizard (*Podarcis gaigeae*) (endemic) and Erhard's wall lizard (*Podarcis erhardii*) on the Aegean islands; Cretan wall lizard (*Podarcis cretensis*) (endemic), Kotschy's gecko (*Mediodactylus kotschy bartoni*) (endemic subspecies), Balkan green lizard (*L. trilineata polylepidota*) (endemic subspecies) and Pori wall lizard (*Podarcis levendis*) (endemic) on Crete; Pygmy algyroides (*A. fitzingeri*) (endemic), Tyrrhenian wall lizard (*Podarcis tiliguerta*) (endemic) and European leaf-toad gecko (*Euleptes europaea*) (endemic) on the Thyrrenian islands; Ibiza wall lizard (*Podarcis pityusensis*) (endemic) and Lilford's wall lizard (*Podarcis lilfordi*) (endemic) on the Balearic islands; Kotschy's gecko (*Mediodactylus kotschy*) on Cyprus and the eastern Mediterranean; the more widespread Moorish gecko (*Tarentola mauritanica*) and Turkish gecko (*Hemidactylus turcicus*) across the Mediterranean. Likewise, the list of insects (Lepidoptera, Coleoptera, Orthoptera) that could be predated upon by bulbuls is very long. Considering documented predation on monarch butterfly (*Danaus plexippus*) on Hawaii (see Q 5.1), this species could also be impacted in southern Spain where it is established yet rare (Gil 2006; Lafranchis 2004). Also similar species of Nymphalidae (and other families such as Papilionidae) with conspicuous colours and/or conspicuous larvae could be impacted in Spain and the Mediterranean, such as the African queen (*Danaus chrysippus*) but documented information is lacking for the risk assessment area.

However, although in theory population declines of native insects and reptiles are possible, it is unlikely predation on (mostly nocturnal) geckos or lizards would effectively lead to species extinctions and there are no documented examples of extinctions caused by red-vented bulbuls elsewhere in its invasive range. Hence, score is moderate but with low confidence because of lack of specific impact studies relating to the risk assessment area.

**Qu. 5.4. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism currently in the risk assessment area?**

including the following elements:

- native species impacted, including red list species, endemic species and species listed in the Birds and Habitats directives
- protected sites impacted, in particular Natura 2000
- habitats impacted, in particular habitats listed in the Habitats Directive, or red list habitats

- the ecological status of water bodies according to the Water Framework Directive and environmental status of the marine environment according to the Marine Strategy Framework Directive

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Comment:

We found no documented impact information for the population around Valencia, which is breeding in suburban gardens and sympatric with the more widely established red-whiskered bulbul (*P. jocosus*) (personal communication Carlos Gutiérrez-Expósito, 2018), nor the individuals in Torremolinos, Málaga (Spain) or the population on Fuerteventura which established around 2000. Currently, in the risk assessment area, there is no evidence that red-vented bulbul occurs or is spreading in high conservation value habitats. As no studies have been conducted on this subject, the confidence on this response is low, however it is generally difficult to provide proof of impact in early invasion stages.

**Qu. 5.5. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism likely to be in the future in the risk assessment area?**

including the following elements:

- native species impacted, including red list species and species listed in the Birds and Habitats directives
- protected sites impacted, in particular Natura 2000
- habitats impacted, in particular habitats listed in the Habitats Directive, or red list habitats
- the ecological status of water bodies according to the Water Framework Directive and environmental status of the marine environment according to the Marine Strategy Framework Directive

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Comment:

Based on what is known of its ecological amplitude and habitat characteristics, the red-vented bulbul could potentially establish and spread in a variety of habitats, mostly (peri)urban habitats as is the case in Torremolinos (Málaga) and in Valencia where the species frequents gardens in family groups. Here,

impact (e.g. through competition) would occur on rather common species (see Q 5.3). However, if the species becomes more widespread, also conservation value habitats could be invaded where the bulbuls could affect species of concern. Habitats protected by the Habitats Directive which could potentially be invaded and impacted upon through seed dispersal of invasive alien plants include sub-Mediterranean and temperate scrub, Mediterranean arborescent matorral (maquis), Mediterranean sclerophyllous forests (e.g. wild olive woodland, cork-oak forests), garrigue (also known as phrygana in the eastern Mediterranean) and maquis shrubland, which is a complex of several possible vegetation types but characterized by densely growing evergreen shrubs. Several of these vegetation types have unique representation as specific habitats of the Habitats Directive on islands in the Mediterranean (e.g. Tyrrhenian islands, Ionian islands, Cyprus, Malta) (based on European Commission 2013). The Mediterranean scrub biome is also home to a number of breeding birds that could be affected by the red-vented bulbul through competition for nesting space and food. These include a range of songbirds (shrikes, warblers, buntings etc.) and include many species protected by the Birds Directive as well as species listed as vulnerable on the IUCN Red List e.g. Iberian grey shrike (*Lanius meridionalis meridionalis*), bunting species such as ortolan bunting (*Emberiza hortulana*) or commoner species of similar habitats like European stonechat (*Saxicola rubicola*). Currently, the red-vented bulbul is present in Valencia (established) and Torremolinos (not established but status remains unclear) (Spain), both areas with typical Mediterranean vegetation that fall within the modelled distribution area for the species. The vulnerable species listed above are also present in that area. Other vertebrate species that could potentially be affected include geckos and lizards, many of which are endemic or have very restricted ranges and are listed on the Annexes II and IV of the EU Habitats Directive.

## Ecosystem Services impacts

**Qu. 5.6. How important is the impact of the organism on provisioning, regulating, and cultural services in its non-native range excluding the risk assessment area?**

- For a list of relevant services use the CICES classification V5.1 provided as an annex.
- Impacts on ecosystem services build on the observed impacts on biodiversity (habitat, species, genetic, functional) but focus exclusively on reflecting these changes in relation to their links with socio-economic well-being.
- Quantitative data should be provided whenever available and references duly reported.
- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Comment:

The red-vented bulbul is a known pest species on horticultural and agricultural produce outside its native range, e.g. in plant nurseries or on fruits and vegetables (see Qu. 5.9). It has become a pest in agriculture and an active disperser of invasive alien plants (Shine et al., 2003). In 1999, Decree N°171CM, prepared by the Délégation à l'Environnement listed red-vented bulbul among three other alien birds as a threat to biodiversity in French Polynesia (Shine et al., 2003).

1 / Provisioning ecosystem services: The species may have an impact on provisioning ecosystem services such as cultivated terrestrial plants grown for nutritional purposes and as ornamentals. The red-vented bulbul can feed on unripe fruits and buds in large flocks (Fox, 2011), and as a consequence, damage to cultivated plants is the most frequently reported impact of the red-vented bulbul in its alien range. However, these studies were conducted in a limited number of places, such as on Hawaii and in New Caledonia (Thibault et al., 2018b). In a global literature review, Thibault et al. (2018c) report damage to at least 52 plant species belonging to 25 families with 67% (35 species) being food plants (fruits and legumes such as papayas, bananas, lychee, mangos, spinach, cucumber, courgette, aubergine, dragon fruit) and 33% (17 species) being ornamental plant species (e.g. orchids, *Hibiscus* spp.). These numbers are underestimations as many reports of consumption by red-vented bulbul do not consider the type of impact (damage to production or seed dispersal). The impact of the red-vented bulbul appears to be particularly serious on Oahu (Hawaii), where the birds are reported consuming several species of fruits, vegetables and flowers, leading to considerable economic losses. In New Caledonia, significant impacts have been recorded for some crops and plant nurseries with up to 35% losses (Caplong and Barjon, 2010). Significant impacts were observed on production fruit trees, with no less than 35% loss in attacked orchards. Damage was recorded on lychee and peach production but also on papaya and other fruits, sometimes up to the total destruction of the orchard (Metzdorf and Brescia, 2008). Moreover, damage to red fruits in general (tomatoes, strawberries) was reported with losses on tomato production of 500 kg per week as is damage to buds and flowers (Metzdorf and Brescia, 2008). Damage to aubergine crops has also been reported, but also other crops such as dragon fruit (*Pitaya sp.*) (Thouzeau-Fonseca, 2013). Conversely, the red-vented bulbul is not considered an agricultural pest in Fiji (Watling, 1979), nor in Houston (Texas, USA) where it was found to consume mainly introduced tropical plant species (Brooks, 2013).

2 / Cultural ecosystem services: Impacts on cultural ecosystem services may include disturbance of the heritage of isolated island ecosystems in case red-vented bulbul establishment and spread comes at the expense of endemic species. This could occur through changes in abundance of native bird species driving a spatial reassembly of the avifauna. Also, this would especially occur when the species would cause changes in vegetation by promoting seed dispersal of unwanted invasive alien plant species, which could alter ecosystem structure and species composition (Watling 1979; Blanvillain, et al., 2003; Thibault et al. 2019) and make landscapes less attractive for recreation and wildlife watching, or impact the qualities of ecosystems with cultural importance. For instance, a study conducted by Spotswood et al. (2013) in French Polynesia showed that the red-vented bulbul prefers the fruit of a highly invasive tree (*Miconia calvescens*) over that of three other species (one alien, two native). Also in New Caledonia, the red-vented bulbul showed preference for non-native species, including the highly invasive *S. terebinthifolius* (Thibault et al., 2018b). In addition, gut transition led to enhanced germination rates and could represent an “invasional meltdown”, a mutualistic relationship between invasive seed dispersers and invasive plant species leading to higher numbers/faster spread rates of both species and possibly major conservation issues, particularly in ecosystems that host a large number of endemic plant species (Thibault et al., 2018b).

These impacts are mostly documented on Pacific islands, not in other areas. In addition, no studies have addressed ecosystem services impact specifically, but there is evidence of economic and ecosystem impact, hence we score confidence as medium.

**Qu. 5.7. How important is the impact of the organism on provisioning, regulating, and cultural services currently in the different biogeographic regions or marine sub-regions where the species has established in the risk assessment area (include any past impact in your response)?**

<b>RESPONSE</b>	<b>minimal</b> minor moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Comment:

No information has been found on ecosystem services impact of the red-vented bulbul where it established in the RA area (Spain). The population in Valencia is breeding in gardens of urbanized areas surrounding the city (personal communication Carlos Gutiérrez-Expósito, 2018).

1 / Provisioning ecosystem services: there may be impacts on provisioning ecosystem services by damage to plants, fruits and legumes grown in gardens or commercial produce (e.g. citrus and tomato around Valencia) but this would probably be very localized (see Q 5.11).

2 / Cultural ecosystem services: If the red-vented bulbul would establish on isolated Mediterranean islands harbouring endemic species, similar effects could occur as documented on Pacific island ecosystems through decreasing ecosystem qualities for observational interactions such as wildlife watching, birding, ecotourism etc. (see Qu. 5.6). As an example, through competition with native bird species a red-vented bulbul invasion could transform avian assemblages in Iberia (see Qu 5.3). Maritime pine (*Pinus pinaster*) forests are a protected European Habitat (Annex I habitat type 2270 - wooded dunes with *P. pinea* and/or *P. pinaster*), and dehesa (Annex I habitat type 6310 - Dehesas with evergreen *Quercus* spp), open parklands of *Quercus ilex rotundifolia* used for cattle grazing, are a well-known, traditional, culturally highly valued landscape in rural Iberia. A large proportion of the surface area (35.3%) of this typically Mediterranean agrosilvopastoral ecosystem is classified by UNESCO as a Biosphere Reserve (Dehesas de Sierra Morena) since 2002 and Sierra Morena is also part of the Natura 2000 network (site code ES0000090) of protected areas since 1997 (Massot 2016). This ecosystem contains a number of typical bird species that are highly valued by birdwatchers (see Qu 5.3). The presence of large populations of bulbuls, which often flock together in noisy family groups, could cause changes in such valued native bird assemblages, including in parks and gardens where people go to appreciate native wildlife.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Comment:

Within the Mediterranean biogeographic region, the red-vented bulbul will likely impact on several ecosystem services, including:

- Provisioning - Biomass - Cultivated terrestrial plants - Cultivated terrestrial plants (including fungi, algae) grown for nutritional purposes
- Regulation & Maintenance - Regulation of physical, chemical, biological conditions - Lifecycle maintenance, habitat and gene pool protection - Seed dispersal
- Cultural - Direct, in-situ and outdoor interactions with living systems that depend on presence in the environmental setting - Physical and experiential interactions with the natural environment - Characteristics of living systems that enable activities promoting health, recuperation or enjoyment through passive or observational interactions
- Cultural - Direct, in-situ and outdoor interactions with living systems that depend on presence in the environmental setting - Physical and experiential interactions with the natural environment - Intellectual and representative interactions with natural environment - Characteristics of living systems that enable aesthetic experiences
- Cultural - Indirect, remote, often indoor interactions with living systems that do not require presence in the environmental setting - Other biotic characteristics that have a non-use value - Characteristics or features of living systems that have an option or bequest value

Besides crop or ornamental plant damage in the endangered area in the Mediterranean (including citrus, tomatoes and strawberry relevant to Iberia, see Qu 5.6), the red-vented bulbul also impacts seed dispersal and could act as a vector for seeds of invasive plant species causing changes in ecosystem structure and species composition of vulnerable Mediterranean island ecosystems harbouring endemic species (for examples see Qu 5.3). This could impact on culturally valued qualities of ecosystems (structure, species composition etc.) that make them attractive to ecotourism, recreation, wildlife watching, or that have cultural and intrinsic value, particularly on Mediterranean islands.

Lastly, since the red-vented bulbul could have an impact on the distribution of less territorial native species, it could alter the species composition in the invasive range, impacting on several cultural ecosystem services as listed above (see Qu 5.6, 5.7).

## **Economic impacts**

**Qu. 5.9. How great is the overall economic cost caused by the organism within its current area of distribution (excluding the risk assessment area), including both costs of / loss due to damage and the cost of current management.**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the world these should be reported here. The assessment of the potential costs of / loss due to damage shall describe those costs quantitatively and/or qualitatively depending on what information is available. Cost of / loss due to damage within different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Comment:

As stated in Qu. 5.8, the red-vented bulbul is considered an agricultural pest species in several parts of its invasive range. The estimated value of the damage to Oahu’s Orchid industry in 1989 was \$300,000 (Fox, 2011) when the red-vented bulbul together with the Japanese white-eye (*Zosterops japonicus*) reportedly destroying up to 75% of Hawaiian *Dendrobium* orchid and *Anthurium* plantations. This also prompted investigations into chemical repellents to keep the birds off orchid plantations (Cummings et al., 1994). Also in New Caledonia, Thibault et al. (2019) report an economic loss of approximately \$18,355 USD for September 2016 alone in tomato plots.

The species is a well-known agricultural pest species in many parts of the world and there are many, although mostly anecdotal, records of economic damages. Many more probably remain unreported, so we assume yearly damages can easily mount up to more than € 1,000,000 and scored major.

**Qu. 5.10. How great is the economic cost of / loss due to damage (excluding costs of management) of the organism currently in the risk assessment area (include any past costs in your response)?**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the EU these should be reported here. Assessment of the potential costs of damage on human health, safety, and the economy, including the cost of non-action. A full economic assessment at EU scale might not be possible, but qualitative data or different case studies from across the EU (or third countries if relevant) may provide useful information to inform decision making. In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. Cost of / loss due to damage within different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

- See guidance to Qu. 5.10.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Comments:

Although Thibault et al. (2019) report considerable economic damages outside the native range (e.g. on tomato production, *Hibiscus* and orchids) (see Qu 5.8 and 5.9), Brooks (2013) reports no damage of that kind in Houston and states that flock sizes remain small (average 2.3 birds/flock, range 1–22) compared to the native range which also limits the potential for damage. Also, although this would involve extra costs, bulbul damage can be mitigated using nets, repellents or other methods (see Annex IV). Spain is an important producer of fresh fruit and vegetables which are mostly exported to other EU Member States and the United Kingdom (<https://wits.worldbank.org/>), with the area of Valencia where the species is currently established as an important citrus region. Tomatoes are also of great economic importance in Spain, as it is the world’s 8th producer, with a production of 5,163 million kilograms, grown on an area of 60,852 hectares ([www.hortoinfo.es](http://www.hortoinfo.es)). In Torremolinos, Málaga, the main crops of economic importance that could potentially be impacted include almonds, sunflowers and olives (Massot 2016), apart from small agricultural produce of vegetables in gardens. In the case where the red-vented bulbul establishes more widely in the risk assessment area, economic damages could occur. However, they would probably be localized and context dependent. Also, methods are available to mitigate or prevent bird damages to sensitive crops (e.g. Tracey et al., 2007).

Another vulnerable receptor is the orchid industry, but damage to the orchid industry seems unlikely, given that most orchids in the risk assessment area are produced in The Netherlands in greenhouses, which is outside of the predicted distribution area of the red-vented bulbul and greenhouses are not easily accessible to birds.

In line with other examples of damages outside the native range, but considering the importance of vegetable production in the Mediterranean, we scored moderate.

**Qu. 5.12. How great are the economic costs / losses associated with managing this organism currently in the risk assessment area (include any past costs in your response)?**

- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”.

<b>RESPONSE</b>	minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Comments:

The species is currently not under management in the risk assessment area, therefore we can say with confidence the current management cost is minimal.

**Qu. 5.13. How great are the economic costs / losses associated with managing this organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 5.12.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Comments:

There are examples of bulbul eradications on islands using a variety of methods (mostly mist netting with or without supplementary shooting, see Annex IV) (Bunbury et al., 2019, Saavedra & Reynolds, 2019, <http://diise.islandconservation.org/>). On Fuerteventura, seven birds were caught in 2010 (Saavedra & Reynolds, 2019). However, the costs of such eradication/control efforts are not documented. As a crude proxy, Holmes et al. (2015) provide costings for island eradications of predators, and show that although the implementation costs per ha can be relatively low, the planning phase, isolation and the presence of human habitation (often the case with red-vented bulbul invasions) can add up to great expense. As a comparison, Parkes et al. (2006) estimated that the costs to achieve eradication of common myna (*A. tristis*) from Mangaia (Cook Islands, 5180 ha) with appropriate levels of monitoring would be about NZ\$100,000 (c. € 55,000), with 80% of that budget needed for preparation and training and surveillance, including detecting surviving birds. However, here, the method proposed was toxic baiting.

As stated in Qu. 5.11, mitigation of bird damage to produce will also involve additional management costs.

Considering the costs described both above and in Holmes et al. (2015) and assuming the red-vented bulbul would establish more widely in the RA area in suburban mainland areas and/or on islands, we scored moderate but since data on costs from the literature are not species specific, confidence is low.

## Social and human health impacts

**Qu. 5.14. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism for the risk assessment area and for third countries, if relevant (e.g. with similar eco-climatic conditions).**

The description of the known impact and the assessment of potential future impact on human health, safety and the economy, shall, if relevant, include information on

- illnesses, allergies or other affections to humans that may derive directly or indirectly from a species;
- damages provoked directly or indirectly by a species with consequences for the safety of people, property or infrastructure;
- direct or indirect disruption of, or other consequences for, an economic or social activity due to the presence of a species.

Social and human health impacts can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>	<b>minimal</b> minor moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high

**Other impacts**

**Qu. 5.16. How important is the impact of the organism as food, a host, a symbiont or a vector for other damaging organisms (e.g. diseases)?**

<b>RESPONSE</b>	minimal <b>minor</b> moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Comments:

Dispersal of parasites by red-vented bulbul is not well documented in its alien range. In its native range, the red-vented bulbul is known to host *Isospora* spp. (Boughton et al., 1938), *Menacanthus eurysternus* (Price 1975), *Bruelia guldum* and *Sturnidoecus guldum* (Ansari 1957) and *Pteroherpis pycnonoti* (Constantinescu et al., unpublished). In 1996, Jarvi et al. (2003) detected no avian malaria (*Plasmodium* spp.) in blood smears, and Atkinson et al. (2006) found no evidence of *Plasmodium*, *Trypanosoma*, *Atoxoplasma* or microfilaria. *Plasmodium* is however present in the south Pacific area. Red-vented bulbuls in Tahiti, however, have been found to carry the zoonotic disease *Chlamydia* (Blanvillain et al., 2013).

**Qu. 5.17. How important might other impacts not already covered by previous questions be resulting from introduction of the organism?**

<b>RESPONSE</b>	<b>minimal</b> minor moderate major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Comments:

No other possible impacts were found.

**Qu. 5.18. How important are the expected impacts of the organism despite any natural control by other organisms, such as predators, parasites or pathogens that may already be present in the risk assessment area?**

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Comments:

The red-vented bulbul is not particularly vulnerable to predation. In its native range, a study carried out by Zia et al. (2017) found that predation rate on the red-vented bulbul was only 6% in eggs and 9% in nestlings. Predators in the study area included bird species like eagles and barn owl (*Tyto alba*), and rodents like the black rat (*Rattus rattus*). These species or similar species are also present in the risk assessment area, possibly impacting the red-vented bulbul. However, if these only have minor effects in the native range, it is unlikely that their impact will be higher in the introduced range, where they are not used to hunt on the red-vented bulbul. Likely predators of the red-vented bulbul in Valencia and Torremolinos, and by extension the risk assessment area, include the booted eagle (*Hieraetus pennatus* Gmelin, 1788), Bonelli's eagle (*Aquila fasciata* Vieillot, 1822), the northern goshawk (*Accipiter gentilis* Linnaeus, 1758) and the sparrowhawk (*Accipiter nisus* Linnaeus, 1758). The latter might become the most important predator of the red-vented bulbul in its invasive range, since it mainly preys upon species similar to the red-vented bulbul regarding size, behaviour and habitat, such as the house sparrow (*Passer domesticus* Linnaeus, 1758), common blackbird (*Turdus merula* Linnaeus, 1758), starlings and pigeons. Other birds of prey may take the eggs of the red-vented bulbul, as will mammalian predators like the stone martin (*Martes foina* Erxleben, 1777) and European pine marten (*Martes martes* Linnaeus, 1758). Since the red-vented bulbul nests in trees, it will not be vulnerable to ground predators such as foxes or stoats.

Although the red-vented bulbul is a known host to several parasites in its native range, including *Isoospora* spp. (Boughton et al., 1938), *Menacanthus eurysternus* (Price 1975), *Bruelia guldum* and *Sturnidoecus guldum* (Ansari 1957) and *Pteroherpis pycnonoti* (Constantinescu et al., unpublished), no impacts of these parasites on the red-vented bulbul were found.

No information was found on impact of pathogens on the red-vented bulbul.

For more information, see Qu. 3.5.

-----------------	---	-------------------	------------------------------

Response:

See answers to Qu. 5.3, 5.5, 5.8, 5.11, 5.13, 5.15 and 5.16.

**Qu. 5.20. Estimate the overall impact in the risk assessment area in foreseeable climate change conditions. In addition, details of overall impact in relevant biogeographical regions should be provided.**

Thorough assessment of the overall impact on biodiversity and ecosystem services, with impacts on economy as well as social and human health as aggravating factors, under future conditions.

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response:

The proportion of the area suitable for establishment in the Mediterranean biogeographical region is predicted to double under RCP 2.6 and to triple under RCP 4.5 by 2070 (see Qu. 3.14, Annex VII). Therefore, it is moderately likely that the overall impacts will increase too.

## RISK SUMMARIES

	RESPONSE	CONFIDENCE	COMMENT
<b>Summarise Introduction*</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	low medium <b>high</b>	The species is already present in zoological gardens and private collections in multiple countries within the risk assessment area. There is also the possibility that the species is introduced for private bird collections although quantitative data are lacking. Introductions as stowaways are less likely.
<b>Summarise Entry*</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	low <b>medium</b> high	The red-vented bulbul is kept as a pet and is on display in zoological garden. Escapes and releases have happened before in several countries in the risk assessment area and entry is likely to occur in the future. Stowaways on ships might enter the risk assessment area as well, as the species is established on the Canary islands.
<b>Summarise Establishment*</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	low <b>medium</b> high	The species already established on at least two locations in the risk assessment area (Spain). The Mediterranean bioregion, including Mediterranean islands, is generally vulnerable to invasion by red-vented bulbul, both under current and future climatic conditions. The red-vented bulbul is most likely to establish in (peri)urban areas with a mediterranean or (semi-)arid climate.
<b>Summarise Spread*</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	low <b>medium</b> high	The species is classified as a rather sedentary species, showing possible movements depending on environmental conditions. Indeed, spread is limited in Spanish mainland populations, although densities are still limited here and the species has to compete with red-whiskered bulbul. However, the invasion on Fuerteventura, where the species invaded the entire island in a few decades and has shown important range expansion in a short period of time, as well as the Pacific

			invasion, show red-vented bulbul is able to spread moderately rapidly or rapidly in insular contexts.
<b>Summarise Impact*</b>	minimal minor <b>moderate</b> major massive	low <b>medium</b> high	The red-vented bulbul can impact on native species and ecosystems through competition, frugivory, by spreading alien plants, hybridising with bulbul species, by predating on (in)vertebrates and by pathogen transmission. It is also an agricultural pest in parts of its alien range. However, although declines and niche contraction in sensitive and protected species are possible, no extinctions caused by red-vented bulbul have been documented so far.
<b>Conclusion of the risk assessment (overall risk)</b>	low <b>moderate</b> high	low <b>medium</b> high	Considering the potential of red-vented bulbul to cause population declines in native species, documented contractions of niches of native species in its alien range but no extinctions, moderate spread capacity, the limited area suitable for establishment in the risk assessment area but presence of sensitive island biota, local and reversible effects on ecosystem services and the potential for moderate economic damages, we scored moderate impact. This score is in line with a recent, global, environmental impact assessment of alien birds using EICAT.

\*in current climate conditions and in foreseeable future climate conditions

## Distribution Summary

Please answer as follows:

- Yes if recorded, established or invasive
- if not recorded, established or invasive
- ? Unknown; data deficient

The columns refer to the answers to Questions A5 to A12 under Section A.

For data on marine species at the Member State level, delete Member States that have no marine borders. In all other cases, provide answers for all columns.

### Member States and the United Kingdom

## **ANNEX I Scoring of Likelihoods of Events**

(taken from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

<b>Score</b>	<b>Description</b>	<b>Frequency</b>
Very unlikely	This sort of event is theoretically possible, but is never known to have occurred and is not expected to occur	1 in 10,000 years
Unlikely	This sort of event has not occurred anywhere in living memory	1 in 1,000 years
Moderately likely	This sort of event has occurred somewhere at least once in recent years, but not locally	1 in 100 years
Likely	This sort of event has happened on several occasions elsewhere, or on at least one occasion locally in recent years	1 in 10 years
Very likely	This sort of event happens continually and would be expected to occur	Once a year

## ANNEX II Scoring of Magnitude of Impacts

(modified from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

Score	Biodiversity and ecosystem impact	Ecosystem Services impact	Economic impact (Monetary loss and response costs per year)	Social and human health impact, and other impacts
	<i>Question 5.1-5</i>	<i>Question 5.6-8</i>	<i>Question 5.9-13</i>	<i>Question 5.14-18</i>
Minimal	Local, short-term population loss, no significant ecosystem effect	No services affected <sup>7</sup>	Up to 10,000 Euro	No social disruption. Local, mild, short-term reversible effects to individuals.
Minor	Some ecosystem impact, reversible changes, localised	Local and temporary, reversible effects to one or few services	10,000-100,000 Euro	Significant concern expressed at local level. Mild short-term reversible effects to identifiable groups, localised.
Moderate	Measurable long-term damage to populations and ecosystem, but reversible; little spread, no extinction	Measureable, temporary, local and reversible effects on one or several services	100,000-1,000,000 Euro	Temporary changes to normal activities at local level. Minor irreversible effects and/or larger numbers covered by reversible effects, localised.
Major	Long-term irreversible ecosystem change, spreading beyond local area	Local and irreversible or widespread and reversible effects on one / several services	1,000,000-10,000,000 Euro	Some permanent change of activity locally, concern expressed over wider area. Significant irreversible effects locally or reversible effects over large area.
Massive	Widespread, long-term population loss or extinction, affecting several species with serious ecosystem effects	Widespread and irreversible effects on one / several services	Above 10,000,000 Euro	Long-term social change, significant loss of employment, migration from affected area. Widespread, severe, long-term, irreversible health effects.

<sup>7</sup> Not to be confused with “no impact”.

## ANNEX III Scoring of Confidence Levels

(modified from Bacher et al., 2017)

Each answer provided in the risk assessment must include an assessment of the level of confidence attached to that answer, reflecting the possibility that information needed for the answer is not available or is insufficient or available but conflicting.

The responses in the risk assessment should clearly support the choice of the confidence level.

Confidence level	Description
Low	There is no direct observational evidence to support the assessment, e.g. only inferred data have been used as supporting evidence <i>and/or</i> Impacts are recorded at a spatial scale which is unlikely to be relevant to the assessment area <i>and/or</i> Evidence is poor and difficult to interpret, e.g. because it is strongly ambiguous <i>and/or</i> The information sources are considered to be of low quality or contain information that is unreliable.
Medium	There is some direct observational evidence to support the assessment, but some information is inferred <i>and/or</i> Impacts are recorded at a small spatial scale, but rescaling of the data to relevant scales of the assessment area is considered reliable, or to embrace little uncertainty <i>and/or</i> The interpretation of the data is to some extent ambiguous or contradictory.
High	There is direct relevant observational evidence to support the assessment (including causality) <i>and</i> Impacts are recorded at a comparable scale <i>and/or</i> There are reliable/good quality data sources on impacts of the taxa <i>and</i> The interpretation of data/information is straightforward <i>and/or</i> Data/information are not controversial or contradictory.

## ANNEX IV Ecosystem services classification (CICES V5.1, simplified) and examples

For the purposes of this risk assessment, please feel free to use what seems as the most appropriate category / level / combination of impact (Section – Division – Group), reflecting information available.

Section	Division	Group	Examples (i.e. relevant CICES “classes”)
Provisioning	Biomass	<b>Cultivated <i>terrestrial</i> plants</b>	<p>Cultivated terrestrial plants (including fungi, algae) grown for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from cultivated plants, fungi, algae and bacteria for direct use or processing (excluding genetic materials);            Cultivated plants (including fungi, algae) grown as a <u>source of energy</u></p> <p><i>Example: negative impacts of non-native organisms to crops, orchards, timber etc.</i></p>
		<b>Cultivated <i>aquatic</i> plants</b>	<p>Plants cultivated by in- situ aquaculture grown for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from in-situ aquaculture for direct use or processing (excluding genetic materials);            Plants cultivated by in- situ aquaculture grown as an <u>energy source</u>.</p> <p><i>Example: negative impacts of non-native organisms to aquatic plants cultivated for nutrition, gardening etc. purposes.</i></p>
		<b>Reared animals</b>	<p>Animals reared for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from reared animals for direct use or processing (excluding genetic materials);            Animals reared to provide <u>energy</u> (including mechanical)</p> <p><i>Example: negative impacts of non-native organisms to livestock</i></p>
		<b>Reared <i>aquatic</i> animals</b>	<p>Animals reared by in-situ aquaculture for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from animals grown by in-situ aquaculture for direct use or processing (excluding genetic materials);            Animals reared by in-situ aquaculture as an <u>energy source</u></p> <p><i>Example: negative impacts of non-native organisms to fish farming</i></p>
		<b>Wild plants</b> (terrestrial and aquatic)	<p>Wild plants (terrestrial and aquatic, including fungi, algae) used for <u>nutrition</u>;  <u>Fibres and other materials</u> from wild plants for direct use or processing (excluding genetic materials);            Wild plants (terrestrial and aquatic, including fungi, algae) used as a <u>source of energy</u></p> <p><i>Example: reduction in the availability of wild plants (e.g. wild berries, ornamentals) due to non-native organisms (competition, spread of disease etc.)</i></p>
		<b>Wild animals</b> (terrestrial and aquatic)	<p>Wild animals (terrestrial and aquatic) used for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from wild animals for direct use or processing (excluding genetic materials);            Wild animals (terrestrial and aquatic) used as a <u>source of energy</u></p> <p><i>Example: reduction in the availability of wild animals (e.g. fish stocks, game) due to non-native organisms (competition,</i></p>

			<i>predations, spread of disease etc.)</i>
	<b>Genetic material</b> from all biota	<b>Genetic material</b> from plants, algae or fungi	<p><u>Seeds, spores and other plant materials</u> collected for maintaining or establishing a population; Higher and lower plants (whole organisms) used to <u>breed new strains or varieties</u>; Individual genes extracted from higher and lower plants for the <u>design and construction of new biological entities</u></p> <p><i>Example: negative impacts of non-native organisms due to interbreeding</i></p>
		<b>Genetic material</b> from animals	<p>Animal material collected for the purposes of maintaining or establishing a population; Wild animals (whole organisms) used to breed new strains or varieties; Individual genes extracted from organisms for the design and construction of new biological entities</p> <p><i>Example: negative impacts of non-native organisms due to interbreeding</i></p>
	<b>Water<sup>8</sup></b>	<b>Surface water</b> used for nutrition, materials or energy	<p>Surface water for <u>drinking</u>; Surface water used as a material (<u>non-drinking purposes</u>); Freshwater surface water, coastal and marine water used as an <u>energy source</u></p> <p><i>Example: loss of access to surface water due to spread of non-native organisms</i></p>
		<b>Ground water</b> for used for nutrition, materials or energy	<p>Ground (and subsurface) water for <u>drinking</u>; Ground water (and subsurface) used as a material (<u>non-drinking purposes</u>); Ground water (and subsurface) used as an <u>energy source</u></p> <p><i>Example: reduced availability of ground water due to spread of non-native organisms and associated increase of ground water consumption by vegetation.</i></p>
<b>Regulation &amp; Maintenance</b>	<b>Transformation</b> of biochemical or physical inputs to ecosystems	<b>Mediation of wastes or toxic substances</b> of anthropogenic origin by living processes	<p><u>Bio-remediation</u> by microorganisms, algae, plants, and animals; <u>Filtration/sequestration/storage/accumulation</u> by microorganisms, algae, plants, and animals</p> <p><i>Example: changes caused by non-native organisms to ecosystem functioning and ability to filtrate etc. waste or toxics</i></p>
		<b>Mediation of nuisances</b> of anthropogenic origin	<p><u>Smell reduction</u>; <u>noise attenuation</u>; <u>visual screening</u> (e.g. by means of green infrastructure)</p> <p><i>Example: changes caused by non-native organisms to ecosystem structure, leading to reduced ability to mediate nuisances.</i></p>
	<b>Regulation</b> of physical, chemical, biological conditions	<b>Baseline flows and extreme event</b> regulation	<p>Control of <u>erosion</u> rates; Buffering and attenuation of <u>mass movement</u>; <u>Hydrological cycle and water flow regulation</u> (Including flood control, and coastal protection); <u>Wind</u> protection; <u>Fire</u> protection</p> <p><i>Example: changes caused by non-native organisms to ecosystem functioning or structure leading to, for example, destabilisation of soil, increased risk or intensity of wild fires etc.</i></p>

<sup>8</sup> Note: in the CICES classification provisioning of water is considered as an abiotic service whereas the rest of ecosystem services listed here are considered biotic.

		<p><b>Lifecycle maintenance, habitat and gene pool protection</b></p>	<p><u>Pollination</u> (or 'gamete' dispersal in a marine context); <u>Seed dispersal</u>; Maintaining <u>nursery populations and habitats</u> (Including gene pool protection)</p> <p><i>Example: changes caused by non-native organisms to the abundance and/or distribution of wild pollinators; changes to the availability / quality of nursery habitats for fisheries</i></p>
		<p><b>Pest and disease control</b></p>	<p>Pest control; Disease control</p> <p><i>Example: changes caused by non-native organisms to the abundance and/or distribution of pests</i></p>
		<p><b>Soil quality regulation</b></p>	<p><u>Weathering processes</u> and their effect on soil quality; <u>Decomposition and fixing processes</u> and their effect on soil quality</p> <p><i>Example: changes caused by non-native organisms to vegetation structure and/or soil fauna leading to reduced soil quality</i></p>
		<p><b>Water conditions</b></p>	<p>Regulation of the <u>chemical condition</u> of freshwaters by living processes; Regulation of the chemical condition of salt waters by living processes</p> <p><i>Example: changes caused by non-native organisms to buffer strips along water courses that remove nutrients in runoff and/or fish communities that regulate the resilience and resistance of water bodies to eutrophication</i></p>
		<p><b>Atmospheric composition and conditions</b></p>	<p>Regulation of <u>chemical composition</u> of atmosphere and oceans; Regulation of <u>temperature and humidity</u>, including ventilation and transpiration</p> <p><i>Example: changes caused by non-native organisms to ecosystems' ability to sequester carbon and/or evaporative cooling (e.g. by urban trees)</i></p>
Cultural	Direct, in-situ and outdoor interactions with living systems that depend on presence in the environmental setting	<p><b>Physical and experiential interactions with natural environment</b></p>	<p>Characteristics of living systems that that enable activities promoting health, recuperation or enjoyment through <u>active or immersive interactions</u>;</p> <p>Characteristics of living systems that enable activities promoting health, recuperation or enjoyment through <u>passive or observational interactions</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that make it attractive for recreation, wild life watching etc.</i></p>
		<p><b>Intellectual and representative interactions with natural environment</b></p>	<p>Characteristics of living systems that enable <u>scientific investigation</u> or the creation of traditional ecological knowledge;</p> <p>Characteristics of living systems that enable <u>education and training</u>;</p> <p>Characteristics of living systems that are resonant in terms of <u>culture or heritage</u>;</p> <p>Characteristics of living systems that enable <u>aesthetic experiences</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have cultural importance</i></p>

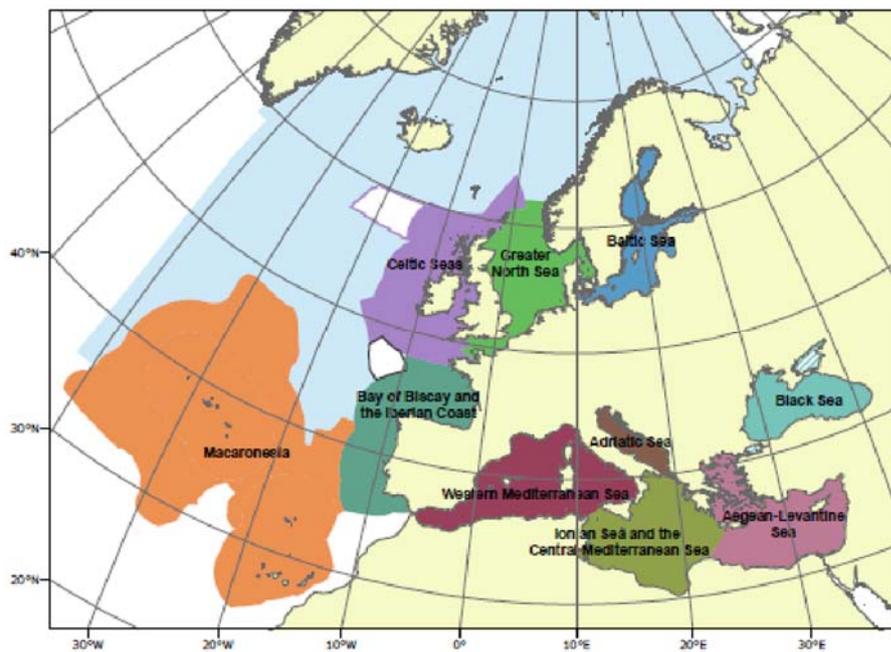

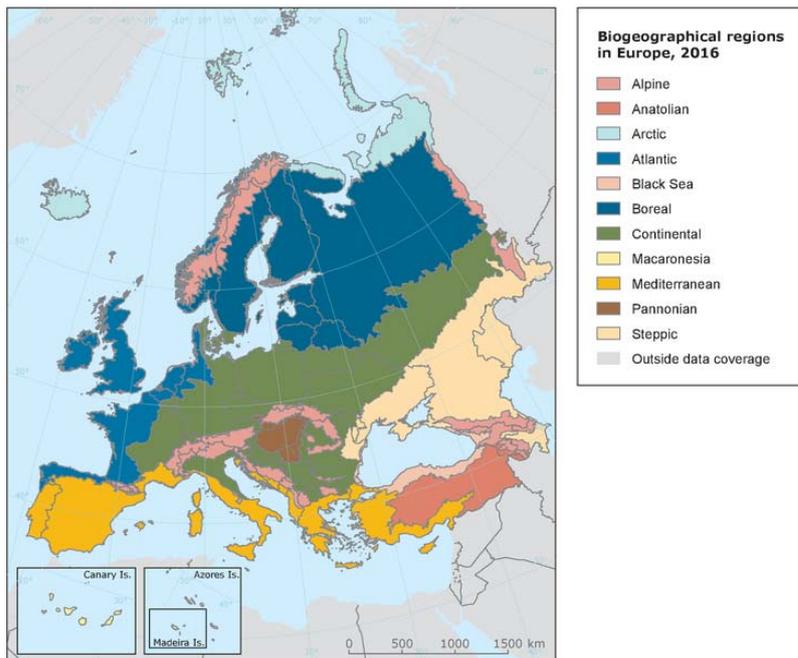

<p><b>Indirect, remote, often indoor interactions</b> with living systems that do not require presence in the environmental setting</p>	<p><b>Spiritual, symbolic</b> and other interactions with natural environment</p>	<p>Elements of living systems that have <u>symbolic meaning</u>;  Elements of living systems that have <u>sacred or religious meaning</u>;  Elements of living systems used for <u>entertainment or representation</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have sacred or religious meaning</i></p>
	<p>Other biotic characteristics that have a <b>non-use value</b></p>	<p>Characteristics or features of living systems that have an <u>existence value</u>;  Characteristics or features of living systems that have an <u>option or bequest value</u></p> <p><i>Example: changes caused by non-native organisms to ecosystems designated as wilderness areas, habitats of endangered species etc.</i></p>

## **ANNEX VII Projection of climatic suitability for *Pycnonotus cafer* establishment**

Björn Beckmann, Martin Thibault, Tim Adriaens, Yasmine Verzelen, Riccardo Scalera, Beth Purse and Dan Chapman

31 October 2019

### ***Aim***

To project the suitability for potential establishment of *Pycnonotus cafer* in Europe, under current and predicted future climatic conditions.

### ***Data for modelling***

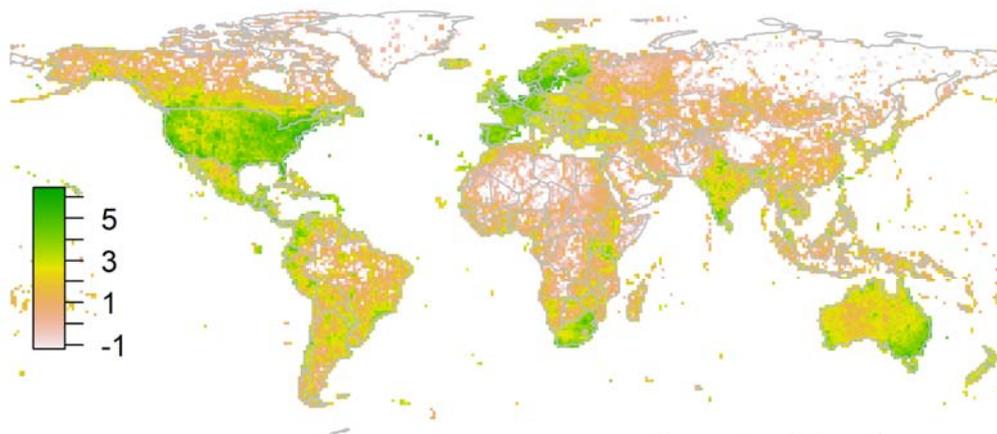

Species occurrence data were obtained from the Global Biodiversity Information Facility (GBIF) (245716 records), the Biodiversity Information Serving Our Nation database (BISON) (8660 records), iNaturalist (358 records), the Integrated Digitized Biocollections (iDigBio) (42 records), and a small number of additional records from the risk assessment team. We scrutinised occurrence records from regions where the species is not known to be established and removed any dubious records (e.g. fossils, captive records) or where the georeferencing was too imprecise (e.g. records referenced to a country or island centroid) or outside of the coverage of the predictor layers (e.g. small island or coastal occurrences). The remaining records were gridded at a 0.25 x 0.25 degree resolution for modelling, yielding 3381 grid cells with occurrences (Figure 1a). As a proxy for recording effort, the density of Aves records held by GBIF was also compiled on the same grid (Figure 1b).

**Figure 1.** (a) Occurrence records obtained for *Pycnonotus cafer* and used in the modelling, showing native and invaded distributions. (b) The recording density of Aves on GBIF, which was used as a proxy for recording effort.

(a) Species distribution used in modelling

(b) Estimated recording effort (log<sub>10</sub>-scaled)

Climate data were selected from the 'Bioclim' variables contained within the WorldClim database (Hijmans et al., 2005), originally at 5 arcminute resolution (0.083 x 0.083 degrees of longitude/latitude) and aggregated to a 0.25 x 0.25 degree grid for use in the model.

Based on the biology of *Pycnonotus cafer*, the following climate variables were used in the modelling:

- Annual mean temperature (Bio1)
- Minimum temperature of the coldest month (Bio6)
- Mean temperature of the warmest quarter (Bio10)
- Annual precipitation (Bio12)
- Precipitation of the wettest month (Bio13)
- Precipitation of the driest month (Bio14)

To estimate the effect of climate change on the potential distribution, equivalent modelled future climate conditions for the 2070s under the Representative Concentration Pathways (RCP) 2.6 and 4.5 were also obtained. These represent low and medium emissions scenarios, respectively. The above variables were obtained as averages of outputs of eight Global Climate Models (BCC-CSM1-1, CCSM4, GISS-E2-R, HadGEM2-AO, IPSL-CM5A-LR, MIROC-ESM, MRI-CGCM3, NorESM1-M), downscaled and calibrated against the WorldClim baseline (see [http://www.worldclim.org/cmip5\\_5m](http://www.worldclim.org/cmip5_5m)).

The following habitat layers were also used:

- Tree cover (Tree): This was estimated from the MODerate-resolution Imaging Spectroradiometer (MODIS) satellite continuous tree cover raster product, produced by the Global Land Cover Facility (<http://glcf.umd.edu/data/vcf/>). The raw product contains the percentage cover by trees in each 0.002083 x 0.002083 degree grid cell. We aggregated this to the mean cover in our 0.25 x 0.25 degree grid cells.
- Human influence index (HII): As many non-native invasive species associate with anthropogenically disturbed habitats. We used the Global Human Influence Index Dataset of the Last of the Wild Project (Wildlife Conservation Society - WCS & Center for International Earth Science Information Network - CIESIN - Columbia University 2005), which is developed from nine global data layers covering human population pressure (population density), human land use and infrastructure (built-up areas, nighttime lights, land use/land cover) and human access (coastlines, roads, railroads, navigable rivers). The index ranges between 0 and 1 and was ln+1 transformed for the modelling to improve normality.

### ***Species distribution model***

A presence-background (presence-only) ensemble modelling strategy was employed using the BIOMOD2 R package v3.3-7.1 (Thuiller et al., 2019, Thuiller et al., 2009). These models contrast the environment at the species' occurrence locations against a random sample of the global background environmental conditions (often termed 'pseudo-absences') in order to characterise and project suitability for occurrence. This approach has been developed for distributions that are in equilibrium with the environment. Because invasive species' distributions are not at equilibrium and subject to dispersal constraints at a global scale, we took care to minimise the inclusion of locations suitable for the species but where it has not been able to disperse to (Chapman et al., 2019). Therefore the background sampling region included:

- The area accessible by native *Pycnonotus cafer* populations, in which the species is likely to have had sufficient time to disperse to all locations. Based on presumed maximum dispersal distances, the accessible region was defined as a 300km buffer around the native range occurrences; AND
- A 50km buffer around the non-native occurrences, encompassing regions likely to have had high propagule pressure for introduction by humans and/or dispersal of the species; AND
- Regions where we have an *a priori* expectation of high unsuitability for the species so that absence is assumed irrespective of dispersal constraints (see Figure 2). The following rules were applied to define a region expected to be highly unsuitable for *Pycnonotus cafer* at the spatial scale of the model:
  - Annual mean temperature (Bio1) < 4°C
  - Annual precipitation (Bio12) < 4 (i.e. <55mm, as the Bioclim variable is on a natural log scale)

Altogether, only 0.5% of occurrence grid cells were located in the unsuitable background region.

Within the background region, 10 samples of 5000 randomly sampled grid cells were obtained, weighting the sampling by recording effort (Figure 2).

**Figure 2.** The background from which pseudo-absence samples were taken in the modelling of *Pycnonotus cafer*. Samples were taken from a 300km buffer around the native range and a 50km buffer around non-native occurrences (together forming the accessible background), and from areas expected to be highly unsuitable for the species (the unsuitable background region). Samples were weighted by a proxy for recording effort (Figure 1(b)).

Each dataset (i.e. combination of the presences and the individual background samples) was randomly split into 80% for model training and 20% for model evaluation. With each training dataset, seven statistical algorithms were fitted with the default BIOMOD2 settings and rescaled using logistic regression, except where specified below:

- Generalised linear model (GLM)
- Generalised boosting model (GBM)
- Generalised additive model (GAM) with a maximum of four degrees of freedom per smoothing spline
- Artificial neural network (ANN)
- Multivariate adaptive regression splines (MARS)
- Random forest (RF)
- Maxent

Since the background sample was larger than the number of occurrences, prevalence fitting weights were applied to give equal overall importance to the occurrences and the background. Normalised variable importance was assessed and variable response functions were produced using BIOMOD2's default procedure.

Model predictive performance was assessed by the following three measures:

- AUC, the area under the receiver operating characteristic curve (Fielding & Bell 1997). Predictions of presence-absence models can be compared with a subset of records set aside for model evaluation (here 20%) by constructing a confusion matrix with the number of true positive, false positive, false negative and true negative cases. For models generating non-dichotomous scores (as here) a threshold can be applied to transform the scores into a dichotomous set of presence-absence predictions. Two measures that can be derived from the confusion matrix are sensitivity (the proportion of observed presences that are predicted as such, quantifying omission errors), and specificity (the proportion of observed absences that are predicted as such, quantifying commission errors). A receiver operating characteristic (ROC) curve can be constructed by using all possible thresholds to classify the scores into confusion matrices, obtaining sensitivity and specificity for each matrix, and plotting sensitivity against the corresponding proportion of false positives (equal to  $1 - \text{specificity}$ ). The use of all possible thresholds avoids the need for a selection of a single threshold, which is often arbitrary, and allows appreciation of the trade-off between sensitivity and specificity. The area under the ROC curve (AUC) is often used as a single threshold-independent measure for model performance (Manel, Williams & Ormerod 2001). AUC is the probability that a randomly selected presence has a higher model-predicted suitability than a randomly selected absence (Allouche et al., 2006).
- Cohen's Kappa (Cohen 1960). This measure corrects the overall accuracy of model predictions (ratio of the sum of true presences plus true absences to the total number of records) by the accuracy expected to occur by chance. The kappa statistic ranges from -1 to +1, where +1 indicates perfect agreement and values of zero or less indicate a performance no better than random. Advantages of kappa are its simplicity, the fact that both commission and omission errors are accounted for in one parameter, and its relative tolerance to zero values in the confusion matrix (Manel, Williams & Ormerod 2001). However, Kappa has been criticised for being sensitive to prevalence (the proportion of sites in which the species was recorded as present) and may therefore be inappropriate for comparisons of model accuracy between species or regions (McPherson, Jetz & Rogers 2004, Allouche et al., 2006).
- TSS, the true skill statistic (Allouche et al., 2006). TSS is defined as sensitivity + specificity - 1, and corrects for Kappa's dependency on prevalence. TSS compares the number of correct forecasts, minus those attributable to random guessing, to that of a hypothetical set of perfect forecasts. Like kappa, TSS takes into account both omission and commission errors, and success as a result of random guessing, and ranges from -1 to +1, where +1 indicates perfect agreement and values of zero or less indicate a performance no better than random (Allouche et al., 2006).

An ensemble model was created by first rejecting poorly performing algorithms with relatively extreme low AUC values and then averaging the predictions of the remaining algorithms, weighted by their AUC. To identify poorly performing algorithms, AUC values were converted into modified z-scores based on their difference to the median and the median absolute deviation across all algorithms (Iglewicz & Hoaglin, 1993). Algorithms with  $z < -2$  were rejected. In this way, ensemble projections were made for each dataset and then averaged to give an overall suitability, as well as its standard deviation. The projections were then classified into suitable and unsuitable regions using the 'minROCDist' method, which minimizes the distance between the ROC plot and the upper left corner of the plot (point (0,1)).

We also produced limiting factor maps for Europe following Elith et al. (2010). For this, projections were made separately with each individual variable fixed at a near-optimal value. These were chosen as the median values at the occurrence grid cells. Then, the most strongly limiting factors were identified as the one resulting in the highest increase in suitability in each grid cell.

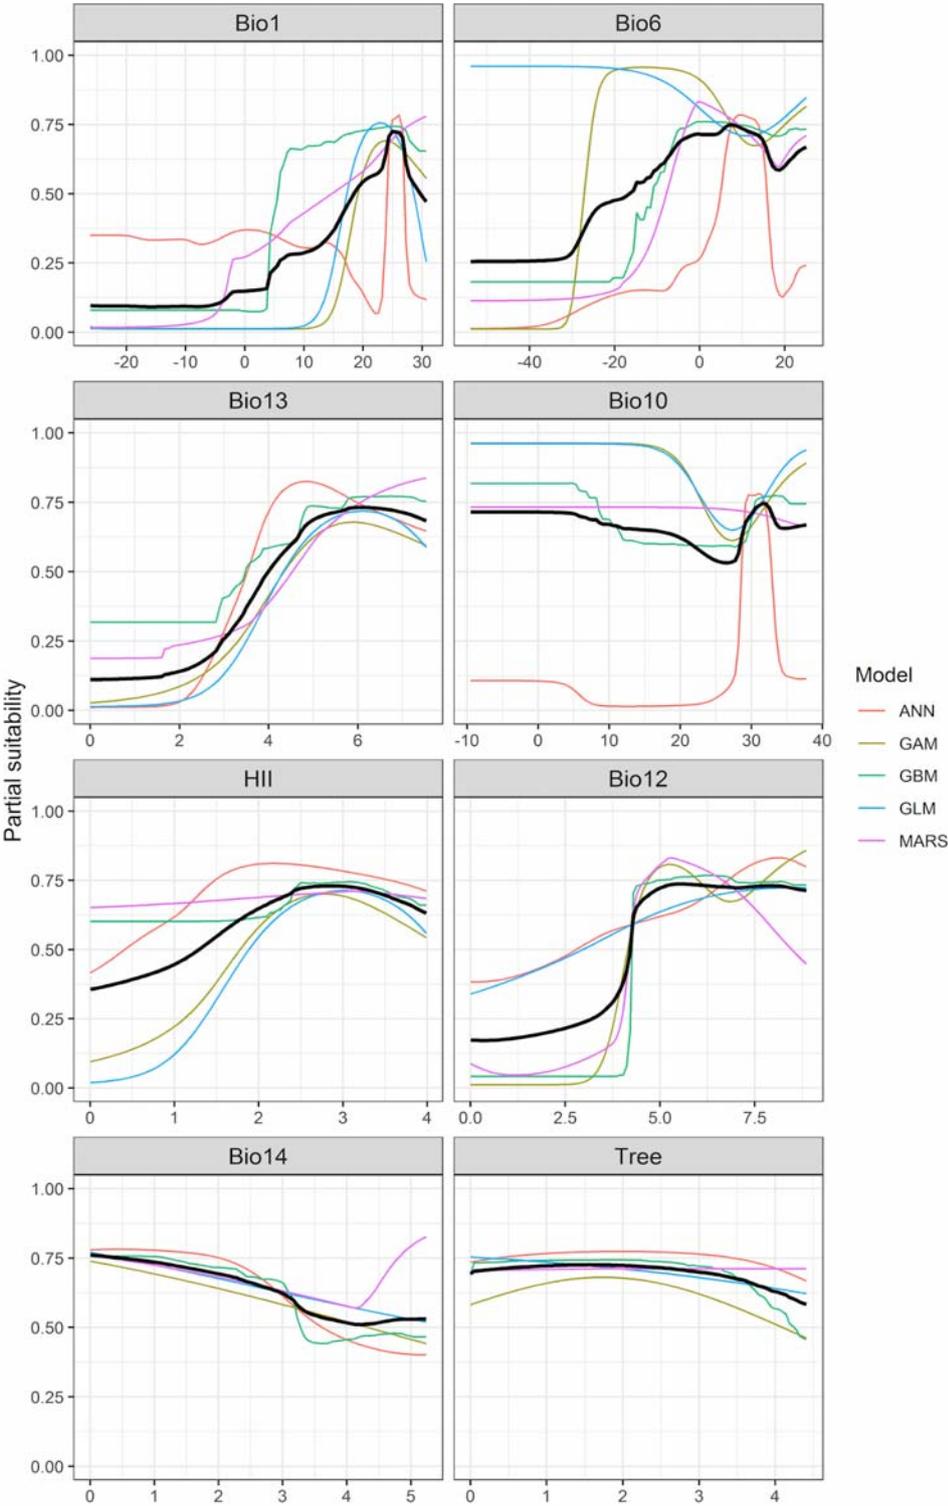

## Results

The ensemble model suggested that suitability for *Pycnonotus cafer* was most strongly determined by Annual mean temperature (Bio1), accounting for 42.9% of variation explained, followed by Mean temperature of the warmest quarter (Bio10) (23.5%), Precipitation of the wettest month (Bio13) (10.2%), Minimum temperature of the coldest month (Bio6) (9.4%), Human influence index (HII) (5.7%), Annual precipitation (Bio12) (5.3%), Precipitation of the driest month (Bio14) (2.2%) and Global tree cover (Tree) (0.8%) (Table 1, Figure 3).

**Table 1.** Summary of the cross-validation predictive performance (AUC, Kappa, TSS) and variable importance of the fitted model algorithms and the ensemble (AUC-weighted average of the best performing algorithms). Results are the average from models fitted to 10 different background samples of the data.

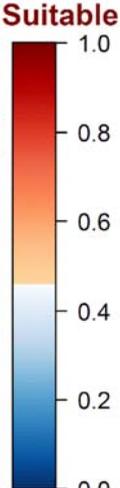

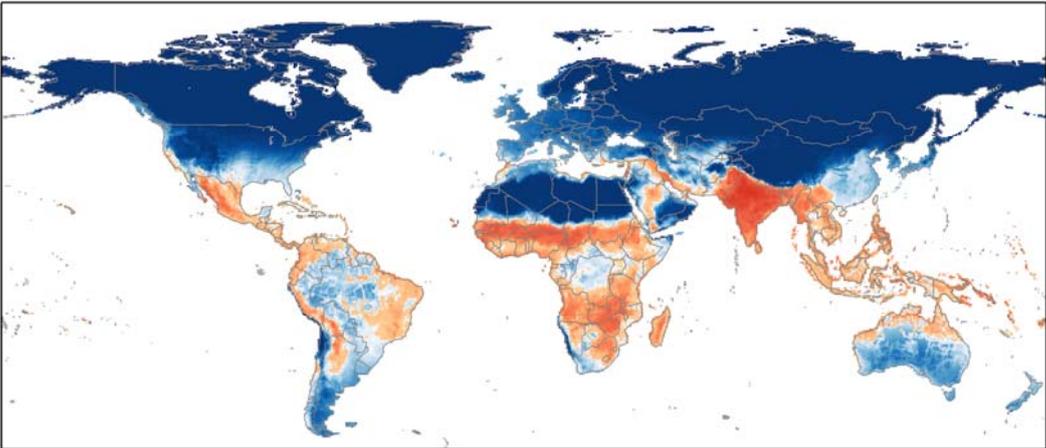

Algorithm	AUC	Kappa	TSS	Used in the ensemble	variable importance (%)								
					Annual mean temperature (Bio1)	Mean temperature of the warmest quarter (Bio10)	Precipitation of the wettest month (Bio13)	Minimum temperature of the coldest month (Bio6)	Human influence index (HII)	Annual precipitation (Bio12)	Precipitation of the driest month (Bio14)	Global tree cover (Tree)	
GLM	0.840	0.488	0.614	yes	60	7	10	9	12	1	1	0	
GAM	0.841	0.503	0.616	yes	56	16	7	7	8	4	1	1	
ANN	0.847	0.530	0.650	yes	22	31	8	25	5	4	3	2	
GBM	0.839	0.512	0.624	yes	42	29	11	4	2	8	3	1	
MARS	0.837	0.488	0.614	yes	35	34	16	1	1	11	2	0	
RF	0.697	0.478	0.609	no	20	14	13	17	9	10	10	8	
Maxent	0.835	0.500	0.613	no	39	34	7	4	7	6	2	2	
<b>Ensemble</b>	<b>0.846</b>	<b>0.522</b>	<b>0.628</b>		<b>43</b>	<b>24</b>	<b>10</b>	<b>9</b>	<b>6</b>	<b>5</b>	<b>2</b>	<b>1</b>	

**Figure 3.** Partial response plots from the fitted models. Thin coloured lines show responses from the algorithms in the ensemble, while the thick black line is their ensemble. In each plot, other model variables are held at their median value in the training data. Some of the divergence among algorithms is because of their different treatment of interactions among variables.

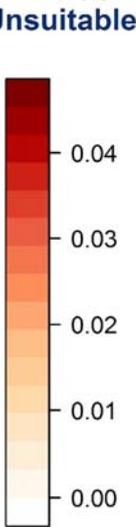

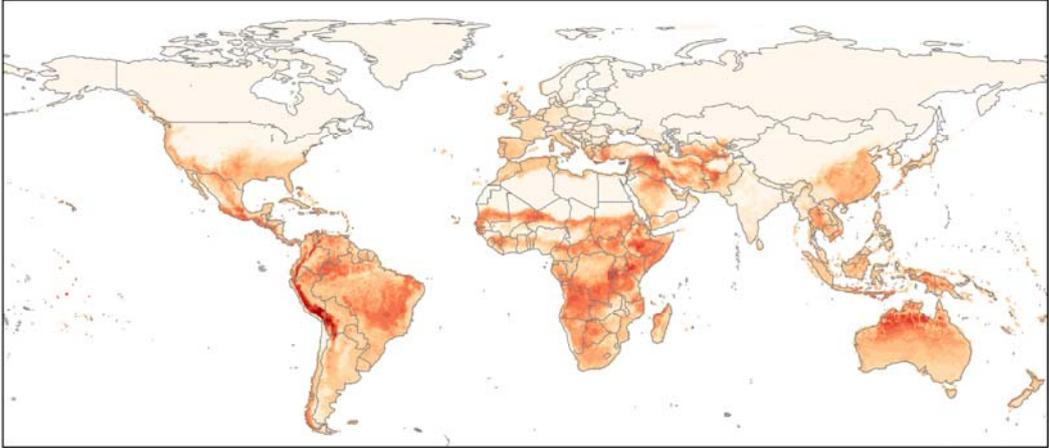

**Figure 4.** (a) Projected global suitability for *Pycnonotus cafer* establishment in the current climate. For visualisation, the projection has been aggregated to a 0.5 x 0.5 degree resolution, by taking the maximum suitability of constituent higher resolution grid cells. Values > 0.46 may be suitable for the species. Grey areas have missing data in a predictor layer. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

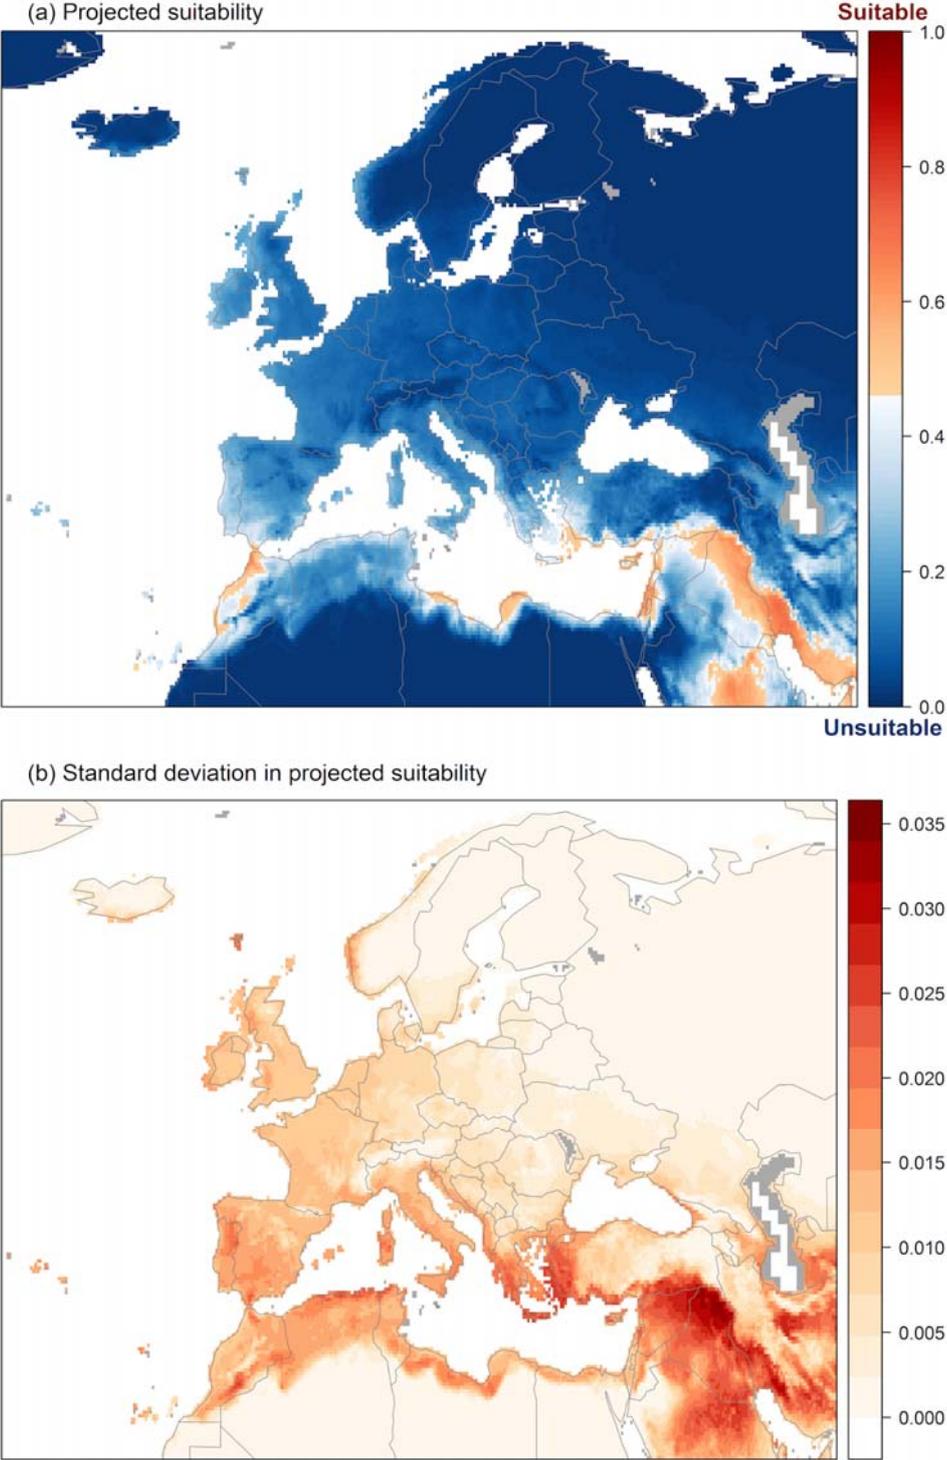

(a) Projected suitability

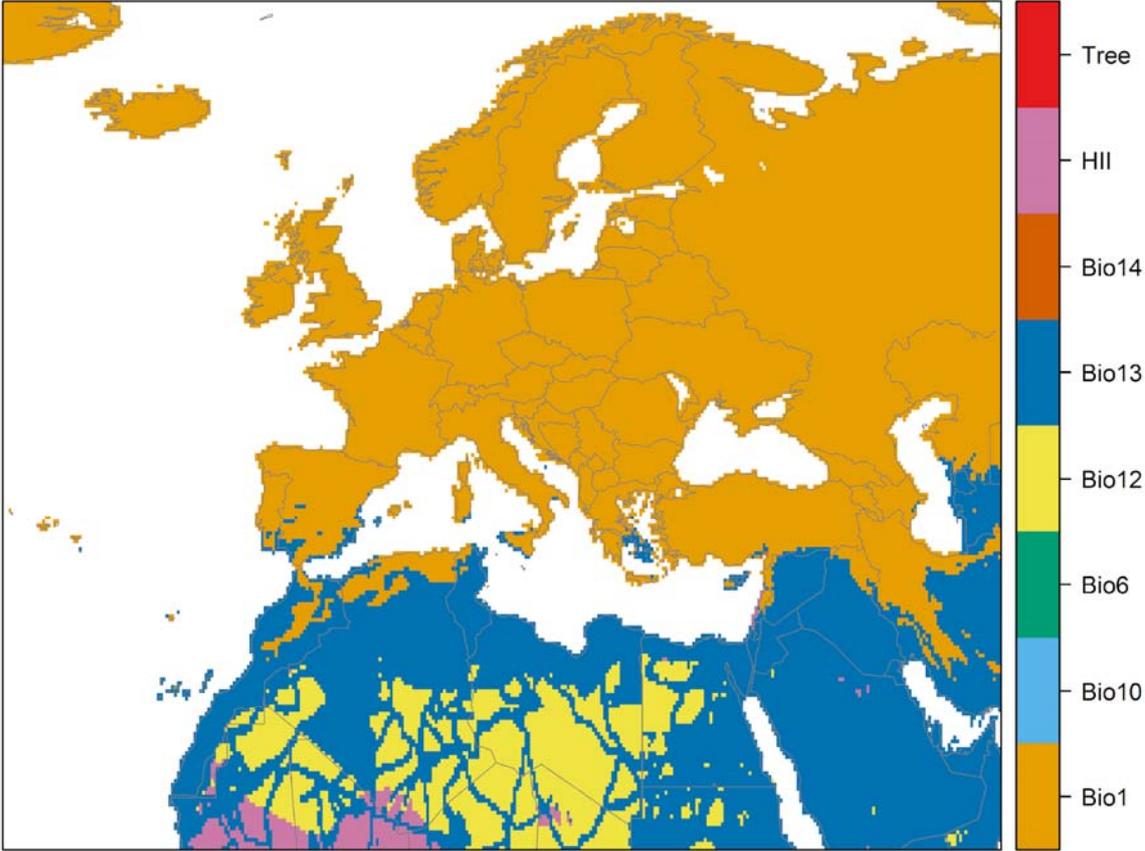

(b) Standard deviation in projected suitability

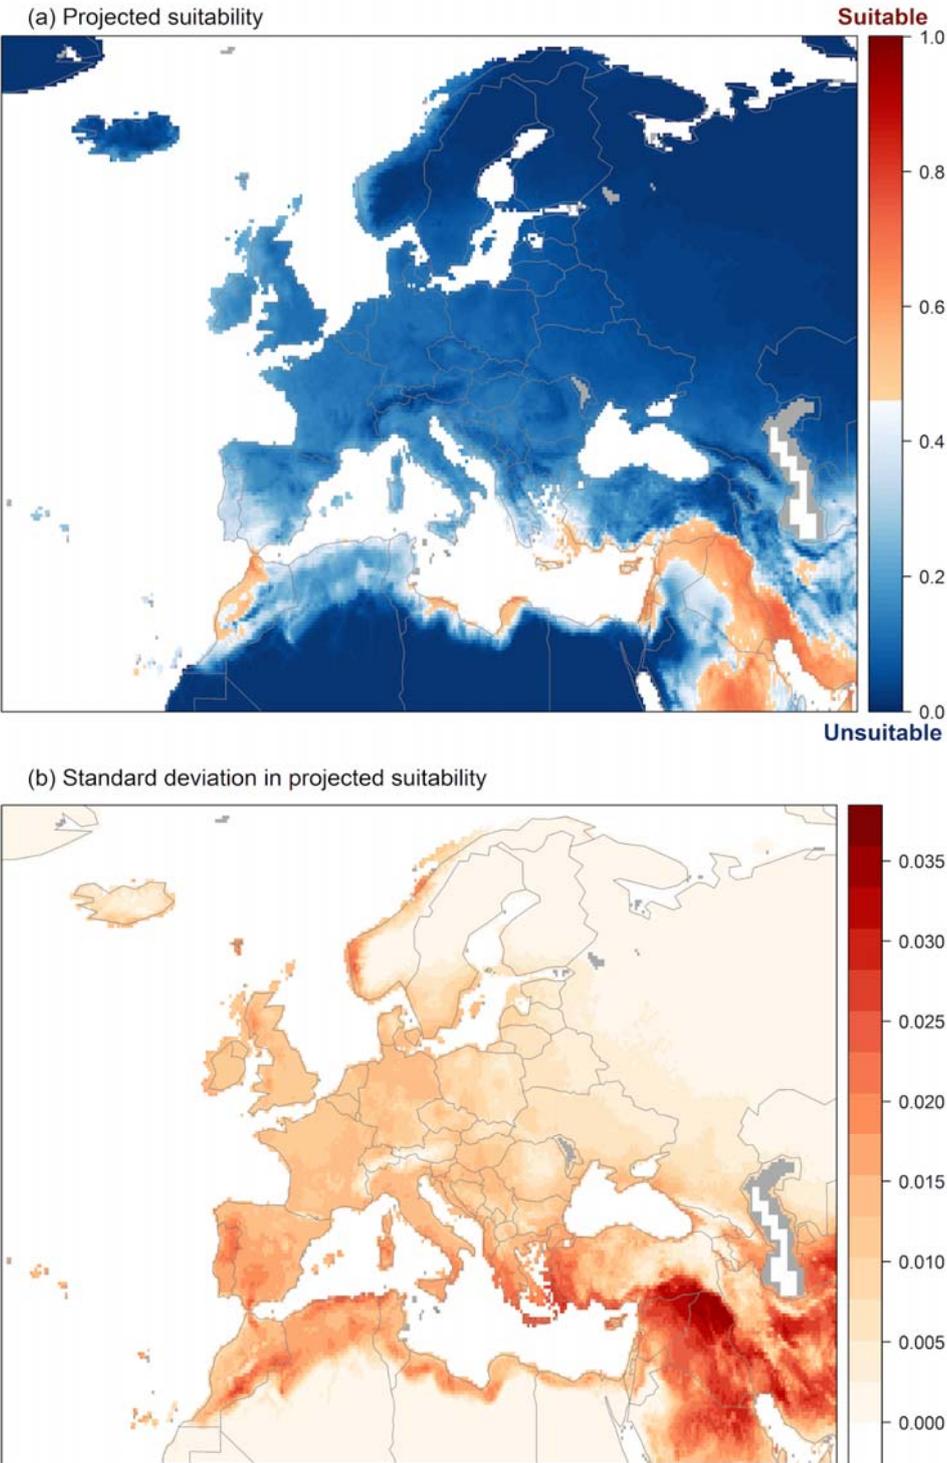

**Figure 5.** (a) Projected current suitability for *Pycnonotus cafer* establishment in Europe and the Mediterranean region. Grey areas have missing data in a predictor layer. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

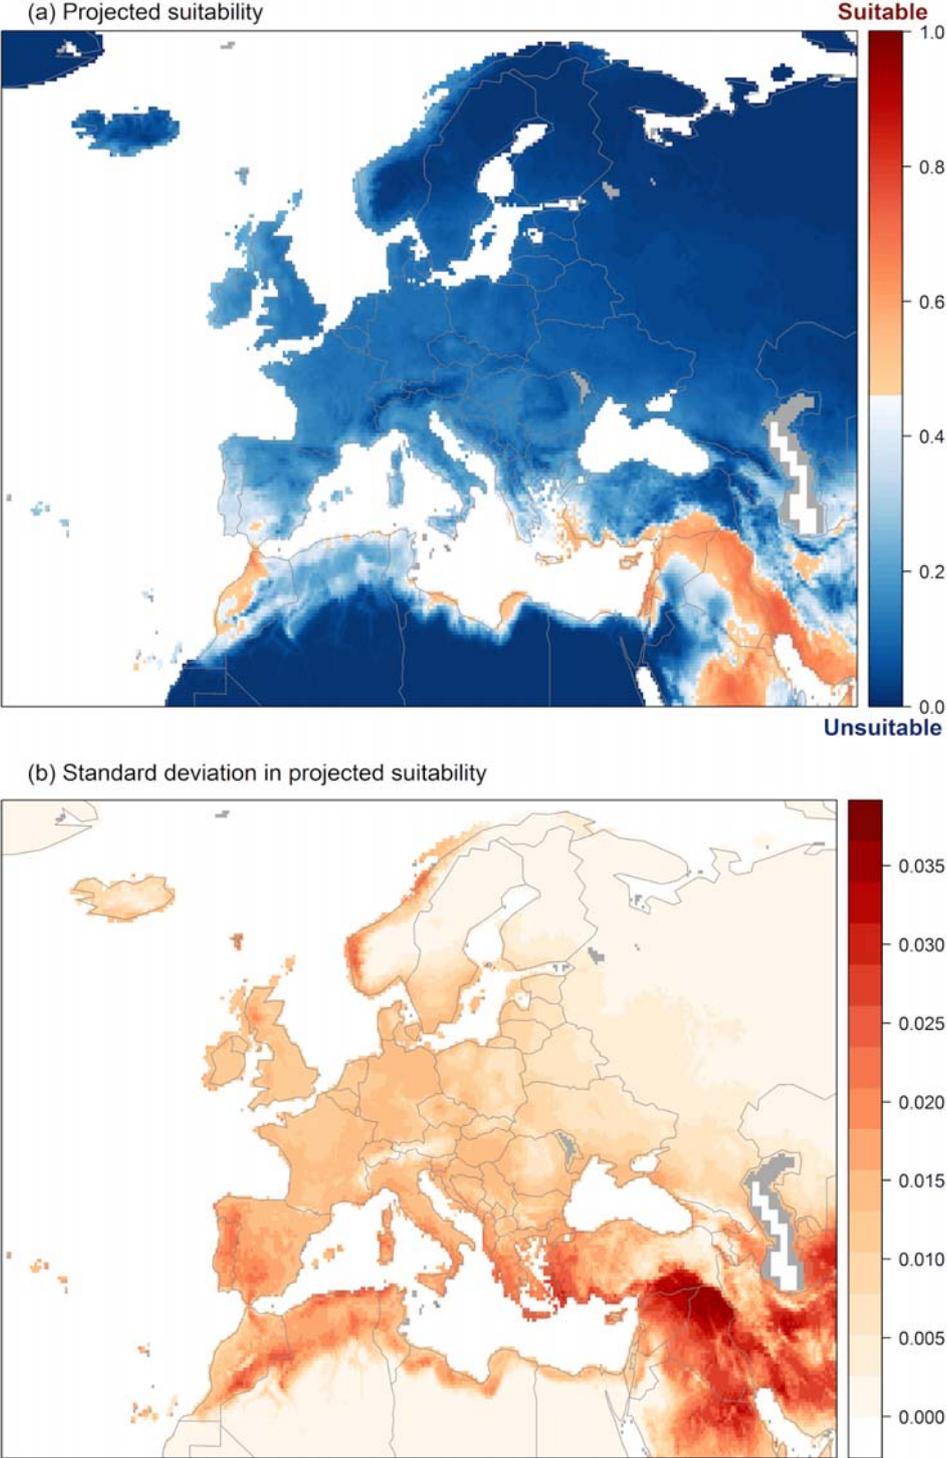

**Figure 6.** The most strongly limiting factors for *Pycnonotus cafer* establishment estimated by the model in Europe and the Mediterranean region in current climatic conditions.

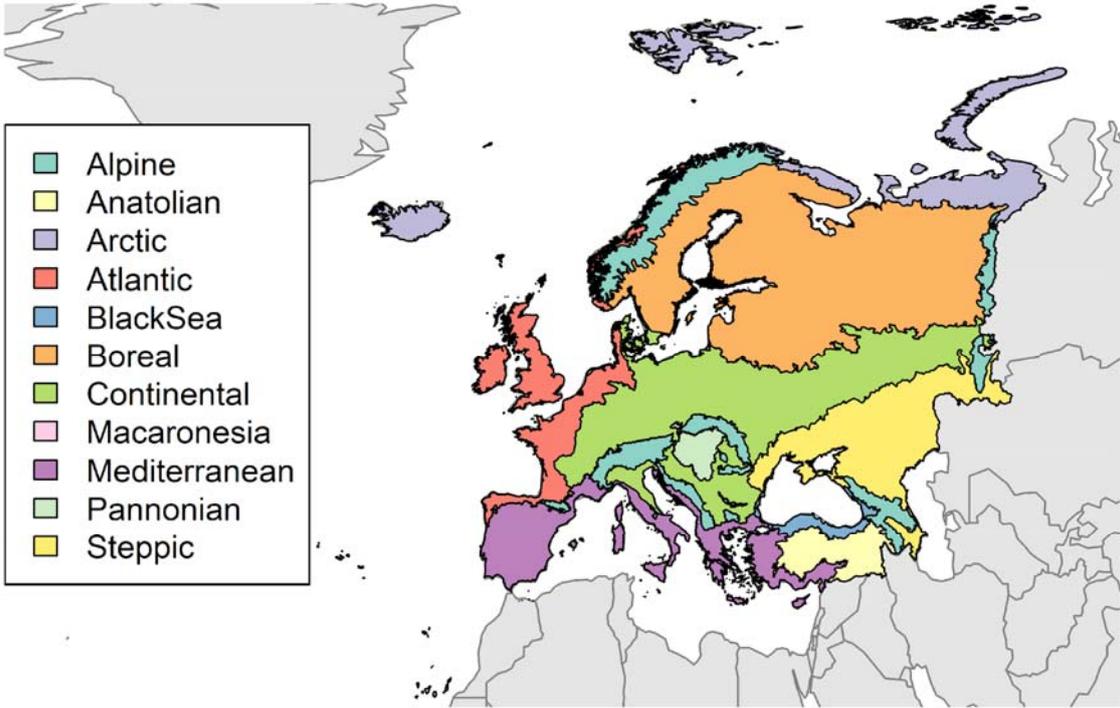

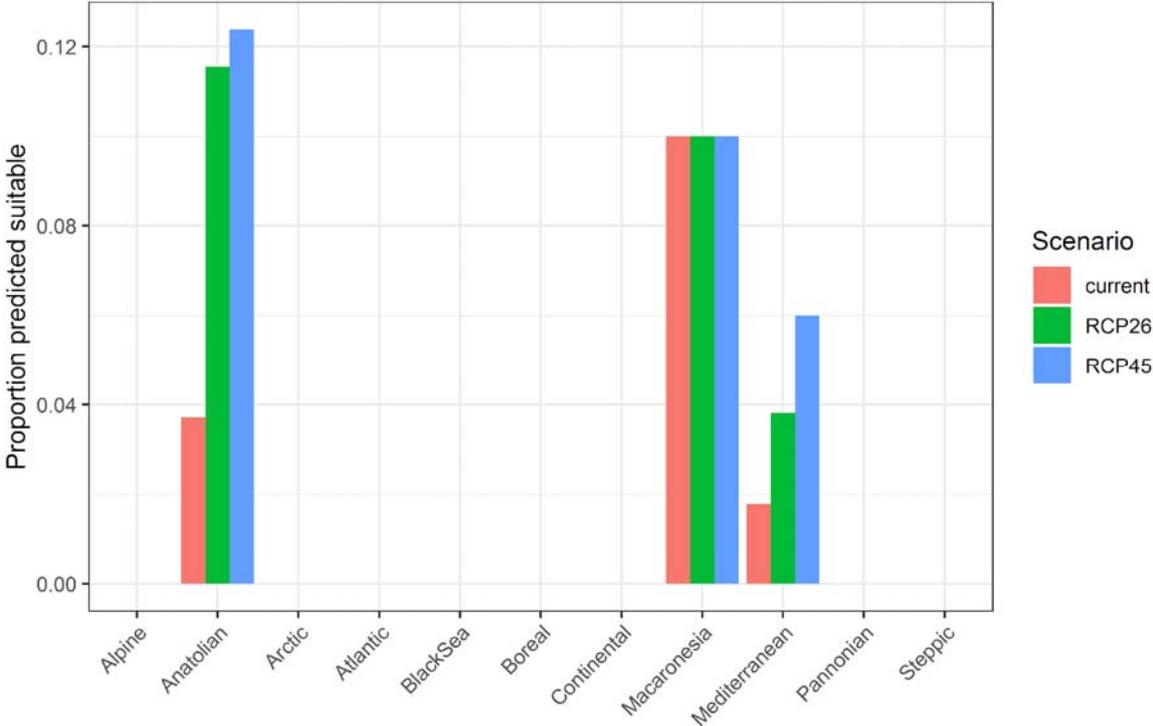

**Figure 7.** (a) Projected suitability for *Pycnonotus cafer* establishment in Europe and the Mediterranean region in the 2070s under climate change scenario RCP2.6, equivalent to Figure 5. Grey areas have missing data in a predictor layer. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

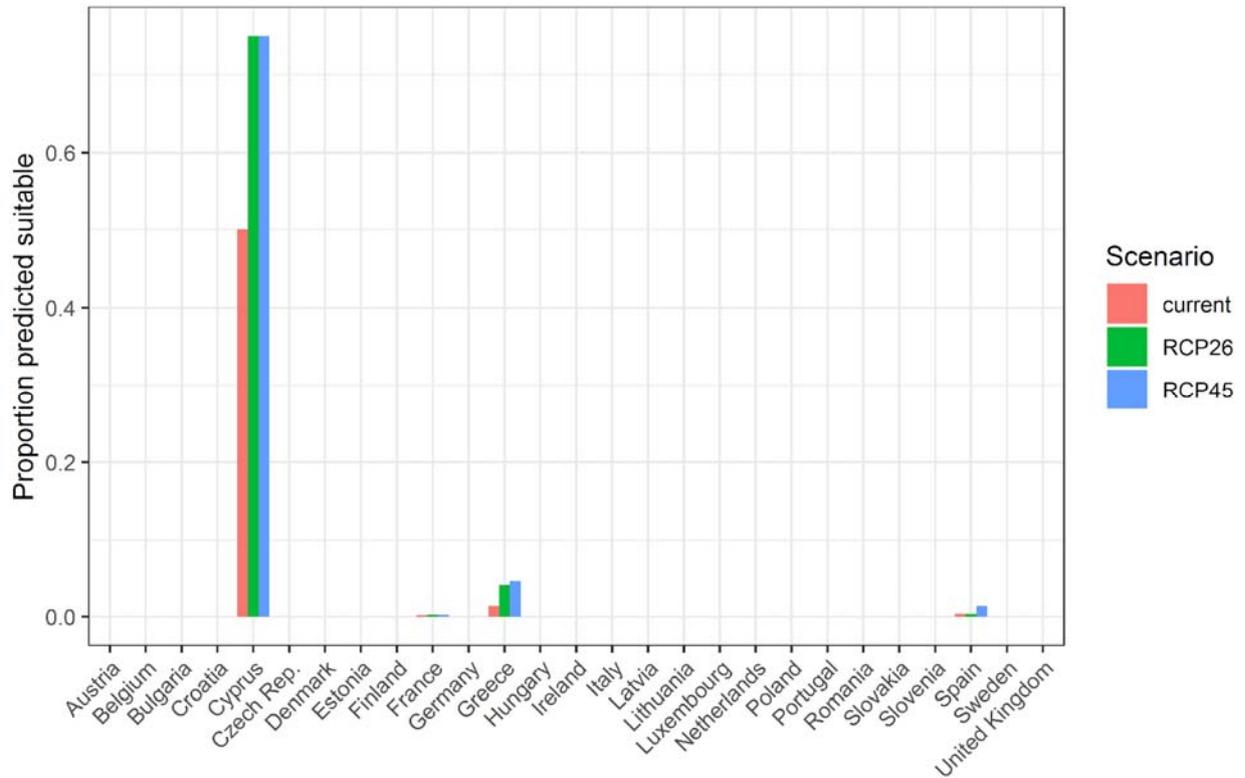

**Figure 8.** (a) Projected suitability for *Pycnonotus cafer* establishment in Europe and the Mediterranean region in the 2070s under climate change scenario RCP4.5, equivalent to Figure 5. Grey areas have missing data in a predictor layer. (b) Uncertainty in the ensemble projections, expressed as the among-algorithm standard deviation in predicted suitability, averaged across the 10 datasets.

**Figure 9.** Variation in projected suitability for *Pycnonotus cafer* establishment among Biogeographical regions of Europe (<https://www.eea.europa.eu/data-and-maps/data/biogeographical-regions-europe-3>). The bar plots show the proportion of grid cells in each region classified as suitable in the current climate and projected climate for the 2070s under two RCP emissions scenarios. The location of each region is also shown. The Arctic and Macaronesian biogeographical regions are not part of the study area, but are included for completeness.

**Figure 10.** Variation in projected suitability for *Pycnonotus cafer* establishment among European Union countries and the United Kingdom. The bar plots show the proportion of grid cells in each country classified as suitable in the current climate and projected climate for the 2070s under two RCP emissions scenarios. Malta has been excluded because the Human Influence Index dataset lacks coverage for Malta.

### ***Caveats to the modelling***

To remove spatial recording biases, the selection of the background sample was weighted by the density of Aves records on the Global Biodiversity Information Facility (GBIF). While this is preferable to not accounting for recording bias at all, it may not provide the perfect measure of recording bias.

There was substantial variation among modelling algorithms in the partial response plots (Figure 3). In part this will reflect their different treatment of interactions among variables. Since partial plots are made with other variables held at their median, there may be values of a particular variable at which this does not provide a realistic combination of variables to predict from.

Other variables potentially affecting the distribution of the species, such as land cover were not included in the model.

## SECTION A – Organism Information and Screening

**A1. Identify the organism. Is it clearly a single taxonomic entity and can it be adequately distinguished from other entities of the same rank?**

including the following elements:

- the taxonomic family, order and class to which the species belongs;
- the scientific name and author of the species, as well as a list of the most common synonym names;
- names used in commerce (if any)
- a list of the most common subspecies, lower taxa, varieties, breeds or hybrids

As a general rule, one risk assessment should be developed for a single species. However, there may be cases where it may be justified to develop one risk assessment covering more than one species (e.g. species belonging to the same genus with comparable or identical features and impact). It shall be clearly stated if the risk assessment covers more than one species, or if it excludes or only includes certain subspecies, lower taxa, hybrids, varieties or breeds (and if so, which subspecies, lower taxa, hybrids, varieties or breeds). Any such choice must be properly justified.

Response:

**Scientific name** (Class: Order: Family): *Vespa mandarinia* Smith, 1852 (Insecta: Hymenoptera: Vespidae)

**Most common synonyms:**

*Vespa japonica* Rad., 1857

*Vespa latilineata* Cameron, 1903

*Vespa magnifica* Smith, 1852

*Vespa sonani* Matsumura, 1930

**Common English name:** Asian giant hornet

**Other common names:** calabrone gigante asiatico (IT), Asiatische Riesenhornisse (GE), frelon géant (FR)

**Subspecies:** Various sub-species and colour forms with different geographic ranges and varying in colours have been described in the literature. Archer (1995) mentions three sub-species *V. mandarinia mandarinia* (in China, Japan, Russia and Korea); *V. mandarinia magnifica* (Northern India, Nepal, Bhutan, Burma, Laos, Peninsular Malaysia, western China); *V. mandarinia nobilis* (Taiwan). *Vespa mandarinia japonica* is sometimes cited as sub-species but is rather a colour form (Archer 1995). All sub-species will be treated together in this risk assessment. No hybrids with other species are known.

**A2. Provide information on the existence of other species that look very similar [that may be detected in the risk assessment area, either in the environment, in confinement or associated with a pathway of introduction]**

Include both native and non-native species that could be confused with the species being assessed, including the following elements:

- other alien species with similar invasive characteristics, to be avoided as substitute species (in this case preparing a risk assessment for more than one species together may be considered);
- other alien species without similar invasive characteristics, potential substitute species;
- native species, potential misidentification and mis-targeting

Response:

There are 22 *Vespa* spp. worldwide, all occurring in some parts of Asia (Archer 2008; Smith Pardo et al. 2020). Four of them also occur in Europe: *Vespa crabro* L. and *V. orientalis* L. are native to Europe and *V. velutina* Lepeletier is an invasive alien species from East Asia. The fourth species, *V. bicolor* F., also non-native to Europe, is present in a small area in southern Spain since at least 2013 but does not seem to spread (Castro et al. 2019). All non-native species could potentially be invasive in Europe, but this risk assessment concerns *V. mandarinia*.

*Vespa mandarinia* can easily be separated from the four species occurring in Europe using morphological characters (Archer 1995, 2012; Smith Pardo et al. 2020). The most obvious character is the size of the wasps, the smallest workers of *V. mandarinia* measuring at least 35 mm (queens can exceed 50 mm) whereas only the largest queens of *V. crabro* reach 35 mm. It is most similar to *Vespa soror* du Buysson (a south-East Asian species) but the two species can be distinguished by the colour of their abdomen. In *V. soror*, the third to the sixth gastral terga in the female and to the seventh gastral terga in the male are black, whereas, in *V. mandarinia*, these terga are at least partly orange (Archer 1995).

**A3. Does a relevant earlier risk assessment exist? Give details of any previous risk assessment, including the final scores and its validity in relation to the risk assessment area.**

Response:

Two partial risk assessments have been produced for North America. Norderus et al. (2021) conducted a risk assessment of the establishment of *V. mandarinia* specifically on the Pacific Northwest and Zhu et al. (2020) assessed its ecological niche and invasion potential. None of the two, however, provide detailed assessments of the magnitude of impact. USDA (2020) has produced “New Pest Response Guidelines” following the recent observations of *V. mandarinia* in North. In Europe, risk assessments have been produced for *V. velutina* after this species became established (e.g. Marris et al. 2011) and, thus, although helpful, they are not fully relevant for *V. mandarinia* in Europe, where it is not yet present.

**A4. Where is the organism native?**

including the following elements:

- an indication of the continent or part of a continent, climatic zone and habitat where the species is naturally occurring

- if applicable, indicate whether the species could naturally spread into the risk assessment area

Response:

*Vespa mandarinia* is native to Asia, occurring in at least 9 Köppen climates from the continental, temperate and tropical groups. It has been recorded in the following countries: China, Japan, Russia, South Korea, India, Buthan, Nepal, Myanmar, Laos, Malaysia, Thailand, Vietnam (Archer 1995; GBIF 2020; Smith Pardo et al. 2020; USDA 2020). Smith Pardo et al. (2020) also includes Sri Lanka but Kumar and Srinivasan (2010) consider this as an error. The distribution records in Asia are indicated in Figure 1.

In Japan, *V. mandarinia* is associated with hilly country (850-1900m), nesting in the ground at a depth of 6-60cm. Nests are started in small mammal burrows and decayed root spaces. These cavities can be enlarged by the workers removing soil particles. A few nests have been found in hollow trees and a mud wall 1-2m above the ground. (Archer 2008). As for all Vespidae, nest building requires a sufficient amount of humidity and water availability (Matsuura and Yamane 1990)

*Vespa mandarinia* is a good flier but considering the distances involved, it cannot naturally spread on its own from its native area to the risk assessment area.

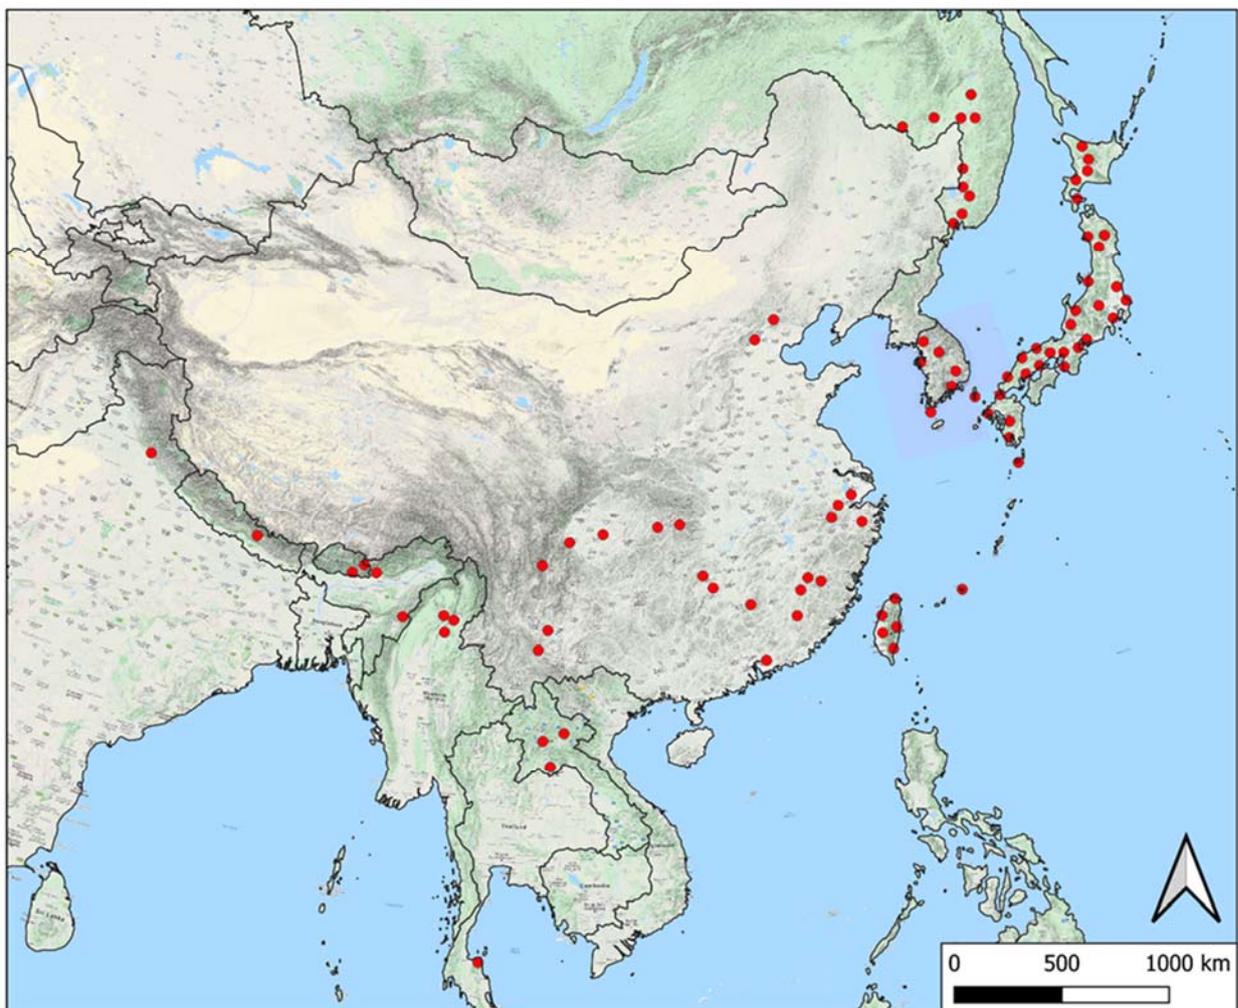

Figure 1. Distribution of *V. mandarinia* in Asia (background map from Google). Only the sites where precise occurrences are known are indicated in the map.

**A5. What is the global non-native distribution of the organism outside the risk assessment area?**

Response:

The first record outside its native range was in August and September 2019, when workers and a nest were found in Nanaimo, Vancouver Island, British Columbia, Canada. In 2019, workers were also observed on the mainland, in White Rock, south of Vancouver and close-by at two sites (Blaine and Bellingham) in Washington State (USA), suggesting that nests were also present on the mainland (USDA 2020). In May 2020, a live individual queen was captured at Langley, British Columbia and, by September 2020, several queens, workers and a male were also found in Custer, Birch Bay and Bellingham, Washington (Norderud et al. 2021; WSDA 2021). In October 2020, a nest was found and destroyed in Blaine and a new dead male was discovered in June 2021 in near Marysville (all Washington, WSDA 2021). Genetic analyses showed that the nest found on Vancouver Island and the individual found in Washington State belong to different lineages (Wilson et al. 2020).

**A6. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species been recorded and where is it established? The information needs be given separately for recorded (including casual or transient occurrences) and established occurrences. “Established” means the process of an alien species successfully producing viable offspring with the likelihood of continued survival<sup>2</sup>.**

**A6a. Recorded: List regions**

**A6b. Established: List regions**

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

- Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea.

Comment on the sources of information on which the response is based and discuss any uncertainty in the response.

For delimitation of EU biogeographical regions please refer to <https://www.eea.europa.eu/data-and-maps/figures/biogeographical-regions-in-europe-2> (see also Annex VI).

<sup>2</sup> Convention on Biological Diversity, Decision VI/23

For delimitation of EU marine regions and subregions consider the Marine Strategy Framework Directive areas; please refer to <https://www.eea.europa.eu/data-and-maps/data/msfd-regions-and-subregions/technical-document/pdf> (see also Annex VI).

Response (6a):

No record yet in the risk assessment area. In GBIF (2020), a record from Germany could not be traced to the original source and seems erroneous.

Response (6b):

No establishment yet in the risk assessment area.

**A7. In which biogeographic region(s) or marine subregion(s) in the risk assessment area could the species establish in the future under current climate and under foreseeable climate change? The information needs to be given separately for current climate and under foreseeable climate change conditions.**

**A7a. Current climate: List regions**

**A7b. Future climate: List regions**

With regard to EU biogeographic and marine (sub)regions, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

Response (7a):

Based on present occurrences and the limited bioecological data available about the hornet, a CLIMEX model has been built, which integrates the weekly responses of an organism to climate using a series of annual indices.

The model (Seehansen and Kenis, unpublished) is described in Annex VIII. In CLIMEX, the potential for population growth is modeled combining growth based on temperature and soil moisture during favorable conditions using a Growth Index (GI), and stress indices (cold, wet, hot, dry) to determine the effect of abiotic stress on survival in unfavorable conditions. The growth and stress indices are calculated weekly and then combined into an overall annual index of climatic suitability, the

Ecoclimatic Index (EI). The EI ranges from 0 (no persistence possible) to 100 (optimal conditions), but in temperate climates, the maximum EI value is rather close to 50 and values of >20 are known to be sufficient to support substantial population densities.

The model shows that in its native range, *V. mandarinia* is mainly predicted to be present in humid subtropical and humid oceanic climates (Figure 2). The northern distribution of *V. mandarinia* is mainly limited by cold stress during the harsh winters of the subarctic regions and dry stress in the highlands and Mongolian desert. The southern and western distribution limits are mainly defined by heat stress.

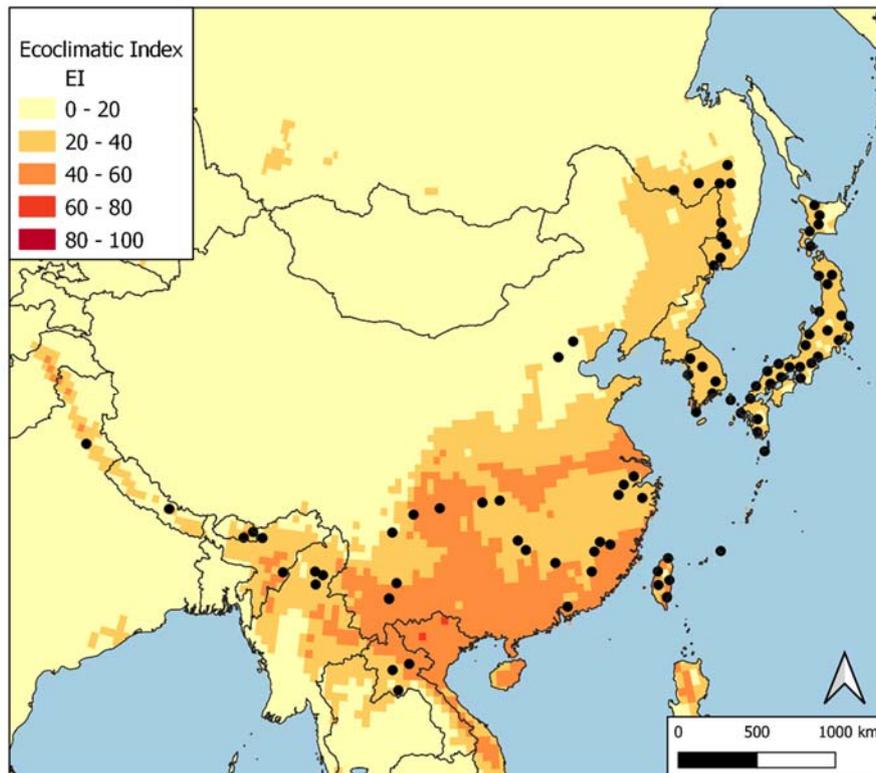

Figure 2: Observed (black points) and potential distribution of *V. mandarinia* in its native Asia as predicted by the Ecoclimatic Index (EI) from the CLIMEX model. Locations with EI>20 can be considered as climatically suitable for establishment and growth of *V. mandarinia*.

Under current climate, the most suitable biogeographic regions of Europe are predicted to be the Continental and Atlantic regions and the most humid parts of the Mediterranean, Black Sea and Pannonian regions (Figure 3). The Arctic, Boreal and Alpine regions will probably be too cold for establishment. The hornet is predicted to experience cold stress in the Alps, and in the subarctic region low mean temperatures, as well as a relatively short and dry growing season restrict population growth. The Steppic regions appear too dry to be suitable for *V. mandarinia*, defining the predicted southern distribution limits through dry stress. However, irrigated areas or humid microclimates may provide favourable areas for the hornet in the south.

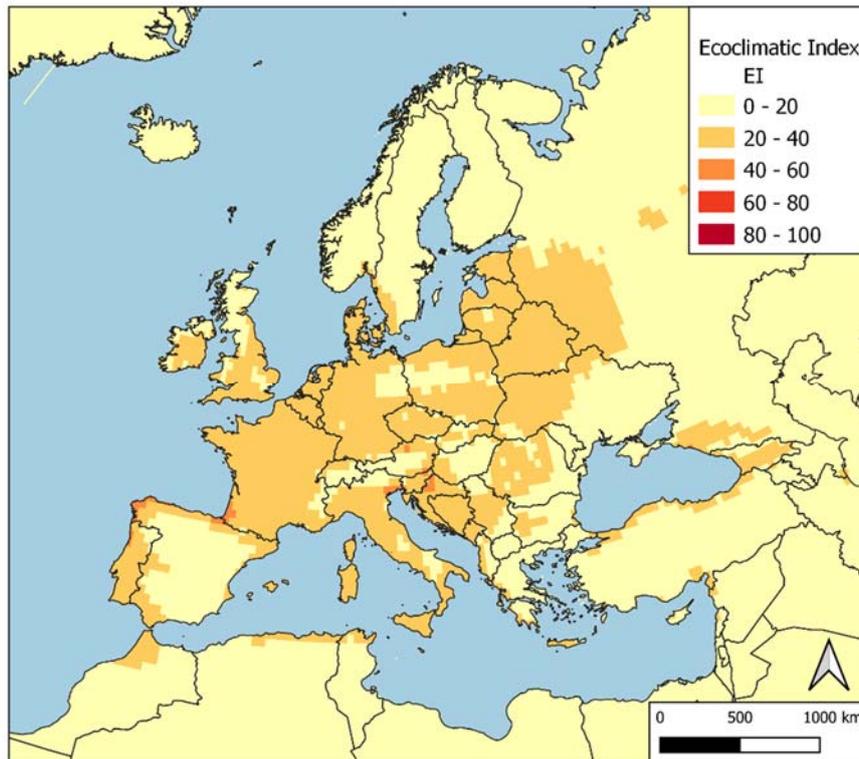

Figure 3: Potential distribution of *V. mandarinia* in Europe and northern Africa as predicted by the Ecoclimatic Index (EI) from the CLIMEX model. Locations with  $EI > 20$  can be considered as climatically suitable for establishment and growth of *V. mandarinia*.

Response (7b):

A CLIMEX Ecoclimatic Index map (Figure 4) shows the likely occurrence of *V. mandarinia* in Europe in 2080, following the A1B climate change scenario, which is comparable to the RCP 4.5 scenario (RCP scenarios are not available in CLIMEX). In the future, increases in average temperatures are likely to favour establishment in the warmest areas of the Boreal and Alpine regions. In contrast, increased summer drought in Southern and Eastern Europe will make some parts of the Mediterranean and Continental regions and most of the Pannonian, Black Sea and Steppic regions unsuitable without irrigation. Especially the predicted loss of suitable area in north-eastern Europe are due to dryer summers that may severely restrict population growth of the hornet.

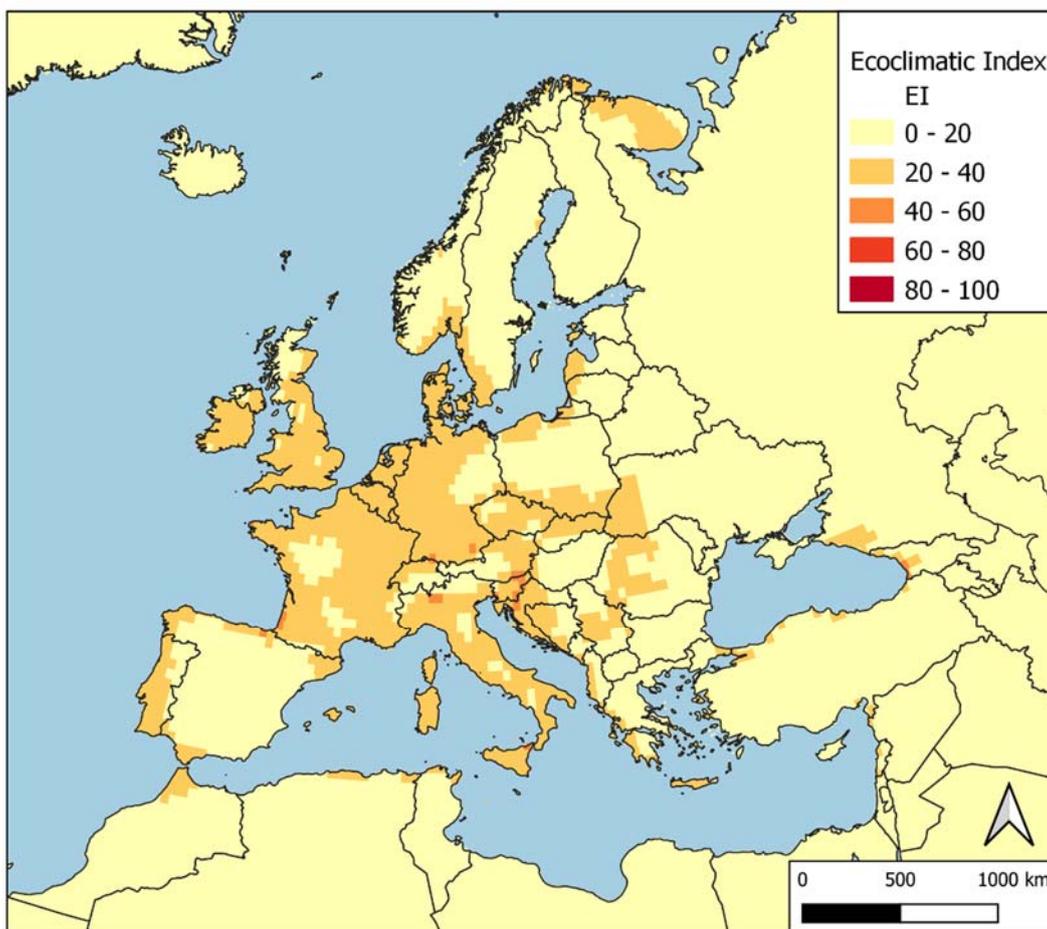

Figure 4: Potential distribution of *V. mandarinia* in Europe and northern Africa in 2080, as predicted by the Ecoclimatic Index (EI) from the CLIMEX model using the A1B scenario. Locations with  $EI > 20$  can be considered as climatically suitable for establishment and growth of *V. mandarinia*.

**A8. In which EU Member States has the species been recorded and in which EU Member States has it established? List them with an indication of the timeline of observations. The information needs be given separately for recorded and established occurrences.**

**A8a. Recorded: List Member States**

**A8b. Established: List Member States**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden, United Kingdom

The description of the invasion history of the species shall include information on countries invaded and an indication of the timeline of the first observations, establishment and spread.

Response (8a):

No record yet in the risk assessment area. In GBIF (2020), a record from Germany seems erroneous

Response (8b):

No establishment yet in the risk assessment area

**A9. In which EU Member States could the species establish in the future under current climate and under foreseeable climate change? The information needs be given separately for current climate and under foreseeable climate change conditions.**

**A9a. Current climate: List Member States**

**A9b. Future climate: List Member States**

With regard to EU Member States, see above.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the risk assessment (e.g. increase in average winter temperature, increase in drought periods)

The assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

Response (9a):

Almost all member states are at least partly suitable for establishment. Establishment in Finland and Sweden will probably be limited by cold average temperatures whereas, in Cyprus, drought may hamper establishment (Figure 3).

Response (9b):

In the future, under the A1B scenario (see Q A7b) climate may become suitable at higher altitudes and latitudes, e.g. in Sweden and Finland because of increased average temperatures in particular during brood development, whereas Eastern European and Mediterranean countries may become less suitable because of increased summer droughts (Figure 4).

**A10. Is the organism known to be invasive (i.e. to threaten or adversely impact upon biodiversity and related ecosystem services) anywhere outside the risk assessment area?**

Response:

No information is available on the species impact in invaded areas.

Since August 2019, a nest and workers have been found at three sites in British Columbia, Canada and a nest and various specimens have been found at several locations in Washington State, USA (USDA 2020; WSDA 2021). However, it is not known whether these populations will become invasive.

Many Vespinae, including *Vespa* spp., are invasive worldwide, threatening biodiversity and various ecosystem services. See Beggs et al. (2011) for a review on the ecological effects of invasive alien Vespidae. The mechanisms of ecological impacts of invasive Vespidae include: direct predation on native species, in particular invertebrates; competition for food (invertebrates, honeydew, sap runs etc.) with other insects but also birds; competition for space, in particular other vespids; predation on honeybees and wild bees affecting pollination services, etc.

**A11. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Freshwater / terrestrial biogeographic regions:

- Alpine, Atlantic, Black Sea, Boreal, Continental, Mediterranean, Pannonian, Steppic

Marine regions:

- Baltic Sea, North-east Atlantic Ocean, Mediterranean Sea, Black Sea

Marine subregions:

Greater North Sea, incl. the Kattegat and the English Channel, Celtic Seas, Bay of Biscay and the Iberian Coast, Western Mediterranean Sea, Adriatic Sea, Ionian Sea, Central Mediterranean Sea, Aegean-Levantine Sea

Response:

The species is not yet present in the risk assessment area.

**A12. In which EU Member States has the species shown signs of invasiveness? Indicate the area endangered by the organism as detailed as possible.**

Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden, United Kingdom

Response:

The species is not yet present in the risk assessment area.

**A13. Describe any known socio-economic benefits of the organism.**

including the following elements:

- Description of known uses for the species, including a list and description of known uses in the risk assessment area and third countries, if relevant.
- Description of social and economic benefits deriving from those uses, including a description of the environmental, social and economic relevance of each of those uses and an indication of associated beneficiaries, quantitatively and/or qualitatively depending on what information is available.

If the information available is not sufficient to provide a description of those benefits for the entire risk assessment area, qualitative data or different case studies from across the risk assessment area or third countries shall be used, if available.

Response:

In Asia, larvae and pupae of *V. mandarinia* are considered a delicacy. They are traded and consumed in various ways. They are also considered to have medicinal properties (Nonaka 2008; Ying et al. 2008; Ho 2019). To our knowledge, live *V. mandarinia* are not traded in Europe but at least one entire nest containing live larvae and pupae was intercepted in USA (Smith Pardo et al. 2020) suggesting that illegal trade of nests does occur outside Asia.

## SECTION B – Detailed assessment

### Important instructions:

- In the case of lack of information the assessors are requested to use a standardized answer: “No information has been found.”
- With regard to the scoring of the likelihood of events or the magnitude of impacts see Annexes I and II.
- With regard to the confidence levels, see Annex III.
- Highlight the selected response score and confidence level in **bold** but keep the other scores in normal text (so that the selected score is evident in the final document).

## 1 PROBABILITY OF INTRODUCTION AND ENTRY

### Important instructions:

- **Introduction** is the movement of the species into the risk assessment area (it may be either in captive conditions and/or in the environment, depending on the relevant pathways).
- **Entry** is the release/escape/arrival in the environment, i.e. occurrence in the wild
- Introduction and entry may coincide for species entering through pathways such as “corridor” or “unaided”, but it also may differ. If different, please consider all relevant pathways, both for the introduction into the risk assessment area and the entry in the environment.
- The classification of pathways developed by the Convention of Biological Diversity (CBD) should be used (see Annex IV). For detailed explanations of the CBD pathway classification scheme consult the IUCN/CEH guidance document<sup>3</sup> and the provided key to pathways<sup>4</sup>.
- For organisms which are already present (recorded or established) in the risk assessment area, the likelihood of introduction and entry should be scored as “very likely” by default.
- Repeated (independent) introductions and entries at separate locations in the risk assessment area should be considered here (see Qu. 1.7).

**Qu. 1.1. List relevant pathways through which the organism could be introduced into the risk assessment area and/or enter into the environment. Where possible give details about the specific origins and end points of the pathways as well as a description of any associated commodities.**

For each pathway answer questions 1.2 to 1.7 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 1.2a, 1.3a, etc. and then 1.2b, 1.3b etc. for the next pathway.

In this context a pathway is the route or mechanism of introduction and/or entry of the species.

<sup>3</sup> <https://circabc.europa.eu/sd/a/738e82a8-f0a6-47c6-8f3b-aeddb535b83b/TSSR-2016-010%20CBD%20categories%20on%20pathways%20Final.pdf>

<sup>4</sup> <https://circabc.europa.eu/sd/a/0aeba7f1-c8c2-45a1-9ba3-bcb91a9f039d/TSSR-2016-010%20CBD%20pathways%20key%20full%20only.pdf>

The description of commodities with which the introduction of the species is generally associated shall include a list and description of commodities with an indication of associated risks (e.g. the volume of trade; the likelihood of a commodity being contaminated or acting as vector).

If there are no active pathways or potential future pathways this should be stated explicitly here, and there is no need to answer the questions 1.2-1.9.

The pathways considered in this risk assessment are:

- A. Transport - Contaminant (nursery material)
- B. Transport - Contaminant (transportation of habitat material) (other than nursery material)
- C. Transport - Stowaway (container/bulk)
- D. Escaped from confinement (live food and live bait)

*Vespa mandarinia* presently occurs too far from the risk assessment area to consider that the hornet can enter “unaided”. Thus, all pathways considered here will be human-assisted. There is very limited information on the potential pathways that can be used by *V. mandarinia* to enter new continents. Non-native Vespidae are not listed as quarantine pests in the EU and, therefore, records do not appear in the national and international lists of intercepted pests. Thus, there is hardly any information available from Europe except that the congeneric and invasive alien species *Vespa velutina* probably arrived in Europe in bonsai pottery from Asia (Arca et al. 2015). Smith Pardo et al. (2020) mentioned that, from 2010 to 2018, there have been close to 50 interceptions of *Vespa* spp. and *Vespula* spp. at US ports of entry and that little less than half of those interceptions were hornets, including *V. mandarinia*. They did not mention on which pathways and which commodities these interceptions were made. However, these data, and the recent introductions of *V. mandarinia* in North America (USDA 2020) along with various *Vespa* spp., *Vespula* spp. and *Polistes* spp. worldwide (Beggs et al. 2011) show that vespids, including *V. mandarinia* can be transported between continents. While queens, males and workers can potentially travel, only mated queens will be able to build a new colony. *Vespa mandarinia* queens overwinter singly, usually in cavities excavated in the soil, or occasionally in rotten wood or straw. Thus, the transport of mated queens from autumn to spring (before, during and after overwintering) is the most likely means of long-distance dispersal. Single queens may unintentionally be transported as contaminant of soil (e.g. soil for construction, potted plants) or rotten wood or straw in which they overwinter, or as stowaway in any kind of good in containers. Theoretically, a mated queen could also travel freely, outside containers, in ships or planes but these pathways were considered too unlikely to be mentioned here.

The introduction of a single mated queen is potentially sufficient to establish a colony. The introduction of *V. velutina* in France was due to a single queen that had mated multiple times, or a very small number of overwintering queens that had mated singly (Arca et al. 2015).

One of the interceptions of significance in USA mentioned by Smith Pardo et al. (2020) was an entire nest of *V. mandarinia* containing live brood and pupae that was sent via express courier from Asia, probably for consumption or as traditional medicine (USDA 2020). Thus, intentional importations of nests are considered here as well.

#### **A. Transport - Contaminant (nursery material)**

**Qu. 1.2a. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response:

The introduction and/or entry along this pathway is unintentional. Queens overwinter mainly in a hole that they have excavated in the soil (Matsuura and Sakagami 1973; Archer 1995). Thus, any kind of soil or similar substrate that is transported with nursery material can potentially transport an overwintering queen.

**Qu. 1.3a. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response:

There is no data on *V. mandarinia* or other *Vespa* spp. travelling in potted plants. The import of soil and related substrates to Europe has been much reduced in recent years. Nevertheless, a large amount of plants still arrive in Europe with soil or in pots (with substrates) from East Asia every year and, although the soil/substrate is supposed to be sterile, it is possible that hornets can enter the soil/substrates just before or during transport.

**Qu. 1.4a. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

Queens are very strong insects. They do not feed nor reproduce in their overwintering site (Matsuura and Sakagami 1973; Archer 1995) and can probably survive long ship journeys.

**Qu. 1.5a. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response:

In international horticultural trade, plant material is supposed to be free of pests and soil/substrate should be sterile, but hornets can enter the soil/substrates after treatments, just before or during transport. Only a small portion of the plant material imported to the EU is inspected and the imported pots are quickly dispersed into the EU (Eschen et al. 2015).

**Qu. 1.6a. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

Although a *V. mandarinia* queen is rather big (4-5 cm), the cavity in which it overwinters is usually plugged (Archer 1995) and it can easily remain undetected during intercontinental transport and dispatching to the final destinations.

**Qu. 1.7a. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated	<b>CONFIDENCE</b>	low
	<b>widespread</b>		medium
	ubiquitous		<b>high</b>

Response:

Horticultural products can enter the risk assessment area at various ports of entry and are usually quickly distributed within the EU. Queens are good fliers and can build nests in various environments (Matsuura and Sakagami 1973; Archer 1995). Thus, they would have no difficulty in reaching suitable habitats for nesting.

**Qu. 1.8a. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	<b>low</b>
	unlikely		medium
	<b>moderately likely</b>		high
	likely		
	very likely		

Response:

There is no data on this pathway and it is not clear how frequently queens could enter soil and other substrates accompanying traded potted plants and other plant material. Probably this is a rather infrequent event considering that large amounts of soil or other substrates are transported every year into the EU and no occurrence of *V. mandarinia* has been ever recorded in Europe. However, once a queen has entered the commodity to build its overwintering site, the probability of arriving safely and entering the risk assessment area is rather high, considering that queens are strong and long-lived animals, and that the cavity in which they overwinter is usually plugged.

**B. Transport - Contaminant (transportation of habitat material) (other than nursery material)**

**Qu. 1.2b. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response:

The introduction and/or entry along this pathway is unintentional. Queens overwinter mainly in a hole that they have excavated in the soil, but also occasionally in rotting wood, piles of straw, etc. (Matsuura and Sakagami 1973; Archer 1995). Thus, this pathway covers these overwintering substrates other than soil in potted plants, which is covered in pathway A above.

**Qu. 1.3b. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response:

There is no data on *V. mandarinia* or other *Vespa* spp. travelling in suitable habitats such as straw and rotting wood. While rotting wood is unlikely to be imported intentionally, various amounts of items made of straw arrive in Europe from East Asia every year and it is possible that these can host overwintering hornets. Items made of straw may include handicraft, horticulture and gardening material, packing material, etc.

**Qu. 1.4b. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

Queens are very strong insects. They do not feed nor reproduce in their overwintering site (Matsuura and Sakagami 1973; Archer 1995) and can probably survive long ship journeys.

**Qu. 1.5b. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response:

There is no data on existing management practices on imported straw items. These can be quickly dispatched to the whole risk assessment area.

**Qu. 1.6b. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

Although a *V. mandarinia* queen is rather big (4-5 cm), the cavity in which it overwinters is usually plugged (Archer 1995) and it can easily remain undetected during transport and dispatching to the final destinations.

**Qu. 1.7b. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated	<b>CONFIDENCE</b>	low
	<b>widespread</b>		medium
	ubiquitous		<b>high</b>

Response:

Such commodities can enter the risk assessment area at various ports of entry and can be quickly distributed within the EU. Queens are good fliers and can build nests in various environments (Matsuura and Sakagami 1973; Archer 1995). Thus, they would have no difficulty in reaching suitable habitats for nesting.

**Qu. 1.8b. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely	<b>CONFIDENCE</b>	<b>low</b>
	unlikely		medium
	<b>moderately likely</b>		high
	likely		
	very likely		

Response:

There is no data on this pathway and it is not clear how frequently queens could be transported in straw material, rotting wood and similar overwintering habitats. Probably this is an infrequent event. However, once a queen has entered the commodity to build its overwintering site, the probability of arriving safely and entering the risk assessment area is rather high, considering that queens are strong and long-lived animals, and that the cavity in which they overwinter is usually plugged.

**C. Transport-Stowaway (container/bulk)**

**Qu. 1.2c. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response:

The introduction and/or entry along this pathway is unintentional. In their search for overwintering sites, or when emerging from overwintering sites between autumn and spring, queens can easily hide in various type of containers and can be shipped with any kind of good in containers with various transport means (ships and planes).

**Qu. 1.3c. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response:

There is no data to define which goods and containers are the most likely to carry queens. However, the number and variety of commodities and containers that can potentially transport queens is unlimited and, thus, we believe that queens are more likely to be transported as stowaways in containers than as contaminants of soil. At arrival, queens can easily escape and build a nest in the vicinity of the port of entry, or be transported with the container into any region of the risk assessment area.

**Qu. 1.4c. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

Queens are very strong insects. They do not feed nor reproduce in their overwintering site (Matsuura and Sakagami 1973; Archer 1995). Thus, they can probably survive long journeys, especially if they find an overwintering site in the container. Once the container is open and the commodity has been delivered, the queen can escape and easily find a suitable habitat for nesting since nests are commonly found in various habitats from forests to urban green spaces (Matsuura and Sakagami 1973; USDA 2020).

**Qu. 1.5c. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response:

This will depend on the management practices used in the transport conditions but none will target Vespidae and it is unlikely that any management practice will affect the transported queen along the pathway and within the risk assessment area after transport and dispatching to the final destination.

**Qu. 1.6c. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

Queens are very big (4-5 cm) and may be quite obvious when they simply hitchhike in a container. However, overwintering queens are usually hidden and are easily missed when transported.

**Qu. 1.7c. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response:

Containers can enter the risk assessment area at various ports of entry and can also be quickly sent anywhere within the EU. Queens are good fliers and can build nests in various environments, from forests to urban areas (Matsuura and Sakagami 1973; Archer 1995; USDA 2020). Thus, they would have no difficulty in reaching suitable habitats for nesting.

**Qu. 1.8c. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response:

There is no data on this pathway and it is not clear how frequently queens could be transported as stowaway between continents. However, considering that the number and variety of commodities and containers that can potentially transport queens is unlimited, queens are probably more likely to be transported as stowaway than as contaminant of soil or straw.

#### **D. Escaped from confinement (live food and live baits)**

**Qu. 1.2d. Is introduction and/or entry along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?**

<b>RESPONSE</b>	<b>intentional</b> unintentional	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response:

This pathway has been added because among the ca. 50 reported interceptions of Vespidae in ports of entry in USA, one was an entire nest of *V. mandarinia* with live larvae and pupae sent by express courier from Asia (Smith-Pardo et al. 2020). It is not known precisely why this nest was sent to USA, but it is likely that it was for human consumption. In Asia, larvae and pupae of *V. mandarinia* are considered a delicacy, and consumed in various ways. They are also considered to have medicinal properties (Nonaka 2008; Ying et al. 2008; Ho 2019). Larvae and pupae are consumed fresh. People collect nests and leave larvae and pupae alive within the combs of the nests until they are ready to be prepared (Nonaka 2008).

**Qu. 1.3d. How likely is it that large numbers of the organism will be introduced and/or enter into the environment through this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.
- an indication of the propagule pressure (e.g. estimated volume or number of individuals / propagules, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if relevant, comment on the likelihood of introduction and/or entry based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in subsequent establishment whereas for others high propagule pressure (many thousands of individuals) may not.

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low medium high
-----------------	--	-------------------	-----------------------

Response:

Such shipments are probably rare events, but these nests may contain hundreds of larvae and pupae that can become adults and escape, if they are not consumed, representing a potential pathway of introduction (USDA 2020).

**Qu. 1.4d. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

Depending on the time of year, the larvae and pupae in the nests may be workers, males or reproductive females. However, hornet-hunters usually harvest nests late in the season when workers are rearing sexuals. Thus, it is likely that hornets harvested for consumption would contain high-risk castes, i.e. sexuals (Nonaka 2008; USDA 2020). Larvae are likely to die during transport if they are not yet mature, in the absence of adult hornet caretakers. In contrast, pupae are likely to remain alive and viable for an extended period. These have the potential to mature into adults and escape to establish a population (USDA 2020). The larvae or pupae in nests will not reproduce or increase during transport.

**Qu. 1.5d. How likely is the organism to survive existing management practices before and during transport and storage along the pathway?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

There is no particular management in such express courier shipments, which are usually delivered within a few days. However, larvae and pupae are meant to be preserved, cooked and eaten and only if the nests are discarded will the insects escape into the wild. Furthermore, even if they are sexuals, they have to mate to establish in the following year.

**Qu. 1.6d. How likely is the organism to be introduced into the risk assessment area or entry into the environment undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

Most such express courier shipments are not opened at ports of entry and usually remain undetected until the recipient receives it. However, larvae and pupae are meant to be preserved, cooked and eaten and only if the nests are discarded will the insects escape into the wild. Furthermore, even if they are sexuals, they have to mate to establish in the following year.

**Qu. 1.7d. How isolated or widespread are possible points of introduction and/or entry into the environment in the risk assessment area?**

<b>RESPONSE</b>	isolated <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response:

The recipient can be anywhere in the risk assessment area.

**Qu. 1.8d. Estimate the overall likelihood of introduction into the risk assessment area and/or entry into the environment based on this pathway?**

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

The likelihood of introduction along this pathway is unlikely because such shipments are probably very rare events, particularly to Europe. Furthermore, if such a nest was delivered to the recipient, it would likely be for human consumption. Finally, if some hornets escaped, they would have to be of both sexes, mate (45% of *V. mandarinia* queens emerging from nests are not fertilized (Archer 2012)), and the queen would need to survive the winter. This, such a pathway of introduction is much less likely than those involving a mated queen arriving as contaminant or as stowaway.

**Qu. 1.9. Estimate the overall likelihood of introduction into the risk assessment area or entry into the environment based on all pathways and specify if different in relevant biogeographical regions in current conditions.**

Provide a thorough assessment of the risk of introduction in relevant biogeographical regions in current conditions: providing insight in to the risk of introduction into the risk assessment area.

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b>	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

	very likely		
--	-------------	--	--

Response:

Data on pathways of invasion of *Vespa* spp. and Vespidea in general are hardly available. However, considering the high numbers of -detrimental- introductions of invasive Vespidae worldwide in recent years (Beggs et al. 2011; USDA 2020), it is likely that non-intentional transports of wasps and hornets are rather common. The transport of mated *Vespa mandarinia* queens from autumn to spring is the most likely means of long-distance dispersion and only mated queens are able to build a new colony. Single queens may unintentionally be transported as contaminant of soil or rotten wood or straw in which they overwinter, or as stowaway in any kind of good, container or vehicle. Considering that the number and variety of commodities and containers that can potentially transport queens is unlimited, queens are probably more likely to be transported as stowaway.

The likelihood of introduction into the risk assessment area or entry into the environment based on all pathways does not vary among biogeographical regions.

**Qu. 1.10. Estimate the overall likelihood of introduction into the risk assessment area or entry into the environment based on all pathways in foreseeable climate change conditions?**

Thorough assessment of the risk of introduction in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of introduction (e.g. change in trade or user preferences)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely introduction within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response:

Climate change should not influence negatively or positively the likelihood of introduction into the risk assessment area.

## 2 PROBABILITY OF ESTABLISHMENT

**Important instructions:**

- For organisms which are already established in parts of the risk assessment area or have previously been eradicated, the likelihood of establishment should be scored as “very likely” by default.
- Discuss the risk also for those parts of the risk assessment area, where the species is not yet established.

**Qu. 2.1. How likely is it that the organism will be able to establish in the risk assessment area based on similarity of climatic and abiotic conditions in its distribution elsewhere in the world?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response:

The climate model made for this risk assessment (Figures 2-4) suggests that a large part of the risk assessment area is climatically suitable for the establishment of *V. mandarinia*, whose native distribution includes a wide variety of abiotic conditions and climates (present in at least 9 Köppen climates from the continental, temperate and tropical groups) from the Russian Far East in the north to Thailand and Malaysia in the south (Matsuura and Sakagami 1973; Matsuura and Yamane 1990; Archer 1995). The climate model showed that, under current climate, the most suitable biogeographic regions are the Continental and Atlantic regions (Figure 3, see also Annex VIII). Establishment will also be possible in the most humid parts of the Mediterranean, Black Sea and Pannonian regions. The Arctic, Boreal and Alpine regions will probably be too cold for establishment while the Steppic region appear too dry to be suitable for *V. mandarinia*. However, in this last region, irrigated areas or humid microclimates may be favourable for the hornet. The ecological niche model developed by Zhu et al. (2020) mostly for North America also shows a global risk map and the ecological suitability presented for Europe is very similar to the CLIMEX model presented in Figure 3 and Annex VIII, with the exception of Fennoscandia which is presented as largely suitable.

**Qu. 2.2. How widespread are habitats or species necessary for the survival, development and multiplication of the organism in the risk assessment area? Consider if the organism specifically requires another species to complete its life cycle.**

<b>RESPONSE</b>	very isolated isolated moderately widespread <b>widespread</b> ubiquitous	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response:

In its area of origin, *V. mandarinia* is widespread and inhabits a large variety of habitats and is particularly abundant in forests and urban green spaces (USDA 2020). *Vespa mandarinia* does not have particular ecological requirements except that nest building and maintaining require humidity. Nests are built mainly in cavities in the soil, such as rodent or reptile burrows, or in rotten tree root systems. They are polyphagous, feeding on a large variety of prey, mainly insects, as well as sugary food such as tree sap and fruits (Matsuura and Sakagami 1973; Matsuura and Yamane 1990; Archer 1995).

**Qu. 2.3. How likely is it that establishment will occur despite competition from existing species in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

In its area of origin, *V. mandarinia* co-occurs with several hornet and other wasps, among which *V. crabro* and *V. velutina*, which are two of the three hornets occurring in Europe. Matsuura and Yamane (1990) provide a detailed review of the competitive interactions among *Vespa* spp. and also with other vespidae genera. In general, they consider that the differences in the life history traits among *Vespa* spp. (e.g. different nesting or foraging behaviour) reduce interspecific competition. However, in most cases, when interspecific competition exists, it is in favour of *V. mandarinia*. For example, in spring, queens eat fermenting sap that seeps from tree wounds, which they fiercely defend against other insects, including other *V. mandarinia* queens (Matsuura and Sakagami, 1973; Matsuura, 1984). Recently, Kwon and Choi (2020) showed that, in Korea, *V. mandarinia* had the highest aggressive score towards other hornet species, including the European hornet *V. crabro*. *Vespa mandarinia* is not only able to attack bee hives but it is also the only hornet that can organize group attacks and complete destructions of nests of other *Vespa* spp. (including *V. crabro*) and *Vespula* spp., as described in Matsuura and Sakagami (1973) and Matsuura and Yamane (1990).

**Qu. 2.4. How likely is it that establishment will occur despite predators, parasites or pathogens already present in the risk assessment area?**

<b>RESPONSE</b>	N/A very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response:

Although *Vespa* spp. have a whole range of natural enemies, most of them are not species-specific (Matsuura and Yamane, 1990). Natural enemies of the European hornet such as parasitic insects and nematodes (Turchi and Derijard 2018) and various birds (Monceau et al. 2014) have not been able to prevent the establishment and spread of the invasive alien *Vespa velutina*. This latter is not controlled by natural enemies in Europe, at least when in the nest. Predation on single queens and workers has been poorly studied.

**Qu. 2.5. How likely is the organism to establish despite existing management practices in the risk assessment area? Explain if existing management practices could facilitate establishment.**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

In the European countries affected by the invasion of *V. velutina*, management practices in place to control the spread of the invasive alien species (see management annex), including trapping and nest destruction, may facilitate rapid responses against *V. mandarinia* and help prevent its establishment (Turchi and Derijard 2018). However, the two species strongly differ in their nesting behavior, *V. mandarinia*'s nests being underground whereas *V. velutina*, as *V. crabro*, nest are mainly built in trees and buildings (Matsuura and Yamane 2020).

**Qu. 2.6. How likely is it that biological properties of the organism would allow it to survive eradication campaigns in the risk assessment area?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response:

Eradication campaigns would include (1) the finding and destruction of nests in case individuals are found; (2) trapping campaigns to assess the presence of hornets in the eradication region. Underground nests are not easy to locate but protocols are available (USDA 2020, and see management annex). Depending on the time of the year during which the nests are found, queens may have already left (from October on) and will then be very difficult to localize. One of the main biological properties that makes eradication difficult is the high reproductive and dispersal rate of the organism. It is likely that if early eradication fails, the outbreak would increase in scale to a point that would make eradication very difficult.

**Qu. 2.7. How likely are the biological characteristics of the organism to facilitate its establishment in the risk assessment area?**

including the following elements:

- a list and description of the reproduction mechanisms of the species in relation to the environmental conditions in the risk assessment area
- an indication of the propagule pressure of the species (e.g. number of gametes, seeds, eggs or propagules, number of reproductive cycles per year) of each of those reproduction mechanisms in relation to the environmental conditions in the risk assessment area.
- If relevant, comment on the likelihood of establishment based on propagule pressure (i.e. for some species low propagule pressure (1-2 individuals) could result in establishment whereas for others high propagule pressure (many thousands of individuals) may not.
- If relevant, comment on the adaptability of the organism to facilitate its establishment and if low genetic diversity in the founder population would have an influence on establishment.

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

The life cycle of *V. mandarinia* is described in details in Matsuura and Sakagami (1973), Matsuura and Yamane (1990) and Archer (1995) and can be summarized as follows. Mated queens overwinter in moist soil cavities, rotting wood or piles of straw. The entrance of the cavity is plugged and the queen passes the winter hanging from the top of the chamber. In spring, they start feeding to develop their ovaries, and search for a nesting site in soil (e.g. rodent's burrow) or in root systems of rotten trees. Then, queens build their nest, first alone and then with the first workers. In summer, the queens become totally nest-bounded. Mature nests contain an average of 2,712 cells, but this number is highly variable, and cells can be reused two or three times in the season (Matsuura and Koike, 2002). In autumn, the nests start producing sexuals. An average colony will produce about 212 males and 205 females (Archer, 1995). Males emerge before females and wait for females at the nests' entrance to mate. Males die before the winter and mated females overwinter. This biology allows single females to colonize, alone, a new area and produce sufficient amounts of sexuals to ensure their establishment.

It has been shown that the *V. velutina* established in France originated from one or a few queens (Arca et al. 2015), suggesting that a very low propagule pressure is sufficient for the establishment of hornet species.

**Qu. 2.8. If the organism does not establish, then how likely is it that casual populations will continue to occur?**

Consider, for example, a species which cannot reproduce in the risk assessment area, because of unsuitable climatic conditions or host plants, but is present because of recurring introduction, entry and release events. This may also apply for long-living organisms.

<b>RESPONSE</b>	very unlikely <b>unlikely</b> moderately likely likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

Introductions of hornets are probably rather unlikely events but little information is available on introduction events.

**Qu. 2.9. Estimate the overall likelihood of establishment in the risk assessment area under current climatic conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under current climatic conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in current conditions: providing insight in the risk of establishment in (new areas in) the risk assessment area.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

If queens are introduced, establishment can be considered very likely in a large part of the risk assessment area, considering the climatic suitability (Figure 3), the availability of suitable habitats, the ability of single mated queens to colonize new areas, the high fecundity and the high competitiveness of the species (Matsuura and Sakagami 1973; Matsuura and Yamane 1990; Archer 1995). Climate models suggest that the establishment would be particularly likely in the Continental and Atlantic regions (Figure 3). Establishment will also be possible in the most humid parts of the Mediterranean, Black Sea and Pannonian regions. The Arctic, boreal and Alpine regions will probably be too cold for

establishment while the Steppic regions appear too dry to be suitable for *V. mandarinia*. However, in this last region, irrigated areas or humid microclimates may be favourable for the hornet.

**Qu. 2.10. Estimate the overall likelihood of establishment in the risk assessment area under foreseeable climate change conditions. In addition, details of the likelihood of establishment in relevant biogeographical regions under foreseeable climate change conditions should be provided.**

Thorough assessment of the risk of establishment in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk.

With regard to climate change, provide information on

- the applied timeframe (e.g. 2050/2070)
- the applied scenario (e.g. RCP 4.5)
- what aspects of climate change are most likely to affect the likelihood of establishment (e.g. increase in average winter temperature, increase in drought periods)

The thorough assessment does not have to include a full range of simulations on the basis of different climate change scenarios, as long as an assessment of likely establishment within a medium timeframe scenario (e.g. 30-50 years) with a clear explanation of the assumptions is provided. However, if new, original models are executed for this risk assessment, the following RCP pathways shall be applied: RCP 2.6 (likely range of 0.4-1.6°C global warming increase by 2065) and RCP 4.5 (likely range of 0.9-2.0°C global warming increase by 2065). Otherwise, the choice of the assessed scenario has to be explained.

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

Considering the wide climatic suitability of *V. mandarinia*, the general likelihood of establishment in Europe will not change under climate change scenarios. However, it is predicted that, with time, northern regions and high elevation areas will become more suitable because increased temperatures will allow the full development of a nest in summer whereas the Mediterranean and Continental Regions will become less suitable because of increased drought whereas humidity is needed for the building and maintenance of vespids nests.

### 3 PROBABILITY OF SPREAD

**Important instructions:**

- Spread is defined as the expansion of the geographical distribution of an alien species within the risk assessment area.
- Repeated releases at separate locations do not represent continuous spread and should be considered in the probability of introduction and entry section (Qu. 1.7).

**Qu. 3.1. How important is the expected spread of this organism within the risk assessment area by natural means? (List and comment on each of the mechanisms for natural spread.)** including the following elements:

- a list and description of the natural spread mechanisms of the species in relation to the environmental conditions in the risk assessment area.
- an indication of the rate of spread discussed in relation to the species biology and the environmental conditions in the risk assessment area.

The description of spread patterns here refers to the CBD pathway category “Unaided (Natural Spread)”. It should include elements of the species life history and behavioural traits able to explain its ability to spread, including: reproduction or growth strategy, dispersal capacity, longevity, dietary requirements, environmental and climatic requirements, specialist or generalist characteristics.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response:

*Vespa mandarinia* workers and queens are strong fliers. Workers usually forage in a radius of one to two kilometers around their nest but are capable of foraging up to eight kilometers away from the nest (Matsuura and Sakagami 1973). There is no reliable data on the flying capacities of queens. Abe et al. (1995) reported that *V. mandarinia* can fly at speeds of over 30 kilometers per hour and cover about 100 km in a single day but this information needs verification (USDA 2020). For comparison, queens of the invasive *V. velutina* can fly an average of 25 km/day in flight mill experiments (Sauvard et al. 2018). In nature, queens may not spread that fast, but they may cover very long distances during their extensive flight periods (i.e., before and after hibernation). *Vespa velutina* has spread an average of 78 km/year in the first years of its invasion in France (Robinet et al. 2017), but only 18 km/year in Italy (Bertolino et al. 2016) and 10–20 km/year in South Korea (Choi et al. 2012). Human-mediated dispersal may not be necessarily responsible for the hornet’s rapid range expansion even though the initial jumps to UK, Portugal or the Netherlands are likely due to transport of goods (Robinet et al. 2017, 2019).

**Qu. 3.2a. List and describe relevant pathways of spread other than "unaided". For each pathway answer questions 3.3 to 3.9 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 3.3a, 3.4a, etc. and then 3.3b, 3.4b etc. for the next pathway.**

including the following elements:

- a list and description of pathways of spread with an indication of their importance and associated risks (e.g. the likelihood of spread in the risk assessment area, based on these pathways; likelihood of survival, or reproduction, or increase during transport and storage; ability and likelihood of transfer from the pathway to a suitable habitat or host) in relation to the environmental conditions in the risk assessment area.
- an indication of the rate of spread for each pathway discussed in relation to the species biology and the environmental conditions in the risk assessment area.
- All relevant pathways of spread (except “Unaided (Natural Spread)”, which is assessed in Qu. 3.1) should be considered. The classification of pathways developed by the Convention of Biological Diversity shall be used (see Annex IV).

Even though workers could be transported by humans, only the transport of mated queens will allow the species to spread. And, because the transport of full, active nests in summer is highly unlikely, only the transport of mated queens from autumn to spring should be considered. Single queens may unintentionally be transported as contaminant of nursery material and transportation of habitat material in which they overwinter or as stowaway in any kind of good, container or vehicle.

The pathways of spread considered in the risk assessment are:

- A. Transport - Contaminant (nursery material)
- B. Transport - Contaminant (other than soil of nursery material)
- C. Transport - stowaway (Container/Bulk)
- D. Transport - stowaway (vehicles)

**A. Transport - Contaminant (nursery material)**

**Qu. 3.3a. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional	<b>CONFIDENCE</b>	low
	<b>unintentional</b>		medium
			<b>high</b>

Response:

Queens overwinter mainly in a hole that they have excavated in the soil. (Matsuura and Sakagami 1973; Archer 1995). Thus, any kind of soil or similar substrate related to the movement of nursery material, in particular soil in potted plants can potentially transport an overwintering queen.

**Qu. 3.4a. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

Only one mated queen is needed to form a colony in a newly invaded region, as observed in the arrival and spread of *V. velutina* in Europe (Arca et al. 2015; Robinet et al. 2017; 2019), and it is assumed that this could occur also for *V. mandarinia*.

**Qu. 3.5a. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

Queens are very strong insects. They do not feed nor reproduce in their overwintering site (Matsuura and Sakagami 1973; Archer 1995). Soil of potted plants is likely to remain intact during transport.

**Qu. 3.6a. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely	<b>CONFIDENCE</b>	<b>low</b> medium
-----------------	---------------------------	-------------------	----------------------

	moderately likely <b>likely</b> very likely		high
--	---	--	------

Response:

Phytosanitary practices in the horticultural sector may accidentally harm queens hidden in soil of potted plants when plants are treated with insecticides. However only some of the plants traded or moved within EU are treated with insecticides.

**Qu. 3.7a. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

Although the organism is rather big, the cavity in which a queen overwinters is usually plugged (Archer 1995) and it can easily remain undetected during transport until a viable population is established.

**Qu. 3.8a. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

Queens are good fliers and can build nests in various habitats, from forests to urban green areas (Matsuura and Sakagami 1973; Archer 1995). Thus, they would have no difficulty in reaching suitable habitats for nesting.

**Qu. 3.9a. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area. (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly slowly moderately <b>rapidly</b> very rapidly	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response:

The spread of overwintering queens in soil is likely, considering the amount of soil in the horticulture sector transported within the risk assessment area. However, it must be noted that, almost two decades after the invasion of *V. velutina* in Europe, and after having invaded nine countries, little is known about the part of human-mediated dispersal in the fast spread of the hornet and on the underlying mechanisms (Robinet et al. 2017; 2019).

**B. Transport - Contaminant (transportation of habitat material) (other than soil of nursery material)**

**Qu. 3.3b. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response:

Queens overwinter mainly in a hole that they have excavated in the soil, but also occasionally in rotting wood, piles of straw, etc. (Matsuura and Sakagami 1973; Archer 1995). Thus, any kind of soil or similar substrate, except soil of nursery material (e.g. soil for construction), straw, rotting wood, etc. can potentially transport an overwintering queen.

**Qu. 3.4b. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication

- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

Only one mated *V. mandarinia* queen is needed to form a colony in a newly invaded region, as observed in the arrival and spread of *V. velutina* in Europe (Arca et al. 2015; Robinet et al. 2017; 2019) and it is assumed that this could occur also for *V. mandarinia*.

**Qu. 3.5b. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	--	-------------------	------------------------------

Response:

Queens are very strong insects. They do not feed nor reproduce in their overwintering site. Soil is often shaken during transport, which will not favour the survival of the queen. However, other substrates such as straw can be easily transported undisturbed, soil of potted plants is more likely to remain intact.

**Qu. 3.6b. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

Within the risk assessment area, soil not related to nursery material and straw are usually transported without management practice.

**Qu. 3.7b. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

Although a *V. mandarinia* queen is very big, the cavity in which a queen overwinters is usually plugged (Archer 1995) and it can easily remain undetected during transport until a viable population is established.

**Qu. 3.8b. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

Queens are good fliers and can build nests in various habitats, from forests to urban green areas (Matsuura and Sakagami 1973; Archer 1995). Thus, they would have no difficulty in reaching suitable habitats for nesting.

**Qu. 3.9b. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area. (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly slowly moderately	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	-------------------------------------	-------------------	------------------------------

	<b>rapidly</b> very rapidly		
--	--------------------------------	--	--

Response:

The spread of overwintering queens in soil is likely, considering the amount of soil, straw and other potential overwintering substrates transported within the risk assessment area. However, it must be noted that, almost two decades after the invasion of *V. velutina* in Europe, and after having invaded ten countries, very little is known about the part of human-mediated dispersal in the fast spread of the hornet and on the underlying mechanisms (Robinet et al. 2017; 2019)

### C. Transport - stowaway (Container/Bulk)

**Qu. 3.3c. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response:

Mated queens can travel hidden in many sorts of containers containing any kind of goods (e.g. pottery, fruits, meat/fish, furniture, etc.), before or after having built an overwintering site.

**Qu. 3.4c. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

Only one mated queen is needed to form a colony in a newly invaded region, as observed in the arrival and spread of *V. velutina* in Europe (Arca et al. 2015; Robinet et al. 2017; 2019), and it is assumed that this could occur also for *V. mandarinia*.

**Qu. 3.5c. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

Queens are very strong insects that can survive harsh conditions. Transports of containers within the risk assessment areas are usually very short. In winter, queens do not feed much and can stay hidden a long time. They do not reproduce during that period (Matsuura and Sakagami 1973).

**Qu. 3.6c. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

This will depend on the management practices used in the containers' transport conditions but none will target Vespidae and it is unlikely that management practices will affect the transported queen within the risk assessment area.

**Qu. 3.7c. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

	very likely		
--	-------------	--	--

Response:

Queens are very big (4-5 cm) and are quite obvious when the container is inspected. However, in large containers queens in winter are usually hidden in the transported goods and are easily missed when transported.

**Qu. 3.8c. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

Queens are good fliers and can build nests in various habitats, from forests to urban green areas (Matsuura and Sakagami 1973; Archer 1995). Thus, from the arrival destination of the container, they would have no difficulty in reaching suitable habitats for nesting or finding overwintering sites, depending in the season.

**Qu. 3.9c. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area. (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly slowly moderately <b>rapidly</b> very rapidly	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response:

The spread of queens in winter in any kind of container is likely and may be fast, considering the amount of opportunities to be transported that way. However, it must be noted that, almost two decades after the invasion of *V. velutina* in Europe, and after having invaded ten countries, very little is known about the part of human-mediated dispersal in the fast spread of the hornet and on the underlying mechanisms (Robinet et al. 2017; 2019).

**D. Transport - stowaway (vehicles)**

**Qu. 3.3d. Is spread along this pathway intentional (e.g. the organism is deliberately transported from one place to another) or unintentional (e.g. the organism is a contaminant of translocated goods within the risk assessment area)?**

<b>RESPONSE</b>	intentional <b>unintentional</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	-------------------------------------	-------------------	------------------------------

Response:

Mated queens can travel hidden in many types of vehicles, e.g. trucks, trains, cars, etc., before or after having built an overwintering site.

**Qu. 3.4d. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?**

including the following elements:

- an indication of the propagule pressure (e.g. estimated volume or number of specimens, or frequency of passage through pathway), including the likelihood of reinvasion after eradication
- if appropriate, indicate the rate of spread along this pathway
- if appropriate, include an explanation of the relevance of the number of individuals for spread with regard to the biology of species (e.g. some species may not necessarily rely on large numbers of individuals).

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

Only one mated queen is needed to form a colony in a newly invaded region, as observed in the arrival and spread of *V. velutina* in Europe (Arca et al. 2015; Robinet et al. 2017; 2019), and it is assumed that this could occur also for *V. mandarinia*.

**Qu. 3.5d. How likely is the organism to survive, reproduce, or increase during transport and storage along the pathway (excluding management practices that would kill the organism)?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

Queens are very strong and long-lived insects. Journeys in vehicles within the risk assessment areas can be very short and queens would surely survive such short journeys. Mated females will start building nests only in spring (Matsuura and Sakagami 1973; Archer 1995).

**Qu. 3.6d. How likely is the organism to survive existing management practices during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

This will depend on the management practices used in the vehicles (usually very little in the EU) but none will target Vespidae and it is unlikely that management practices will affect the transported queen.

**Qu. 3.7d. How likely is the organism to spread in the risk assessment area undetected?**

<b>RESPONSE</b>	very unlikely unlikely <b>moderately likely</b> likely very likely	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	--	-------------------	------------------------------

Response:

Queens are very big (4-5 cm) and are quite obvious when they simply hitchhike in a vehicle. However, in winter queens are usually not moving as actively as workers and, thus, a hidden queen can be transported undetected in large vehicles (trucks, trains), but less so in cars.

**Qu. 3.8d. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host during spread?**

<b>RESPONSE</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	--	-------------------	------------------------------

Response:

Queens are good fliers and can build nests in various habitats, from forests to urban green areas (Matsuura and Sakagami 1973; Archer 1995). Thus, from the arrival destination of the vehicle (or during transport), they would have no difficulty in reaching suitable habitats for nesting or finding overwintering sites, depending in the season.

**Qu. 3.9d. Estimate the overall potential rate of spread based on this pathway in relation to the environmental conditions in the risk assessment area. (please provide quantitative data where possible).**

<b>RESPONSE</b>	very slowly slowly <b>moderately</b> rapidly very rapidly	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response:

The spread of *V. mandarinia* queens in winter in any kind of vehicle is possible and may be fast. However, it must be noted that, almost two decades after the invasion of *V. velutina* in Europe, and after having invaded ten countries, very little is known about the part of human-mediated dispersal in the fast spread of the hornet and on the underlying mechanisms (Robinet et al. 2017; 2019).

*End of pathway assessment, repeat Qu. 3.3 to 3.9. as necessary using separate identifiers.*

**Qu. 3.10. Within the risk assessment area, how difficult would it be to contain the organism in relation to these pathways of spread?**

<b>RESPONSE</b>	very easy easy	<b>CONFIDENCE</b>	low <b>medium</b>
-----------------	-------------------	-------------------	----------------------

	with some difficulty difficult <b>very difficult</b>		high
--	--	--	------

Response:

Despite numerous efforts, all countries have failed to contain the spread of *V. velutina* in Europe, with the potential exception of UK and Mallorca where the species may have been eradicated (Monceau et al. 2014; Robinet et al. 2019; Jones et al. 2020; Leza et al. 2021), so it is doubtful that they would be more successful with *V. mandarinia*. Eradication may be easier than containment. Eradication successes against invasive alien Vespidae have been reported elsewhere in the world, e.g. against *Vespula germanica* in Western Australia (Tennant et al. 2011), suggesting that eradication would be possible if carried out at a very early stage of the invasion. However, once there is an established and spreading population it will be very difficult to contain its spread.

**Qu. 3.11. Estimate the overall potential rate of spread in relevant biogeographical regions under current conditions for this organism in the risk assessment area (indicate any key issues and provide quantitative data where possible).**

Thorough assessment of the risk of spread in relevant biogeographical regions in current conditions, providing insight in the risk of spread into (new areas in) the risk assessment area.

<b>RESPONSE</b>	very slowly slowly moderately rapidly <b>very rapidly</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response:

Considering the strong flying capacities of the queens, their ability to travel as soil contaminant or as stowaway in various types of containers, and based on the fast spread of *V. velutina* in Europe, which invaded 10 countries in 16 years, it is highly likely that *V. mandarinia* would spread very rapidly in the risk assessment area, in particular in the most favourable biogeographical regions such as continental and atlantic regions.

**Qu. 3.12. Estimate the overall potential rate of spread in relevant biogeographical regions in foreseeable climate change conditions (provide quantitative data where possible).**

Thorough assessment of the risk of spread in relevant biogeographical regions in foreseeable climate change conditions: explaining how foreseeable climate change conditions will influence this risk, specifically if rates of spread are likely slowed down or accelerated.

<b>RESPONSE</b>	very slowly slowly	<b>CONFIDENCE</b>	low medium
-----------------	-----------------------	-------------------	---------------

	moderately rapidly <b>very rapidly</b>		<b>high</b>
--	--	--	-------------

Response:

The general risk of spread in the risk assessment area should not be influenced by changing climatic conditions, but spread may become more or less likely depending on whether regions become more or less suitable for the organism (see section on likelihood of establishment). It may also become more rapid spread better survival, faster growth.

## 4 MAGNITUDE OF IMPACT

Important instructions:

- Questions 4.1-4.5 relate to biodiversity and ecosystem impacts, 4.6-4.8 to impacts on ecosystem services, 4.9-4.13 to economic impact, 4.14-4.15 to social and human health impact, and 4.16-4.18 to other impacts. These impacts can be interlinked, for example, a disease may cause impacts on biodiversity and/or ecosystem functioning that leads to impacts on ecosystem services and finally economic impacts. In such cases the assessor should try to note the different impacts where most appropriate, cross-referencing between questions when needed.
- Each set of questions starts with the impact elsewhere in the world, then considers impacts in the risk assessment area (=EU excluding outermost regions) separating known impacts to date (i.e. past and current impacts) from potential future impacts (including foreseeable climate change).
- Only negative impacts are considered in this section (socio-economic benefits are considered in Qu. A.7)

### Biodiversity and ecosystem impacts

**Qu. 4.1. How important is the impact of the organism on biodiversity at all levels of organisation caused by the organism in its non-native range excluding the risk assessment area?**

including the following elements:

- Biodiversity means the variability among living organisms from all sources, including terrestrial, marine and other aquatic ecosystems and the ecological complexes of which they are part; this includes diversity within species, between species and of ecosystems
- impacted chemical, physical or structural characteristics and functioning of ecosystems

RESPONSE	N/A	CONFIDENCE	low
	minimal		medium

	major		
	massive		

Response:

*Vespa mandarinia* has never been studied outside its native range. It was only recently observed invading Western North America. Therefore, it is too early to assess impacts in its non-native range.

**Qu. 4.2. How important is the current known impact of the organism on biodiversity at all levels of organisation (e.g. decline in native species, changes in native species communities, hybridisation) in the risk assessment area (include any past impact in your response)?**

Discuss impacts that are currently occurring or are likely occurring or have occurred in the past in the risk assessment area. Where there is no direct evidence of impact in the risk assessment area (for example no studies have been conducted), evidence from outside of the risk assessment area can be used to infer impacts within the risk assessment area.

<b>RESPONSE</b>	N/A minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response:

*Vespa mandarinia* is not present in the risk assessment area.

**Qu. 4.3. How important is the potential future impact of the organism on biodiversity at all levels of organisation likely to be in the risk assessment area?**

See comment above. The potential future impact shall be assessed only for the risk assessment area.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response:

*Vespa mandarinia* can directly affect biodiversity in two ways: as predator of invertebrates or as competitors of other organisms, in particular Vespidae. Based on our knowledge of the insect in its native range, where it is a voracious predator and strong competitor, the impact on biodiversity may be major or massive. However, since it has not yet been invasive anywhere (the new introduction into North America is too recent to gather any information on impact) an assessment on impact on biodiversity can only be made with very low confidence.

Firstly, *Vespa mandarinia* is a polyphagous predator on a whole spectrum of large invertebrates such as caterpillars, spiders, mantids, beetles, etc. (USDA 2020). However, the most spectacular predatory behaviour of *V. mandarinia* is its mass attacks against nests of other social Hymenoptera, such as bees and wasps of the genera *Vespa*, *Vespula* and *Polistes*, during which they attack, kill and occupy nests, sometimes during several days, to feed their own larvae (Matsuura and Sakagami 1973; Matsuura and Yamane 1990). Such behaviour has also been observed against *V. crabro* in Japan (Matsuura 1984).

Secondly, it competes with other vespids for nesting sites and food. Data from its native range suggests that it can outcompete other vespids (Matsuura and Yamane 1990). In spring, queens eat fermenting sap that seeps from tree wounds, which they fiercely defend against other insects,

(Matsuura and Sakagami 1973; Matsuura 1984). Differences in nesting behaviour reduce interspecific competition among Vespidae. In Europe, *V. mandarinia* would not compete with *V. velutina* that usually nests in tree branches. But *Vespula* spp. and *V. crabro* are more generalist and partly nest in soil cavities or tree holes and could therefore be adversely affected by *V. mandarinia*. Competition with other organisms is also likely. For example, the invasion of the European *Vespula vulgaris* in New Zealand resulted in severe competition for food (sap runs, honeydew etc.) and in the decline of several bird and insect species (Beggs et al. 2011). In Japan, *V. mandarinia* also feeds abundantly on tree sap and is known to occupy the highest position in terms of interspecific relationship and to monopolize tree sap and other food sources by chasing off all visitors, not only other *Vespa* species but any other kind of insect, including beetles, butterflies and moths (Matsuura and Yamane 1990)

The potential impact of its likely predation on honey bees also may have an impact on biodiversity because it may affect pollination services (see Q. 4.8).

**Qu. 4.4. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism currently in the risk assessment area?**  
including the following elements:

- native species impacted, including red list species, endemic species and species listed in the Birds and Habitats directives
- protected sites impacted, in particular Natura 2000
- habitats impacted, in particular habitats listed in the Habitats Directive, or red list habitats
- the ecological status of water bodies according to the Water Framework Directive and environmental status of the marine environment according to the Marine Strategy Framework Directive

Response:

*Vespa mandarinia* is not present in the risk assessment area.

**Qu. 4.5. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism likely to be in the future in the risk assessment area?**  
including the following elements:

- native species impacted, including red list species and species listed in the Birds and Habitats directives
- protected sites impacted, in particular Natura 2000
- habitats impacted, in particular habitats listed in the Habitats Directive, or red list habitats

- the ecological status of water bodies according to the Water Framework Directive and environmental status of the marine environment according to the Marine Strategy Framework Directive

<b>RESPONSE</b>	minimal minor <b>moderate</b> major massive	<b>CONFIDENCE</b>	<b>low</b> medium high
-----------------	---	-------------------	------------------------------

Response:

At present, it is very difficult to assess which native species would be most affected by *V. mandarinia* and, thus, whether a decline in conservation value will occur. However, it can be assumed that one of the most likely affected species may be *V. crabro* (see Qu. 4.3), which is a red list species in some countries and regions (e.g. in Germany, and in Austria, States of Steiermark and Oberösterreich). More generally, *V. mandarinia* is known to prey on large insects such as scarab and longhorn beetles (Matsuura 1988), mantids (Matsuura 1984), and large caterpillars (Matsuura and Sakagami 1973) and it is likely that, if introduced into Europe, they will prey on red list and protected insects, including species listed in the Habitats directive.

It is not yet possible to assess whether protected sites and habitats will be particularly invaded by the hornet, but it is highly likely that many of them will be invaded, in particular those in the Atlantic and Continental biogeographic regions containing forest areas.

## Ecosystem Services impacts

**Qu. 4.6. How important is the impact of the organism on provisioning, regulating, and cultural services in its non-native range excluding the risk assessment area?**

- For a list of services use the CICES classification V5.1 provided in Annex V.
- Impacts on ecosystem services build on the observed impacts on biodiversity (habitat, species, genetic, functional) but focus exclusively on reflecting these changes in relation to their links with socio-economic well-being.
- Quantitative data should be provided whenever available and references duly reported.
- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”.

<b>RESPONSE</b>	N/A minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high

*Vespa mandarinia* has never been studied outside its native range. It was only recently observed invading Western North America.

**Qu. 4.7. How important is the impact of the organism on provisioning, regulating, and cultural services currently in the different biogeographic regions or marine sub-regions where the species has established in the risk assessment area (include any past impact in your response)?**

- See guidance to Qu. 4.6.

<b>RESPONSE</b>	N/A minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response:

*Vespa mandarinia* is not present in the risk assessment area.

**Qu. 4.8. How important is the impact of the organism on provisioning, regulating, and cultural services likely to be in the different biogeographic regions or marine sub-regions where the species can establish in the risk assessment area in the future?**

- See guidance to Qu. 4.6.

<b>RESPONSE</b>	minimal minor moderate major <b>massive</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response:

*Vespa mandarinia* may affect provisioning and regulating ecosystem services mainly through its potential impact on honeybees and wild pollinators, i.e. on pollination services. Impacts on provisioning services include effects on biomass of cultivated and wild plants and reared animals; impacts on regulating services include effects on life cycle maintenance. The effect on honeybees in Europe may be particularly important. In Asia, it is considered as a major predator of honey bees (see Qu. 4.9). Its impact is much higher than that of *V. velutina*, which is threatening apiculture in Western Europe (Monceau et al. 2014). *Vespa mandarinia*, being an additional threat to the European apiculture and pollinators, may have the following consequences. European beekeeping and honey

production are already threatened by various factors, such as parasites, viruses, insecticides, climate change, habitat fragmentation, small hive beetle (*Aethina tumida*) and *Vespa velutina*. The additional threat of *V. mandarinia* may lead to the abandonment of beekeeping activity, which would affect the European honey production. In addition, many crops rely mainly on honey bees and other bees (which may also be affected) for pollination. A further decline of honey bees and wild bees may have serious effects on yields. Fedele et al. (2019) provide a method to assess the impact on apple, pear and peach production through pollination reduction, but their numbers provided are based on a pollination reduction of 65% which is probably exaggerated. In fact, there is presently no reliable quantification on the effect of *V. velutina* on honeybee populations and, as a result, on pollination of cultivated and also of wild plants. In a recent study in Spain, it was observed that *V. velutina* affects pollination of a wild native plant, *Mentha suaveolens*, through changes in abundance and behaviour of floral visitors, including honeybees, bumblebees, small hymenopterans and syrphids (Rojas-Nossa and Calviño-Cancela 2020).

**Economic impacts**

**Qu. 4.9. How great is the overall economic cost caused by the organism within its current area of distribution (excluding the risk assessment area), including both costs of / loss due to damage and the cost of current management.**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the world these should be reported here. The assessment of the potential costs of / loss due to damage shall describe those costs quantitatively and/or qualitatively depending on what information is available. Cost of / loss due to damage within different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage. As far as possible, it would be useful to separate costs of / loss due to the organism from costs of current management.

<b>RESPONSE</b>	minimal minor moderate <b>major</b> massive	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response:

To our knowledge, there is no quantitative data on economic costs related to *V. mandarinia* in its area or origin. But there are at least two categories of damage that lead to economic costs.

Firstly, according to Matsuura and Yamane (1990), *Vespa mandarinia* is considered as “the most serious enemy of both cultivated and wild honeybees in Japan”. In Asia, it is considered to have a much higher impact on honey bees than *V. velutina*, which is threatening apiculture in Western Europe. As for *V. velutina* and other hornets, workers can attack and kill bees singly at the entrance to hives. However, the most damaging attack strategy, called the “slaughter strategy”, consists in attacking a hive in groups of a few dozen workers. An entire bee hive of 30’000 bees can be destroyed in a few hours. The hornets first kill the guard bees to enter the hive, then kill the other bees to finally retrieve the bee larvae and pupa to bring them to their own larvae. This process can take several days

during which the attacked hive will be occupied by the hornets. This strategy has been described in details by Matsuura and Sakagami (1973). In Japan, many beekeepers transfer hives in summer from mountains to plains to avoid the attacks of *V. mandarinia* (Matsuura and Sakagami, 1973). It must be noted that *V. mandarinia* is particularly damaging for the European honey bee *Apis mellifera* while the Asian species *Apis cerana* has developed defense mechanisms such as passive retreat and rapid mass attacks to heat up and kill the hornets (Matsuura and Sakagami 1973).

Economic costs are also related to *V. mandarinia* being a human nuisance. In particular, its impact on human health through its painful stings may trigger serious costs (see Qu 4.14). Furthermore, the economics of recreational activities and tourism in places where the hornets could be prevalent.

**Qu. 4.10. How great is the economic cost of / loss due to damage (excluding costs of management) of the organism currently in the risk assessment area (include any past costs in your response)?**

- Where economic costs of / loss due to the organism have been quantified for a species anywhere in the EU these should be reported here. Assessment of the potential costs of damage on human health, safety, and the economy, including the cost of non-action. A full economic assessment at EU scale might not be possible, but qualitative data or different case studies from across the EU (or third countries if relevant) may provide useful information to inform decision making. In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”. Cost of / loss due to damage within different economic sectors can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>	N/A	<b>CONFIDENCE</b>	low
	minimal		medium
	minor		high
	moderate		
	major		
	massive		

Response:

*Vespa mandarinia* is not present in the risk assessment area.

**Qu. 4.11. How great is the economic cost of / loss due to damage (excluding costs of management) of the organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.10.

<b>RESPONSE</b>	minimal	<b>CONFIDENCE</b>	low
	minor		<b>medium</b>
	moderate		high
	major		

	<b>massive</b>		
--	----------------	--	--

Response:

Given that *Vespa mandarinia* is a serious pest in its native range through its impact on honey bees and human health, there is no reason to think that impacts would be lower in climatically suitable areas in Europe. *Vespa velutina* became a more serious predator of honey bees in Europe than in East Asia, where *V. mandarinia* is considered as much more problematic for honey bees and human health than *V. velutina*. In addition, *V. mandarinia* is particularly damaging for the European honey bee *Apis mellifera* while the Asian species *Apis cerana* has developed defence mechanisms such as passive retreat and rapid mass attacks to heat up and kill the hornets (Matsuura and Sakagami 1973). European beekeeping and honey production are already threatened by a series of various factors, such as parasites, viruses, insecticides, climate change, habitat fragmentation, small hive beetle and *Vespa velutina*. The additional threat of *V. mandarinia* may lead to the abandonment of bee hives, which would affect the European production of honey. In France alone, the annual revenue from apiculture was €135M in 2015 (Barbet-Massin et al. 2020). Even a small reduction in honey production by *V. mandarinia* may lead to substantial losses for the sector in Europe. In addition, many crops rely mainly on honey bees and other bees (which may also be affected) for pollination. A further decline of honey bees and wild bees may have serious effects on crop yields, as estimated for *V. velutina* (Fedele et al. 2019). It is estimated that the yearly pollination services to agriculture are worth €2 billion in France alone (Gallai et al. 2009), so, even a very small effect of *V. mandarinia* on pollination services would lead to severe losses.

**Qu. 4.12. How great are the economic costs / losses associated with managing this organism currently in the risk assessment area (include any past costs in your response)?**

- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”.

<b>RESPONSE</b>	<b>N/A</b>	<b>CONFIDENCE</b>	low medium high
	minimal minor moderate major massive		

Response:

*Vespa mandarinia* is not present in the risk assessment area.

**Qu. 4.13. How great are the economic costs / losses associated with managing this organism likely to be in the future in the risk assessment area?**

- See guidance to Qu. 4.12.

<b>RESPONSE</b>	minimal minor moderate major <b>massive</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response:

Management costs will depend on the magnitude of impact in the risk assessment area, which cannot be assessed precisely for the moment, since the organism is not yet in the risk assessment area and is just starting to invade another region for the first time. To assess management costs, it is best to use the invasion of *V. velutina* in Europe as comparison. Management costs related to *V. velutina* have never been assessed globally. They mainly consist of (1) surveillance programmes and information campaigns in the recently invaded areas, (2) locating and destroying nests, (3) trapping campaigns to capture queens in spring (these are not always considered effective but widely practiced), (4) various management strategies to protect hives; and (5) funding research programmes. So far, only the cost of nest removal has been precisely quantified. Barbet-Massin et al. (2020) estimated that nest destruction cost €23 million between 2006 and 2015 in France. The yearly cost is increasing as the species keeps spreading and could reach €11.9 million in France, €9.0 million in Italy and €8.6 million in the United Kingdom, if the species fills its current climatically suitable distribution. The authors also stated that, “although more work will be needed to estimate the cost of the Asian yellow-legged hornet on apiculture and pollination services, they likely exceed the current costs of control with nest destruction. It could thus be worth increasing control efforts by aiming at destroying a higher percentage of nests”.

The introduction of *V. mandarinia* in Europe would require similar management strategies, keeping in mind that *V. mandarinia* is considered as being more problematic than *V. velutina* in East Asia. The cost of nest removal (100-400 Eur/nest) for *V. velutina* may be different for *V. mandarinia*, which nests in the soil rather than in trees and buildings.

## Social and human health impacts

**Qu. 4.14. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism for the risk assessment area and for third countries, if relevant (e.g. with similar eco-climatic conditions).**

The description of the known impact and the assessment of potential future impact on human health, safety and the economy, shall, if relevant, include information on

- illnesses, allergies or other affections to humans that may derive directly or indirectly from a species;
- damages provoked directly or indirectly by a species with consequences for the safety of people, property or infrastructure;
- direct or indirect disruption of, or other consequences for, an economic or social activity due to the presence of a species.

Social and human health impacts can be a direct or indirect consequence of the earlier-noted impacts on ecosystem services. In such case, please provide an indication of the interlinkage.

<b>RESPONSE</b>	minimal minor moderate major <b>massive</b>	<b>CONFIDENCE</b>	low medium <b>high</b>
-----------------	---	-------------------	------------------------------

Response:

*Vespa mandarinia* has a powerful sting, which is a hazard to human health. Workers can be aggressive when they feel that their nest is threatened and, since nests are in the ground, they are easily overlooked by walkers. In Japan, fatalities due to *V. mandarinia* stings are estimated to range from 30 to 50 persons each year (Yanagawa et al. 2008). While most victims are allergic and die from anaphylaxis or sudden cardiac arrest, others die from multiple organ failure including rhabdomyolysis, renal failure, liver dysfunction, respiratory failure, and disseminated intravascular coagulopathy. In China, in a three months period in July - October 2013, *V. mandarinia* killed 42 and injured 1,675 people in three cities in the southern part of Shaanxi Province (Liu et al. 2016).

**Qu. 4.15. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism in the future for the risk assessment area.**

- In absence of specific studies or other direct evidences this should be clearly stated by using the standard answer “No information has been found on the issue”. This is necessary to avoid confusion between “no information found” and “no impact found”.

<b>RESPONSE</b>	minimal minor moderate major <b>massive</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response:

In some European countries, the invasion of *V. velutina* in Europe led to a significant increase in casualties due to hornet stings (e.g. in Spain, Feás 2021; Vidal 2021) (): *Vespa mandarinia*'s stings are more painful and dangerous, and workers can be more aggressive because the nests are more accessible and easily overlooked. If, as observed for *V. velutina*, *V. mandarinia* becomes more abundant in the invaded range than in its native range, this hornet could become a serious human health issue.

## Other impacts

**Qu. 4.16. How important is the organism in facilitating other damaging organisms (e.g. diseases) as food source, a host, a symbiont or a vector etc.?**

<b>RESPONSE</b>	N/A minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response:

No information found.

**Qu. 4.17. How important might other impacts not already covered by previous questions be resulting from introduction of the organism?**

<b>RESPONSE</b>	N/A minimal minor moderate major massive	<b>CONFIDENCE</b>	low medium high
-----------------	---	-------------------	-----------------------

Response:

No information found.

**Qu. 4.18. How important are the expected impacts of the organism despite any natural control by other organisms, such as predators, parasites or pathogens that may already be present in the risk assessment area?**

<b>RESPONSE</b>	minimal minor moderate major <b>massive</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response:

Although *Vespa* spp. have a whole range of natural enemies, such as parasitic insects and nematodes and birds, most of them are not species-specific (Matsuura and Yamane, 1990). Natural enemies of the European hornet have not been able to prevent the invasion of *Vespa velutina* in Europe (Monceau et al. 2014; Turchi and Derijard 2018). Colonies of the latter do not seem to be controlled by natural enemies in Europe. Predation on single queens and workers has been poorly studied and may be more important. It is not clear how the impact of *V. velutina* would be without natural enemies.

**Qu. 4.19. Estimate the overall impact in the risk assessment area under current climate conditions. In addition, details of overall impact in relevant biogeographical regions should be provided.**

Thorough assessment of the overall impact on biodiversity and ecosystem services, with impacts on economy as well as social and human health as aggravating factors, in current conditions.

<b>RESPONSE</b>	minimal minor moderate major <b>massive</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response:

If introduced into the risk assessment area, *V. mandarinia* is likely to cause severe impacts on the economy, the environment and human health, mainly through its aggressive predatory behaviour towards honey bees and other insects and its harmful stings to humans. The severity of these impacts remains difficult to assess. However, in Asia, *V. mandarinia* is considered, in all aspects, more harmful than *V. velutina*, which is already regarded a serious invasive alien species. Impacts are likely to be higher in regions that are most favourable for *V. mandarinia*, in particular the Continental and Atlantic regions and part of the Mediterranean region (see section 2 on likelihood of establishment).

**Qu. 4.20. Estimate the overall impact in the risk assessment area in foreseeable climate change conditions. In addition, details of overall impact in relevant biogeographical regions should be provided.**

Thorough assessment of the overall impact on biodiversity and ecosystem services, with impacts on economy as well as social and human health as aggravating factors, under future conditions.

<b>RESPONSE</b>	minimal minor moderate major <b>massive</b>	<b>CONFIDENCE</b>	low <b>medium</b> high
-----------------	---	-------------------	------------------------------

Response:

Climate change is likely to modify the geographical distribution of impact magnitude (i.e. increase in the north, decrease in the south and east), but not the average magnitude of impact for the risk assessment area in general.

<b>RISK SUMMARIES</b>			
	<b>RESPONSE</b>	<b>CONFIDENCE</b>	<b>COMMENT</b>
<b>Summarise Introduction and Entry*</b>	very unlikely unlikely moderately likely <b>likely</b> very likely	<b>low</b> medium high	Data on pathways of invasion of <i>Vespa</i> spp. are rare. However, considering the high numbers of introductions of invasive Vespidae worldwide in recent years, it is likely that non-intentional transports of wasps and hornets are rather common. The transport of mated <i>Vespa mandarinia</i> queens from autumn to spring is the most likely mean of long-distance dispersal. Single queens may unintentionally be transported as contaminants of soil or straws in which they overwinter, or as stowaways in any kind of good, container or vehicle. Climate change should not affect the likelihood of introduction.
<b>Summarise Establishment*</b>	very unlikely unlikely moderately likely likely <b>very likely</b>	low medium <b>high</b>	If queens are introduced, establishment can be considered very likely in a large part of the risk assessment area, considering the climatic suitability, the availability of suitable habitats, the ability of single mated queens to colonize new areas, the high fecundity and the high competitiveness of the species. Climate models suggest that the establishment would be particularly likely in the Continental and Atlantic regions, and parts of the Mediterranean region. The general likelihood of establishment in Europe will not change under climate change scenarios, even though some regions may become less and others more favourable.

<b>Summarise Spread*</b>	very slowly slowly moderately rapidly <b>very rapidly</b>	low medium <b>high</b>	Considering the strong flying capacities of the queens, their ability to travel as soil contaminants or as stowaways in various types of containers, and based on the fast spread of <i>V. velutina</i> in Europe, it is highly likely that <i>V. mandarinia</i> would spread rapidly in the risk assessment area. The general risk of spread in the risk assessment area will not be influenced by changing climatic conditions, but spread may become more or less easy depending on whether regions become more or less suitable for the organism.
<b>Summarise Impact*</b>	minimal minor moderate major <b>massive</b>	low <b>medium</b> high	If introduced into the risk assessment area, <i>V. mandarinia</i> is likely to cause severe impacts on the economy, the environment and human health, mainly through its aggressive predatory behaviour towards honey bees and other insects and its harmful stings to humans. The severity of these impacts remains difficult to assess. However, in Asia, <i>V. mandarinia</i> is considered, in all aspects, more harmful than <i>V. velutina</i> , which is already regarded a serious invasive species. Climate change is likely to modify the geographical distribution of impact magnitude but not the average magnitude of impact for the risk assessment area.
<b>Conclusion of the risk assessment (overall risk)</b>	low moderate <b>high</b>	low <b>medium</b> high	The likelihood of introduction of <i>V. mandarinia</i> can only be assessed with low confidence because of a lack of quantitative data on interceptions and pathways of entry. In contrast, establishment is highly likely in a

			large part of the risk assessment area and, if the organism becomes established, there is little doubt that it will spread fast and cause significant environmental, economic and social impacts.

## Distribution Summary

Please answer as follows:

- Yes if recorded, established or invasive
- if not recorded, established or invasive
- ? Unknown; data deficient

The columns refer to the answers to Questions A5 to A12 under Section A.

For data on marine species at the Member State level, delete Member States that have no marine borders.

In all other cases, provide answers for all columns.

### Member States and the United Kingdom

	Recorded	Established (currently)	Possible establishment (under current climate)	Possible establishment (under foreseeable climate)	Invasive (currently)

## ANNEX I Scoring of Likelihoods of Events

(taken from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

<b>Score</b>	<b>Description</b>	<b>Frequency</b>
Very unlikely	This sort of event is theoretically possible, but is never known to have occurred and is not expected to occur	1 in 10,000 years
Unlikely	This sort of event has occurred somewhere at least once in the last millenium	1 in 1,000 years
Moderately likely	This sort of event has occurred somewhere at least once in the last century	1 in 100 years
Likely	This sort of event has happened on several occasions elsewhere, or on at least once in the last decade	1 in 10 years
Very likely	This sort of event happens continually and would be expected to occur	Once a year

## ANNEX II Scoring of Magnitude of Impacts

(modified from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

Score	Biodiversity and ecosystem impact	Ecosystem Services impact	Economic impact (Monetary loss and response costs per year)	Social and human health impact, and other impacts
	<i>Question 5.1-5</i>	<i>Question 5.6-8</i>	<i>Question 5.9-13</i>	<i>Question 5.14-18</i>
Minimal	Local, short-term population loss, no significant ecosystem effect	No services affected <sup>5</sup>	Up to 10,000 Euro	No social disruption. Local, mild, short-term reversible effects to individuals.
Minor	Some ecosystem impact, reversible changes, localised	Local and temporary, reversible effects to one or few services	10,000-100,000 Euro	Significant concern expressed at local level. Mild short-term reversible effects to identifiable groups, localised.
Moderate	Measureable long-term damage to populations and ecosystem, but reversible; little spread, no extinction	Measureable, temporary, local and reversible effects on one or several services	100,000-1,000,000 Euro	Temporary changes to normal activities at local level. Minor irreversible effects and/or larger numbers covered by reversible effects, localised.
Major	Long-term irreversible ecosystem change, spreading beyond local area	Local and irreversible or widespread and reversible effects on one / several services	1,000,000-10,000,000 Euro	Some permanent change of activity locally, concern expressed over wider area. Significant irreversible effects locally or reversible effects over large area.
Massive	Widespread, long-term population loss or extinction, affecting several species with serious ecosystem effects	Widespread and irreversible effects on one / several services	Above 10,000,000 Euro	Long-term social change, significant loss of employment, migration from affected area. Widespread, severe, long-term, irreversible health effects.

<sup>5</sup> Not to be confused with “no impact”.

## ANNEX III Scoring of Confidence Levels

(modified from Bacher et al. 2017)

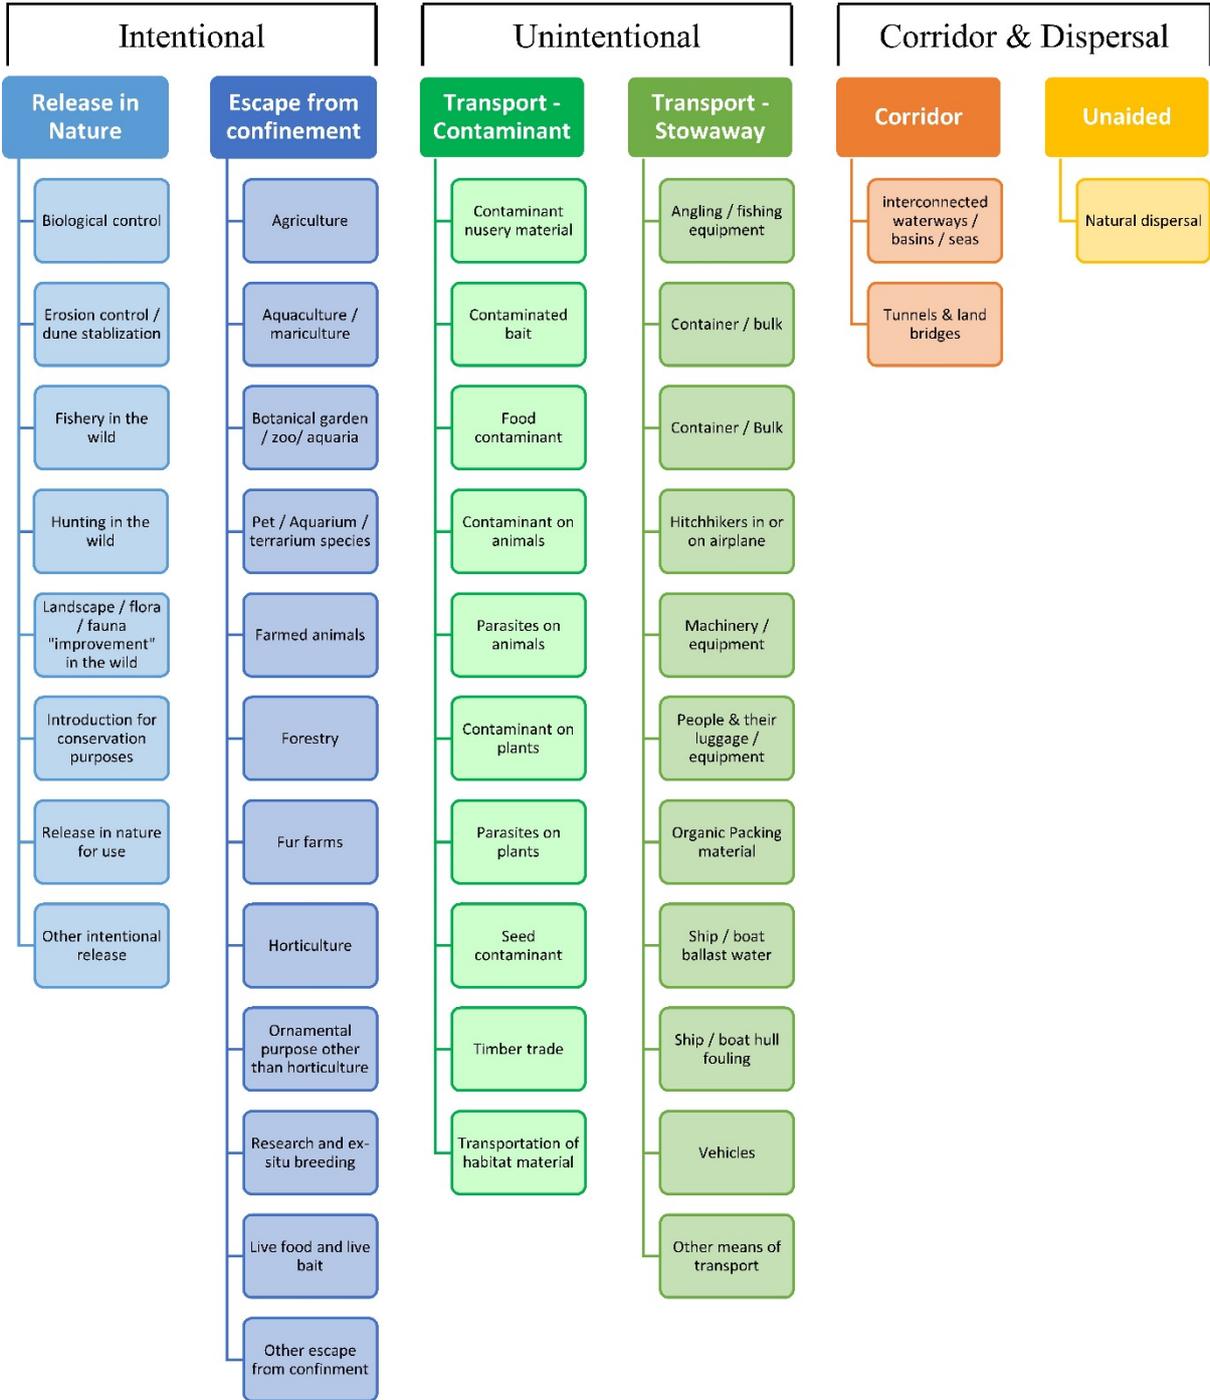

Each answer provided in the risk assessment must include an assessment of the level of confidence attached to that answer, reflecting the possibility that information needed for the answer is not available or is insufficient or available but conflicting.

The responses in the risk assessment should clearly support the choice of the confidence level.

Confidence level	Description
Low	There is no direct observational evidence to support the assessment, e.g. only inferred data have been used as supporting evidence <i>and/or</i> Impacts are recorded at a spatial scale which is unlikely to be relevant to the assessment area <i>and/or</i> Evidence is poor and difficult to interpret, e.g. because it is strongly ambiguous <i>and/or</i> The information sources are considered to be of low quality or contain information that is unreliable.
Medium	There is some direct observational evidence to support the assessment, but some information is inferred <i>and/or</i> Impacts are recorded at a small spatial scale, but rescaling of the data to relevant scales of the assessment area is considered reliable, or to embrace little uncertainty <i>and/or</i> The interpretation of the data is to some extent ambiguous or contradictory.
High	There is direct relevant observational evidence to support the assessment (including causality) <i>and</i> Impacts are recorded at a comparable scale <i>and/or</i> There are reliable/good quality data sources on impacts of the taxa <i>and</i> The interpretation of data/information is straightforward <i>and/or</i> Data/information are not controversial or contradictory.

# ANNEX IV CBD pathway categorisation scheme

Overview of CBD pathway categorisation scheme showing how the 44 pathways relate to the six main pathway categories. All of the pathways can be broadly classified into 1) those that involve intentional transport (blue), 2) those in which the taxa are unintentionally transported (green) and 3) those where taxa moved between regions without direct transportation by humans and/or via artificial corridors (orange and yellow). **Note that the pathways in the category “Escape from confinement” can be considered intentional for the introduction into the risk assessment area and unintentional for the entry into the environment.**

## ANNEX V Ecosystem services classification (CICES V5.1, simplified) and examples

For the purposes of this risk assessment, please feel free to use what seems as the most appropriate category / level / combination of impact (Section – Division – Group), reflecting information available.

Section	Division	Group	Examples (i.e. relevant CICES “classes”)
Provisioning	Biomass	<b>Cultivated <i>terrestrial</i> plants</b>	<p>Cultivated terrestrial plants (including fungi, algae) grown for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from cultivated plants, fungi, algae and bacteria for direct use or processing (excluding genetic materials);            Cultivated plants (including fungi, algae) grown as a <u>source of energy</u></p> <p><i>Example: negative impacts of non-native organisms to crops, orchards, timber etc.</i></p>
		<b>Cultivated <i>aquatic</i> plants</b>	<p>Plants cultivated by in- situ aquaculture grown for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from in-situ aquaculture for direct use or processing (excluding genetic materials);            Plants cultivated by in- situ aquaculture grown as an <u>energy source</u>.</p> <p><i>Example: negative impacts of non-native organisms to aquatic plants cultivated for nutrition, gardening etc. purposes.</i></p>
		<b>Reared animals</b>	<p>Animals reared for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from reared animals for direct use or processing (excluding genetic materials);            Animals reared to provide <u>energy</u> (including mechanical)</p> <p><i>Example: negative impacts of non-native organisms to livestock</i></p>
		<b>Reared <i>aquatic</i> animals</b>	<p>Animals reared by in-situ aquaculture for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from animals grown by in-situ aquaculture for direct use or processing (excluding genetic materials);            Animals reared by in-situ aquaculture as an <u>energy source</u></p> <p><i>Example: negative impacts of non-native organisms to fish farming</i></p>
		<b>Wild plants</b> (terrestrial and aquatic)	<p>Wild plants (terrestrial and aquatic, including fungi, algae) used for <u>nutrition</u>;  <u>Fibres and other materials</u> from wild plants for direct use or processing (excluding genetic materials);            Wild plants (terrestrial and aquatic, including fungi, algae) used as a <u>source of energy</u></p> <p><i>Example: reduction in the availability of wild plants (e.g. wild berries, ornamentals) due to non-native organisms (competition, spread of disease etc.)</i></p>
		<b>Wild animals</b> (terrestrial and aquatic)	<p>Wild animals (terrestrial and aquatic) used for <u>nutritional purposes</u>;  <u>Fibres and other materials</u> from wild animals for direct use or processing (excluding genetic materials);            Wild animals (terrestrial and aquatic) used as a <u>source of energy</u></p>

			<i>Example: reduction in the availability of wild animals (e.g. fish stocks, game) due to non-native organisms (competition, predations, spread of disease etc.)</i>
	<b>Genetic material</b> from all biota	<b>Genetic material</b> from plants, algae or fungi	<p><u>Seeds, spores and other plant materials</u> collected for maintaining or establishing a population; Higher and lower plants (whole organisms) used to <u>breed new strains or varieties</u>; Individual genes extracted from higher and lower plants for the <u>design and construction of new biological entities</u></p> <p><i>Example: negative impacts of non-native organisms due to interbreeding</i></p>
		<b>Genetic material</b> from animals	<p>Animal material collected for the purposes of maintaining or establishing a population; Wild animals (whole organisms) used to breed new strains or varieties; Individual genes extracted from organisms for the design and construction of new biological entities</p> <p><i>Example: negative impacts of non-native organisms due to interbreeding</i></p>
	<b>Water</b> <sup>6</sup>	<b>Surface water</b> used for nutrition, materials or energy	<p>Surface water for <u>drinking</u>; Surface water used as a material (<u>non-drinking purposes</u>); Freshwater surface water, coastal and marine water used as an <u>energy source</u></p> <p><i>Example: loss of access to surface water due to spread of non-native organisms</i></p>
		<b>Ground water</b> for used for nutrition, materials or energy	<p>Ground (and subsurface) water for <u>drinking</u>; Ground water (and subsurface) used as a material (<u>non-drinking purposes</u>); Ground water (and subsurface) used as an <u>energy source</u></p> <p><i>Example: reduced availability of ground water due to spread of non-native organisms and associated increase of ground water consumption by vegetation.</i></p>
<b>Regulation &amp; Maintenance</b>	<b>Transformation</b> of biochemical or physical inputs to ecosystems	<b>Mediation of wastes or toxic substances</b> of anthropogenic origin by living processes	<p><u>Bio-remediation</u> by micro-organisms, algae, plants, and animals; <u>Filtration/sequestration/storage/accumulation</u> by micro-organisms, algae, plants, and animals</p> <p><i>Example: changes caused by non-native organisms to ecosystem functioning and ability to filtrate etc. waste or toxics</i></p>
		<b>Mediation of nuisances</b> of anthropogenic origin	<p><u>Smell reduction</u>; <u>noise attenuation</u>; <u>visual screening</u> (e.g. by means of green infrastructure)</p> <p><i>Example: changes caused by non-native organisms to ecosystem structure, leading to reduced ability to mediate nuisances.</i></p>
	<b>Regulation</b> of physical, chemical, biological conditions	<b>Baseline flows and extreme event</b> regulation	<p>Control of <u>erosion</u> rates; Buffering and attenuation of <u>mass movement</u>; <u>Hydrological cycle and water flow regulation</u> (Including flood control, and coastal protection); <u>Wind</u> protection; <u>Fire</u> protection</p>

<sup>6</sup> Note: in the CICES classification provisioning of water is considered as an abiotic service whereas the rest of ecosystem services listed here are considered biotic.

			<p><i>Example: changes caused by non-native organisms to ecosystem functioning or structure leading to, for example, destabilisation of soil, increased risk or intensity of wild fires etc.</i></p>
		<p><b>Lifecycle maintenance, habitat and gene pool protection</b></p>	<p>Pollination (or 'gamete' dispersal in a marine context); <u>Seed dispersal</u>; Maintaining <u>nursery populations and habitats</u> (Including gene pool protection)</p> <p><i>Example: changes caused by non-native organisms to the abundance and/or distribution of wild pollinators; changes to the availability / quality of nursery habitats for fisheries</i></p>
		<p><b>Pest and disease control</b></p>	<p>Pest control; Disease control</p> <p><i>Example: changes caused by non-native organisms to the abundance and/or distribution of pests</i></p>
		<p><b>Soil quality regulation</b></p>	<p><u>Weathering processes</u> and their effect on soil quality; <u>Decomposition and fixing processes</u> and their effect on soil quality</p> <p><i>Example: changes caused by non-native organisms to vegetation structure and/or soil fauna leading to reduced soil quality</i></p>
		<p><b>Water conditions</b></p>	<p>Regulation of the <u>chemical condition</u> of freshwaters by living processes; Regulation of the chemical condition of salt waters by living processes</p> <p><i>Example: changes caused by non-native organisms to buffer strips along water courses that remove nutrients in runoff and/or fish communities that regulate the resilience and resistance of water bodies to eutrophication</i></p>
		<p><b>Atmospheric composition and conditions</b></p>	<p>Regulation of <u>chemical composition</u> of atmosphere and oceans; Regulation of <u>temperature and humidity</u>, including ventilation and transpiration</p> <p><i>Example: changes caused by non-native organisms to ecosystems' ability to sequester carbon and/or evaporative cooling (e.g. by urban trees)</i></p>
<b>Cultural</b>	<b>Direct, in-situ and outdoor interactions</b> with living systems that depend on presence in the environmental setting	<p><b>Physical and experiential</b> interactions with natural environment</p>	<p>Characteristics of living systems that that enable activities promoting health, recuperation or enjoyment through <u>active or immersive interactions</u>;</p> <p>Characteristics of living systems that enable activities promoting health, recuperation or enjoyment through <u>passive or observational interactions</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that make it attractive for recreation, wild life watching etc.</i></p>
		<p><b>Intellectual and representative</b> interactions with natural environment</p>	<p>Characteristics of living systems that enable <u>scientific investigation</u> or the creation of traditional ecological knowledge;</p> <p>Characteristics of living systems that enable <u>education and training</u>;</p> <p>Characteristics of living systems that are resonant in terms of <u>culture or heritage</u>;</p> <p>Characteristics of living systems that enable <u>aesthetic experiences</u></p>

			<i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have cultural importance</i>
	<b>Indirect, remote, often indoor interactions</b> with living systems that do not require presence in the environmental setting	<b>Spiritual, symbolic</b> and other interactions with natural environment	Elements of living systems that have <u>symbolic meaning</u> ; Elements of living systems that have <u>sacred or religious meaning</u> ; Elements of living systems used for <u>entertainment or representation</u>  <i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have sacred or religious meaning</i>
		Other biotic characteristics that have a <b>non-use value</b>	Characteristics or features of living systems that have an <u>existence value</u> ; Characteristics or features of living systems that have an <u>option or bequest value</u>  <i>Example: changes caused by non-native organisms to ecosystems designated as wilderness areas, habitats of endangered species etc.</i>

# ANNEX VIII Modelling the potential geographic distribution of the Asian giant hornet *Vespa mandarinia* using CLIMEX

M. Lukas Seehausen & Marc Kenis

## Methods

### About CLIMEX

The bioclimatic models were developed using CLIMEX 4.1 (Kriticos et al. 2016) that integrates the weekly responses of a population to climate using a series of annual indices. The bioclimatic modelling process has been previously described in numerous publications (Vera et al. 2002; Sutherst and Maywald 2005; Poutsma et al. 2008; Olfert et al. 2012), and thus, only a brief description of the CLIMEX program and parameters is provided here. CLIMEX uses an annual Growth Index (GI) to describe the potential for population growth as a function of temperature and soil moisture during favorable conditions, and stress indices (cold, wet, hot, dry) to determine the effect of abiotic stress on survival in unfavorable conditions. The weekly GI is a function of temperature (TI), diapause (DI) and moisture (MI). The growth and stress indices are calculated weekly and then combined into an overall annual index of climatic suitability, the Ecoclimatic Index (EI), which ranges from EI = 0 for locations where the species is not able to persist to EI = 100 for locations that are optimal for the species. However, in temperate climates, the maximum EI value is rather close to 50 and values of >20 are usually considered sufficient to support substantial population densities (Sutherst et al. 2007).

### Fitting CLIMEX parameters

Very little is known about the ecoclimatic responses of *V. mandarinia*. Therefore, initial model parameter values were based on the slightly modified values for *V. germanica*, published for the congeneric Asian hornet *Vespa velutina* by Ibáñez-Justicia and Loomans (2011) and Park and Jung (2016). However, because *V. mandarinia* is clearly more cold-tolerant, as especially indicated by its northern distribution in Russia (Siberian Zoological Museum), we further modified the values, especially of the cold stress parameters, until the simulated potential geographical distribution indicated by the Ecoclimatic Index (EI) agreed with the currently known native distribution of *V. mandarinia*.

The CliMond10 climate data set was used as input into the model to predict the native Asian and the potential distribution in Europe and North America (Kriticos et al. 2012). The CliMond data set was developed for species bioclimatic modelling, including both correlative and process-based mechanistic models. The 10' gridded data set includes a hybrid historical data set (based on CRU CL2.0 and WorldClim; centered on 1975). A climate data set with a lower resolution, 30' gridded data, but including more recent data, centered on 1995, was used for modeling the potential distribution and stresses at the global scale. The potential distribution of *V. mandarinia* in 2080 as predicted by the Ecoclimatic Index was modelled using the A1B scenario included in the CLIMEX software.

The CLIMEX parameter values for the present models were calibrated as follows: The limiting low and lower optimal soil moisture were almost the same as for the *V. germanica* models, allowing development above the permanent wilting point. However, upper optimal and limiting high soil moisture were decreased, reflecting the fact that hornet activity is decreased at heavy rainfalls (Rodríguez-Flores et al. 2018). Wet stress starting at 200% (index=2.0) water holding capacity (i.e., significant water run-off) with a relatively steep increase also reflects this fact, while allowing for heavy rain falls that the hornet may experiences in southern Asia. Dry stress parameters were kept the same as specified for the *V. germanica* model.

Observations of *V. velutina*'s colonies activity in France indicated that no activity outside the nest takes place at air temperatures <10°C (Perrard et al. 2009). However, to include *V. mandarinia*'s presence in

south-eastern Russia and northern Japan, the limiting low temperature and also the day-degree threshold temperature for the accumulation of cold stress was decreased to 8°C. The lower optimal temperature was kept as for the *V. germanica* model, however, the upper optimal temperature and the limiting high temperature for development were slightly increased (by 2°C), allowing for the hornet's southern distribution limits and reflecting the fact that this species rather nests in concealed places, such as in the ground at a depth of 6-60cm, e.g. in small mammal burrows or decayed root spaces, or in hollow trees (Matsuura & Sakagami 1973; Archer 1995). The limiting high temperature for development is relatively difficult to measure for hornets, because they are known to actively adjust air temperature in nests through behaviors such as ventilation, regurgitation of water, and wing vibration (Perrard et al. 2009). Therefore, values for limiting high temperatures and heat stress were adjusted in an iterative manner until the native distribution was accurately predicted by the model. However, the resulting values are similar to those previously published for *Vespa velutina* (Ibáñez-Justicia and Loomans 2011; Park and Jung 2016).

The cold stress threshold temperature and its rate of increase were estimated based on the information that mated queens overwinter protected in special cavities excavated into moderately moist soil. The entrance of the cavity is plugged and the queen passes the winter hanging from the top of the chamber (Matsuura and Sakagami 1973; Archer 1995). Thus, the hornet can withstand temperatures well below the freezing point and would only be affected by cold stress if the soil under the snow freezes deep enough. However, once the temperature falls below a critical threshold, queens are expected to freeze to death rather quickly. Like for heat stress, the values for the cold stress threshold and its rate were adjusted in an iterative manner until the native distribution was accurately predicted by the model. The resulting cold stress threshold was -30°C with a rate of -0.0007. It has to be understood that this value is a threshold value for air temperature, and does not reflect soil temperatures under the snow.

Degree-days per generation are not used in this model because like other hornets, foundresses of *V. mandarinia* produce offspring continuously over the season without discrete generations.

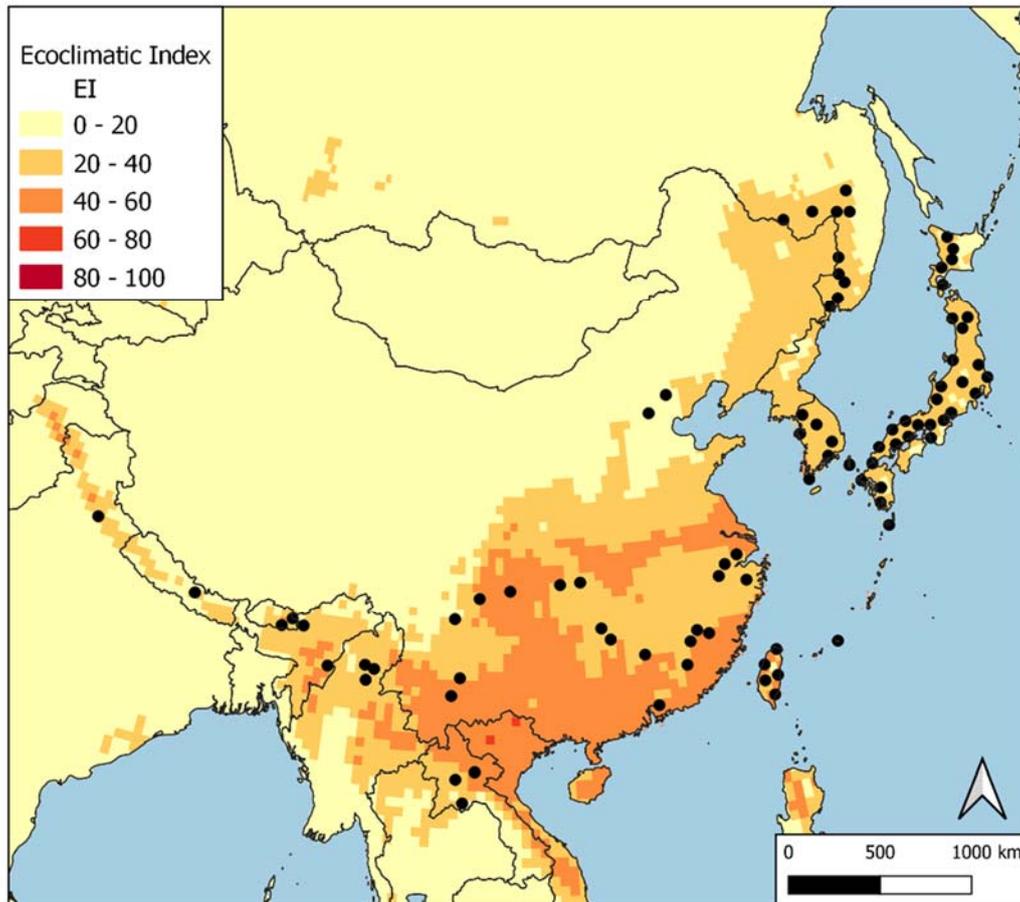

## Results

The resulting parameters (Table 1) lead to an accurately predicted native distribution (Figure A1). The global distribution of the Ecoclimatic Index indicating the potential distribution of *V. mandarinia*, as well as the heat stress, cold stress, and dry stress that are limiting its potential distribution are shown in Figure A2. Figure A3 represents the potential distribution of *V. mandarinia* in Europe and northern Africa as predicted by the Ecoclimatic Index from the CLIMEX model and Figure A4 shows the potential distribution of *V. mandarinia* in the same area in 2080 using the A1B scenario.

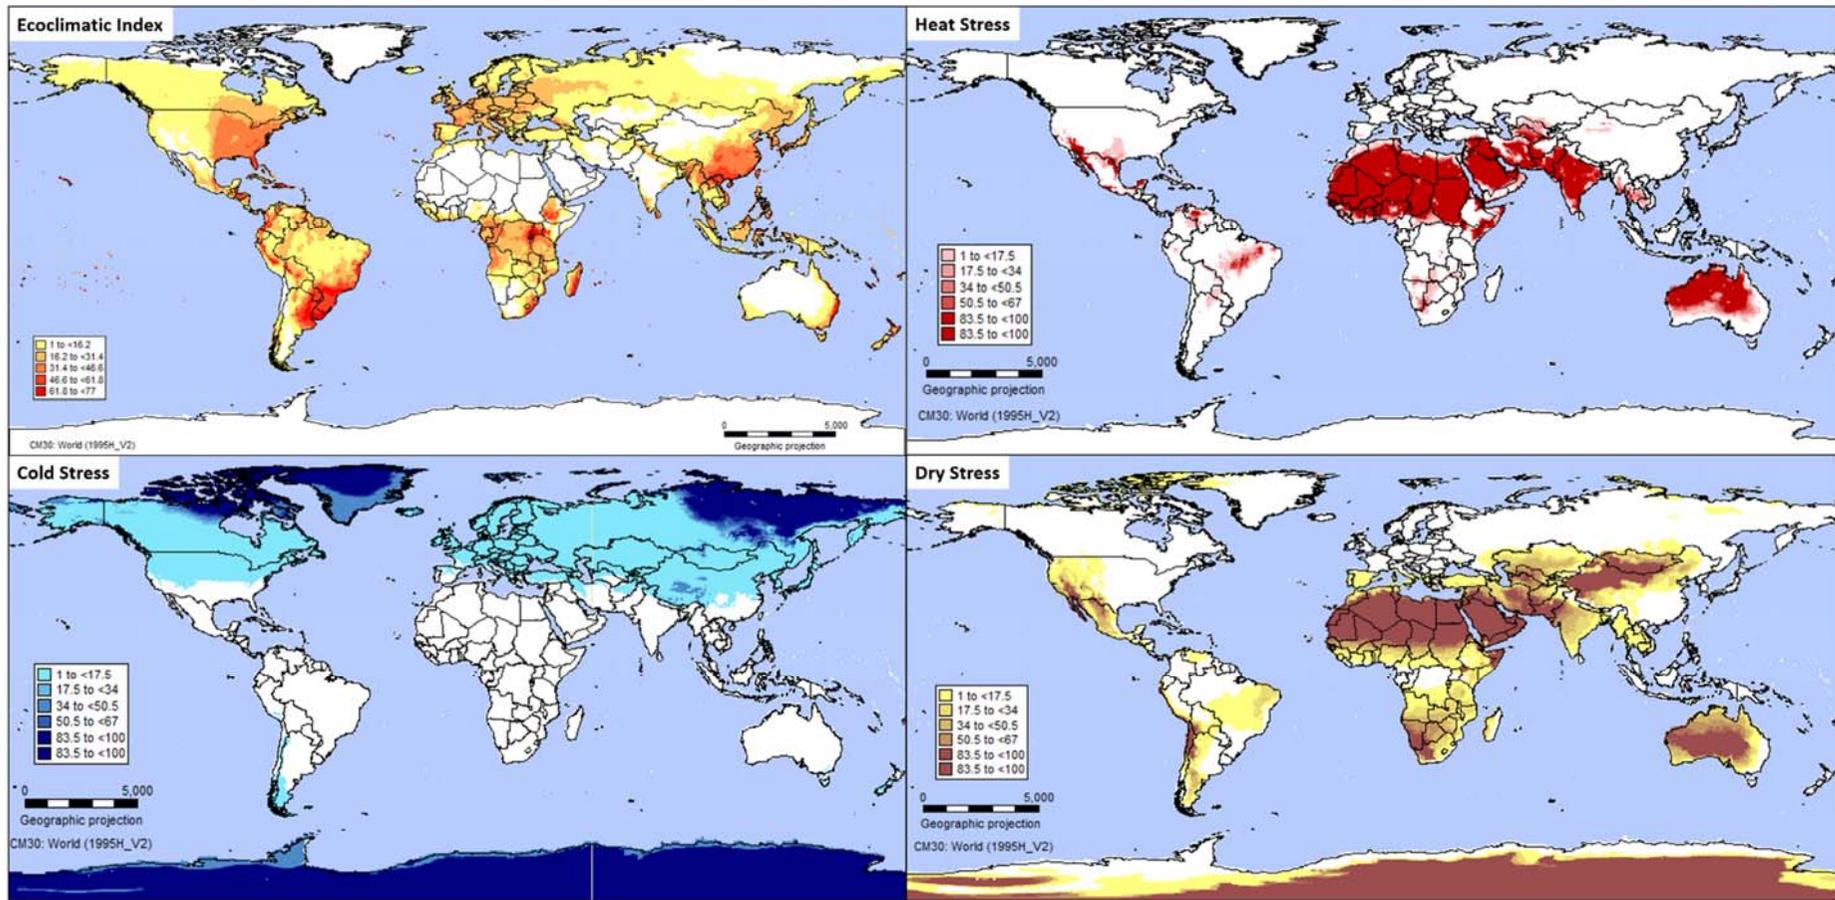

Results are discussed in the risk assessment.

**Table 1:** CLIMEX model parameters used to predict the distribution of *Vespa mandarinia* in non-native areas around the world.

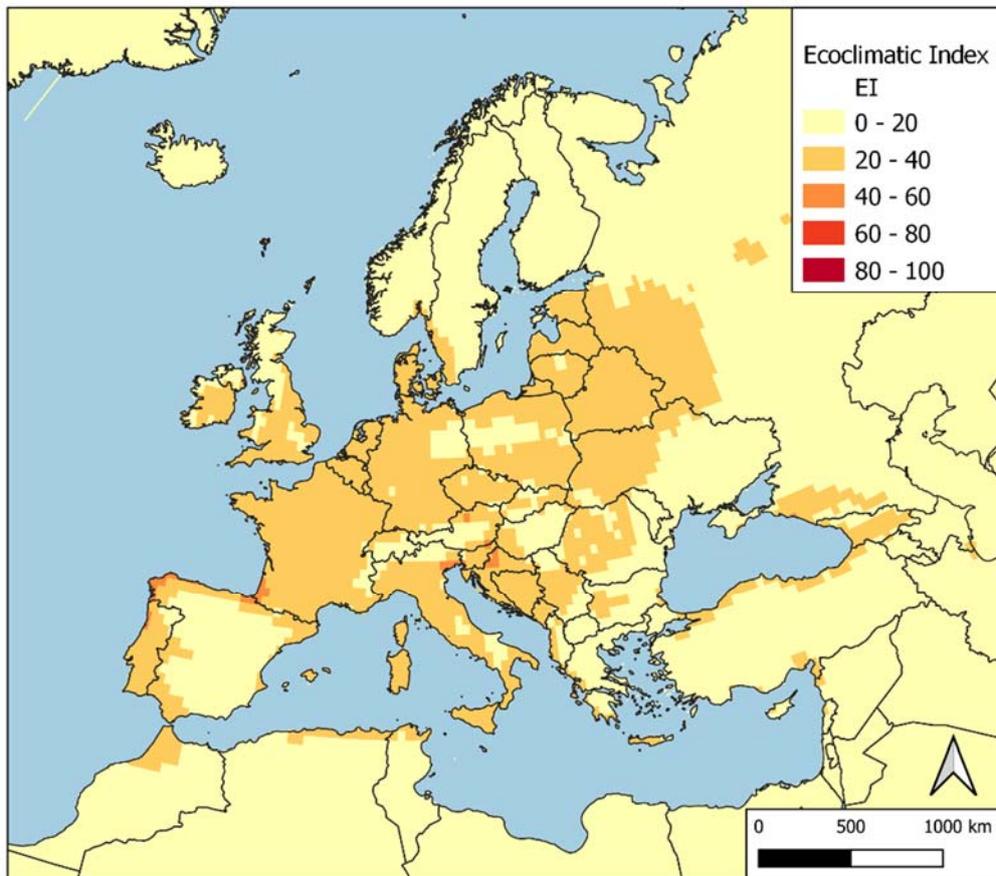

<b>Group</b>	<b>Parameter</b>	<b>Description</b>	<b>Value</b>
Moisture Index	SMO	Limiting low soil moisture	0.15
	SM1	Lower optimal soil moisture	0.6
	SM2	Upper optimal soil moisture	1
	SM3	Limiting high soil moisture	2
Temperature Index	DV0	Limiting low temperature	8°C
	DV1	Lower optimal temperature	18°C
	DV2	Upper optimal temperature	28°C
	DV3	Limiting high temperature	34°C
Cold Stress	TTCS	Cold stress threshold	-30°C
	THCS	Cold stress temperature rate	-0.0007
	DTCS	Cold stress degree-day threshold	8°C
	DHCS	Cold stress degree-day rate	-0.00001
	TTCSA	Average cold stress degree-day threshold	8
	THCSA		0
Heat Stress	TTHS	Heat stress temperature threshold	34°C
	THHS	Heat stress temperature rate	0.003
	DTHS		0
	DHHS		0
Dry Stress	SMDS	Dry stress threshold	0.15
	HDS	Dry stress rate	-0.008
Wet Stress	SMWS	Wet stress threshold	2.0
	HWS	Wet stress rate	0.002
Day-degree accumulation above DV0	DV0	Limiting low temperature	8°C
	DV3	Limiting high temperature	34°C
	MTS	Model time step	7
Day-degree accumulation above DVCS	DVCS	Cold stress DD threshold temperature	8°C

<b>RISK SUMMARIES</b>			
	<b>RESPONSE</b>	<b>CONFIDENCE<sup>2</sup></b>	<b>COMMENT</b>
<b>Summarise Entry<sup>3</sup></b>	very likely	high	The species is already present in the risk assessment area via two main pathways (pet trade and research) which are still active. Facilities hosting captive populations are already present in several countries, hence the risk of entry is very high.
<b>Summarise Establishment<sup>4</sup></b>	very likely	high	The species is already successfully established in the risk assessment area. There is also evidence that suitable conditions for the species are present in other countries where there are not yet established populations.
<b>Summarise Spread<sup>5</sup></b>	rapidly	medium	Many studies have shown that the species may rapidly disperse by natural means (i.e. through ecological corridors) in the risk assessment area, facilitated by both the occurring environmental conditions and the species' intrinsic dispersal capacities.
<b>Summarise Impact<sup>6</sup></b>	moderate	medium	<i>Xenopus laevis</i> can affect native species by competition and predation. In particular there is substantial evidence that it predated on amphibians (either eggs, tadpoles and adults), fish, and several

<sup>2</sup> In a scale of low / medium / high, see Annex II

<sup>3</sup> In a scale of very unlikely / unlikely / moderately likely / likely / very likely, see Annex I

<sup>4</sup> In a scale of very unlikely / unlikely / moderately likely / likely / very likely, see Annex I

<sup>5</sup> In a scale of very slowly / slowly / moderately / rapidly / very rapidly

<sup>6</sup> In a scale of minimal / minor / moderate / major / massive, see Annex II

			groups of invertebrates, (particularly on macro-invertebrate communities), although there is no conclusive evidence of impact on their populations. Furthermore, there is evidence of <i>Xenopus laevis</i> potentially functioning as a reservoir for <i>Bd</i> and other pathogens. However, to date there is no evidence that <i>Xenopus laevis</i> has caused impact on native amphibians through pathogen transmission.
<b>Conclusion of the risk assessment<sup>7</sup></b>	moderate	medium	The species is known to be invasive in the risk assessment area. Further releases, escapes (or spread) may occur in areas which are not yet colonised, leading to the successful establishment of new populations, hence increasing the overall impact associated with the occurrence of <i>Xenopus laevis</i> in the wild.

**Distribution Summary:**

The columns refer to the answers to Questions A6 to A12 under Section A. See also Annex VI.

The answers in the tables below indicate the following:

- Yes recorded, established or invasive
- not recorded, established or invasive
- ? Unknown; data deficient

Member States and the United Kingdom

	Recorded	Established (currently)	Possible establishment (under current climate)	Possible establishment (under foreseeable climate)	Invasive (currently)
Austria				Yes	
Belgium	Yes		Yes	Yes	
Bulgaria				Yes	
Croatia				Yes	
Cyprus				Yes	
Czech Republic				Yes	
Denmark			Yes	Yes	
Estonia				Yes	
Finland				Yes	
France	Yes	Yes	Yes	Yes	Yes

Pannonian				Yes	
Steppic				Yes	

<b>SECTION A – Organism Information and Screening</b>	
<b>Organism Information</b>	<b>RESPONSE</b>
<p>A1. Identify the organism. Is it clearly a single taxonomic entity and can it be adequately distinguished from other entities of the same rank?</p>	<p>This risk assessment covers only one species, <i>Xenopus laevis</i> (Daudin, 1802), the African Clawed Frog or Common Platanna (Class: Amphibia; Order: Anura; Family: Pipidae; Genus: <i>Xenopus</i>).</p> <p>The African Clawed Frog is also known as Platanna, Common Platanna, Common Clawed Frog, Clawed Toad, Clawed Frog, Upland Clawed Frog, Smooth Clawed Frog, African Clawed Toad, Upland Clawed Frog, Common Clawed Frog, Common Clawed Toad, African Clawed Frog (Frost 2018).</p> <p><i>X. laevis</i> belongs to a genus that comprises at least 29 species, half of which occur in Central Africa (Evans et al. 2015). According to Evans et al. (2015) although <i>Xenopus</i> is easily distinguished from other frog genera, discriminating the relevant species based solely on morphological characters can be difficult.</p> <p>Distinguishing <i>X. laevis</i> from other species of the same genus is usually no problem where they occur, as no other species is as large as <i>X. laevis</i>. Otherwise, some difficulties may be faced in the case of hybrids (John Measey pers. comm. 2018). As summarised by Measey (2016) <i>X. laevis</i> has undergone significant taxonomic revision following a comprehensive molecular study by Furman et al. (2015). The result of this revision is that what was previously known as <i>X. l. laevis</i> is now known as <i>X. laevis</i> with all other subspecies being recognised as full species, and some newly described species included as well (Evans et al., 2015).</p> <p>In fact, as reported by Furman et al. (2015) within <i>X. laevis</i> sensu lato, the analyses show at least four lineages: <i>X. laevis</i> (southern Africa, including Malawi and South Africa), <i>X. poweri</i> (Central Africa, including Nigeria, Cameroon, Zambia, and Botswana), <i>X. petersii</i> (West Central Africa, including the Republic of Congo, western DRC, and Angola) and <i>X. victorianus</i></p>

(East Africa, including Kenya, Uganda, Rwanda, Burundi, eastern DRC, and Tanzania). The data potentially support the transfer of *X. l. sudanensis* to the synonymy of *X. poweri* (instead of *X. laevis*), while *X. l. bunyoniensis* should be tentatively considered a synonym of *X. victorianus*.

Reciprocal crosses between individuals of *X. laevis* sensu lato (that were probably from South Africa), and individuals from Uganda or Botswana, both produced fertile offspring, thus gene flow between these species is possible (Furman et al. 2015). *X. laevis* is also known to hybridise with *Xenopus gilli*. The hybrids of these species pose no intrinsic invasive threat, except for the conservation of the latter species, which is also affected by predation and competition by *X. laevis* (Measey et al. 2017). Hybrids are also known in the wild, in hybrid zones, with *X. poweri* (conjecture) and *X. muelleri* (Fischer et al 2000). However, since we cannot exclude the possibility that hybrids are present in trade and/or in the populations established in the wild, this risk assessment should apply to all *X. laevis* hybrids as well. This is justified by the fact that while some physiological features may be different, the overall impact would be the same. As a remark, this assessment is for *X. laevis*, but unless otherwise stated, all statements apply to any hybrids as well as albino *X. laevis* (albino individuals belong exactly to the same *X. laevis* species).

Here follows a list of the most common synonym names of *X. laevis* according to Frost (2018):

- *Bufo laevis* Daudin, 1802
- *Dactylethera boiei* (Wagler, 1827)
- *Dactylethra bufonia* (Merrem, 1820)
- *Dactylethra capensis* Cuvier, 1830
- *Dactylethra delalandii* Cuvier, 1849
- *Dactylethra laevis* (Daudin, 1802)
- *Engystoma laevis* (Daudin, 1802)
- *Leptopus boiei* (Wagler, 1827)
- *Leptopus oxydactylus* Mayer, 1835
- *Pipa africana* Mayer, 1835
- *Pipa bufonia* Merrem, 1820

	<ul style="list-style-type: none"> <li>• <i>Pipa laevis</i> (Daudin, 1802)</li> <li>• <i>Tremeropugus typicus</i> Smith, 1831</li> <li>• <i>Xenopus boiei</i> Wagler, 1827</li> <li>• <i>X. laevis</i> ssp. <i>bunyoniensis</i> Loveridge, 1932</li> <li>• <i>X. laevis</i> ssp. <i>sudanensis</i> Perret, 1966</li> </ul>
<p>A2. Provide information on the existence of other species that look very similar [that may be detected in the risk assessment area, either in the wild, in confinement or associated with a pathway of introduction]</p>	<p><i>X. laevis</i> is not difficult to distinguish from other anurans occurring in Europe (either native or alien ones). In general, the body of <i>X. laevis</i> has a flattened shape. Adult males measure around 90 mm in males, and females 100 mm, although larger individuals are known (John Measey pers. comm. 2018). The skin is smooth and slippery, with peculiar lateral lines along its sides. The eyes are positioned at the top of a small head, which lacks a tongue and eardrums. The hind legs are very developed and webbed (with black claws on the first three toes), while the front limbs are rather small. Colour varies from yellowish to olive grey or dark brown with spots (but albino forms are also common in trade). Tadpoles are easily distinguished from other (native) anurans, particularly because of their distinctive barbells next to the mouth, mid-water suspension feeding and often near transparent, especially when small.</p> <p>Other <i>Xenopus</i> species may be found in the trade. Examples are <i>X. tropicalis</i> and <i>X. epitropicalis</i>, which Tinsley &amp; McCoid (1996) considered regularly imported to Europe with tropical fish from West Africa (although the source seems a bit outdated in this context). However, there is no evidence about the occurrence of such species in the wild in the risk assessment area.</p>
<p>A3. Does a relevant earlier risk assessment exist? (give details of any previous risk assessment and its validity in relation to the risk assessment area)</p>	<p>Some risk assessments exist for the species, i.e. for Great Britain, USA, and Australia.</p> <p>In the risk assessment for Great Britain the risk attributed to the species is low, with a medium level of uncertainty (NNSS 2011). According to this assessment “<i>X. laevis</i> was having very minimal impacts in the UK, given the very few populations occurring in the wild” (which in fact are considered currently extinct, see details below), and the reduced ability to reproduce and further spread in the country (even if climate change would facilitate this). The only concern would be the unknown impact related to the possible spread of diseases (including the chytrid fungus) to native amphibians, and of possible unforeseen scenarios due to future climate</p>

changes. However the conclusions of the GB risk assessment cannot be extended to other EU regions, given the different climate and habitat conditions, which are definitely more suitable for the species, e.g. in the Mediterranean area.

In the USA an Ecological Risk Screening Summary was made by the U.S. Fish and Wildlife Service (Anonymous 2017). The overall risk assessment category attributed to the species is “high”, as the climate matched well in many states, and the certainty of the assessment was deemed medium (given the taxonomic uncertainties noted for the target species). Similarly, in Australia *X. laevis* has been assigned an establishment risk rank of “extreme” (Page et al. 2008). Since these assessments focus on the occurrence of the species in the US and Australia, their validity is limited by the difference in ecological, geographical and climatic conditions compared to the EU situation. Moreover, in the case of the US, the assessment should be revised in the light of the noted taxonomic uncertainties that are now resolved (John Measey pers. comm. 2018).

A number of studies aimed at ranking the impact of amphibians were also carried out at either the global level (e.g. Kumschick et al. 2017a, Kumschick et al. 2017b, Kraus 2015, Measey et al. 2016, Measey et al. 2020) or EU level (e.g. Kopecký et al. 2016). For example, Kumschick et al. (2017b) discussed the application of the Environmental Impact Classification for Alien Taxa (EICAT, see Hawkins et al. 2015 for details on the methodology) on amphibians following two independent assessments made by Kraus (2015) and Kumschick et al. (2017a). The results showed that the impact classification is relatively “high” for *X. laevis*, despite some minor difference between the two assessments: respectively Massive (MV, irreversible community-level changes) and Major (MR, impact on a native community that is reversible). This difference seems justified by the practical interpretation and assignment of disease impacts in the absence of direct evidence of transmission from alien to native species, especially in relation to chytridiomycosis. The study was recently repeated (Measey et al. 2020) and the impact score for *Xenopus laevis* was confirmed as Major, while the confidence score changed from medium to high. It is also worth mentioning that the SEICAT assessment found little documented evidence for socio-economic impacts, except in the species native range where it can be a predator in aquaculture (Bacher et al. 2018).

	<p>Measey et al. (2016) used the generic impact scoring system (GISS) to carry out a global assessment of alien amphibians. In particular <i>X. laevis</i> was the second top scoring amphibian for impact on native ecosystems (considering the sum for environmental and economic scores together) only after the invasive Cane toad <i>Rhinella marina</i>.</p> <p>Finally, it is worth mentioning Kopecký et al. (2016) who applied a risk assessment model (RAM) to ornamental amphibians traded in the EU. <i>X. laevis</i> was used as a reference species (together with <i>L. catesbeianus</i>) and was considered to have a moderate risk (the RAM value is 0.365), with an AmphISK invasion score of 10 (on a scale -10 to 33). This system however does not provide overwhelming evidence of risk, because as pointed out by the authors the RAM establishment value cannot be viewed as a precise estimation of the probability of establishment, but rather provides a relative ranking of ornamental amphibians traded in the EU.</p> <p>As a general remark regarding the scoring of the impact discussed above, it is important to consider that the categories used by this risk assessment (see Annex II) are different to those used by EICAT (according to which a major impact is reversible, contrary to the definition in Annex II which considers a major impact as irreversible). For example, as confirmed by John Measey (pers. comm. 2018) on the data used for this assessment made by Kumschick et al. (2017b), <i>X. laevis</i> was scored Major (within the EICAT scheme) on the basis of two studies (i.e. Lillo et al 2011, Grosselet et al 2005) both regarding predation, which suggest local extinction of native species (both were given medium confidence). However, the same impact under this risk assessment is considered as Moderate according to guidance in Annex II.</p>
<p>A4. Where is the organism native?</p>	<p>The full range of <i>X. laevis</i> covers much of southern Africa: South Africa, Lesotho, Swaziland, Namibia, parts of Botswana, Zimbabwe, parts of Mozambique and extending north into Malawi (Measey 2016, Ihlow et al. 2016).</p> <p>It means that native populations are distributed from winter rainfall regions in the south-western Cape region to summer rainfall regions in the north; and from sea level to 3,000 m in Lesotho (Measey 2004, De Busschere et al. 2016). As summarised by the Global Invasive Species Database (2015) <i>X. laevis</i> is a water-dependent species occurring in a very wide range of</p>

	<p>habitats, including heavily modified anthropogenic habitats. It lives in all sorts of water bodies, including streams, but tends to avoid large rivers, and water bodies with predatory fish. It reaches its highest densities in eutrophic water. It has very high reproductive potential. It is a highly opportunistic species, and colonizes newly created, apparently isolated, water bodies with apparent ease. <i>Xenopus laevis</i> exhibits high tolerance to salty water, pH variation (5-9, but there is evidence of the species breeding below pH 4, according to John Measey pers. comm. 2018), temperature variation (2-35+), and is capable of aestivation during dry periods.</p> <p>The species cannot spread naturally from its native range into the risk assessment area.</p>
<p>A5. What is the global non-native distribution of the organism outside the risk assessment area?</p>	<p>As reviewed by Measey et al. (2012) the global non-native distribution of the species is known to include four continents: North America, South America, Asia and Europe. In particular, established populations are present in different states of the USA, Chile, Japan. The species was recently recorded in China (Wang et al. 2019). There are historic records also for Mexico, Java, Israel, and Ascension Island, but with the notable exception of Mexico (where the species occurrence was recently confirmed, see Peralta-García et al. 2014) the presence of the species in these countries is not confirmed. Regarding Europe, see details under points A7-A9 below.</p>
<p>A6. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species been recorded and where is it established?</p>	<p>The species was recorded and is established in both the Mediterranean and Atlantic biogeographic regions (see details in A8).</p>
<p>A7. In which biogeographic region(s) or marine subregion(s) in the risk assessment area could the species establish in the future under current climate and under foreseeable climate change?</p>	<p>Current climate conditions: Mediterranean, Atlantic, Continental and Alpine biogeographic regions</p> <p>Foreseeable climate change conditions: all biogeographic regions, with the exception of the Boreal and Arctic, may be suitable (at least in part) depending on the different models used (see ANNEX VI). However the confidence level is very low, as we were not able to retrieve precise information on future climate, given the methodological constraints and the lack of accurate information available on the species location and taxonomy. For details on the assumptions</p>

made in relation to climate change see annex VI: projection of climatic suitability.

Recent studies have shown that native phylogeographic lineages have contributed differently to invasive *X. laevis* populations, but most of the introductions have probably been from the Mediterranean climate zone in the southwest of the Western Cape Province, South Africa, where *X. laevis* occurs naturally. For example, according to genetic and historical data the populations established in Europe, and in particular in Italy (Sicily), Portugal and France, seem to involve individuals from the south-western Cape region in South Africa (De Busschere et al. 2016, Lillo et al 2013). In France however another distinct native phylogeographic lineage is involved, i.e. from other regions of South Africa (De Busschere et al. 2016, Rödder et al. 2017). The identification of source populations is particularly relevant for the purpose of this document, because phenotypic as well as genotypic traits of colonizing individuals might influence the invasion process and success, particularly in such cases where there is extensive population differentiation within the native range (De Busschere et al. 2016).

To assess the future distribution under current climate, Measey et al. (2012) used a single lineage of the species from the southwestern Cape of South Africa for their species distribution models (SDMs). As a result, the optimal uninvasion bioclimatic space was identified in isolated parts of France and Portugal only, while a large suitable climatic potential was identified for most of southern Portugal and adjoining Spain, as well as central and southern France, and mainland Italy. Such data are consistent with the finding of Ihlow et al. (2016), who used the entire range as well as invasive populations and who predicted particularly high probabilities in Europe, namely in Portugal, eastern Spain, southern France, and Italy. Furthermore, Ihlow et al. (2016) highlight areas in Spain (including the Balearic Islands), mainland Italy (including Sardinia), and southern France (including Corsica) to be highly vulnerable to potential invasions, as these regions exhibit suitable climatic conditions for *X. laevis* and are adjacent to established invasive populations. According to Measey et al. (2012) a few suitable areas were found also in the United Kingdom outside southern coastal areas, plus Greece, Ireland, Germany, Belgium, Denmark and the Netherlands (for details see maps developed by Measey et al. 2012). On the other hand, Ihlow et al. (2016) predict only moderate probability for Great Britain, where populations from Wales and Lincolnshire have recently been extirpated. Therefore, while the optimal area would fall within the Mediterranean and Atlantic

biogeographic regions only, the maps annexed to the study seem to suggest the presence of suitable areas also within the Continental and Alpine regions.

Under foreseeable climate change, using species distribution models (SDMs), Ihlow et al. (2016) assessed the global invasion potential of this species for 2070 following four IPCC scenarios (i.e. RCP2.6, RCP4.5, RCP6, RCP8.5). In particular, the potential range size was predicted to expand in north-western Europe, especially in France and Great Britain, where new regional conditions may promote new invasions or the spread of established invasive populations. The Mediterranean area was already considered suitable and still is under all climate change scenarios. The maps shown in the paper by Ihlow et al. (2016) do not allow for a precise identification of the biogeographic regions where the species could establish in the future under foreseeable climate change. However, it seems that most biogeographic regions in Europe will become suitable for the species.

Rödger et al. (2017) demonstrated that invasive populations of *X. laevis* are established well beyond the species' multivariate realized niche in southern Africa. Hybridization of different lineages may have enabled a shift in the species' fundamental niche. Given the magnitude of the detected niche shifts, the usefulness of climate matching approaches to assess invasion risk for this species is challenged, as it might frequently underestimate the true potential distribution when a geographic subset of the species' realized distribution is used for model training. It can be expected that the true invasion potential for *X. laevis* is larger than its estimated potential distribution based on its currently realized niche (Rödger et al. 2017).

Similarly, in a recent study, Ginal et al. (2020) stressed that *X. laevis* is a species with a strongly underestimated invasive potential. They point out that the correlative approaches which characterized the previous SDMs (Ihlow et al., 2016; Measey et al., 2012, Rödger et al., 2017) can be vulnerable to extrapolation errors when projecting species' distributions in nonnative ranges. Therefore, to better assess the species' full invasive potential, the authors developed a process-based model based on physiological data like critical thermal limits and temperature-dependent performance. The study suggested a high risk of invasion for most parts of Europe that could be assessed. In particular, according to Ginal et al. (2020), large parts of western and southern Europe as well as many Mediterranean islands are predicted as being climatically

	<p>suitable for <i>X. laevis</i>. This also includes the currently (or formerly) occupied areas of Portugal, France, and Wales. Sicily is predicted as unsuitable, which the authors state is probably due to the low density of waterbodies, preventing assessment by their waterbody availability layer. Extensive “MESS” areas, which highlight possible extrapolation errors, occur in central to eastern Europe as well as in cold mountain ranges such as the Alps and Pyrenees, where predictions should be treated with caution.</p>
<p>A8. In which EU member states has the species been recorded and in which EU member states has it established? List them with an indication of the timeline of observations.</p>	<p>Recorded in the following Member States: Belgium, France, Portugal, Italy, Spain, Sweden, Germany, Netherlands; and in the United Kingdom.</p> <p>Established: France, Portugal, Italy.</p> <p>In general, the situation has been quite dynamic in the last years, mostly due to the fact that introductions are usually followed by a lag of around 15 years between the export of animals and the rise in invasive populations (van Sittert and Measey 2016). In general, it can take between 2 and 25 years or more for first reports of introductions to be released (Measey et al. 2012). As discussed in detail below, the species is currently considered established in France, Portugal and Italy (Sicily). Until recently, the species was considered established also in the UK, where it is currently considered extinct.</p> <p>According to Frazer (1964) the first introduction in the UK occurred in Kent in 1955, but did not succeed. The UK was also home of the first invasive population established in Europe, namely on the Isle of Wight, due to an introduction around 1962 (Tinsley et al. 2015a, Tinsley &amp; McCoid, 1996, van Sittert and Measey 2016). In the UK, in addition to the population on the Isle of Wight, now probably extinct, there have also been two established populations, namely in Glamorgan (Wales), and Lincolnshire (England). They were both the subject of an eradication programme and are considered recently extinct, although the causative factors were possibly the exceptional weather conditions (in conjunction with specific habitat and population characteristics) (Tinsley et al. 2015a). In any case, follow-up monitoring is still required in South Wales (John Measey, pers. comm. 2018). The species was also reported in 1987 and 1990 in two ponds to the southeast of London, although these do not appear to have survived,</p>

and in the southwest of England, but no established populations have been found (see review made by NNSS 2011).

In Portugal the species was first found in 2006 and first reported in 2007, but the first introduction may have occurred in Oeiras in 1979 (Sousa et al. 2018).

In Italy, the only known population of *X. laevis* is on the island of Sicily where the date, site and cause of first release are all unknown (Measey et al. 2012). The first documented occurrence dates back to 1999, while the first report was in 2004. In peninsular Italy, the presence of two adults of *X. laevis* was reported in 2017 for the Lombardia region, in the Groane park (see <http://www.parcogroane.it/wordpress/wp-content/uploads/2017/08/Report-censimento-anfibi-Progetto-LIFE-GESTIRE-2020-1.pdf>).

In France animals were officially first reported in 1998. However, residents of the area suggested that this frog had been present since the early 1980s (Fouquet 2001, Fouquet and Measey 2006, Measey et al. 2012). A new population of *X. laevis* has been discovered in Toulouse in 2018 (see <http://especies-exotiques-envahissantes.fr/decouverte-xenope-lisse-occitanie/>). As reported on the mentioned link, this discovery brings to four the number of known sites of occurrence of *X. laevis* in France. Indeed, in addition to the main nucleus located in between four departments (Deux-Sèvres, Vienne, Maine-et-Loire, Loire-Atlantique), a population was discovered in 2015 in Ambarès-et-Lagrave, near Bordeaux, then another one in La Chapelle-d'Armentières, near Lille, in 2018. The latter population is close to the Belgium border, where an individual was already reported in 2006 (see below).

In Spain, the presence of *X. laevis* was reported in Montjuïc (Barcelona) in 2007, where about 30 larvae were found. A year later, six individuals were found in the Parc del Laberint d'Horta. Both the larvae and the adults found were removed from the environment (EXOCAT database [http://exocatdb.creaf.cat/base\\_dades/#](http://exocatdb.creaf.cat/base_dades/#)), and the species is now considered eradicated (Pascual et al. 2007).

In Sweden, a single animal exists in the collection of the Gothenberg Natural History Museum collected in 2007 (Measey et al. 2012). However, this record is not reliable as the locality

	<p>reported by Measey et al. (2012) is in fact a name of a person who received a dead frog from another person (Melanie Josefsson in litt. 2018).</p> <p>In Germany, <i>X. laevis</i> specimens have been collected in the Hamburg area, following a release in 1991 by animal rights activists (Tinsley and McCoid, 1996; Rabitsch et al., 2013). Their current status is unknown, but it is very likely that they have disappeared.</p> <p>In the Netherlands there are records of an adult individual caught near Gorichem in 1974 and of tadpoles collected near Utrecht in 1979 (Tinsley and McCoid, 1996). The National Database Flora and Fauna has no recent records for the species in the Netherlands, confirming that the species has not established populations (<a href="http://www.ndff.nl">www.ndff.nl</a>, see also <a href="https://www.verspreidingsatlas.nl/soortenlijst/amfibieen">https://www.verspreidingsatlas.nl/soortenlijst/amfibieen</a>).</p> <p>In Belgium, as reported in the Hyla (amphibian and reptile working group of the ngo Natuurpunt) database, 30 <i>X. laevis</i> larvae were found at Antwerp University pond in 2008 (observer Bart Vervust). Their current status is unknown. Two other individuals were found in Ploegsteert (Wallonia) as reported on <a href="http://observations.be">observations.be</a>, one in 2006 (an albino specimen) and one in 2016. The area is at the border with the French area where in 2018 a new population of the species was reported, as stated above. However, an eDNA study currently in progress has confirmed that no population occurs on the Flemish side of the border (Van Doorn et al. 2021, unpublished report).</p> <p>According to Measey (2017) wild caught <i>X. laevis</i> are also reported to have been imported into the USA from the Czech Republic and Switzerland over the period 1999-2005. Such records are however presumed anomalies and should be treated with suspicion, as no invasive populations are known in these countries. On the other hand, as the source of information are records from USFW for animals imported into the USA, they could be specimens caught in the wild in South Africa and then exported to USA via the Czech Republic or Switzerland (John Measey, pers. comm. 2018).</p>
<p>A9. In which EU member states could the species establish in the future under current</p>	<p>Current climate conditions: France, Portugal, Italy, Spain, Sweden, Germany, Netherlands, Greece, Ireland, Belgium, Denmark; and the United Kingdom</p>

<p>climate and under foreseeable climate change?</p>	<p>Foreseeable climate change conditions: all EU countries may be suitable (at least in part) depending on the different model used (see ANNEX VI). However, the confidence level is very low, as model projections for the current climate vary widely, and projections for future climates are not available for all models. We could not retrieve precise information on future climate, given the methodological constraints and the lack of accurate information available on the species location and taxonomy. Ginal et al. (2020), in their distribution model paper, did not include future climate scenarios. For details see comments on point A7.</p>
<p>A10. Is the organism known to be invasive (i.e. to threaten or adversely impact upon biodiversity and related ecosystem services) anywhere outside the risk assessment area?</p>	<p>There is evidence of invasiveness in the USA, Chile and Japan (see section on impacts below for more details).</p>
<p>A11. In which biogeographic region(s) or marine subregion(s) in the risk assessment area has the species shown signs of invasiveness?</p>	<p>The species has shown signs of invasiveness in both the Mediterranean and Atlantic biogeographic regions, i.e. in all areas where populations are established. For details see section on “magnitude of impact”, points 2.13-2.30 below.</p>
<p>A12. In which EU member states has the species shown signs of invasiveness?</p>	<p>The species has shown signs of invasiveness in all EU Member States where populations are established, i.e. France, Portugal and Italy (Sicily).</p>
<p>A13. Describe any known socio-economic benefits of the organism.</p>	<p><i>Xenopus laevis</i> is a species substantially important in relation to research activities in the risk assessment area and globally (amongst others in oncology, endocrinology, developmental biology and anatomical studies), see e.g. Gurdon and Hopwood, 2000, Hardwick and Philpott, 2015 and Blum and Ott, 2018). The species was used to diagnose pregnancy, but this is apparently no longer a practice in the risk assessment area, and we may exclude its use for this purpose in other parts of the world too. The species is also traded as pet for aquaria and garden ponds.</p> <p><b><u>Pet trade</u></b> In relation to the pet sector, sales and associated ancillary product sales of <i>X. laevis</i> are significant, particularly in UK.</p>

According to data provided by the European Pet Organization to the European Commission (EPO 2018), in the UK, the annual revenue for the pet sector from *X. laevis* is in the estimated range of between 168,500 euros to 3 million euros but they consider this is likely to be a conservative estimate. This species is also likely to be economically important to other Member States where trade in this species (as a pet) is permitted, although EPO acknowledges that this may be to a lesser degree when compared to the UK. Furthermore, EPO consider that an albino morph of *Xenopus laevis* is dominant in the pet trade.

More in detail, according to EPO (2018) from the data from those Member States where *X. laevis* is traded by the pet sector, individual animals are sold for values between 1 euro to 11,30 euros depending on the Member State. Therefore, in terms of the total trade based on the information collated by EPO, between the different countries there is a very broad range in the trade values of this species (based on the number of individuals sold), with numbers ranging from a lowest value of 275 euros per annum to as high as 1 million euros per annum. If ancillary products e.g. aquariums, dry goods etc. are factored in, this figure is significantly higher with a conservative estimate of 3 million euros per year across EU and UK. While EPO (2018) does not provide a breakdown per country, they clarify that “*the proportion of sales of animals (and therefore ancillary products) varies significantly between Member States, with the UK representing the highest values whilst those reported for the Netherlands and France being significantly lower*”. Due to the skewed nature of the raw data (which EPO was unable to provide given that it is highly commercially sensitive), EPO was unable to provide median or average estimated trade revenues. However, EPO noted that the figures provided are likely to be a conservative estimate. In the UK, the annual revenue from *X. laevis* for the pet sector could be anywhere between 168,500 euros to 3 million euros. This represents a very broad range, which means that banning this species could have an impact for pet stores related activities in some EU countries.

The species is available for purchase within the risk assessment area also on the internet, e.g. <https://www.sivissen-onlineshop.be/fr/shop/grenouille-apprendre-plus/>  
<https://www.oxyfish.fr/especes-variees/33346-xenopus-laevis-albino-1-5-2-cm.html>  
<https://www.ebay.co.uk/itm/Albino-African-Clawed-Frog-Xenopus-Laevis-/264926197064>

(accessed on 05/02/2021).

### **Research activities**

In relation to the use of the species in research activities, this frog had a significant role in the history of 20th century science. It became one of four vertebrate species universally recognised as representing a standard biological model (van Sittert and Measey 2016, Gurdon and Hopwood, 2000). The paramount importance of this species in research activities is well illustrated by the concern expressed by EXRC (2019) calling for a “full socio-economic impact assessment of the effect of a ban on *X. laevis*” to be undertaken, and asking that “complete protection for the use of this species as one of the key experimental organisms of biomedical and environmental research is assured by any actions taken as a result of this risk assessment”. In their call, EXRC (2019) indicate that more than 38000 papers are found by a search for “*Xenopus laevis*” in the online archive of biomedical scientific publications Pubmed. Research based on *Xenopus laevis* includes the work by Sir John Gurdon, awarded in 2012 with the Nobel Prize in Physiology or Medicine<sup>8</sup>.

The use of the species in research activities in the EU is regulated by Directive 2010/63/EU of the European Parliament and of the Council of 22 September 2010 on the protection of animals used for scientific purposes<sup>9</sup>. According to this, specimens of *Xenopus laevis* and *Xenopus tropicalis* may only be used in procedures where those animals have been bred for use in “procedures”. Animals taken from the wild shall not be used in procedures but exemptions may be granted to this rule. “Procedure” means any use, invasive or non-invasive, of an animal for experimental or other scientific purposes, with known or unknown outcome, or educational purposes, which may cause the animal a level of pain, suffering, distress or lasting harm equivalent to, or higher than, that caused by the introduction of a needle in accordance with good veterinary practice. Furthermore, Member States shall ensure that all breeders, suppliers

---

<sup>8</sup> <https://www.nobelprize.org/prizes/medicine/2012/gurdon/facts/>

<sup>9</sup> <https://eur-lex.europa.eu/legal-content/EN/TXT/PDF/?uri=CELEX:02010L0063-20190626&from=EN>

and users are authorised by, and registered with, the Member State’s competent authority and keep records of number, origin, source etc. of animals.

Statistical data covering the EU 28 Member States (EU28) data over the period 2015-2017 were published in early 2020<sup>10</sup>. These statistics cover both *X. laevis* and *X. tropicalis* (data is collected for both species together). According to these, the number of “all uses” for these two species, i.e. the number of times these species were needed for scientific purposes in a given year in EU28 (first use and any subsequent reuse) were:

- in 2015: 18,990 uses of which 42.9% were reuses
- in 2016: 27,904 uses of which 33.70% were reuses
- in 2017: 21,443 uses of which 36.90% were reuses

For the purpose of the above, the “use” of an animal within a project extends from the time the procedure (or first procedure/technique in a series) is applied to it, to the time when the observations, or the collection of data (or other products) for a particular scientific purpose (usually a single experiment or test), are completed. “Reuse” indicates any subsequent use of an animal, which has already completed a procedure (or series of procedures/techniques) for a particular scientific purpose, and for which any animal would suffice. Reuse of *Xenopus* is relatively high. “All uses” (first use and any subsequent reuse) indicate the number of times these species were needed for scientific purposes in a given year in the EU.

EXRC (2019) estimated on basis of a literature review carried out a decade earlier that somewhere between 300 and 400 labs across Europe rely on *X. laevis* for their work. They furthermore estimate that the population of *X. laevis* used for developmental biology alone is over 52,000 animals based on unpublished survey data of 210 laboratories worldwide. Based on contributions from scientists using *Xenopus* in their research, affiliated to 22 Universities and research institutes in Belgium, Denmark, France, Germany, Ireland, Italy and the United Kingdom, EXRC (2019) also indicated that these scientists had in 2019 32,55million EUR in grant income, supporting over 100 early career-scientists. Furthermore, in a given academic

---

<sup>10</sup> [https://ec.europa.eu/environment/chemicals/lab\\_animals/reports\\_en.htm](https://ec.europa.eu/environment/chemicals/lab_animals/reports_en.htm)

year in these 22 institutions over 600 students would be taught fundamentals of cell and developmental biology using *X. laevis*. EXRC (2019) consider that for most of the experiments that use *X. laevis*, there are no alternatives (e.g. egg extracts, oocyte-based receptor assays, developmental biology using traditional techniques), for genetic approaches to cell and developmental biology *X. tropicalis* can be used but the investment needed for labs to change to this species would be very considerable.

EXRC (2019) also consider that research using *Xenopus* contributes very strongly to the Commission and Society's aim to replace the use of mammals such as mice in biological and biomedical experimentation (the so-called 3Rs of reduction, refinement and replacement). The use of *Xenopus* in place of mice is a refinement of experimental design that supports Directive 2010/63/EU.

Biomedical research has resulted also to commercial use of *Xenopus* embryos and tadpoles for in vivo drug discovery purposes and the technology has been protected by European and US patents (EP2409149, US Patent 9945845). In addition to its widespread role in biomedical research, *X. laevis* is used for testing environmental contamination and the teratogenic potential of new products. These tests are usually carried out commercially and examples include water testing by "Watchfrog" (<https://www.watchfrog.fr>) and the well-established "Frog Embryo Teratogenesis Assay-Xenopus (FETAX)" which is routinely used since early 2000's as a developmental toxicity screening test for pharmaceutical candidate compounds (Leconte and Mouche, 2013).

According to EXRC (2019), most laboratories import animals either from the CRB *Xenopus* in Rennes, NASCO in the US or the EXRC; only a few breed their own.

Indeed, within the risk assessment area, specialised suppliers of *Xenopus laevis* (and other *Xenopus* species) exist in the risk assessment area, e.g. in France and UK. See for example <http://www.xenbase.org/other/obtain.do>, <https://xenopusresource.org/how-to-order> and <https://xenopus.univ-rennes1.fr/tarifs-0> (assessed on 05/02/2021). Data from Measey (2017) show that there are some imports into the US from other countries with known invasive populations (Chile, UK and France), but in small quantities (< 100 animals), and of captive bred

	<p>animals usually for medical or scientific purposes and are thus presumably not from invasive populations. Animals in France were being harvested by Xenopus Express in France, although it is unknown whether or not this practice continues (John Measey, pers. comm. 2018). According to trade data of the U.S Fish and Wildlife Service presented in Measey (2017), live individuals of <i>X. laevis</i> were imported into the USA from EU countries such as Czech Republic, Germany, and Italy (therefore, including countries without known populations established in the wild, like Czech Republic and Germany). This could involve re-exports (see also section A8 on this).</p>
--	--

## SECTION B – Detailed assessment

### Important instructions:

- In the case of lack of information the assessors are requested to use a standardized answer: “No information has been found.”
- The classification of pathways developed by the Convention of Biological Diversity shall be used For detailed explanations of the CBD pathway classification scheme consult the IUCN/CEH guidance document<sup>11</sup> and the provided key to pathways<sup>12</sup>.
- With regard to the scoring of the likelihood of events or the magnitude of impacts see Annexes I and II.
- With regard to the confidence levels, see Annex III.

### PROBABILITY OF INTRODUCTION and ENTRY

#### Important instructions:

- Introduction is the movement of the species into the risk assessment area.
- Entry is the release/escape/arrival in the environment, i.e. occurrence in the wild. Not to be confused with spread, the movement of an organism within the risk assessment area.
- For organisms which are already present in the risk assessment area, only complete this section for current active or if relevant potential future pathways. This section need not be completed for organisms which have entered in the past and have no current pathway of introduction and entry.

QUESTION	RESPONSE [chose one entry, delete all others]	CONFIDENCE [chose one entry, delete all others]	COMMENT
1.1. How many active pathways are relevant to the potential introduction of this organism?  (If there are no active pathways or potential future	<b>few</b>	<b>high</b>	In Europe, the occurrence of <i>X. laevis</i> in the wild is thought to be a consequence of its use as a research model in laboratories and as a pet (Measey et al. 2012, Tinsley et al. 2015a, Rebelo

<sup>11</sup> <https://circabc.europa.eu/sd/a/738e82a8-f0a6-47c6-8f3b-aeddb535b83b/TSSR-2016-010%20CBD%20categories%20on%20pathways%20Final.pdf>

<sup>12</sup> <https://circabc.europa.eu/sd/a/0aeba7f1-c8c2-45a1-9ba3-bcb91a9f039d/TSSR-2016-010%20CBD%20pathways%20key%20full%20only.pdf>

<p>pathways respond N/A and move to the Establishment section)</p>			<p>et al. 2010). The main active pathways are therefore the following:                  1) Pet/aquarium/terrarium species (escape from confinement);                  2) Research and ex-situ breeding (in facilities) (escape from confinement).</p> <p>As pointed out by Tinsley &amp; McCoid (1996), it may be due to many factors, such as loss of interest, end of an experiment, misguided ethics or curiosity, which occasionally results in the release of captives. Deliberate release are also reported, along with escapes (Measey et al. 2012). The actual scale of releases and escapes is unknown. In fact, in most cases the exact cause is only inferred retrospectively, as the species is often detected only many years after its deliberate or accidental introduction. For example, in Portugal the species lived undetected for more than 20 years (Sousa et al. 2018). In such cases, it is clear that it is not possible to establish the intentionality of the introduction without the relevant events being appropriately documented.</p>
<p>1.2. List relevant pathways through which the organism could be introduced. Where possible give detail about the specific origins and end points of the pathways as well as a description of any associated commodities.</p> <p>For each pathway answer questions 1.3 to 1.10 (copy</p>	<p>1) Pet/aquarium/terrarium species (escape from confinement)                  2) Research and ex-situ breeding</p>		<p>In addition to the use of the species as a research model in laboratories and as a pet (which leads to the main two active pathways already identified), other uses are known.</p> <p>For example, the species has been used in schools for training in labs (e.g. dissections etc.),</p>

<p>and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 1.3a, 1.4a, etc. and then 1.3b, 1.4b etc. for the next pathway.</p>	<p>(in facilities) (escape from confinement)</p>		<p>which can be a source of animals released in the wild. While there is no documented evidence of such releases in Europe, in the US, schools are known to ditch their stock when legislation changed making keeping invasive species illegal. The law changed without making any provision for people already keeping them (John Measey, pers. comm. 2018). In any case, the use of animals in schools is treated here under the pathway “Research and ex-situ breeding (in facilities)”, see point 1.4b below.</p> <p>As reported by Weldon et al. (2007) in South Africa <i>X. laevis</i> is appreciated as live bait for freshwater angling (despite this practice being illegal). As a consequence, fishermen are known to seed dams with <i>X. laevis</i> in order to produce a local supply of live bait (Measey et al. 2017). However, this is not considered an active pathway in Europe.</p> <p>Zoo exhibit of this species is also mentioned as a former pathway in the late 1900s (Vredenburg et al. 2013), and although the species is still present in public zoos/aquaria, zoos (escape from confinement) are not considered as an important pathway of introduction of the species in Europe. Whilst there is no data available on the total population within all zoological collections in the EU, information was provided by EAZA (European Association of Zoos and Aquaria) on populations kept at approximately 300 of their</p>
---	--	--	---

			Member zoos and aquariums in 26 EU Member States (with the exceptions of Cyprus and Malta). The information provided by EAZA (EAZA, pers. comm. 2018) indicates that 84 specimens in total are kept by 15 zoo/aquarium EAZA Members in 10 Member States (BE, HU, DK, NL, IE, DE, PT, PL, EE, FR) and the United Kingdom. On top of this, in total 5 specimens of the subspecies <i>Xenopus laevis</i> are kept by 1 zoos/aquariums EAZA Members in one Member State (CZ). This data comes from the animal care and management software provided by Species360 Zoological Information Management System (ZIMS) (zims.Species360.org, 2018) whose usage is widespread throughout the EAZA Membership. It must be noted that the actual situation might slightly differ if the species has been recorded under a different/older taxonomic name (as in the case of <i>X. laevis</i> ).
Pathway name:	<b>1) Pet/aquarium/terrarium species (escape from confinement)</b>		
1.3a. Is introduction along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?	<b>intentional</b>	<b>high</b>	<i>X. laevis</i> is traded by the pet sector in several Member States of the EU as well as in UK, with the albino morph being predominant in this trade. The species is also traded through e-commerce

<p>(if intentional, only answer questions 1.4, 1.9, 1.10, 1.11 – delete other rows<sup>13</sup>)</p>			<p>and other internet platforms (although numbers are unknown). The introduction in the risk assessment area through this pathway is intentional. However, the entry into the environment is either intentional or unintentional, depending on whether it is the result of deliberate releases or accidental escapes.</p> <p>Despite the general lack of documented evidence regarding the significance of this pathway for the entry of the species into the environment, there are indications that this pathway is active in Europe, as well as in other parts of the world. For example, according to Measey et al. (2012) the source of a population once occurring near Scunthorpe, Humberside, in the north-east of England, is thought to be due to the closure of a pet shop and the deliberate release of adults in the mid-1990s. EPO-OFI (2019) on the other hand consider that there seems to be no substantive evidence that the closure of the pet shop led to a deliberate release or that the speculated pet shop ever kept <i>Xenopus</i>. They consider it possible that the population in question existed prior to the closure of this shop.</p> <p>The trade and possession of the species is not regulated in most Member States and EPO</p>
--	--	--	---

<sup>13</sup> While the pathways of introduction are considered intentional, it was considered necessary to answer all questions since the subsequent entry into environment could be either intentional or unintentional.

		<p>(2018) reported that trade is ongoing between different countries in the risk assessment area (the Netherlands, Czech Republic) and the UK. On the other hand, the species is regulated in other Member States, subjecting its trade and/or possession to diverse national measures, e.g.</p> <ul style="list-style-type: none"> <li>• Possession and trading of <i>X. laevis</i> is prohibited in Spain (Real Decreto 630/2013, de 2 de Agosto<sup>14</sup>).</li> <li>• In Portugal, the species is included in the national list of invasive alien species under the Decree-law of 1999 and subsequently that of 2019<sup>15</sup>.</li> <li>• In France, the release of the species into the environment is forbidden<sup>16</sup>. Keeping the species requires an authorisation and a certificate of competence (though this is not limited to professionals) and it is prohibited to exhibit the species for sale<sup>17</sup>.</li> </ul> <p>In Chile there is evidence of continuous releases (meaning that animals were moved from within the invasion area to a new area) which helped the species spread, and which are presumed to be connected with the use of animals in the pet trade, as private owners were suspected of dumping them (Lobos &amp; Jaksic 2005, Measey et</p>
--	--	--

<sup>14</sup> <https://www.boe.es/buscar/act.php?id=BOE-A-2013-8565>

<sup>15</sup> Decreto-Lei n.o 565/99 de 21 de Dezembro and Decreto-Lei n.º 92/2019 de 10 de julho

<sup>16</sup> Arrêté du 14 février 2018 propagation des espèces animales exotiques envahissantes sur le territoire métropolitain – Annexe I

<sup>17</sup> Arrêté du 8 octobre 2018 fixant les règles générales de détention d'animaux d'espèces non domestiques – Article 14

			<p>al. 2012). Also in the USA, there is evidence of animal importer dumping unwanted stock, e.g. in Florida (King and Krakauer 1966), or intentionally released by a single person, in Arizona (Somma 2018, Tinsley and McCoid, 1996).</p>
<p>1.4a. How likely is it that large numbers of the organism will travel along this pathway from the point(s) of origin over the course of one year?</p> <p>Subnote: In your comment discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.</p>	<p><b>very likely</b></p>	<p><b>medium</b></p>	<p>In general, information on the origin of animals, exact number of individuals in trade and those in captivity, is not available. Also, no information could be retrieved on number of introduction events and number of individuals (either adults or larvae) escaped and/or released in the environment, hence it is not possible to assess the propagule pressure.</p> <p>However, according to the European Pet Organization (EPO 2018) in relation to animal traded in the UK, <i>X. laevis</i> is captive bred and none are wild caught. The extent of breeding in other EU Member States is unknown. In terms of numbers traded the data provided (EPO 2018) suggest a widespread range between the different countries with the lowest value being 100 animals sold per annum to the highest value of tens of thousands of animals being sold per annum. Therefore, due to this wide range of values, EPO was unable to provide median or average numbers/volumes due to the skewed nature of the raw data. EPO did not provide the raw data given that this information is commercially sensitive. It is however evident that</p>

		<p>the highest numbers concern the trade within UK.</p> <p>Information from other regions may help to figure out the dimension of the problem although the pet trade markets in the USA and Europe may not be directly comparable. As regards the USA, it is worth mentioning that across the last decades <i>X. laevis</i> trade has changed dramatically in terms of primary purpose, frogs' origin and numbers of animals traded. The species was originally distributed for pregnancy testing and laboratory use, but in the last 15 years, the size of the trade for medicine and science dropped to only 0.1% of imports, with the pet trade commanding 99.6% (Measey 2017). Trade figures reported by Measey (2017) for the USA are impressive (see also Herrel and van der Meijden, 2014). Whilst trade for medical and scientific purposes is now minimal (a few hundred animals per year), the pet trade imported 1.83 million live animals over the last 15 years (a total of 1,856 shipments which ranged from single animals to 11.5 thousand individuals). Just to give an idea of the global trade network supporting such trade, 75% of these animals are imported from Hong Kong (although it is possible that many animals originate from mainland China or elsewhere). It is also worth noting that all of these animals from China appear to be albinos, and there are currently no published reports of invasive albino populations, despite a single exception recently found in China (John Measey, pers. comm. 2018,</p>
--	--	--

		<p>Wang et al. 2019). Only 5,600 animals were imported from the native area in South Africa, and this trade ceased in 2003. Nearly 200,000 individuals were imported from Chile and the majority of these were reported as being wild caught, suggesting that the invasive population there is being exported for the US pet trade (Measey 2017).</p> <p>Given the supposed widespread presence of this species in the pet trade in several countries, the risk of reinvasion after eradication is to be considered as likely as a first introduction. There are no specific studies providing an indication of the propagule pressure, but single gravid females can indicatively contain from 1,000 to 27,000 eggs per clutch (noting though that the number of 27,000 is not the norm, numbers are usually much less). Furthermore, females will produce multiple clutches in a season under favourable conditions (Global Invasive Species Database 2015), therefore even a handful of individuals may be sufficient to start a new population.</p> <p>In fact, as shown by Lobos et al. (2014), the invasion of <i>X. laevis</i> in Chile has been successful for at least 30 years, in spite of low genetic variability, few events of introduction, low propagule pressure, and bottlenecks in the founding population. Also according to Measey et al. (2012) propagule pressure plays a pivotal role in the establishment of <i>X. laevis</i>, as some</p>
--	--	---

			populations became established after the release of large numbers of animals from breeding facilities (laboratory and pet supplies). Other evidence of populations that have established from very few individuals is not available (John Measey, pers. comm. 2018).
1.5a. How likely is the organism to survive during passage along the pathway (excluding management practices that would kill the organism)?  Subnote: In your comment consider whether the organism could multiply along the pathway.	<b>very likely</b>	<b>medium</b>	The species is able to survive during passage along the pathway, as demonstrated by the fact that it has been frequently traded and that the origin of some populations successfully established after animals being released in (or escaped into) the wild is attributed to this pathway.
1.6a. How likely is the organism to survive existing management practices during passage along the pathway?	<b>very likely</b>	<b>low</b>	No information has been found. Trade is intentional, and as such there is no management practice in place to prevent the species entering the risk assessment area. Also, there are no known specific practices for preventing this species from escaping or being released in the wild. Existing biosecurity guidance concentrates in the prevention of disease transmission when species are transferred (OATA 2012).
1.7a. How likely is the organism to enter the risk assessment area undetected?	<b>very likely</b>	<b>high</b>	While animals intentionally introduced in the risk assessment area for the pet trade are not undetected, those being introduced in the wild as a consequence of accidental escapes or intentional releases can be undetected for many years (see point 2.7a below)

<p>1.8a. How likely is the organism to arrive during the months of the year most appropriate for establishment?</p>	<p><b>moderately likely</b></p>	<p><b>medium</b></p>	<p>We are not certain whether any particular time of the year is more appropriate for establishment. It is likely that <i>X. laevis</i> could establish during any month of the year. In any case, traded animals may arrive and be released or escape at any time during the year in Europe, but data about frequency and months of the year are unknown.</p>
<p>1.9a. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host?</p>	<p><b>moderately likely</b></p>	<p><b>medium</b></p>	<p>It is likely that people who deliberately release <i>X. laevis</i> into the wild will do it in what they consider the most suitable habitat. As a remark, <i>X. laevis</i> is a vigorously adaptable species which may virtually inhabit any type of water bodies, including lakes and rivers, as well as permanent and temporary ponds, over a wide range of altitudes and temperatures (Measey 1998). Besides <i>X. laevis</i> thrives in disturbed landscapes and artificial habitats, like ponds, wells, dams, irrigation canals and other domestic and agricultural water sources (Tinsley et al. 2015a, Lobos &amp; Jaksic 2005). This clearly increases the likelihood of the species being introduced, either intentionally or accidentally, into suitable habitats. There is also a high likelihood that additional translocations by humans within the risk assessment area may occur (see also Qu. 2.1 and 2.2), hence increasing the opportunities for the species introduction within the risk assessment area.</p> <p>In addition, as pointed out by Measey et al. (2012) biosecurity at breeding facilities is clearly</p>

			<p>of paramount importance.</p> <p>It is reasonable to assume that maintenance staff in pet wholesaler/retailer premises may have received in-house training, as also suggested by EPO 2019. Furthermore, codes of conduct (e.g. Council of Europe, 2011) call for promoting awareness of invasiveness and of the need not to release pets in the environment in general. However, care sheets addressed to keepers of <i>X. laevis</i> as pets available in the public domain concentrate on animal welfare considerations with very little or no information regarding the prevention of escapes and in any case with no advice against releases into environment and the potential environmental impacts of such releases (e.g. Reed 2009, amphibian.co.uk).</p>
1.10a. Estimate the overall likelihood of entry into the risk assessment area based on this pathway?	<b>very likely</b>	<b>high</b>	<p>In current conditions, it is very likely that the species will enter the environment within the risk assessment area through this pathway. The species is known to be present in the pet trade in Europe, and has already been recorded in the wild in the region, possibly also as a consequence of this pathway.</p>
Pathway name:	<b>2) Research and ex-situ breeding (in facilities) (escape from confinement)</b>		
1.3b. Is introduction along this pathway intentional (e.g. the organism is imported for trade) or unintentional (e.g. the organism is a contaminant of imported goods)?	<b>intentional</b>	<b>high</b>	<p>The species is traded as model amphibian in scientific research, and as such the introduction in the risk assessment area through this pathway is intentional. However, entry into the environment is</p>

<p>(if intentional, only answer questions 1.4, 1.9, 1.10, 1.11 – delete other rows)</p>			<p>either intentional or unintentional, depending on whether it is the result of deliberate releases or accidental escapes. Despite the general lack of documented evidence regarding the exact pathway of introduction for this species, there are clues of this pathway being active in Europe, as well as in other parts of the world. For example, in France the suspected origin of the species was a breeding facility of the CNRS in Fronteau, Bouillé St Paul (Fouquet 2001), a laboratory supplier for French research institutions (Measey et al. 2012). In Portugal, the species was likely introduced following a flood of the 1979/1980 winter in the laboratories, where the species was used, although this is unconfirmed (Rebelo 2010, Sousa et al. 2018).</p>
<p>1.4b. How likely is it that large numbers of the organism will travel along this pathway from the point(s) of origin over the course of one year?</p> <p>Subnote: In your comment discuss how likely the organism is to get onto the pathway in the first place. Also comment on the volume of movement along this pathway.</p>	<p><b>very likely</b></p>	<p><b>high</b></p>	<p>There is evidence linking the occurrence of invasive alien populations with the trade and use of this species for biomedical research, although other secondary pathways seem to be involved as well (van Sittert &amp; Measey 2016).</p> <p>The history of the use and trade of the species started in the 1930s with the use in pregnancy testing until the 1960s, and later for laboratory use as model organism (Gurdon and Hopwood 2000, Measey et al. 2012, Tinsley et al. 2015a, van Sittert &amp; Measey 2016). This led to exports of thousands of live animals from its native South African Cape region to laboratories, first to the United Kingdom and eventually all over the world. By 1970, as</p>

		<p>demonstrated by van Sittert &amp; Measey (2016), <i>X. laevis</i> was the world’s most widely distributed amphibian: institutions in 48 countries were supplied with live animals on all continents except Antarctica. In fact, as summarized by Weldon et al. (2007), the use of this species as a model amphibian in scientific research (i.e. genetics, molecular biology, embryology, biochemistry and ecotoxicology) was increasingly popular in the 1970s, and <i>X. laevis</i> became the most widely used amphibian in research in the 1990s. In terms of numbers, over 10,000 animals were exported annually from South Africa between 1998 and 2004 to 132 facilities situated in 30 countries (Weldon et al. 2007). However, there is still no known information on how many animals were shipped privately and where they were shipped to, during this period. Additionally, the secondary movement between places that were supplied also appears to be important (John Measey, pers. comm. 2018).</p> <p><i>X. laevis</i> was also used for educational and training purposes in schools and universities (e.g. dissection classes). However, this use seems declining markedly due to ethical concerns and financial constraints (Reed 2005).</p> <p>Of note here is the link between tadpoles and home teaching: in many cases, the tadpoles are reared in large numbers and then many are euthanized. Some individuals will give tadpoles over to parents to</p>
--	--	--

			<p>raise them at home, or liberate tadpoles. This is less likely in the pet trade, but may happen in tertiary education institutes where <i>X. laevis</i> is a teaching model (John Measey, pers. comm. 2018).</p> <p>Given the widespread presence of this species in research facilities in several countries (see section A13), the risk of reinvasion after eradication is to be considered as likely as a first introduction.</p>
<p>1.5b. How likely is the organism to survive during passage along the pathway (excluding management practices that would kill the organism)?</p> <p>Subnote: In your comment consider whether the organism could multiply along the pathway.</p>	<b>very likely</b>	<b>medium</b>	<p>The species is able to survive during passage along the pathway. Actually, specimens are intentionally transported for use in laboratories. According to EXRC (2019), most laboratories import animals either from the CRB Xenopus in Rennes, NASCO in the US or the EXRC; only a few breed their own. I.e. every effort is made that specimens survive the transport in the best condition possible.</p>
<p>1.6b. How likely is the organism to survive existing management practices during passage along the pathway?</p>	<b>likely</b>	<b>low</b>	<p>No exhaustive information has been found. Movements of animals for their use in research activities is intentional, and as such there is no management practice in place to prevent the species being introduced into the risk assessment area. Specimens shipped to laboratories may be done mostly by specialised services, but the main reason seems to be the reduction of stress to which the animals will be subject to.</p>
<p>1.7b. How likely is the organism to enter the risk assessment area undetected?</p>	<b>very likely</b>	<b>high</b>	<p>The intentional introduction of animals in the risk assessment area for use in research activities cannot go undetected, but those animals being</p>

			introduced in the wild as a consequence of accidental escapes or intentional releases can be undetected for many years (see point 2.7a below).
1.8b. How likely is the organism to arrive during the months of the year most appropriate for establishment?	<b>moderately likely</b>	<b>medium</b>	We are not certain whether any particular time of the year is more appropriate for establishment. It is likely that <i>X. laevis</i> could establish during any month of the year. In any case, traded animals may arrive and be released or escape at any time during the year in Europe, but data about frequency and months of the year are unknown.
1.9b. How likely is the organism to be able to transfer from the pathway to a suitable habitat or host?	<b>moderately likely</b>	<b>medium</b>	As pointed out in the GB risk assessment for the species (NNS 2011), most of the African clawed frogs that are present in captivity in the UK are owned by commercial laboratories, which will be careful to prevent escapes. These laboratories are generally run by competent people who have an interest in amphibians and who realise the negative consequences of releasing these animals into the wild. Measey et al. (2012) seem less optimistic, as they recognise that biosecurity at breeding facilities is clearly of paramount importance, but the maintenance staff in laboratories may not have appropriate information or relevant training. In fact according to Measey et al. (2012) in at least one case tadpoles of <i>X. laevis</i> were released routinely for many years into a pond of university property, despite the fact that the person releasing these tadpoles was instructed to euthanise them. In another case, tadpoles had been given to local schools and friends for learning purposes (Measey

		<p>et al. 2012). Releases or escapes and successful establishment of populations in the wild have been attributed in the past to this pathway. Laboratory security has been increasingly improving over the years so escapes are now considered much less likely. However, people working with alien species (even when in special facilities) should be made aware of the issues concerning release (John Measey, pers. comm. 2018).</p> <p>In this regard, it should be noted that guidance available in the public domain usually refers to animal welfare considerations with little emphasis to biosecurity rules. Reed (2005) for example states: <i>“Containers must prevent escape and should allow space for sufficient volume and depth of water and for enrichment such as refuges to be added. A tank size of 65 x 45 x 45cms has been recommended ... for holding four to five frogs in 5 to 10 litres of water. A tank of this depth should (depending upon the water depth) prevent Xenopus from jumping out. An overhanging lip will further act to prevent escapes”</i>. Similarly, the UK Code of Practice for the Housing and Care of animals bred for scientific purposes (UK Home Office, 2014) is mostly about animal welfare and not about prevention of environmental impacts due to escapes or releases of animals in the environment.</p> <p>In conclusion, the likelihood of the species being intentionally released in the wild, in a suitable habitat, cannot be excluded. Furthermore, there is</p>
--	--	--

			<p>always the risk of unexpected events which may cause the escape of the animals, as was the case in Portugal where a laboratory experienced flooding, although this event was not confirmed (Measey et al. 2012, Sousa et al. 2018).</p> <p>As an additional remark, Measey et al. (2012) expressed concern about the future risk of laboratory populations of <i>X. laevis</i> which - due to the possible replacement of this species with <i>X. tropicalis</i> as a research model organism - may be dismissed and dumped in the environment. In fact, although there are no documented instances with respect to academic replacement of model organisms, there are examples of this in the US where school pets became illegal to keep and animals were dumped (John Measey, pers. comm. 2018). Given the instruction to euthanize a large number of animals, many people will still choose to dump living animals into the natural environment, if they do not have specific knowledge of the potential consequences of such release (John Measey, pers. comm. 2018).</p>
<p>1.10b. Estimate the overall likelihood of entry into the risk assessment area based on this pathway?</p>	<p><b>likely</b></p>	<p><b>high</b></p>	<p>In current conditions, it is likely that the species can still enter into the wild in the risk assessment area based on this pathway. The species is already present in research facilities in Europe, and has already been recorded in the wild in the risk assessment region, possibly as a consequence of this pathway.</p>

<p><i>End of pathway assessment, repeat as necessary.</i></p>			
<p>1.11. Estimate the overall likelihood of entry into the risk assessment area based on all pathways and specify if different in relevant biogeographical regions in current conditions (comment on the key issues that lead to this conclusion).</p>	<p><b>very likely</b></p>	<p><b>high</b></p>	<p>The overall likelihood of entry into the risk assessment area based on all pathways is very high in current conditions, particularly given the fact that the species is present in trade and in breeding facilities in many countries, possibly in all biogeographical regions.</p>
<p>1.12. Estimate the overall likelihood of entry into the risk assessment area based on all pathways in foreseeable climate change conditions?</p>	<p><b>very likely</b></p>	<p><b>medium</b></p>	<p>As reported by Tinsley et al. (2015a) the species originates from Western Cape, South Africa, and has been introduced on four continents, mostly in areas with a similar Mediterranean climate, but also in cooler environments (where persistence for many decades suggests a capacity for long-term adaptation). This suggests that recent climate warming might enhance invasion ability, favouring range expansion, population growth and negative effects on native faunas (Tinsley et al. 2015a). The introductions occurring well out of the Mediterranean climate zone, show the risk that an increasing number of invasions may occur, and that these <b>are not</b> reported in the literature very quickly (John Measey, pers. comm. 2018).</p> <p>In fact, under foreseeable climate change, the global invasion potential of this species for 2070 assessed by Ihlow et al. (2016) following four IPCC scenarios (i.e. RCP2.6, RCP4.5, RCP6, RCP8.5) may expand in north-western Europe and the Mediterranean area. In fact recent studies show</p>

			<p>that invasive populations of <i>X. laevis</i> are established well beyond the species' multivariate realized niche in southern Africa (Rödder et al. 2017). The maps shown in the paper by Ihlow et al. (2016) and Rödder et al. (2017) do not allow a precise identification of the biogeographic regions where the species could establish in the future under foreseeable climate change.</p> <p>A recent study by Ginal et al. (2020) revealed a much higher risk of invasion, especially for most parts of Europe. However, it does not provide detailed maps for countries and biogeographic regions showing the precise potential invasive range of the species in Europe.</p> <p>In conclusion, the likelihood of entry into the risk assessment area based on all pathways in foreseeable climate change condition is likely to be the same as in current conditions (see above). However, no documented evidence exists to support this statement.</p>
--	--	--	---

<b>PROBABILITY OF ESTABLISHMENT</b>			
<p>Important instructions:</p> <ul style="list-style-type: none"> <li>For organisms which are already established in parts of the risk assessment area, answer the questions with regard to those areas, where the species is not yet established. If the species is established in all Member States, continue with Question 1.16.</li> </ul>			
<b>QUESTION</b>	<b>RESPONSE</b>	<b>CONFIDENCE</b>	<b>COMMENT</b>
1.13. How likely is it that the organism will be able to establish in the risk assessment area based on the similarity between climatic conditions within it and the organism's current distribution?	<b>very likely</b>	<b>high</b>	According to Measey et al. (2012) a large suitable climatic potential was identified for most of southern Portugal and adjoining Spain, as well as central and southern France, and mainland Italy. Such data are consistent with the findings of Ihlow et al. (2016), who highlighted areas in the main Mediterranean islands (namely the Balearic Islands, Sardinia, and Corsica) to be highly vulnerable to potential invasions. According to Measey et al. (2012), a few suitable areas were found in the United Kingdom outside southern coastal areas, plus Greece, Ireland, Germany, Belgium, Denmark and the Netherlands (for details see maps developed by Measey et al. 2012). Ihlow et al. (2016) predict only moderate probability for Great Britain. Despite this, the species has had persistent populations in the UK that are now extinct.
1.14. How likely is it that the organism will be able to establish in the risk assessment area based on the similarity between other abiotic conditions within it	<b>very likely</b>	<b>high</b>	<i>X. laevis</i> is a vigorously adaptable species which may virtually inhabit any type of water bodies, including lakes and rivers, as well as

<p>and the organism's current distribution?</p>			<p>permanent and temporary ponds, over a wide range of altitudes and temperatures (Measey 1998). Besides that, <i>X. laevis</i> thrives in disturbed landscapes and artificial habitats, like ponds, wells, dams, irrigation canals and other domestic and agricultural water sources (Tinsley et al. 2015a, Lobos &amp; Jaksic 2005). These habitats are widespread all over the EU, including countries where the species is not yet established. Additionally, Moreira et al (2017) have recently documented that this species can breed in both lotic and lentic environments. The use of lotic habitats may open up even more habitats for breeding, and may contribute to the maintenance of the invasive population even in the absence of lentic sites.</p>
<p>1.15. How widespread are habitats or species necessary for the survival, development and multiplication of the organism in the risk assessment area?</p>	<p><b>widespread</b></p>	<p><b>high</b></p>	<p><i>Xenopus</i> species in sub-Saharan Africa inhabit virtually all water bodies, including large rivers and lakes, as well as permanent and temporary ponds over a wide range of altitudes and temperatures (Measey 1998). According to John Measey (pers. comm. 2018), animals are often found in very low abundance (and occasionally very high) in natural systems, but numbers can become overwhelming in modified habitats. The latter are normally enriched and eutrophic, which probably helps build up their numbers. Measey et al. (2012) pointed out that comparatively few reports exist of <i>X. laevis</i> in</p>

		<p>its natural habitat, hence the lack of knowledge about the native ecology and natural dispersal of this globally invasive species. However, there are a few studies on the invasive range which provide useful information on this regard. For example, according to a study on habitat suitability carried out in Chile, Lobos et al. (2013) confirm that lentic aquatic environments, with slow drainage and murky waters, highly connected, human-disturbed, and part of an irrigation system of small streams and canals, account for the highest probabilities of successful establishment of <i>X. laevis</i> within the area of invasion. As reported by Lobos &amp; Jaksic (2005) <i>X. laevis</i> in Chile lives from almost sea level up to 620m, and inhabit quite a diverse array of habitats with regard to water temperature, dissolved oxygen, pH, and electric conductivity, indicating a high degree of adaptability and colonization potential.</p> <p>In France, the species is found in a wide range of aquatic habitats and seems to have progressed very quickly along river valleys. Large rivers do not present barriers to the expansion of the species (and may even support further spread). It is likely that it used for its spread the watercourse or the wetlands associated to the river Loire (LIFE CROAA, pers. comm. 2019). Also a recent study by Ginal et al. (2020) has pointed out the</p>
--	--	--

		<p>importance of river networks in assisting the expansion even in areas with moderately suitable conditions. In the case of the French population, the same authors expressed concern that an ongoing shift in the fundamental niche of the French population combined with scenarios of climate change could lead to further expansion into new ranges, which are currently predicted to be unsuitable for this species. In particular, the French invasive population seems to make use of hydrographic networks and has now reached the Loire River catchment which covers about 20% of the French national territory (Ginal et al. 2020).</p> <p>It is also worth noting that animals are found in isolated ponds that are unconnected, like in France and Sicily, which means that <i>X. laevis</i> is able to move overland (John Measey pers. comm. 2018). Overland movements amongst various types of lentic and lotic water bodies seem to be frequent in this species (Ginal et al. 2021) although the possible contribution of man-mediated releases should be also taken into account in these cases.</p> <p>A study by Moreira et al (2017) in Portugal documented that <i>X. laevis</i> breeds in small streams and ponds, suggesting that while lentic sites are most likely responsible for population booms, the potential reproduction</p>
--	--	---

			<p>in lotic sites may contribute to the maintenance of the invasive population even in the absence of lentic sites.</p> <p>There are numerous ponds, lakes and other water bodies that are potentially suitable for the survival, development and multiplication of this species in the risk assessment area.</p>
1.16. If the organism requires another species for critical stages in its life cycle then how likely is the organism to become associated with such species in the risk assessment area ?	<b>NA</b>		There is no information suggesting that <i>X. laevis</i> requires another species for critical stages in its life cycle.
1.17. How likely is it that establishment will occur despite competition from existing species in the risk assessment area?	<b>very likely</b>	<b>high</b>	<p><i>X. laevis</i> has only a few competitors that may prevent its establishment in the EU, the most effective being fish (e.g. eels), but the species may find suitable habitats where such competitors are absent (see Tinsley et al. 2015a). According to John Measey (pers. comm. 2018) fish appear to influence where animals will colonise, and it is possible that this could be used to prevent further invasions (e.g. a ring of ponds with introduced fish). Other non-native competitors are mentioned by Prinsloo et al. (1981), i.e. the Chinese silver carp, <i>Hypophthalmichthys molitrix</i>, as both the tadpoles and the silver carp compete for phytoplankton as food, and the Chinese bighead carp <i>Aristichthys nobilis</i> (zooplankton feeder). <i>Xenopus laevis</i> may live in the same ponds as crabs and terrapins, and undergo</p>

			<p>significant predation and mutilation from these groups, but without moving (John Measey, pers. comm. 2018).</p>
<p>1.18. How likely is it that establishment will occur despite predators, parasites or pathogens already present in the risk assessment area?</p>	<p><b>very likely</b></p>	<p><b>high</b></p>	<p>In Africa, <i>X. laevis</i> have evolved morphological, behavioural, and biochemical predator avoidance strategies, and in extralimital situations, for example in California, it is likely that predatory pressure is considerably reduced (for example by occupying sites lacking predatory fish), thus contributing to the success and spread of <i>X. laevis</i> (McCoid and Fritts, 1980).</p> <p>Despite the lack of dedicated studies on the issue, the situation in the EU may be similar (as demonstrated also by the successful spread of the species in some countries). However, a recent study by Kruger et al. (2019) shows anti-predator response of <i>X. laevis</i> to a Dytiscid beetle (<i>Dytiscus dimidiatus</i>), probably a generic response, and even to the invasive crayfish <i>Procambarus clarkii</i>. These responses were observed in naïve tadpoles suggesting that anti-predator behaviour are evolving in the invasive range, in France at least.</p> <p>In principle, <i>X. laevis</i> can be a prey for several species, including fish, snakes, birds and mammals. For example, in the UK, <i>X. laevis</i> may be eaten by fish and amphibian predators</p>

		<p>including herons, American mink (<i>Neovison vison</i>) and, possibly, grass snakes (<i>Natrix helvetica</i>). Eels are potential predators too (Tinsley et al. 2015a). During a study in western France, Eggert and Fouquet (2006) showed that predation by the polecat (<i>Mustela putorius</i>) was deemed the major adult mortality factor, together with (assumed) freezing. Predation by gulls has been observed on a site with high density in a wastewater treatment unit (LIFE CROAA, pers. comm. 2019).</p> <p>In its native range in South Africa, <i>X. laevis</i> is eaten by large fish, turtles, frogs, snakes, aquatic insects, and birds (Lafferty &amp; Page, 1997). This list is actually far longer. Almost every predator eats the adults, crabs eat the eggs and larvae, and odonates and fish eat the tadpoles (John Measey, pers. comm. 2018). Similarly, in its introduced range outside the EU, i.e. in Chile, three bird species were observed to prey on <i>X. laevis</i>: Night heron (<i>Nycticorax nycticorax</i>), Kelp gull (<i>Larus dominicanus</i>) and Burrowing owl (<i>Speotyto cunicularia</i>) (Lobos &amp; Jaksic (2005). In the USA <i>X. laevis</i> is preyed upon by Two-striped Garter Snakes (<i>Thamnophis hammondi</i>). Large fish, and the American Bullfrog, (<i>Lithobates catesbeianus</i>) are considered to be potential predators as well (Lafferty &amp; Page, 1997). Additionally, according to Prinsloo et</p>
--	--	---

			<p>al. (1981), the largemouth bass (<i>Micropterus salmoides</i>) is a known “biological control” against <i>X. laevis</i>. A recent study by Lobos (2020) carried out in Chile through laboratory assays provided evidence of the vulnerability of <i>X. laevis</i> to the eastern mosquitofish (<i>Gambusia holbrooki</i>). The results seemed confirmed by the recent establishment of <i>G. holbrooki</i> in a site which resulted in a collapse in the reproduction and adult populations of <i>X. laevis</i>. <i>Gambusia holbrooki</i> is an invasive alien species in Europe, but its impact on <i>X. laevis</i> was not yet studied in this region.</p> <p>Regarding parasites and pathogens, <i>X. laevis</i> carries a rather diverse parasite load, and does not seem to be particularly affected by any of them. In Portugal for example, this species was found to be infected by autochthonous parasites, probably as spillover from <i>Pelophylax perezi</i> (Rodrigues 2014). However, the parasite burden was not as high as in the species they co-exist with, or as high as in the habitats where it is native, which in fact could enable this species to dominate the streams where it was recently introduced.</p>
<p>1.19. How likely is the organism to establish despite existing management practices in the risk assessment area?</p>	<p><b>very likely</b></p>	<p><b>medium</b></p>	<p>There are no specific management practices in place in the EU which may prevent the organism from establishing wild populations (as demonstrated by the successful establishment of the species in some</p>

			<p>countries). Fish species released (e.g. for sport and angling) may predate on <i>X. laevis</i>, like the non-native largemouth bass (<i>Micropterus salmoides</i>) but this is not considered as a practice targeted to the management of <i>X. laevis</i> in the risk assessment area. Release of <i>Micropterus salmoides</i> as biological control agent of <i>Xenopus laevis</i> was tried in South Africa (Prinsloo et al. 1981). The species may anyway occupy sites lacking predatory fish.</p>
<p>1.20. How likely are existing management practices in the risk assessment area to facilitate establishment?</p>	<p><b>moderately likely</b></p>	<p><b>low</b></p>	<p>Overall, the species is known to thrive in highly disturbed habitats. For example, in southern California this is considered a common factor in all established populations (McCoid and Fritts, 1980). Therefore, it is likely that management of water bodies facilitates the establishment of the species by contributing to the creation of suitable habitats.</p> <p>However, there are opposite views. For example, management of UK water bodies and connecting habitats tends to be more intense than in many parts of the natural range of <i>X. laevis</i> which would in fact be more likely to hinder, rather than aid, establishment (NNSS 2011).</p> <p>Certain methods of wastewater treatment seems to facilitate the establishment of the species. In France and South Africa, the</p>

			<p>species thrives in units for the treatment of domestic wastewater. These are a string of connected ponds with no specific treatment but with eutrophic waters and higher temperature than other water bodies. In the context of the ongoing LIFE project CROAA (2016-2022), such ponds were fenced and a single unit yielded several thousand captured individuals in less than a year (LIFE CROAA, pers. comm. 2019).</p>
<p>1.21. How likely is it that biological properties of the organism would allow it to survive eradication campaigns in the risk assessment area?</p>	<p><b>likely</b></p>	<p><b>medium</b></p>	<p>The species went likely extinct by natural means in the UK. However, eradication at a few sites (Measey et al. 2012) using a deliberate, targeted eradication campaign to eliminate the species fairly rapidly was considered a possibility, although follow-up surveys and control measures would be necessary (NNSS 2011).</p> <p>Small eradication campaigns were carried out successfully in the UK, Spain, and the USA (Measey et al. 2012) but in general this was only possible in small areas and at an early stage of invasion. The chances of success seem related more to the specificities of the water bodies affected (e.g. type, size, and overall network) rather than to the biological properties of the species. For example, care must be taken about when this is done as individuals are capable of surviving in the ground for many months (John Measey, pers.</p>

			<p>comm. 2018). Otherwise it is clear that the appropriate methodologies need to be identified carefully in relation to the species biological properties. For example, high concentrations of Rotenone failed to eradicate clawed frogs in Los Angeles County (St. Amant, 1975), because clawed frogs are air breathers (McCoid and Fritts, 1980). In France, a complete eradication of the species is considered impossible in the valley of the Loire due to the large size of the population and the high landscape connectivity of potential habitats (LIFE CROAA, pers. comm. 2019). Furthermore, survival of a handful of individuals could be enough to prevent complete eradication (a single gravid female can contain from 1,000 to 27,000 eggs per clutch, and will produce multiple clutches in a season under favourable conditions).</p>
<p>1.22. How likely are the biological characteristics of the organism to facilitate its establishment in the risk assessment area?</p>	<p><b>very likely</b></p>	<p><b>high</b></p>	<p>There are no specific studies providing an indication of the propagule pressure, but a single gravid female can contain from 1,000 to 27,000 eggs per clutch, and will produce multiple clutches in a season under favourable conditions (Global Invasive Species Database 2015), therefore in principle only a handful of individuals may be sufficient to start a new population.</p> <p>As shown by Lobos et al. (2014), the invasion</p>

		<p>of <i>X. laevis</i> in Chile has been successful for at least 30 years, in spite of low genetic variability, few events of introduction, low propagule pressure, and bottlenecks in the founding population (although the number of released frogs is unknown, see Lobos and Jaksic 2005). According to Measey et al. (2012) propagule pressure plays a pivotal role in the establishment of <i>X. laevis</i>, as some populations became established after the release of large numbers of animals from breeding facilities (laboratory and pet supplies). Also De Villiers et al (2016) found that small numbers of <i>X. laevis</i> can produce hundreds of adults within relatively short periods (e.g. 18 months).</p> <p><i>X. laevis</i> is principally aquatic throughout its life. In general, tadpoles take 3 months to metamorphosis, and sexual maturity is achieved within one year (Global Invasive Species Database 2015) although this may happen only in certain circumstances (i.e. this was in California and may even be greater than in its native range in South Africa according to John Measey, pers. comm. 2018). Field studies by Tinsley et al. (2015a) showed that in favourable conditions there may be good recruitment, fast individual growth rates and large body size; maximum longevity exceeds 23 years. After all, the reproductive biology of the species seems very flexible. For</p>
--	--	---

			<p>example in its alien range in the US <i>X. laevis</i> reproduction reportedly occurred in most months of the year, in contrast to the shorter breeding season in South Africa (McCoid and Fritts, 1980). Also in its native range in South Africa, where the breeding season is poorly reported, seems to cover two distinct areas where the breeding times are opposite (John Measey, pers. comm. 2018).</p> <p>In the UK, <i>X. laevis</i> appeared not to breed prolifically under current climatic conditions, but a large recruitment event was considered possible should suitable weather conditions occur for even one season within the period covered by the occurrence of this species in the wild (NNSS 2011).</p> <p>In France, adults move between neighbouring ponds (about 15% of marked individuals). This means that they can evade local unfavourable condition in a site to move to another. Their good dispersal capacity, physiological resistance, and high productivity seems to make populations rather resilient (LIFE CROAA, pers. comm. 2019).</p>
<p>1.23. How likely is the adaptability of the organism to facilitate its establishment?</p>	<p><b>very likely</b></p>	<p><b>high</b></p>	<p>As summarized by Measey et al. (2012) <i>X. laevis</i> is characterized by a suite of physiological and behavioural traits which makes this anuran very robust and versatile, enabling it to cope with dehydration, high levels of salinity, starvation and anoxic</p>

		<p>conditions. Both adults and larvae perform well over a wide range of temperatures, and larvae can metamorphose in a wide range of temperatures. Behavioural traits include their capability to migrate overland, to survive drought by burrowing into drying mud and to starve for up to 12 months (see Measey et al. 2012, Tinsley et al. 2015a). For example, during drought in the UK, <i>X. laevis</i> could survive in isolated pools in the river course, in subterranean water bodies and by burying themselves in mud (Tinsley et al. 2015a). Additionally, <i>X. laevis</i> shows specific adaptations to aquatic life, including retention of the lateral line system in adults, aquatic chemoreceptors and a body structure particularly adapted for swimming (Elepfandt 1996).</p> <p><i>X. laevis</i> is a very adaptable species, which may virtually inhabit any type of waterbody, including lakes and rivers, as well as permanent and temporary ponds, over a wide range of altitudes and temperatures (Measey 1998). Besides <i>X. laevis</i> thrives in disturbed landscapes and artificial habitats, like ponds, wells, dams, irrigation canals and other domestic and agricultural water sources (Tinsley et al. 2015a, Lobos &amp; Jaksic 2005).</p> <p>After all, as pointed out by Tinsley &amp; McCoid (1996), the hardiness which has made <i>X. laevis</i></p>
--	--	---

			<p>ideal for laboratory maintenance, has proved to be a considerable advantage for adaptation to new environments. Recent studies show that invasive populations of <i>X. laevis</i> are established well beyond the species' multivariate realized niche in southern Africa (Rödder et al. 2017). As pointed out by John Measey (pers. comm. 2018) it is worth considering that the native range of <i>X. laevis</i> is tropical to Mediterranean, hence from arid desert areas to high rainfall zones, and from sea level to 3000 m asl: this encompasses a massive climatic envelope but does not include their fundamental niche which is likely to have been much larger at the LGM.</p> <p>In addition, the broad global trophic niche of <i>X. laevis</i> and its ability to adapt its diet according to local conditions further contribute to the strong invasive potential of this species (Courant et al. 2017a). The results of the study by Measey et al. (2016) indicate that no prey categories are strongly selected for, suggesting that <i>X. laevis</i> does not usually specialize its diet and hence does not develop a population specific dietary niche. This characteristic may enhance its capacity to establish and spread in novel environments. Furthermore, field data confirm that adults may rely on their own offspring as a food source, enabling older individuals to survive periods of food shortage by exploiting the</p>
--	--	--	--

			<p>algal populations eaten by their tadpoles (Tinsley and McCoid 1996), although tadpoles are limited to a certain niche by being obligate suspension feeders (John Measey, pers. comm. 2018).</p> <p>A recent study by Kruger et al. (2019) shows anti-predator response of <i>X. laevis</i> to a Dytiscidae beetle (<i>Dysticus dimidiatus</i>), probably a generic response, and even to the invasive crayfish <i>Procambarus clarkii</i>. These responses were observed in naïve tadpoles suggesting that anti-predator behaviour are evolving in the invasive range, in France at least.</p>
<p>1.24. How likely is it that the organism could establish despite low genetic diversity in the founder population?</p>	<p><b>likely</b></p>	<p><b>high</b></p>	<p>As shown by a study by Lobos et al. (2014), the invasion of <i>X. laevis</i> in Chile has been successful for at least 30 years, in spite of low genetic variability, few events of introduction, low propagule pressure, and bottlenecks in the founding population (although such low diversity may be not as meaningful as claimed as the study focused on mtDNA, according to John Measey, pers. comm. 2018). Therefore, low genetic diversity is not expected to be a problem for the species invasion process. It is also worth mentioning that these are tetraploid animals, and that this may mitigate against potential bottlenecks (John Measey, pers. comm. 2018).</p>

<p>1.25. Based on the history of invasion by this organism elsewhere in the world, how likely is it to establish in the risk assessment area? (If possible, specify the instances in the comments box.)</p>	<p><b>very likely</b></p>	<p><b>high</b></p>	<p>The species has already shown to be able to successfully establish viable populations in the risk assessment area, e.g. in Portugal, France and Italy.</p>
<p>1.26. If the organism does not establish, then how likely is it that casual populations will continue to occur?</p> <p>Subnote: Red-eared Terrapin, a species which cannot re-produce in GB but is present because of continual release, is an example of a transient species.</p>	<p><b>likely</b></p>	<p><b>medium</b></p>	<p>It is likely that high number of individuals are still kept and bred in captivity in the risk assessment area, which leads to a certain risk of some being intentionally or accidentally released in the wild, building up casual occurrences (like happened in the past and led to the occurrence of the populations recorded in the risk assessment area and beyond).</p>
<p>1.27. Estimate the overall likelihood of establishment in relevant biogeographical regions in current conditions (mention any key issues in the comment box).</p>	<p><b>very likely</b></p>	<p><b>high</b></p>	<p>According to the studies carried out by Measey et al. (2012) and Ihlow et al. (2016) suitable areas (plus some limited optimal areas) fall within the Mediterranean and Atlantic biogeographic regions, as well as the Continental and Alpine regions. Established populations are already present in the former, but not in the latter. A recent study by Ginal et al. (2020) revealed a much higher risk of invasion, especially for most parts of Europe. However, it does not provide detailed maps for countries and biogeographic regions showing the precise potential invasive range of the species in Europe.</p>
<p>1.28. Estimate the overall likelihood of establishment in relevant biogeographical regions in foreseeable climate change conditions</p>	<p><b>very likely</b></p>	<p><b>high</b></p>	<p>Under foreseeable climate change, the global invasion potential of this species in 2070 assessed by Ihlow et al. (2016) following four</p>

			<p>IPCC scenarios (i.e. RCP2.6, RCP4.5, RCP6, RCP8.5) may expand into northwestern Europe and the Mediterranean area. The maps shown in the paper by Ihlow et al. (2016) do not allow a precise identification of the biogeographic regions where the species could establish in the future under foreseeable climate change. However, it seems that most biogeographic regions may become suitable for the species.</p> <p>A recent study by Ginal et al. (2020) revealed a much higher risk of invasion, especially for most parts of Europe. However, it does not provide detailed maps for countries and biogeographic regions showing the precise potential invasive range of the species in Europe.</p>
--	--	--	---

<b>PROBABILITY OF SPREAD</b>			
<p>Important notes:</p> <ul style="list-style-type: none"> <li>• Spread is defined as the expansion of the geographical distribution of an alien species within the risk assessment area.</li> <li>• Repeated releases at separate locations do not represent spread and should be considered in the probability of introduction and entry section. In other words, intentional anthropogenic “spread” via release or escape should be dealt within the introduction and entry section.</li> </ul>			
<b>QUESTION</b>	<b>RESPONSE</b>	<b>CONFIDENCE</b>	<b>COMMENT</b>
<p>2.1. How important is the expected spread of this organism within the risk assessment area by natural means? (Please list and comment on each of the mechanisms for natural spread.)</p>	<p><b>moderate</b></p>	<p><b>high</b></p>	<p>As summarized by Ihlow et al. (2016) once introduced, the species may rapidly disperse by natural means using irrigation canals, ponds, and rivers as migration corridors, but also performs terrestrial migrations (even without rainfall). It should be noted, however, that movement through streams and irrigation channels appears to be much faster than overland movement (Fouquet and Measey 2006). In a study that compared <i>X. laevis</i> invading an urban area with 2 other species, Vimercati et al (2017) suggested that they may be slower, but build up densities much higher and are arduous to detect.</p> <p>Indicative figures of estimated rate of dispersal are available from a few studies in both the species native and alien range. For example, estimated annual spread of feral populations varied between 1 and over 2 km in France (Fouquet and Measey 2006, LIFE CROAA, pers. comm. 2019) and 5.4 km in Chile (Lobos &amp; Jaksic 2005).</p>

		<p>In particular, a study by Fouquet and Measey (2006) in France showed that, while lotic corridors are used by this principally aquatic species, most ponds are colonised through overland migration. According to Fouquet and Measey (2006) <i>X. laevis</i> is able to detect the presence of non-colonised ponds at a distance, and orient towards them. According to Fouquet and Measey (2006) the terrestrial spread can be estimated at approximately 1 km per year. In Italy, although the rate of spread is not sufficiently assessed, observations were made of newly colonized ponds at a distance of between 400 and 700 m from the nearest pond occupied by <i>X. laevis</i>, where it is likely that most individuals disperse overland (irrigation ditches are not present in the area and the ponds are not connected with each other) or are facilitated by a few temporary streams (Measey et al. 2012). In France, the network of road ditches is dense and these can be filled with water during some periods of the year, which may contribute to enhance survival during overland migration (LIFE CROAA, pers. comm. 2019).</p> <p>Natural spread in the UK appears to have been very slow or non-existent (NNSS 2011) but animals occurred in a very particular system, and spread out of this area would have been very difficult (John Measey, pers. comm. 2018). Additionally, Measey and Tinsley (1998)</p>
--	--	--

		<p>reported a female travelling 0.2 km in 48 hours. Also in Portugal, according to the result of a recent study by Ginal et al. (2021) the spread of the <i>X. laevis</i> population was comparatively slow compared to the populations in Sicily and France which seem to be spreading fast. This was likely due to the complex topology affecting the habitat connectivity, along with a generalised poor habitat quality of the streams and/or presence of predatory fish, as well as some inherent features of the Mediterranean climate.</p> <p>Overland dispersal rates appear to be slower, compared to situations with ponds close to downstream dispersal corridors (Measey et al. 2012), but as reported by both Faraone et al. (2008) and Fouquet and Measey (2006), population dispersal by terrestrial movement seems prevalent in Italy and France. In particular, in France overland movements of 0.5 km per year are reported (Grosselet et al. 2006), and an adult female followed by radio telemetry moved overland 80 m from a pond through a pasture, crossing a wooded hedge and reaching a puddle 20 centimetres deep (Eggert and Fouquet 2006). According to Measey (2016) distances moved overland were from 40 m to 2 km (although the 2 km distance could have included use of a river), which is comparable to distances travelled by other terrestrial amphibians. There is no apparent difference between native and invasive ranges, besides, walls and thick vegetation are regularly</p>
--	--	--

		<p>traversed). In fact, in native populations in South Africa a female moved over 2.3 km in less than 6 weeks (De Villiers and Measey 2017).</p> <p>Loupe et al. (2017) found differences in mobility at the range edge of an expanding invasive population of <i>X. laevis</i> in the west of France; in particular individuals from the range edge had a greater stamina and had longer legs compared to individuals at the centre of the range, suggesting fast evolutionary optimization of dispersal abilities. This of course may have implications for conservation because spatial sorting on the range edge resulting in the evolution of locomotory capacity may lead to an accelerated increase in the spread of this invasive species in France. Also, Courant et al. (2017b) found that the level of resources allocated to reproduction was lower at the periphery of the colonized range compared to the centre and may be the result of changes in trade-offs between life-history traits. Such a pattern could be explained by interspecific competition or enhanced investment in dispersal capacity.</p> <p>There is evidence that additional translocations by humans within the risk assessment area may occur, as has been the case in Chile (Measey, pers. comm), however intentional anthropogenic “spread” via release or escape was dealt with in the introduction and entry section (see guidance in the heading above), to avoid duplication of</p>
--	--	---

			information regarding the relevant pathways.
<p>2.2. How important is the expected spread of this organism within the risk assessment area by human assistance? (Please list and comment on each of the mechanisms for human-assisted spread) and provide a description of the associated commodities.</p>	<p><b>Minimal</b></p>	<p><b>low</b></p>	<p>There is no evidence of spread by human assistance in the risk assessment area, with the exception of intentional releases or escapes from captive bred populations, which however pertains to the mechanism of entry (hence this is discussed in the relative section). For example, a new Sicilian population of this species was recently described by Faraone et al. (2017) according to whom the hypothesis of natural expansion along the river basin is doubtful, while the occurrence of a man-mediated introduction event is plausible (although it is not clear whether it could originate from individuals caught in the wild or from labs). Therefore this is to be considered in the context of new entries.</p> <p>On this regard, Lobos &amp; Jaksic (2005) pointed out that all calculations of spread rate should be taken with caution given the possibility that there have been additional translocations by humans.</p> <p>No detailed information was found on the potential transport of <i>X. laevis</i> adults and tadpoles with fish lots, as documented for other amphibian species (e.g. the American bullfrog <i>Lithobates catesbeianus</i>), but there is at least one case in France of suspected translocation of individuals with fish restocking (LIFE CROAA, pers. comm. 2019).</p>

			<p>Sediment transport from waste water units also includes potential possibilities to transport frogs over larger distances (LIFE CROAA, pers. comm. 2019).</p>
<p>2.2a. List and describe relevant pathways of spread. Where possible give detail about the specific origins and end points of the pathways.</p> <p>For each pathway answer questions 2.3 to 2.9 (copy and paste additional rows at the end of this section as necessary). Please attribute unique identifiers to each question if you consider more than one pathway, e.g. 2.3a, 2.4a, etc. and then 2.3b, 2.4b etc. for the next pathway.</p>	<ol style="list-style-type: none"> <li>1) Corridors (Interconnected waterways / basins / seas).</li> <li>2) “Unaided (Natural dispersal across borders of invasive alien species that have been introduced)”.</li> </ol>		<p>The following pathway is involved in the spread of the species:</p> <ol style="list-style-type: none"> <li>1. Corridors (Interconnected waterways / basins / seas).</li> </ol> <p>This pathway fully overlaps with “Unaided (Natural dispersal across borders of invasive alien species that have been introduced)”.</p> <p>The main difference between the two pathways is that in the first one the species will move through the man-made infrastructures occurring in the area (i.e. interconnected waterway corridors such as channels, ditches, etc.) serving as Corridors with its own capabilities. Otherwise, in the Unaided category, the species is expected to move without any support from either humans or infrastructures. For example, the species is able to spread through overland movements (see details on point 2.1 above) which by the way are intrinsically part of the movements through the waterway corridors. For this reason both pathways have been covered in the risk assessment under one single heading (Corridors (Interconnected waterways / basins / seas)).</p> <p>The likelihood of spread in the Union based on these pathways is very high, since the likelihood</p>

			<p>of survival and reaching a suitable habitat is also very high, as documented above.</p> <p>There is evidence of mass overland movements of animals, estimated to number several thousand (e.g. when water bodies dry-out), and that may be driven, at least in part, by the existence of populations with high densities (Measey 2016).</p>
<i>Pathway name:</i>	<b>[Corridors (Interconnected waterways / basins / seas)] including [Unaided (Natural dispersal acrossborders of invasive alien species that have been introduced)].</b>		
2.3a. Is spread along this pathway intentional (e.g. the organism i released at distant localities) or unintentional (the organism i a contaminant of imported goods)?	<b>Unintentional</b>	<b>high</b>	
2.4a. How likely is it that a number of individuals sufficient to originate a viable population will spread along this pathway from the point(s) of origin over the course of one year?	<b>Likely</b>	<b>high</b>	<p>As summarized by Ihlow et al. (2016) once introduced, the species may rapidly disperse by natural means using irrigation canals, ponds, and rivers as migration corridors.</p> <p>There are no specific studies providing an indication of the propagule pressure, but the species is known to have used this pathway successfully in the risk assessment area.</p> <p>However, the likelihood of this pathway to contribute effectively to the species spread is also related to the overall suitability of the area colonised. In the UK for example, small-scale migration was recorded but overall <i>X. laevis</i> did not show any evidence of dispersal into apparently favourable ponds connected by</p>

			<p>drainage channels in adjacent farmland. Furthermore, limited migration ability under typical environmental conditions was recorded within the potential overland migration range in Africa and California (Tinsley et al. 2015a). De Villiers and Measey (2017) tested also the idea of migratory movements but found no evidence. According to Tinsley et al. (2015a) the low temperature regime may have some effects on dispersal behaviour, but recent studies show that <i>X. laevis</i> is able to move even in quite cold weather conditions, hence this clearly does not prevent the species invasion (Eggert &amp; Fouquet 2006).</p> <p>There is no evidence of reinvasion after eradication, but of course this cannot be excluded given the species' ability to spread undetected.</p> <p>For details see comments in point 2.1. above.</p>
<p>2.5a. How likely is the organism to survive during passage along the pathway (excluding management practices that would kill the organism)?</p> <p>Subnote: In your comment consider whether the organism could multiply along the pathway.</p>	<p><b>Likely</b></p>	<p><b>high</b></p>	<p>The species is known for having used this pathway successfully in the risk assessment area, hence the likelihood of survival is probably high if the habitat is suitable.</p> <p>If the interconnected waterways (such as irrigation canals, ponds, and rivers) used as migration corridors coincide with suitable habitats (e.g. lack of predatory fish, etc.) it is possible that the species may reproduce successfully along the pathway.</p>

2.6a. How likely is the organism to survive existing management practices during spread?	<b>Likely</b>	<b>medium</b>	No relevant management practices exist which may prevent the natural spread of the species in Europe. On the contrary, there may be practices that may favour the spread of the species. For example in Chile, the common practice of emptying dams once a year (to extract silt) or the extraction and transport of sediments from wastewater units in France may aggravate the situation by forcing the animals to migrate off periodically (Lobos & Jaksic 2005; LIFE CROAA, pers. comm. 2019).
2.7a. How likely is the organism to spread in the risk assessment area undetected?	<b>Very likely</b>	<b>high</b>	The detection of single individuals or even new populations can be difficult, given the aquatic and elusive nature of the species. Several introduced populations of <i>X. laevis</i> have gone undetected for long time periods, 2–25 years in some cases (Measey et al. 2012). Van Sittert and Measey (2016) estimated that invasion debt rates — lag between the export of African clawed frogs and a rise in invasive populations — were around 15 years.
2.8a. How likely is the organism to be able to transfer to a suitable habitat or host during spread?	<b>Very likely</b>	<b>high</b>	According to Measey et al. (2012) irrigation channels and streams or rivers appear to be the major routes for dispersal for many invasions. When these run close to artificial dams or ponds, large populations quickly become established.
2.9a. Estimate the overall potential for spread within the Union based on this pathway?	<b>Likely</b>	<b>high</b>	As summarized by Ihlow et al. (2016) once introduced, the species may rapidly disperse by natural means using irrigation canals, ponds, and

		<p>rivers as migration corridors.</p> <p>Spread may depend on the presence of canals. For example in Chile, a rapidly expanding viticulture industry has been assumed to have the potential to aid the spread of this invader, through extensive irrigation corridors, into new and previously uncolonized areas (Lobos et al. 2013).</p> <p>However, the likelihood of this pathway to contribute to the species spread is also related to the overall suitability of the area colonised. In the UK for example, <i>X. laevis</i> has been unable to spread far by natural means, despite being established at a small number of sites in the UK for several decades. However, it must be considered that animals occurred in a very particular system, and spread out of this area would have been very difficult (John Measey, pers. comm. 2018). Habitat connectivity is poor in the UK and, in any event, it is rarely simultaneously warm and rainy enough to encourage long distance overland movements by this species (NNSS 2011).</p> <p>In France, to the contrary, the high density of water bodies produces a highly connected landscape for the species. Connectivity, however, also depends on land use and according to experiments, the ability to move varies on different surfaces: individuals have more problems progressing across grass cover than</p>
--	--	---

			<p>across an area with bare soil or forest litter (Vimercati et al. Manuscript in prep.).</p> <p>Sousa et al. (2018) did speculate that artificial lakes of a golf course built between two sites of occurrence of the species in Portugal may have facilitated the dispersal of the species, although this is not confirmed by any definitive evidence.</p>
<i>End of pathway assessment, repeat as necessary.</i>			
2.10. Within the risk assessment area, how difficult would it be to contain the organism in relation to these pathways of spread?	<b>Very difficult</b>	<b>low</b>	<p>Effective containment measures to prevent the spread of <i>X. laevis</i> through the pathway above are the same as those to control/eradicate the species, hence their applicability is clearly context dependent, and depends on the size of the population and the invasion stage.</p>
2.11. Estimate the overall potential for spread in relevant biogeographical regions under current conditions for this organism in the risk assessment area (using the comment box to indicate any key issues).	<b>Rapidly</b>	<b>medium</b>	<p>According to the studies carried out by Measey et al. (2012) and Ihlow et al. (2016) suitable areas (plus some limited optimal areas) fall within the Mediterranean and Atlantic biogeographic regions as well as the Continental and Alpine regions. Established populations are already present in the former, but not in the latter.</p>
2.12. Estimate the overall potential for spread in relevant biogeographical regions in foreseeable climate change conditions	<b>rapidly</b>	<b>medium</b>	<p>Further warming of the climate due to climate change may benefit the species in colonising new areas through natural dispersal. For example, by the 2070s, climate change is predicted to increase suitability in the risk assessment area, although the maps shown in the paper by Ihlow et al.</p>

			(2016) do not allow for a precise identification of the biogeographic regions where the species could establish in the future under foreseeable climate change. However, it seems that most biogeographic regions may become suitable for the species.
--	--	--	--

<b>MAGNITUDE OF IMPACT</b>			
<p>Important instructions:</p> <ul style="list-style-type: none"> <li>• Questions 2.13-2.17 relate to biodiversity and ecosystem impacts, 2.18-2.20 to impacts on ecosystem services, 2.21-2.25 to economic impact, 2.26-2.27 to social and human health impact, and 2.28-2.30 to other impacts. These impacts can be interlinked, for example a disease may cause impacts on biodiversity and/or ecosystem functioning that leads to impacts on ecosystem services and finally economic impacts. In such cases the assessor should try to note the different impacts where most appropriate, cross-referencing between questions when needed.</li> <li>• Each set of questions starts with the impact elsewhere in the world, then considers impacts in the risk assessment area (=EU excluding outermost regions) separating known impacts to date (i.e. past and current impacts) from potential future impacts (including foreseeable climate change).</li> <li>• Only negative impacts are considered in this section (socio-economic benefits are considered in Qu. A.7)</li> </ul>			
<b>QUESTION</b>	<b>RESPONSE</b>	<b>CONFIDENCE</b>	<b>COMMENTS</b>
<b>Biodiversity and ecosystem impacts</b>			
2.13. How important is impact of the organism on biodiversity at all levels of organisation caused by the organism in its non-native range excluding the risk assessment area?	<b>Moderate</b>	<b>medium</b>	<p><i>X. laevis</i> is as a generalist predator able to modify its diet according to available resources (Courant et al. 2017a). Evidence exists of the negative impact on local populations of amphibians, fish, and invertebrates (Measey et al. 2012). In fact <i>X. laevis</i> is known to predate on and compete with native amphibians, including eggs and larvae (Measey et al 2015), and is thought to be a cause of trophic cascades by the consumption of benthic macroinvertebrates (Measey, 1998a; Lobos &amp; Measey, 2002). In contrast, <i>Xenopus</i> tadpoles are primarily phytoplankton feeders (Schramm 1986).</p> <p>In particular, in its native range, competition and</p>

		<p>predation toward other pipid frogs (not present in the EU) was reported – i.e. on the IUCN Endangered Cape platanna (<i>X. gilli</i>) – along with predation on other anurans – i.e. the common Cape River Frog (<i>Amietia fuscigula</i>), the clicking stream frog (<i>Strongylopus grayii</i>) and the Southern Dainty Frog (<i>Cacosternum australis</i>) suggesting a high proportion of anurophagy, of either eggs, tadpole or adults (Vogt et al. 2017).</p> <p>In central Chile, <i>X. laevis</i> preys on essentially three major food types: insects, molluscs and crustaceans, while the only vertebrates found in local diets are <i>Xenopus</i> larvae (Lobos &amp; Jaksic 2005). Indeed, predation on amphibians (including on <i>X. laevis</i> itself) represented the most frequent vertebrate taxon in several studies on the species diet (Measey et al., 2016). Another study by Vogt et al. (2017) found <i>X. laevis</i> to consume large quantities of anuran eggs and larvae.</p> <p>Lastly, fish, like the endangered tidewater goby (<i>Eucyclogobius newberryi</i>), western mosquitofish (<i>Gambusia affinis</i>), and Arroyo Chubs (<i>Gila orcuttii</i>), were found in the gut contents of <i>X. laevis</i> inhabiting the estuary of the Santa Clara River, in California (Lafferty &amp; Page, 1997).</p> <p>Given the lack of evidence of long-term irreversible ecosystem change, the impact was considered moderate (see Annex II and remark in point A3 above).</p>
--	--	---

<p>2.14. How important is the current known impact of the organism on biodiversity at all levels of organisation (e.g. decline in native species, changes in native species communities, hybridisation) in the risk assessment area (include any past impact in your response)?</p>	<p><b>Moderate</b></p>	<p><b>medium</b></p>	<p>Overall, the species impact on the risk assessment area is similar to the impact described in regions beyond the EU.</p> <p>For example, according to Measey (1998) <i>X. laevis</i> in South Wales ate a wide variety and size range of prey. Zoobenthos and zooplankton made the largest contribution to diets, followed by terrestrial invertebrates. Vertebrate preys (other than eggs and larvae of the same species) were also present, i.e. a bank vole (<i>Clethrionomys glareolus</i>) eaten alive or recently dead, and a chick (unidentified) probably eaten as a carrion. In fact, it is important to consider that <i>X. laevis</i> is also able to detect and feed on carrion (Measey 1998).</p> <p>Amaral &amp; Rebelo (2012) confirmed the predation by <i>X. laevis</i> on eggs and adults of native amphibians, as well as on native fish in Portugal. The diet included benthic preys, with water snails (Physidae) being the most important, followed by the invasive American crayfish (<i>Procambarus clarkii</i>), but also native amphibians (including <i>Rana perezi</i> skeletons and egg masses) and fish (among which <i>Cobitis paludica</i>, a vulnerable Iberian endemic). In Portugal, during an eradication program in Oeiras carried out within the LIFE project LIFE17/GIE/ES/000515 Invasaqua, a captured juvenile of <i>X. laevis</i> was reported to prey on <i>Iberochondrostoma lusitanicum</i> (<a href="https://www.wilder.pt/naturalistas/ra-">https://www.wilder.pt/naturalistas/ra-</a></p>
---	------------------------	----------------------	--

		<p>de-unhas-africana-esta-invasora-e-um-caso-de-sucesso-em-portugal/), a critically endangered species according to IUCN realist (Crivelli 2006).</p> <p>In France, Grosselet et al. (2006) speculated that <i>X. laevis</i> may predate on eggs of large newts (i.e. <i>Triturus cristatus</i> and <i>Triturus marmoratus</i>). Also Courant et al. (2018a) showed that species richness of native amphibians was negatively related to the abundance of <i>X. laevis</i>, despite some methodological bias discussed by the authors themselves. In particular, in France a significant decrease in the proportion of nektonic macroinvertebrates was reported in ponds occupied by <i>X. laevis</i> (Courant et al. 2018b).</p> <p>A study by Faraone et al. (2008) in Sicily shows that the most important prey categories are nektonic and planktonic organisms, and confirmed the presence of <i>X. laevis</i> eggs and larvae as well as terrestrial invertebrates (odonates and mayflies) in the diet. Additionally, Lillo et al. (2010) showed that presence of <i>X. laevis</i> in Sicily is associated with a decline in the reproduction of native amphibians (namely <i>Discoglossus pictus</i>, <i>Hyla intermedia</i> and <i>Pelophylax synklepton esculentus</i>). However, no one native amphibian was present in the diet of the species. Only conspecific tadpoles were found, confirming the significant cannibalistic behaviour of this species. The study by Lillo et al. (2010) also shows that the almost total absence of overlap of the trophic niche</p>
--	--	--

			suggests the lack of competition for trophic resources between the alien species and the native ones.
2.15. How important is the potential future impact of the organism on biodiversity at all levels of organisation likely to be in the risk assessment area?	<b>moderate</b>	<b>low</b>	In case of a future expansion of the species range, other native species may be affected. While there is no documented evidence of the species being able to cause the extinction of any native one, it is likely that the level of risk will at least be confirmed as “Moderate” also in the future.
2.16. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism currently in the risk assessment area?	<b>moderate</b>	<b>low</b>	In the light of the suggested impact on the amphibian species occurring in Italy and France and protected by the Habitats directive ( <i>Triturus cristatus</i> is listed in Annex II and IV, while <i>Triturus marmoratus</i> and <i>Discoglossus pictus</i> are listed in Annex IV), the decline in conservation value caused by <i>X. laevis</i> is considered as “Moderate”.
2.17. How important is decline in conservation value with regard to European and national nature conservation legislation caused by the organism likely to be in the future in the risk assessment area?	<b>moderate</b>	<b>low</b>	In case of a future expansion of the species range, other native species may be affected. While there is no documented evidence of the species causing the extinction of any native species, it is likely that the level of risk will at least be “Moderate” in the future.
<b>Ecosystem Services impacts</b>			
2.18 How important is the impact of the organism on provisioning, regulating, and cultural services in its non-native range excluding the risk assessment area?	<b>moderate</b>	<b>high</b>	The impact of <i>X. laevis</i> on ecosystem services is caused by predation with possible accumulative effects in the ecosystem, including increased competition with other species for food (see point

			<p>2.13 and 2.14) and its functioning as a pathogen vector (see point 2.28).</p> <p><i>X. laevis</i> might also have indirect impacts on aquatic systems such as increasing water turbidity and nutrient release caused by <i>X. laevis</i> disturbing the sediment (Lobos and Measey 2002).</p> <p>Consequently, <i>X. laevis</i> has been reported to negatively affect the invaded ecosystems, and as a consequence has been ranked as having the second greatest impact on native ecosystems by any amphibian (Measey et al., 2016). See also the assessments by Kumschick et al. (2017a), Kumschick et al. (2017b) and Kraus (2015) already discussed in point A3 of this document.</p>
<p>2.19. How important is the impact of the organism on provisioning, regulating, and cultural services currently in the different biogeographic regions or marine sub-regions where the species has established in the risk assessment area (include any past impact in your response)?</p>	<b>moderate</b>	<b>high</b>	<p>Overall, the species impact in the risk assessment area is likely to be similar to the impact in regions beyond the EU, as described above, namely on:</p> <ol style="list-style-type: none"> <li>1) Provisioning (Biomass: Reared aquatic animals);</li> <li>2) Regulation &amp; Maintenance (Regulation of physical, chemical, biological conditions: Lifecycle maintenance, habitat and gene pool protection, Pest and disease control, Water conditions).</li> </ol>
<p>2.20. How important is the impact of the organism on provisioning, regulating, and cultural services likely to be in the different biogeographic regions or marine sub-regions where the species can establish in</p>	<b>moderate</b>	<b>low</b>	<p>There is no documented evidence of the species being able to cause other types of impact (compared to those reported in current conditions), hence the level of risk can be expected to be</p>

the risk assessment area in the future?			“moderate” in the future.
<b>Economic impacts</b>			
2.21. How great is the overall economic cost caused by the organism within its current area of distribution (excluding the risk assessment area), including both costs of / loss due to damage and the cost of current management	<b>minor</b>	<b>low</b>	<p>Due to increased predation and/or competition for food, <i>X. laevis</i> is known to interfere with aquaculture, leading to possible economic costs.</p> <p>While no quantitative estimates about the economic impacts are available, in South Africa, for example, <i>X. laevis</i> is considered a threat to fresh-water aquaculture of common carp (<i>Cyprinus carpio</i>) and Chinese silver carp (<i>Hypophthalmichthys molitrix</i>) mostly because of competition for food (Schramm 1987). Additionally, it is considered a constraint on the production of the giant freshwater prawn (<i>Macrobrachium rosenbergii</i>), mainly due to predation (Taylor et al., 1992). Outside its native range, in Japan, the African clawed frog was found to have an impact on aquaculture by preying on juvenile carp (Kokuryo, 2009). In particular, a study by Schramm (1987) in South African aquaculture ponds, revealed that farmed fish larvae constituted a large proportion of <i>X. laevis</i> stomach contents (up to 25%), and that small fish &lt;1 g are particularly vulnerable (although it does not necessarily represent the typical diet of native populations, see Courant et al. 2017a). Furthermore, in a study by Schramm (1987), it seemed likely that competition with <i>X. laevis</i> tadpoles was at least partly responsible for the slower growth of <i>H. molitrix</i>.</p>

		<p>In addition to the above, a reported problem in South Africa concerns the mass migrations leading to large numbers of clawed frogs invading houses and clogging up irrigation pipes (Somma 2018, Tinsley et al., 1996), but also in this case no figure is available.</p> <p>Following the SEICAT scheme developed by Bacher et al. (2018), the impact category for this species should therefore fall in between Minimal concern and Minor.</p> <p>No information/data is available on the costs for management, despite the many management activities carried out on the species. The only exception is an estimation of the man days reported for the control of the species in a pond in South Africa (De Villiers et al 2016). According to the authors, 27 person days for 338 <i>X. laevis</i> from one impoundment were needed, while regular seining could require as little as eight person days per year. As a side note, according to John Measey (pers. comm. 2018) the impoundment size was 603 m<sup>2</sup> (see also Vogt et al 2017).</p> <p>Lastly, a LIFE project aimed at the control of <i>Xenopus laevis</i> - together with the American bullfrog (<i>Lithobates catesbeianus</i>) - is currently in progress (2016-2022) in France: LIFE15 NAT/FR/000864 LIFE CROAA - Control strategies of Alien invasive Amphibians in France (for details, see <a href="https://www.life-croaa.eu">https://www.life-croaa.eu</a>). The</p>
--	--	--

			<p>project, co-funded by the EU through the LIFE program, has a total budget of 3,430,179.00 € (see <a href="http://ec.europa.eu/environment/life/project/Projects/index.cfm?fuseaction=search.dspPage&amp;n_proj_id=5842">http://ec.europa.eu/environment/life/project/Projects/index.cfm?fuseaction=search.dspPage&amp;n_proj_id=5842</a>). However, as this also targets species other than <i>X. laevis</i> are targeted, and since the project is still in progress, it is not possible to have clear figures on removal costs for <i>X. laevis</i> in particular.</p>
<p>2.22. How great is the economic cost of / loss due to damage* of the organism currently in the risk assessment area (include any past costs in your response)?</p> <p>*i.e. excluding costs of management</p>	<b>minimal</b>	<b>low</b>	<p>No information/data is available on the economic costs caused by <i>X. laevis</i>.</p> <p>In the UK the economic losses caused by this species, if any, were considered likely to be minimal given the limited distribution and very small numbers of <i>X. laevis</i> that were present (NNSS 2011).</p>
<p>2.23. How great is the economic cost of / loss due to damage* of the organism likely to be in the future in the risk assessment area?</p> <p>*i.e. excluding costs of management</p>	<b>minimal</b>	<b>low</b>	<p>In case of a future expansion of the species range, some economic impact and associated costs may be evidenced, e.g. on aquaculture activities or other sectors. While there is no documented evidence of the species causing this type of impact in the risk assessment area, it is not possible to exclude that this could happen in the future. However, for the time being it should be considered minimal.</p>
<p>2.24. How great are the economic costs / losses associated with managing this organism currently in the risk assessment area (include any past costs in your response)?</p>	<b>moderate</b>	<b>-medium</b>	<p>The only figures that are available in the risk assessment area concern the activities carried out in France through the project LIFE CROAA, Control strategies Of Alien invasive Amphibians in France (LIFE15 NAT/FR/000864). This project</p>

			aims to limit the expansion of <i>X. laevis</i> along dispersal corridors (together with the eradication/control of <i>Lithobates catesbeianus</i> in several sites). The total budget of this project is of 3.43 million euro and it will be carried out in the period 2016-2022 by the Société Herpétologique de France and other partners. In particular, the costs sustained locally to fight against <i>X. laevis</i> in 2017 and 2018 amounted to 81.000 €. The activities were carried out on a small part of the main introduction site, with the aim of preserving a few sites considered to be at stake due to the presence of native species or located near dispersal areas (LIFE CROAA, pers. comm. 2019).
2.25. How great are the economic costs / losses associated with managing this organism likely to be in the future in the risk assessment area?	<b>major</b>	<b>low</b>	In case of a future expansion of the species range in the risk assessment area, the economic costs / losses associated with managing <i>X. laevis</i> may rise accordingly.
<b>Social and human health impacts</b>			
2.26. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism for the risk assessment area and for third countries, if relevant (e.g. with similar eco-climatic conditions).	<b>minimal</b>	<b>low</b>	No information has been found on the issue.
2.27. How important is social, human health or other impact (not directly included in any earlier categories) caused by the organism in the future for the risk assessment area.	<b>minimal</b>	<b>low</b>	No information has been found on the issue.
<b>Other impacts</b>			

<p>2.28. How important is the impact of the organism as food, a host, a symbiont or a vector for other damaging organisms (e.g. diseases)?</p>	<p><b>minor</b></p>	<p><b>low</b></p>	<p>The most serious impact usually attributed to <i>X. laevis</i> is related to its potential role in the introduction and spread of the chytrid fungus, <i>Batrachochytrium dendrobatidis</i> (<i>Bd</i>), the cause of amphibian deaths and population declines in several parts of the world (Weldon et al. 2004). <i>Bd</i> disease has been implicated in mass mortalities and widespread declines in European amphibian species, like common midwife toad (<i>Alytes obstetricans</i>) (Bosch et al., 2001) and fire salamander (<i>Salamandra salamandra</i>) (Bosch &amp; MartínezSolano, 2006) in Spain. However, to date there is no evidence that <i>X. laevis</i> has functioned in this role of <i>Bd</i> vector or has caused impact on native amphibians through this mechanism. For this reason, the impact of the species was considered “minor” by Kumschick et al. (2017b, see in particular the supporting information annexed to the relevant paper). As a remark, the same authors discussed a previous assessment by Kraus (2015) based on the assumption that <i>X. laevis</i> contributed to the spread of <i>Bd</i> which then caused declines in native species, but which is not demonstrated (De Busschere et al. 2016, John Measey, pers. comm. 2018). Hence a higher score would not be justified.</p> <p><i>Xenopus laevis</i> was also identified as a potential vector of ranavirus (Robert et al., 2007).</p> <p>Although a causal link between <i>X. laevis</i> and the dispersal of these pathogens is not demonstrated</p>
--	---------------------	-------------------	--

		<p>(Measey et al. 2012), this frog could play a role in the spread of disease, by acting as an asymptomatic reservoir/vector for both diseases, without being susceptible or just suffering sublethal effects. This seems to be confirmed at least for the chytrid fungus by studies on either wild or captive animals in the UK, Chile, and USA (Tinsley et al. 2015b, Solís et al. 2010, Soto-Azat et al. 2016, Vredenburg et al. 2013), but not in France (Ouellet et al. 2012).</p> <p>Additionally, <i>X. laevis</i> may carry several other parasites and pathogens, like <i>Chlamydia</i> (Howerth et al. 1984, Reed et al. 2000) and many others, in both its native range and the alien range (Kuperman et al. 2004, Tinsley, 1996). For example, according to Lafferty &amp; Page (1997), three internal parasites were observed in or on the gut (although a complete parasitological assessment was not undertaken). The African tapeworm <i>Cephalochlamys namaquensis</i> was found in intensities from 6-25 individuals (including several mature adults) in the anterior duodenum. It was not previously reported outside of Africa, hence it may have entered other areas with this species. Ciliates of the genus <i>Nyctotherus</i> (0.25 mm trophs) were present in abundance posterior to the section of the gut where tapeworms occurred. Larval nematodes were encysted on the outside of the stomach wall (might be transferred to the birds that eat them, potentially leading to some pathology).</p>
--	--	---

			<p>A recent study (Schoeman et al. 2020) reports seven previously unrecorded nematode species (none of which could be identified to species level) parasitising <i>X. laevis</i> across South Africa. These are adult <i>Capillaria</i> sp. and <i>Falcaustra</i> sp. from the intestine, third stage larvae of <i>Contracaecum</i> sp. encysted in the body cavity, third stage larvae of <i>Paraquimperia</i> sp. and <i>Tanqua</i> sp. from the intestine and two different species of second stage nematode larvae from the lungs and kidneys, respectively. According to Schoeman et al. (2020) this result illustrates that <i>X. laevis</i> is an important parasite reservoir in its native range, with implications for its role in the invasive range.</p> <p>In France, only parasites originating from the frog's native range have been detected so far. This has been found in other areas suggesting that <i>Xenopus</i> also introduces its own parasites in the assessment area (Schoeman et al. 2019). Parasites of <i>X. laevis</i> on its native range have been detected at a high prevalence in western France (<i>Protopolystoma xenopodis</i>: prevalence 19 %, <i>Cephalochlamys namaquensis</i>: prevalence 63%). The same parasites have been found in distinct invasive <i>Xenopus</i> populations. There has been no attempt to determine whether these alien parasites colonized new amphibian hosts in Europe.</p>
2.29. How important might other impacts not already covered by previous questions be resulting from introduction of the organism? (specify in the	NA		No information has been found on the issue.

comment box)			
2.30. How important are the expected impacts of the organism despite any natural control by other organisms, such as predators, parasites or pathogens that may already be present in the risk assessment area?	<b>major</b>	<b>low</b>	The natural control by other organisms, such as predators, parasites or pathogens that may already be present in the risk assessment area, is not expected to mitigate the impact of <i>X. laevis</i> in relation to its role as a vector of dangerous parasites and pathogens to the native fauna.

## **ANNEX I Scoring of Likelihoods of Events**

(taken from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

<b>Score</b>	<b>Description</b>	<b>Frequency</b>
Very unlikely	This sort of event is theoretically possible, but is never known to have occurred and is not expected to occur	1 in 10,000 years
Unlikely	This sort of event has not occurred anywhere in living memory	1 in 1,000 years
Moderately likely	This sort of event has occurred somewhere at least once in recent years, but not locally	1 in 100 years
Likely	This sort of event has happened on several occasions elsewhere, or on at least one occasion locally in recent years	1 in 10 years
Very likely	This sort of event happens continually and would be expected to occur	Once a year

## ANNEX II Scoring of Magnitude of Impacts

(modified from UK Non-native Organism Risk Assessment Scheme User Manual, Version 3.3, 28.02.2005)

Score	Biodiversity and ecosystem impact	Ecosystem Services impact	Economic impact (Monetary loss and response costs per year)	Social and human health impact
	<i>Question 2.18-22</i>	<i>Question 2.23-25</i>	<i>Question 2.26-30</i>	<i>Question 2.31-32</i>
Minimal	Local, short-term population loss, no significant ecosystem effect	No services affected <sup>18</sup>	Up to 10,000 Euro	No social disruption. Local, mild, short-term reversible effects to individuals.
Minor	Some ecosystem impact, reversible changes, localised	Local and temporary, reversible effects to one or few services	10,000-100,000 Euro	Significant concern expressed at local level. Mild short-term reversible effects to identifiable groups, localised.
Moderate	Measureable long-term damage to populations and ecosystem, but little spread, no extinction	Measureable, temporary, local and reversible effects on one or several services	100,000-1,000,000 Euro	Temporary changes to normal activities at local level. Minor irreversible effects and/or larger numbers covered by reversible effects, localised.
Major	Long-term irreversible ecosystem change, spreading beyond local area	Local and irreversible or widespread and reversible effects on one / several services	1,000,000-10,000,000 Euro	Some permanent change of activity locally, concern expressed over wider area. Significant irreversible effects locally or reversible effects over large area.
Massive	Widespread, long-term population loss	Widespread and irreversible effects on one /	Above 10,000,000 Euro	Long-term social change, significant loss of employment,

<sup>18</sup> Not to be confused with „no impact“.

	or extinction, affecting several species with serious ecosystem effects	several services		migration from affected area. Widespread, severe, long-term, irreversible health effects.
--	--	------------------	--	---

### ANNEX III Scoring of Confidence Levels

(modified from Bacher *et al.* 2017)

Confidence level	Description
Low	There is no direct observational evidence to support the assessment, e.g. only inferred data have been used as supporting evidence <i>and/or</i> Impacts are recorded at a spatial scale which is unlikely to be relevant to the assessment area <i>and/or</i> Evidence is poor and difficult to interpret, e.g. because it is strongly ambiguous <i>and/or</i> The information sources are considered to be of low quality or contain information that is unreliable.
Medium	There is some direct observational evidence to support the assessment, but some information is inferred <i>and/or</i> Impacts are recorded at a small spatial scale, but rescaling of the data to relevant scales of the assessment area is considered reliable, or to embrace little uncertainty <i>and/or</i> The interpretation of the data is to some extent ambiguous or contradictory.
High	There is direct relevant observational evidence to support the assessment (including causality) <i>and</i> Impacts are recorded at a comparable scale <i>and/or</i> There are reliable/good quality data sources on impacts of the taxa <i>and</i> The interpretation of data/information is straightforward <i>and/or</i> Data/information are not controversial or contradictory.

## ANNEX IV Ecosystem services classification (CICES V5.1, simplified) and examples

For the purposes of this risk assessment, please feel free to use what seems as the most appropriate category / level / combination of impact (Section – Division – Group), reflecting information available.

Section	Division	Group	Examples (i.e. relevant CICES “classes”)
Provisioning	Biomass	Cultivated <i>terrestrial</i> plants	Cultivated terrestrial plants (including fungi, algae) grown for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from cultivated plants, fungi, algae and bacteria for direct use or processing (excluding genetic materials); Cultivated plants (including fungi, algae) grown as a <u>source of energy</u>  <i>Example: negative impacts of non-native organisms to crops, orchards, timber etc.</i>
		Cultivated <i>aquatic</i> plants	Plants cultivated by in- situ aquaculture grown for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from in-situ aquaculture for direct use or processing (excluding genetic materials); Plants cultivated by in- situ aquaculture grown as an <u>energy source</u> .  <i>Example: negative impacts of non-native organisms to aquatic plants cultivated for nutrition, gardening etc. purposes.</i>
		Reared animals	Animals reared for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from reared animals for direct use or processing (excluding genetic materials); Animals reared to provide <u>energy</u> (including mechanical)  <i>Example: negative impacts of non-native organisms to livestock</i>
		Reared <i>aquatic</i> animals	Animals reared by in-situ aquaculture for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from animals grown by in-situ aquaculture for direct use or processing (excluding genetic materials); Animals reared by in-situ aquaculture as an <u>energy source</u>  <i>Example: negative impacts of non-native organisms to fish farming</i>
		Wild plants (terrestrial and aquatic)	Wild plants (terrestrial and aquatic, including fungi, algae) used for <u>nutrition</u> ; <u>Fibres and other materials</u> from wild plants for direct use or processing (excluding genetic materials); Wild plants (terrestrial and aquatic, including fungi, algae) used as a <u>source of energy</u> <i>Example: reduction in the availability of wild plants (e.g. wild berries, ornamentals) due to non-native organisms (competition, spread of disease etc.)</i>
		Wild animals (terrestrial and aquatic)	Wild animals (terrestrial and aquatic) used for <u>nutritional purposes</u> ; <u>Fibres and other materials</u> from wild animals for direct use or processing (excluding genetic materials); Wild animals (terrestrial and aquatic) used as a <u>source of energy</u>  <i>Example: reduction in the availability of wild animals (e.g. fish stocks, game) due to non-native</i>

			organisms (competition, predations, spread of disease etc.)
	<b>Genetic material</b> from all biota	<b>Genetic material</b> from plants, algae or fungi	<p><u>Seeds, spores and other plant materials</u> collected for maintaining or establishing a population; Higher and lower plants (whole organisms) used to <u>breed new strains or varieties</u>; Individual genes extracted from higher and lower plants for the <u>design and construction of new biological entities</u></p> <p><i>Example: negative impacts of non-native organisms due to interbreeding</i></p>
		<b>Genetic material</b> from animals	<p>Animal material collected for the purposes of maintaining or establishing a population; Wild animals (whole organisms) used to breed new strains or varieties; Individual genes extracted from organisms for the design and construction of new biological entities</p> <p><i>Example: negative impacts of non-native organisms due to interbreeding</i></p>
	<b>Water</b> <sup>19</sup>	<b>Surface water</b> used for nutrition, materials or energy	<p>Surface water for <u>drinking</u>; Surface water used as a material (<u>non-drinking purposes</u>); Freshwater surface water, coastal and marine water used as an <u>energy source</u></p> <p><i>Example: loss of access to surface water due to spread of non-native organisms</i></p>
		<b>Ground water</b> for used for nutrition, materials or energy	<p>Ground (and subsurface) water for <u>drinking</u>; Ground water (and subsurface) used as a material (<u>non-drinking purposes</u>); Ground water (and subsurface) used as an <u>energy source</u></p> <p><i>Example: reduced availability of ground water due to spread of non-native organisms and associated increase of ground water consumption by vegetation.</i></p>
<b>Regulation &amp; Maintenance</b>	Transformation of biochemical or physical inputs to ecosystems	<b>Mediation of wastes or toxic substances</b> of anthropogenic origin by living processes	<p><u>Bio-remediation</u> by micro-organisms, algae, plants, and animals; <u>Filtration/sequestration/storage/accumulation</u> by micro-organisms, algae, plants, and animals</p> <p><i>Example: changes caused by non-native organisms to ecosystem functioning and ability to filtrate etc. waste or toxics</i></p>
		<b>Mediation of nuisances</b> of anthropogenic origin	<p><u>Smell reduction; noise attenuation; visual screening</u> (e.g. by means of green infrastructure)</p> <p><i>Example: changes caused by non-native organisms to ecosystem structure, leading to reduced ability to mediate nuisances.</i></p>
	Regulation of physical, chemical, biological conditions	<b>Baseline flows and extreme event</b> regulation	<p>Control of <u>erosion</u> rates; Buffering and attenuation of <u>mass movement</u>; <u>Hydrological cycle and water flow regulation</u> (Including flood control, and coastal protection); <u>Wind</u> protection; <u>Fire</u> protection</p>

<sup>19</sup> Note: in the CICES classification provisioning of water is considered as an abiotic service whereas the rest of ecosystem services listed here are considered biotic.

			<p><i>Example: changes caused by non-native organisms to ecosystem functioning or structure leading to, for example, destabilisation of soil, increased risk or intensity of wild fires etc.</i></p>
		<b>Lifecycle maintenance</b> , habitat and gene pool protection	<p><u>Pollination</u> (or 'gamete' dispersal in a marine context); <u>Seed dispersal</u>; Maintaining <u>nursery populations and habitats</u> (Including gene pool protection)</p> <p><i>Example: changes caused by non-native organisms to the abundance and/or distribution of wild pollinators; changes to the availability / quality of nursery habitats for fisheries</i></p>
		<b>Pest and disease control</b>	<p>Pest control; Disease control</p> <p><i>Example: changes caused by non-native organisms to the abundance and/or distribution of pests</i></p>
		<b>Soil quality</b> regulation	<p><u>Weathering processes</u> and their effect on soil quality; <u>Decomposition and fixing processes</u> and their effect on soil quality</p> <p><i>Example: changes caused by non-native organisms to vegetation structure and/or soil fauna leading to reduced soil quality</i></p>
		<b>Water</b> conditions	<p>Regulation of the <u>chemical condition</u> of freshwaters by living processes; Regulation of the chemical condition of salt waters by living processes</p> <p><i>Example: changes caused by non-native organisms to buffer strips along water courses that remove nutrients in runoff and/or fish communities that regulate the resilience and resistance of water bodies to eutrophication</i></p>
		<b>Atmospheric</b> composition and conditions	<p>Regulation of <u>chemical composition</u> of atmosphere and oceans; Regulation of <u>temperature and humidity</u>, including ventilation and transpiration</p> <p><i>Example: changes caused by non-native organisms to ecosystems' ability to sequester carbon and/or evaporative cooling (e.g. by urban trees)</i></p>
<b>Cultural</b>	<b>Direct, in-situ and outdoor interactions</b> with living systems that depend on presence in the environmental setting	<b>Physical and experiential</b> interactions with natural environment	<p>Characteristics of living systems that that enable activities promoting health, recuperation or enjoyment through <u>active or immersive interactions</u>; Characteristics of living systems that enable activities promoting health, recuperation or enjoyment through <u>passive or observational interactions</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that make it attractive for recreation, wild life watching etc.</i></p>

		<b>Intellectual and representative</b> interactions with natural environment	<p>Characteristics of living systems that enable <u>scientific investigation</u> or the creation of traditional ecological knowledge;</p> <p>Characteristics of living systems that enable <u>education and training</u>;</p> <p>Characteristics of living systems that are resonant in terms of <u>culture or heritage</u>;</p> <p>Characteristics of living systems that enable <u>aesthetic experiences</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have cultural importance</i></p>
	<b>Indirect, remote, often indoor interactions</b> with living systems that do not require presence in the environmental setting	<b>Spiritual, symbolic</b> and other interactions with natural environment	<p>Elements of living systems that have <u>symbolic meaning</u>;</p> <p>Elements of living systems that have <u>sacred or religious meaning</u>;</p> <p>Elements of living systems used for <u>entertainment or representation</u></p> <p><i>Example: changes caused by non-native organisms to the qualities of ecosystems (structure, species composition etc.) that have sacred or religious meaning</i></p>
		Other biotic characteristics that have a <b>non-use value</b>	<p>Characteristics or features of living systems that have an <u>existence value</u>;</p> <p>Characteristics or features of living systems that have an <u>option or bequest value</u></p> <p><i>Example: changes caused by non-native organisms to ecosystems designated as wilderness areas, habitats of endangered species etc.</i></p>

## ANNEX V EU Biogeographic Regions and MSFD Subregions

See <https://www.eea.europa.eu/data-and-maps/figures/biogeographical-regions-in-europe-2> ,

## **ANNEX VI      Species distribution model**

Projected distributions were obtained from the authors of two existing studies reporting three global-scale species distribution models for *Xenopus laevis* (Measey et al 2012; Ihlow et al 2016). Both studies used a similar distribution database, with more record cleaning in the later paper, and a similar set of input variables and modelling methods (Table 1). However, the three models varied considerably in which climate variables were used to predict suitability (Table 1), suggesting high uncertainty in using the outputs of the models for this assessment.

The authors of both papers supplied shapefiles with the projected suitable regions, revealing marked differences in the European regions predicted to be suitable in the current climate (Figure 1). All models predict substantial suitable regions in Portugal, Spain, France and Italy. The models of Ihlow et al (2016) also predict large suitable regions in eastern Europe, based on a minimum training presence threshold. This threshold probably overestimates the suitable region in Europe as the species has been introduced and recorded in marginal conditions in northern Europe and suitability gradient maps shown in the paper suggest moderate to high suitability only in warm western Mediterranean regions. The predictions from the Measey et al (2012) model should be treated with caution as the Maxent model is less reliable than the ensemble model (John Measey pers. comm. 2018). Also, this study did not consider suitability under different emission scenarios (Table 1). Climate change projections supplied for the 2070s from Ihlow et al (2016) differed markedly between emissions scenarios and the Maxent and Ensemble models. However, these projections do not appear consistent across scenarios (e.g. RCP4.5 should be intermediate between RCP2.6 and RCP6.0, but it is not in all cases) and were probably influenced by an overly liberal minimum training threshold choice.

Overall, the information supplied was considered too uncertain to usefully identify suitable regions beyond the currently invaded regions of Europe.

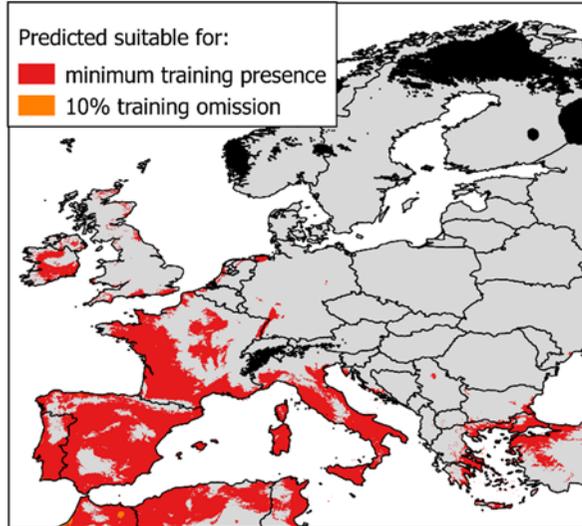

**Table 1.** Comparison of published species distribution models for *Xenopus laevis*.

	Measey et al (2012)	Ihlow et al 2016 (Maxent)	Ihlow et al 2016 (Ensemble)
Number of native range records	1075	826	826
Number of non-native range records	124	99	99
Spatial resolution	2.5 arcminutes	2.5 arcminutes	2.5 arcminutes
Predictor variables from Worldclim	Isothermality (bio3) Minimum temperature of the coldest month (bio6) Temperature annual range (bio7) Mean temperature of the wettest quarter (bio8) Mean temperature of the driest quarter (bio9) Mean temperature of the warmest quarter (bio10) Precipitation seasonality (bio15) Precipitation of wettest quarter (bio16) Precipitation of driest quarter (bio17) Precipitation of coldest quarter (bio19)	Temperature annual range (bio7) Mean temperature of the wettest quarter (bio8) Mean temperature of the driest quarter (bio9) Mean temperature of the warmest quarter (bio10) Mean temperature of the coldest quarter (bio11) Precipitation of wettest quarter (bio16) Precipitation of driest quarter (bio17) Precipitation of the warmest quarter (bio18) Precipitation of coldest quarter (bio19)	Temperature annual range (bio7) Mean temperature of the wettest quarter (bio8) Mean temperature of the driest quarter (bio9) Mean temperature of the warmest quarter (bio10) Mean temperature of the coldest quarter (bio11) Precipitation of wettest quarter (bio16) Precipitation of driest quarter (bio17) Precipitation of the warmest quarter (bio18) Precipitation of coldest quarter (bio19)
Modelling software	Maxent	Maxent	Biomod
Background definition	Radius of 250 km around the records	Radius of 250 km around the records	Radius of 250 km around the records
Reported predictor importance	Isothermality (27.4%) Minimum temperature of coldest month (19.8%) Precipitation of coldest quarter (11.7%) Mean temperature of warmest quarter (10.4%) Mean temperature of wettest quarter (8.8%) Temperature annual range (6.7%) Precipitation of wettest quarter (6.6%)	Precipitation of driest quarter (27.7%) Mean temperature of wettest quarter (16.8%) Mean temperature of coldest quarter (14.5%) Precipitation of warmest quarter (11.4%) Precipitation of coldest quarter (8.3%) Temperature annual range (7.0%) Mean temperature of driest quarter (6.2%) Precipitation of wettest quarter (6.2%) Mean temperature of warmest quarter (1.9%)	Mean temperature of coldest quarter (19.1%) Precipitation of warmest quarter (16.6%) Mean temperature of warmest quarter (13.9%) Precipitation of driest quarter (12.6%) Precipitation of coldest quarter (8.3%) Mean temperature of driest quarter (8.3%) Precipitation of wettest quarter (8.0%) Mean temperature of wettest quarter (7.6%) Temperature annual range (5.0%)

	<b>Measey et al (2012)</b>	<b>Ihlow et al 2016 (Maxent)</b>	<b>Ihlow et al 2016 (Ensemble)</b>
Threshold(s) to project suitable region	Minimum training presence and 10% training omission	Minimum training presence	Minimum training presence
Masking to prevent extrapolation	Multivariate Environmental Similarity Surface (MESS)	Multivariate Environmental Similarity Surface (MESS)	Variable clamping
Climate change scenarios	None	2070s under RCP2.6, RCP4.5, RCP6.0 and RCP8.5	2070s under RCP2.6, RCP4.5, RCP6.0 and RCP8.5

**Figure 1.** Projected European regions suitable for establishment by *Xenopus laevis* from three modelling approaches. In (a) the suitable region is defined using two thresholds, with almost no parts of Europe projected suitable under the stricter 10% omission threshold. The threshold used in (b) and (c) is the minimum training presence, and suitable areas are shaded red. In all plots, regions where extrapolation prevented prediction are shown in black.

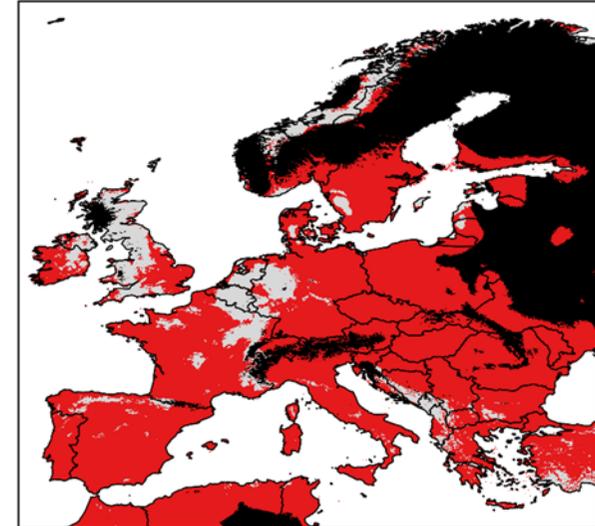

(a) Measey et al (2012) Maxent model

(b) Ihlow et al (2016) Maxent model

(c) Ihlow et al (2016) Ensemble model

**Figure 2.** Variation in projected suitability among Biogeographical regions of Europe (Bundesamt für Naturschutz (BfN), 2003) from the different model outputs supplied. The regions are shown in the right hand map. Measey.1 and Measey.2 differ based on thresholding by the minimum training presence or a stricter 10% omission rate, respectively.

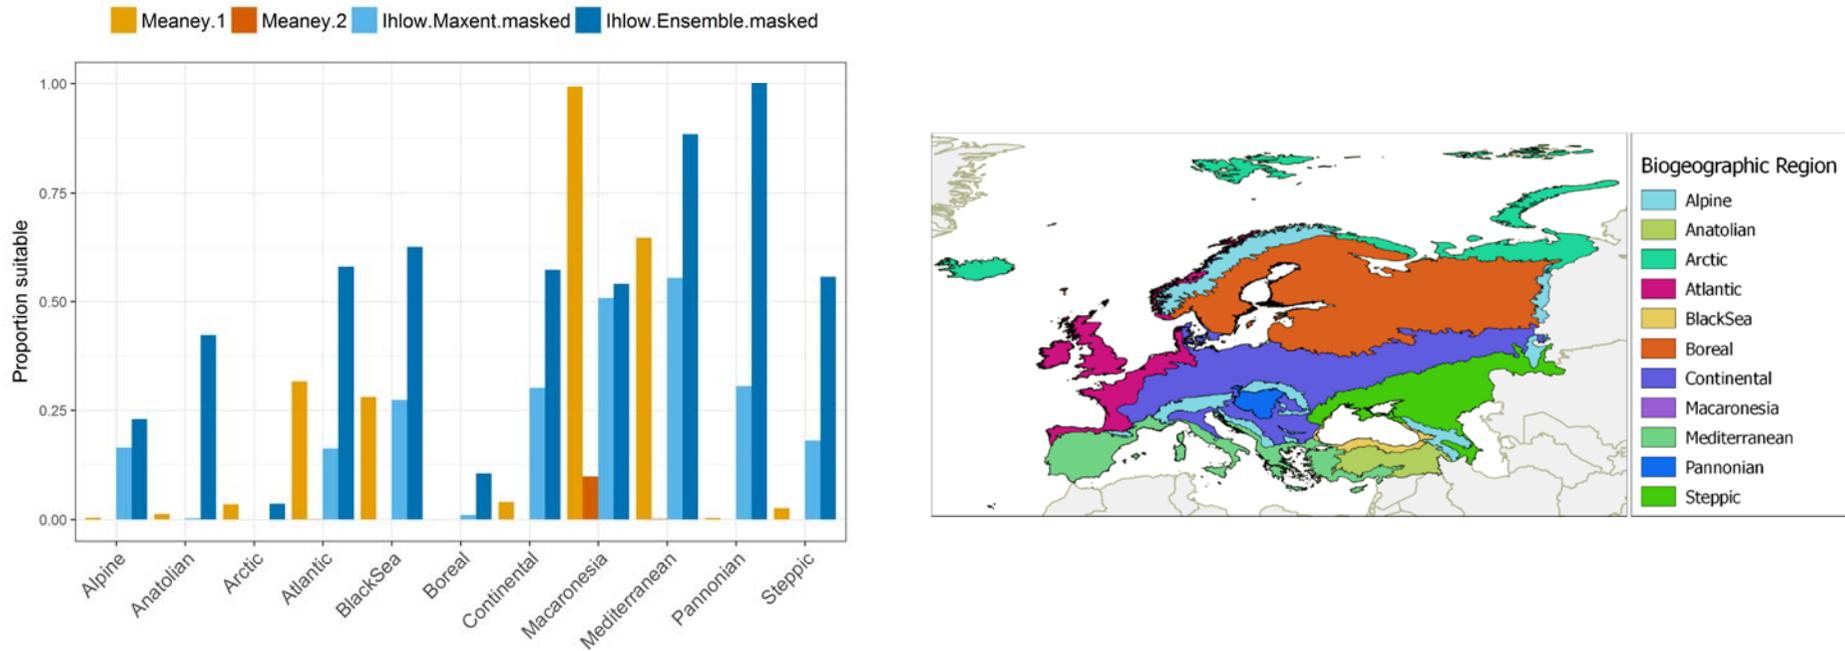

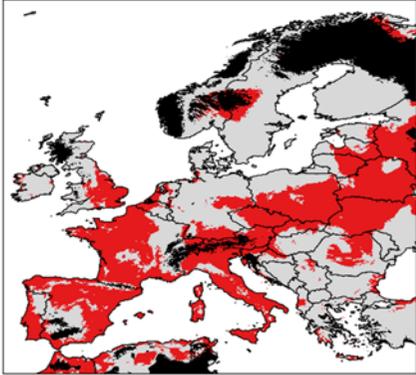

Figure 3. Projected European regions suitable for establishment by *Xenopus laevis* in 2070 under four emissions scenarios. Suitable areas above the suitability of the minimum training presence are shaded red. Regions where extrapolation prevented prediction are shown in black.

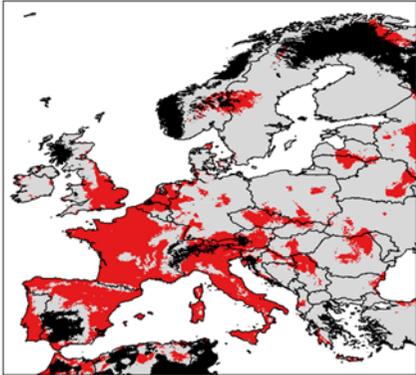

(a) Ihlow et al (2016) Maxent – RCP2.6

(b) Ihlow et al (2016) Ensemble – RCP2.6

(c) Ihlow et al (2016) Maxent – RCP4.5

(d) Ihlow et al (2016) Ensemble – RCP4.5

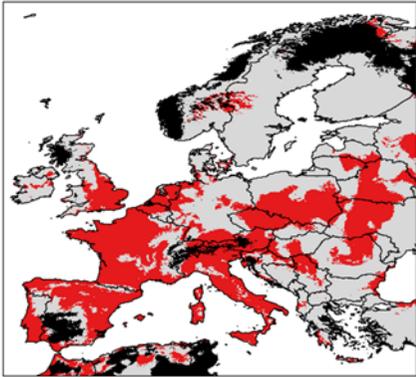

(e) Ihlow et al (2016) Maxent – RCP6.0

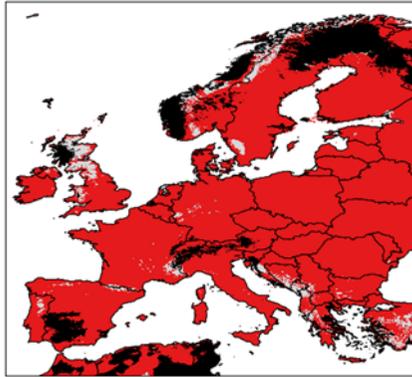

(f) Ihlow et al (2016) Ensemble – RCP6.0

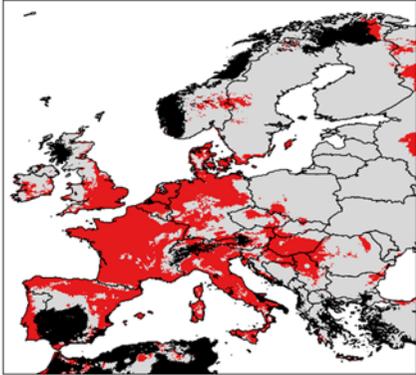

(g) Ihlow et al (2016) Maxent – RCP8.0

(h) Ihlow et al (2016) Ensemble – RCP8.0

## GETTING IN TOUCH WITH THE EU

### **In person**

All over the European Union there are hundreds of Europe Direct information centres. You can find the address of the centre nearest you at: [https://europa.eu/european-union/contact\\_en](https://europa.eu/european-union/contact_en)

### **On the phone or by email**

Europe Direct is a service that answers your questions about the European Union. You can contact this service:

- by Freephone: 00 800 6 7 8 9 10 11 (certain operators may charge for these calls),
- at the following standard number: +32 22999696, or
- by email via: [https://europa.eu/european-union/contact\\_en](https://europa.eu/european-union/contact_en)

## FINDING INFORMATION ABOUT THE EU

### **Online**

Information about the European Union in all the official languages of the EU is available on the Europa website at: [https://europa.eu/european-union/index\\_en](https://europa.eu/european-union/index_en)

### **EU publications**

You can download or order free and priced EU publications from: <https://publications.europa.eu/en/publications>. Multiple copies of free publications may be obtained by contacting Europe Direct or your local information centre (see [https://europa.eu/european-union/contact\\_en](https://europa.eu/european-union/contact_en) ).

### **EU law and related documents**

For access to legal information from the EU, including all EU law since 1952 in all the official language versions, go to EUR-Lex at: <http://eur-lex.europa.eu>

### **Open data from the EU**

The EU Open Data Portal (<http://data.europa.eu/euodp/en>) provides access to datasets from the EU. Data can be downloaded and reused for free, for both commercial and non-commercial purposes.
