HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

SHARP INEQUALITIES RELATED TO WILKER RESULTS

Abd Raouf Chouikha ^{*}

Abstract

In this paper, we interested in Wilker inequalities. We provide finer bounds than known previous. Moreover, bounds are obtained for the following trigonometric function

$$g_n(x) = \left(\frac{\sin(x)}{x} \right)^2 \left(1 - \frac{2 \left(\frac{2x}{\pi} \right)^{2n+2}}{1 - \left(\frac{2x}{\pi} \right)^2} \right) + \frac{\tan(x)}{x}, \quad n \geq 0$$

Key Words and phrases: Trigonometric functions; Sinc function; Inequalities.¹

1 Introduction

For $0 < x < \pi/2$ we know

$$\frac{\sin x}{x} < 1 < \frac{\tan x}{x},$$

or equivalently

$$\frac{x}{\tan x} < 1 < \frac{x}{\sin x}.$$

Exploiting these inequalities to the aim to provide other similar Wilker proposed open problems [21]. One of them is

$$\left(\frac{\sin x}{x} \right)^2 + \frac{\tan x}{x} > 2.$$

Moreover, Wilker asked about the largest constant c such that

$$\left(\frac{\sin x}{x} \right)^2 + \frac{\tan x}{x} > 2 + cx^3 \tan x$$

These problems was solved by Sumner and al. [20] who proved in addition

$$2 + \frac{16}{\pi^4} x^3 \tan x < \left(\frac{\sin x}{x} \right)^2 + \frac{\tan x}{x} < 2 + \frac{8}{45} x^3 \tan x.$$

¹2010 Mathematics Subject Classification : 26D07, 33B10, 33B20, 26D15

As we may remark these constants $\frac{16}{\pi^4}$ and $\frac{8}{45}$ are the limits at 0 and $\pi/2$ of the function

$$x \rightarrow \frac{\left(\frac{\sin x}{x}\right)^2 + \frac{\tan x}{x} - 2}{x^3 \tan x}.$$

Chen and Cheung [5] proved that this function decreases and provided

$$\begin{aligned} 2 + \frac{8x^3}{45} + \frac{16x^5}{315} \tan x &< \left(\frac{\sin x}{x}\right)^2 + \frac{\tan x}{x} < 2 + \frac{8x^3}{45} + \left(\frac{2}{\pi}\right)^6 x^5 \tan x, \\ 2 + \frac{8x^3}{45} + \frac{16x^5}{315} + \frac{104x^7}{4725} \tan x &< \left(\frac{\sin x}{x}\right)^2 + \frac{\tan x}{x} < 2 + \frac{8x^3}{45} + \frac{16x^5}{315} + \left(\frac{12}{\pi}\right)^8 x^7 \tan x. \end{aligned}$$

Moreover, all these constants are the best possible constants.

Later in using a natural approach Mortici [17] gave improvements of that inequalities and produced the following for $0 < x < \pi/2$

$$2 + \frac{1}{\cos x} \left(\frac{8x^4}{45} - \frac{4x^6}{105} \right) < \left(\frac{\sin(x)}{x} \right)^2 + \frac{\tan(x)}{x} < 2 + \frac{1}{\cos x} \left(\frac{8x^4}{45} \right).$$

Malesevic and al. [12] further refined the above inequality for $0 < x < \pi/2$ and $n \in IN$:

$$2 + \frac{1}{\cos x} \sum_{k=2}^{2n+1} (-1)^k D_k x^{2k} < \left(\frac{\sin(x)}{x} \right)^2 + \frac{\tan(x)}{x} < 2 + \frac{1}{\cos x} \sum_{k=2}^{2n} (-1)^k D_k x^{2k},$$

$$\text{where } D_k = \frac{(-9+3^{2k+2}-40k-32k^2)}{4(2k+2)!}.$$

On the other hand, Wu and Srivastava [22, Lemma 3] proved the following dual inequality for $0 < x < \pi/2$

$$\left(\frac{x}{\sin(x)} \right)^2 + \frac{x}{\tan(x)} > 2, \quad 0 < x < \frac{\pi}{2}$$

Mortici [17] improved that result

$$\begin{aligned} \left(\frac{x}{\sin(x)} \right)^2 + \frac{x}{\tan(x)} &> 2 + \frac{2x^4}{45}, \\ \left(\frac{x}{\sin(x)} \right)^2 + \frac{x}{\tan(x)} &> \frac{2 \sin(x)}{x} + \frac{\tan(x)}{x}. \end{aligned}$$

Malesevic and al. [12] further improved the above result for $0 < x < \pi/2$ and $n \in IN$:

$$\left(\frac{x}{\sin(x)} \right)^2 + \frac{x}{\tan(x)} > 2 + \sum_{k=2}^n \frac{|B_{2k}| (2k-2) 2^{2k}}{(2k)!} x^{2k}.$$

Statement 1. [12, Theorem 4 p.9] For $0 < x < \frac{\pi}{2}$

$$(i) \quad 2 + \frac{1}{\cos x} \left(\frac{8x^4}{45} - \frac{4x^6}{105} + \frac{19x^8}{4725} - \frac{37x^{10}}{133650} \right) < \left(\frac{\sin(x)}{x} \right)^2 + \frac{\tan(x)}{x} < 2 + \frac{1}{\cos x} \left(\frac{8x^4}{45} - \frac{4x^6}{105} + \frac{19x^8}{4725} \right).$$

$$(ii) \quad 2 + \frac{1}{\cos x} \left(\frac{8x^4}{45} - \frac{4x^6}{105} + \frac{19x^8}{4725} - \frac{37x^{10}}{133650} + \frac{283x^{12}}{20638800} - \frac{3503x^{14}}{6810604000} \right) < \left(\frac{\sin(x)}{x} \right)^2 + \frac{\tan(x)}{x} < 2 + \frac{1}{\cos x} \left(\frac{8x^4}{45} - \frac{4x^6}{105} + \frac{19x^8}{4725} - \frac{37x^{10}}{133650} + \frac{283x^{12}}{20638800} \right).$$

Statement 2. [12, Theorem 5 p.11] For $0 < x < \frac{\pi}{2}$

$$(i) \quad 2 + \frac{2x^4}{45} + \frac{8x^6}{945} < \left(\frac{x}{\sin(x)} \right)^2 + \frac{x}{\tan(x)} < 2 + \frac{2x^4}{45} + \left(\frac{2}{\pi} \right)^6 \left(-2 + \frac{\pi^2}{4} - \frac{\pi^4}{360} \right) x^6.$$

$$(ii) \quad 2 + \frac{2x^4}{45} + \frac{8x^6}{945} + \frac{2x^8}{1575} < \left(\frac{x}{\sin(x)} \right)^2 + \frac{x}{\tan(x)} < 2 + \frac{2x^4}{45} + \frac{8x^6}{945} + \left(\frac{2}{\pi} \right)^8 \left(-2 + \frac{\pi^2}{4} - \frac{\pi^4}{360} - \frac{\pi^6}{7560} \right) x^8.$$

$$(iii) \quad 2 + \frac{2x^4}{45} + \frac{8x^6}{945} + \frac{2x^8}{1575} + \frac{16x^{10}}{93555} < \left(\frac{x}{\sin(x)} \right)^2 + \frac{x}{\tan(x)} < 2 + \frac{2x^4}{45} + \frac{8x^6}{945} + \frac{2x^8}{1575} + \left(\frac{2}{\pi} \right)^{10} \left(-2 + \frac{\pi^2}{4} - \frac{\pi^4}{360} - \frac{\pi^6}{7560} - \frac{\pi^8}{201600} \right) x^{10}.$$

In this paper, we aim to refine the inequalities mentioned above.

2 The first Wilker inequality

One proved [..]

The first Wilker inequality [21]

$$\left(\frac{\sin(x)}{x} \right)^2 + \frac{\tan(x)}{x} > 2, \quad x \in (0, \frac{\pi}{2})$$

was intensively studied by many authors, e.g, [3],[7],[13],[18],[23] Mortici [17] and Malesevic [12] proved

$$2 + \left(\frac{8}{45} x^4 - \frac{8}{105} x^6 \right) \left(\frac{1}{\cos x} \right) < \left(\frac{\sin(x)}{x} \right)^2 + \frac{\tan(x)}{x} < 2 + \left(\frac{8x^4}{45 \cos(x)} \right).$$

The following result gives bounds which permit to refine some previous ones

Theorem 2-1 *For $0 < x < \pi/2$ the following inequalities holds for $1 \leq m \leq n$ and $p \leq n$*

$$\begin{aligned} & \left(1 - \sum_{k=m+1}^{\infty} \frac{2^{2k+1}}{\pi^{2k}(2^{2k}-2^{\beta})} x^{2k} - \sum_{k=1}^m \frac{2^{2k} |B_{2k}|}{(2k)!} x^{2k} + \sum_{k=3}^n a^k x^{2k-2} \right) \times \\ & \left(2 + \sum_{k=1}^p \frac{2^{2k}(2^{2k}-2) |B_{2k}|}{(2k)!} x^{2k} + \sum_{k=p+1}^n \frac{2^{2k+1}(2^{2k}-2)}{\pi^{2k}(2^{2k}-1)} x^{2k} \right) < \left(\frac{\sin(x)}{x} \right)^2 + \frac{\tan(x)}{x} < \\ & \left(1 - \sum_{k=m+1}^{\infty} \frac{2^{2k+1}}{\pi^{2k}(2^{2k}-1)} x^{2k} + \sum_{k=1}^m \frac{2^{2k} |B_{2k}|}{(2k)!} x^{2k} + \sum_{k=3}^{\infty} a^k x^{2k-2} \right) \times \\ & \left(2 + \sum_{k=1}^p \frac{2^{2k}(2^{2k}-2) |B_{2k}|}{(2k)!} x^{2k} + 2 \left(\frac{2x}{\pi} \right)^{2p+2} \frac{1}{1 - (\frac{2x}{\pi})^2} \right), \end{aligned}$$

where B_{2k} are the Bernoulli numbers and $\beta = 2 + \frac{\ln(1-\frac{6}{\pi^2})}{\ln 2} = 0.6491\dots$ is the Alzer constant.

Proof of Theorem 2-1 Remark at first we may write obviously

$$\left(\frac{\sin(x)}{x} \right)^2 \left(1 + \frac{2x}{\sin(2x)} \right) = \left(\frac{\sin(x)}{x} \right)^2 + \frac{\tan(x)}{x}.$$

Lemma 2-2 *For $0 < x < \pi/2$ the following inequalities holds for any integer $m \geq 5$*

$$\begin{aligned} & \left(\frac{\sin(x)}{x} \right)^2 < 1 - \sum_{k=m+1}^{\infty} \frac{2^{2k+1}}{\pi^{2k}(2^{2k}-1)} x^{2k} + \sum_{k=1}^m \frac{2^{2k} |B_{2k}|}{(2k)!} x^{2k} + \sum_{k=3}^{\infty} a^k x^{2k-2}, \\ & 1 - \sum_{k=m+1}^{\infty} \frac{2^{2k+1}}{\pi^{2k}(2^{2k}-2)} x^{2k} - \sum_{k=1}^m \frac{2^{2k} |B_{2k}|}{(2k)!} x^{2k} + \sum_{k=3}^n a^k x^{2k-2} < \left(\frac{\sin(x)}{x} \right)^2. \end{aligned}$$

Lemma 2-3 For $0 < x < \pi/2$ consider the function

$$f(x) = (\sin x)^2 - x^3 \cot x - \frac{x^6}{15} + \frac{x^8}{945}$$

then $f(x)$ can be expressed as power series $f(x) = \sum_{k \geq 5} a_k x^{2k}$,

$$a_k = \frac{2^{2k-2} |B_{2k-2}|}{(2k-2)!} + \frac{(-1)^{k+1} 2^{2k-1}}{(2k)!} = \frac{2^{2k-2}}{(2k-2)!} \left(|B_{2k-2}| + \frac{(-1)^{k+1}}{(2k-1)k} \right),$$

where B_{2k} are the Bernoulli numbers. Moreover, the coefficients $a_k, k \geq 5$ are all positive:

$$a_5 = \frac{1}{255150}, \quad a_6 = \frac{2}{15436575}, \quad a_7 = \frac{103}{8300667375}, \dots$$

Proof of Lemma 2-3

The following series expansions can be found in [1],[10],[11]

$$\cot x = \frac{1}{x} - \sum_{k=1}^{\infty} \frac{2^{2k} |B_{2k}|}{(2k)!} x^{2k-1}, \quad x \in (0, \pi)$$

and

$$\sin^2 x = \sum_{k=1}^{\infty} (-1)^{k+1} \frac{2^{2k-1}}{(2k)!} x^{2k}, \quad x \in (0, \frac{\pi}{2})$$

$$\begin{aligned} (\sin x)^2 - x^3 \cot x &= \left(\frac{1}{15} x^6 - \frac{1}{945} x^8 + \frac{1}{2835} x^{10} + \frac{8}{467775} x^{12} + \frac{206}{91216125} x^{14} + \right. \\ &\quad \left. \frac{139}{638512875} x^{16} + \frac{10861}{488462349375} x^{18} + \frac{438628}{194896477400625} x^{20} + O(x^{22}) \right). \end{aligned}$$

To prove the positivity of the coefficients a_k , k even we will use the following inequality for Bernoulli numbers established by D'Aniello [9]:

$$\frac{2(2k)!}{\pi^{2k}(2^{2k}-1)} < |B_{2k}| < \frac{2(2k)!}{\pi^{2k}(2^{2k}-2)}.$$

For any odd value of k , we have

$$a_k = \frac{2^{2k-2}}{(2k-2)!} \left(|B_{2k-2}| + \frac{(-1)^{k+1}}{(2k-1)k} \right) = \frac{2^{2k-2}}{(2k-2)!} \left(|B_{2k-2}| + \frac{1}{(2k-1)k} \right) > 0.$$

Consider the even case, then

$$a_k = \frac{2^{2k-2}}{(2k-2)!} \left(|B_{2k-2}| + \frac{-1}{(2k-1)k} \right).$$

By definition of Bernoulli numbers

$$S_n(p) = \sum_{k=0}^{n-1} k^p = \frac{1}{p+1} \sum_{k=0}^p \binom{p+1}{k} B_k n^{p+1-k}.$$

Then for k even

$$a_k = \frac{2^{2k-2}}{(2k-2)!} \left(|B_{2k-2}| - \frac{1}{(2k-1)k} \right) > \frac{2^{2k-2}}{(2k-2)!} \left(\frac{2(2k-2)!}{\pi^{2k-2}(2^{2k-2}-2)} - \frac{1}{(2k-1)k} \right)$$

and

$$a_k < \frac{2^{2k-2}}{(2k-2)!} \left(\frac{2(2k-2)!}{\pi^{2k-2}(2^{2k-2}-1)} - \frac{1}{(2k-1)k} \right).$$

Therefore

$$\begin{aligned} \frac{2^{2k-2} \frac{2(2k-2)!}{\pi^{2k-2}(2^{2k-2}-1)}}{(2k-2)!} + \frac{(-1)^{k+1} 2^{2k-1}}{(2k)!} &< a_k = \frac{2^{2k-2} |B_{2k-2}|}{(2k-2)!} + \frac{(-1)^{k+1} 2^{2k-1}}{(2k)!} \\ &< \frac{2^{2k-2} \frac{2(2k-2)!}{\pi^{2k-2}(2^{2k-2}-2)}}{(2k-2)!} + \frac{(-1)^{k+1} 2^{2k-1}}{(2k)!}. \end{aligned}$$

and

$$\sum_{k \geq 5} \left(\frac{2^{2k-1}}{2\pi^{2k-2}(2^{2k-2}-1)} + \frac{(-1)^{k+1} 2^{2k-1}}{(2k)!} \right) x^{2k} < f(x).$$

Thus it implies the left hand of (4) since for any integer $n \geq 5$ we have

$$\begin{aligned} \cos x &\leq \cos x + \sin x \left(\frac{x^3}{15} - \frac{x^5}{945} \right) + \sin x \sum_{5 \leq k \leq n} a_k x^{2k-3} \\ &\leq \cos x + \sin x \left(\frac{x^3}{15} - \frac{x^5}{945} \right) + \sin x \sum_{5 \leq k \leq \infty} a_k x^{2k-3} = \left(\frac{\sin x}{x} \right)^3. \end{aligned}$$

$$(\sin x)^2 - x^3 \cot x = (\sin x)^2 - x^3 \left(\frac{1}{x} - \sum_{k=1}^{\infty} \frac{2^{2k} |B_{2k}|}{(2k)!} x^{2k-1} \right) =$$

$$(\sin x)^2 - x^2 + \sum_{k=1}^{\infty} \frac{2^{2k} |B_{2k}|}{(2k)!} x^{2k+2} < (\sin x)^2 - x^2 + \sum_{k=1}^{\infty} \frac{2^{2k+1} x^{2k+2}}{\pi^{2k} (2^{2k}-2)}.$$

In the other hand we know that for $k > 1$

$$(2k)! > \sqrt{4\pi k} \left(\frac{2k}{e} \right)^{2k} e^{\frac{1}{24k+1}}.$$

It implies

$$\begin{aligned} \left(\frac{2(2k-2)!}{\pi^{2k-2}(2^{2k-2}-1)} - \frac{1}{(2k-1)k} \right) &> \left(\frac{2\sqrt{4\pi(k-1)}(\frac{2k-2}{e})^{2k-2}e^{\frac{1}{48k-23}}}{\pi^{2k-2}(2^{2k-2}-1)} - \frac{1}{(2k-1)k} \right) > \\ \left(\frac{2\sqrt{4\pi(k-1)}(\frac{2k-2}{\pi e})^{2k-2}}{(2^{2k-2}-1)} - \frac{1}{(2k-1)k} \right) &> \left(\frac{2\sqrt{4\pi(k-1)}(\frac{2k-2}{\pi e})^{2k-2}}{2^{2k-2}} - \frac{1}{(2k-1)k} \right) > \\ \left(2\sqrt{4\pi(k-1)}(\frac{k-1}{\pi e})^{2k-2} - \frac{1}{(2k-1)k} \right). \end{aligned}$$

Thanks to *Maple* we may easily verify that the last expression is non negative as soon as $k > 6$. This means that a_k are non negative.

By this Lemma we deduce

$$\frac{f(x)}{x^2} = \left(\frac{\sin(x)}{x} \right)^2 - x \cot x - \frac{x^4}{15} + \frac{x^6}{945} = \sum_{k \geq 5} a_k x^{2k-2},$$

where

$$a_k = \frac{2^{2k-2}}{(2k-2)!} \left(|B_{2k-2}| + \frac{(-1)^{k+1}}{(2k-1)k} \right).$$

Thus for any integer $n \geq 5$

$$\left(\frac{\sin(x)}{x} \right)^2 = x \cot x + \frac{x^4}{15} - \frac{x^6}{945} + \sum_{k \geq 5} a_k x^{2k-2} \geq x \cot x + \frac{x^4}{15} - \frac{x^6}{945} + \sum_{k=5}^n a_k x^{2k-2}$$

since coefficients $a_k > 0..$

Therefore since by [6, p.] for $x \in (0, \pi)$

$$\begin{aligned} \cot x &= \frac{1}{x} - \frac{x}{3} - \frac{x^3}{45} - \frac{2x^5}{945} - \dots = \frac{1}{x} - \sum_{k=1}^{\infty} \frac{2^{2k} |B_{2k}|}{(2k)!} x^{2k-1} \\ &= \frac{1}{x} - \sum_{k=1}^{n-1} \frac{2^{2k} |B_{2k}|}{(2k)!} x^{2k-1} - \sum_{k=n}^{\infty} \frac{2^{2k} |B_{2k}|}{(2k)!} x^{2k-1}, \end{aligned}$$

and by [9]

$$\frac{2(2k)!}{\pi^{2k}(2^{2k}-1)} < |B_{2k}| < \frac{2(2k)!}{\pi^{2k}(2^{2k}-2)}. \quad (1)$$

Then we deduce the inequalities

$$\sum_{k=n+1}^{\infty} \frac{-2^{2k+1}}{\pi^{2k}(2^{2k}-2)} x^{2k-1} < \cot x - \frac{1}{x} + \sum_{k=1}^n \frac{2^{2k} |B_{2k}|}{(2k)!} x^{2k-1} < \sum_{k=n+1}^{\infty} \frac{-2^{2k+1}}{\pi^{2k}(2^{2k}-1)} x^{2k-1}.$$

Notice that Alzer [2] provides a further result

$$\frac{2(2k)!}{\pi^{2k}(2^{2k}-1)} < |B_{2k}| < \frac{2^{2k+1}(2k)!}{\pi^{2k}(2^{2k}-2^\beta)} < \frac{2^{2k+1}(2k)!}{\pi^{2k}(2^{2k}-2)} \quad (2)$$

where $\beta = 2 + \frac{\ln(1-\frac{6}{\pi^2})}{\ln 2} = 0.6491\dots$ is the best possible constant in the sense that it can not be replaced respectively by any bigger and smaller constant in the double inequality.

We then obtain better inequalities for $\cot x$

$$\sum_{k=n+1}^{\infty} \frac{-2^{2k+1}}{\pi^{2k}(2^{2k}-2^\beta)} x^{2k-1} < \cot x - \frac{1}{x} + \sum_{k=1}^n \frac{2^{2k} |B_{2k}|}{(2k)!} x^{2k-1}.$$

On the other hand, it follows by the same way for any integer $m \geq 5$

$$\begin{aligned} \left(\frac{\sin(x)}{x}\right)^2 &< 1 - \sum_{k=m+1}^{\infty} \frac{2^{2k+1}}{\pi^{2k}(2^{2k}-1)} x^{2k} - \sum_{k=1}^m \frac{2^{2k} |B_{2k}|}{(2k)!} x^{2k} + \sum_{k=3}^{\infty} a^k x^{2k-2}, \\ 1 - \sum_{k=m+1}^{\infty} \frac{2^{2k+1}}{\pi^{2k}(2^{2k}-2^\beta)} x^{2k} - \sum_{k=1}^m \frac{2^{2k} |B_{2k}|}{(2k)!} x^{2k} + \sum_{k=3}^n a^k x^{2k-2} &< \left(\frac{\sin(x)}{x}\right)^2. \end{aligned}$$

Let us consider now expansions trigonometric functions with power series. We will use the Taylor expansions of $\sin(x)$,

$$\sin(x) = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \dots + (-1)^{k-1} \frac{x^{2k-1}}{(2k-1)!} + (-1)^k \frac{\sin \theta x}{(2k+1)!} x^{2k+1}$$

where $0 < \theta < 1$. It is easy to remark that

$$1 - \frac{x^2}{3!} + \frac{x^4}{5!} - \frac{x^6}{7!} < \frac{\sin x}{x} < 1 - \frac{x^2}{3!} + \frac{x^4}{5!} - \frac{x^6}{7!} + \frac{x^8}{9!}$$

for $0 < x < \frac{\pi}{2}$. We then deduce bounds for $\left(\frac{\sin x}{x}\right)^2$

$$\sum_{k=1}^{2p} (-1)^{k+1} \frac{2^{2k+1}}{(2k)!} x^{2k-2} < \left(\frac{\sin x}{x}\right)^2 < \sum_{k=1}^{2p+1} (-1)^{k+1} \frac{2^{2k+1}}{(2k)!} x^{2k-2}.$$

On the other hand, we know that [11 p.145]

$$\frac{1}{\sin x} = \frac{1}{x} + \frac{x}{6} + \frac{7x^3}{360} + \dots = \frac{1}{x} + \sum_{k=1}^{\infty} \frac{(2^{2k}-2) |B_{2k}|}{(2k)!} x^{2k-1}.$$

We then derive the following inequalities for any $n \geq 1$

Lemma 2-4 For $0 < x < \pi/2$ the following inequalities holds for any integer $p \geq 1$

$$2 + \sum_{k=1}^p \frac{2^{2k}(2^{2k}-2) |B_{2k}|}{(2k)!} x^{2k} + \sum_{k=p+1}^n \frac{2^{2k+1}(2^{2k}-2)}{\pi^{2k}(2^{2k}-1)} x^{2k} < 1 + \frac{2x}{\sin 2x} <$$

$$2 + \sum_{k=1}^p \frac{2^{2k}(2^{2k}-2) |B_{2k}|}{(2k)!} x^{2k} + 2 \left(\frac{2x}{\pi}\right)^{2p+2} \frac{1}{1 - (\frac{2x}{\pi})^2}.$$

Indeed, by [11 p.146] one has

$$1 + \frac{2x}{\sin 2x} = 2 + \sum_{k=1}^{\infty} \frac{2^{2k}(2^{2k}-2) |B_{2k}|}{(2k)!} x^{2k} > 2 + \sum_{k=1}^n \frac{2^{2k}(2^{2k}-2) |B_{2k}|}{(2k)!} x^{2k}.$$

Then it follows by (1)

$$\begin{aligned} 2 + \sum_{k=1}^p \frac{2^{2k}(2^{2k}-2) |B_{2k}|}{(2k)!} x^{2k} + \sum_{k=p+1}^n \frac{2^{2k+1}(2^{2k}-2)}{\pi^{2k}(2^{2k}-1)} x^{2k} &< 1 + \frac{2x}{\sin 2x} < \\ 2 + \sum_{k=1}^p \frac{2^{2k}(2^{2k}-2) |B_{2k}|}{(2k)!} x^{2k} + 2 \sum_{k=p+1}^{\infty} \frac{2^{2k}}{\pi^{2k}} x^{2k} &= \\ 2 + \sum_{k=1}^p \frac{2^{2k}(2^{2k}-2) |B_{2k}|}{(2k)!} x^{2k} + 2 \left(\frac{2x}{\pi}\right)^{2p+2} \frac{1}{1 - (\frac{2x}{\pi})^2}. \end{aligned}$$

We may also prove the following frame

$$\frac{2(\frac{2x}{\pi})^{2n+2}}{1 - (\frac{2x}{\pi})^2} - 2 \sum_{k=1}^n \frac{1}{2^k - 1} \left(\frac{2x}{\pi}\right)^{2k} < 1 + \frac{2x}{\sin 2x} < \frac{2}{1 - (\frac{2x}{\pi})^2}.$$

Finally, we get a lower bound for the product

$$\begin{aligned} \left(\frac{\sin(x)}{x}\right)^2 \left(1 + \frac{2x}{\sin 2x}\right) &> \left(1 - \sum_{k=m+1}^{\infty} \frac{2^{2k+1}}{\pi^{2k}(2^{2k}-2^{\beta})} x^{2k} - \sum_{k=1}^m \frac{2^{2k} |B_{2k}|}{(2k)!} x^{2k} + \sum_{k=3}^n a^k x^{2k-2}\right) \times \\ \left(2 + \sum_{k=1}^p \frac{2^{2k}(2^{2k}-2) |B_{2k}|}{(2k)!} x^{2k} + \sum_{k=p+1}^n \frac{2^{2k+1}(2^{2k}-2)}{\pi^{2k}(2^{2k}-1)} x^{2k}\right) &= \phi_{m,n,p}(x). \end{aligned}$$

The upper bound is

$$\begin{aligned} \left(\frac{\sin(x)}{x}\right)^2 \left(1 + \frac{2x}{\sin 2x}\right) &< \left(1 - \sum_{k=m+1}^{\infty} \frac{2^{2k+1}}{\pi^{2k}(2^{2k}-1)} x^{2k} - \sum_{k=1}^m \frac{2^{2k} |B_{2k}|}{(2k)!} x^{2k} + \sum_{k=3}^{\infty} a^k x^{2k-2}\right) \times \\ \left(2 + \sum_{k=1}^p \frac{2^{2k}(2^{2k}-2) |B_{2k}|}{(2k)!} x^{2k} + 2 \left(\frac{2x}{\pi}\right)^{2p+2} \frac{1}{1 - (\frac{2x}{\pi})^2}\right) &= \psi_{m,p}(x). \end{aligned}$$

Thus the following inequalities hold for $0 < x < \pi/2$ and for integers $1 \leq m; 3 \leq n; 1 \leq p \leq n$

$$\phi_{m,n,p}(x) < \left(\frac{\sin(x)}{x}\right)^2 + \frac{\tan(x)}{x} < \psi_{m,p}(x).$$

Theorem 2-1 is then proved.

Examples 2-5 Let $0 < x < \pi/2$. By Theorem 4-1 we are able to precise the lower bound of the Wilker inequality in putting different values of n, p .

- Taking $n = 3$ and $p = m = 2$ we have

$$\phi_{2,4,2} = 2 + \frac{8x^4}{45} < \left(\frac{\sin(x)}{x} \right)^2 + \frac{\tan(x)}{x}.$$

Then we find again a result of [3] since

$$\frac{1}{\cos x} \left(\frac{8x^4}{45} - \frac{4x^6}{105} \right) > \frac{\frac{8x^4}{45} - \frac{4x^6}{105}}{1 - \frac{x^2}{2!} + \frac{x^4}{4!}} > \frac{8x^4}{45}.$$

- Taking $n = 4$ and $p = m = 3$ we find

$$\phi_{3,4,3} = 2 + \frac{8x^4}{45} + \frac{16x^6}{315} < \left(\frac{\sin(x)}{x} \right)^2 + \frac{\tan(x)}{x}.$$

- Taking $n = 5$ and $p = m = 3$ we have

$$\phi_{3,5,3} = 2 + \frac{8x^4}{45} + \frac{16x^6}{315} + \frac{104x^8}{4725} < \left(\frac{\sin(x)}{x} \right)^2 + \frac{\tan(x)}{x}.$$

- Taking $n = 6$ and $p = m = 5$ we have

$$\phi_{5,6,5} = 2 + \frac{8x^4}{45} + \frac{16x^6}{315} + \frac{104x^8}{4725} + \frac{592x^{10}}{66825} < \left(\frac{\sin(x)}{x} \right)^2 + \frac{\tan(x)}{x}.$$

This permits to find again statement 1 (i) [4, p.9]. indeed, since (see lemma 2-6 below) for $0 < x < \pi/2$

$$\cos x > 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \frac{x^8}{8!} - \frac{x^{10}}{10!} + \frac{x^{12}}{12!} - \frac{x^{14}}{14!}$$

we then deduce

$$(\cos x) \left(\frac{8x^4}{45} + \frac{16x^6}{315} + \frac{104x^8}{4725} + \frac{592x^{10}}{66825} \right) > \frac{8}{45} x^4 - \frac{4}{105} x^6 + \frac{19}{4725} x^8 - \frac{37}{133650} x^{10}.$$

- Taking $n = 7$ and $p = m = 4$ we obtain

$$\phi_{4,7,4} = 2 + \frac{8x^4}{45} + \frac{16x^6}{315} + \frac{104x^8}{4725} + \frac{592x^{10}}{66825} + \frac{152912x^{12}}{42567525} < \left(\frac{\sin(x)}{x} \right)^2 + \frac{\tan(x)}{x}.$$

By the same way, using again the lower bound of $\cos x$ we find a result of [4, p.10]

$$(\cos x) \left(2 + \frac{8x^4}{45} + \frac{16x^6}{315} + \frac{104x^8}{4725} + \frac{592x^{10}}{66825} + \frac{152912x^{12}}{42567525} \right) >$$

$$\frac{8}{45}x^4 - \frac{4}{105}x^6 + \frac{19}{4725}x^8 - \frac{37}{133650}x^{10} + \frac{283}{20638800}x^{12} - \frac{3503}{6810804000}x^{14}.$$

Etc...

In the sequel we will find upper and lower bounds of Wilker inequalities which appear to be finer than known previous. Consider at first

Lemma 2-6 *For $0 < x < \pi/2$ the following inequalities holds for any integer $p \geq 1$*

$$\sum_{k=1}^{2p} (-1)^{k+1} \frac{2^{2k+1}}{(2k)!} x^{2k-2} < \left(\frac{\sin x}{x} \right)^2 < \sum_{k=1}^{2p+1} (-1)^{k+1} \frac{2^{2k+1}}{(2k)!} x^{2k-2},$$

$$\sum_{k=1}^{2p+1} (-1)^k \frac{1}{(2k)!} x^{2k} < \cos x < \sum_{k=1}^{2p} (-1)^k \frac{1}{(2k)!} x^{2k}.$$

Let us consider expansions trigonometric functions with power series. We will use the Taylor expansions of $\sin x$, $\cos x$

$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \dots + (-1)^{k-1} \frac{x^{2k-1}}{(2k-1)!} + (-1)^k \frac{\sin \theta x}{(2k+1)!} x^{2k+1},$$

$$\cos x = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \dots + (-1)^k \frac{x^{2k}}{(2k)!} + (-1)^{k+1} \frac{\cos \theta x}{(2k+2)!} x^{2k+2}$$

where $0 < \theta < 1$. It is easy to remark that

$$1 - \frac{x^2}{3!} + \frac{x^4}{5!} - \frac{x^6}{7!} < \frac{\sin x}{x} < 1 - \frac{x^2}{3!} + \frac{x^4}{5!} - \frac{x^6}{7!} + \frac{x^8}{9!}$$

for $0 < x < \frac{\pi}{2}$. We then deduce bounds for $\left(\frac{\sin x}{x}\right)^2 \cos x$

$$\sum_{k=1}^{2p} (-1)^{k+1} \frac{2^{2k+1}}{(2k)!} x^{2k-2} < \left(\frac{\sin x}{x} \right)^2 < \sum_{k=1}^{2p+1} (-1)^{k+1} \frac{2^{2k+1}}{(2k)!} x^{2k-2}.$$

$$\sum_{k=1}^{2p+1} (-1)^k \frac{1}{(2k)!} x^{2k} < \cos x < \sum_{k=1}^{2p} (-1)^k \frac{1}{(2k)!} x^{2k}.$$

By Lemma 2-4 we then derive the following which improves Theorem 2-1

Theorem 2-7 *For $0 < x < \pi/2$ the following inequalities holds for any $q \geq 1, 1 \leq p \leq n$*

$$\left(\sum_{k=1}^{2q} (-1)^{k+1} \frac{2^{2k-1}}{(2k)!} x^{2k-2} \right) \times \left(2 + \sum_{k=1}^p \frac{2^{2k}(2^{2k}-2) |B_{2k}|}{(2k)!} x^{2k} + \sum_{k=p+1}^n \frac{2^{2k+1}(2^{2k}-2)}{\pi^{2k}(2^{2k}-1)} x^{2k} \right)$$

$$< \left(\frac{\sin(x)}{x} \right)^2 + \frac{\tan(x)}{x} < \\ \left(\sum_{k=1}^{2q+1} (-1)^{k+1} \frac{2^{2k-1}}{(2k)!} x^{2k-2} \right) \times \left(2 + \sum_{k=1}^p \frac{2^{2k}(2^{2k}-2) |B_{2k}|}{(2k)!} x^{2k} + 2 \left(\frac{2x}{\pi} \right)^{2p+2} \frac{1}{1 - (\frac{2x}{\pi})^2} \right),$$

where B_{2k} are the Bernoulli numbers.

Corollary 2-8 For $0 < x < \pi/2$ the following inequalities holds for any $n, p, 1 \leq p \leq n$

$$\left(\frac{\sin(x)}{x} \right)^2 \times \left(2 + \sum_{k=1}^p \frac{2^{2k}(2^{2k}-2) |B_{2k}|}{(2k)!} x^{2k} + \frac{2 \left(\frac{2x}{\pi} \right)^{2n+2}}{1 - (\frac{2x}{\pi})^2} - 2 \sum_{k=1}^n \frac{1}{2^k - 1} \left(\frac{2x}{\pi} \right)^{2k} \right) < \\ \left(\frac{\sin(x)}{x} \right)^2 + \frac{\tan(x)}{x} < \\ \left(\frac{\sin(x)}{x} \right)^2 \times \left(2 + \sum_{k=1}^p \frac{2^{2k}(2^{2k}-2) |B_{2k}|}{(2k)!} x^{2k} + \frac{2 \left(\frac{2x}{\pi} \right)^{2n+2}}{1 - (\frac{2x}{\pi})^2} \right).$$

where B_{2k} are the Bernoulli numbers.

Corollary 2-8 means that the following inequalities hold

$$\left(\frac{\sin(x)}{x} \right)^2 \times \left(2 + \sum_{k=1}^p \frac{2^{2k}(2^{2k}-2) |B_{2k}|}{(2k)!} x^{2k} - 2 \sum_{k=1}^n \frac{1}{2^k - 1} \left(\frac{2x}{\pi} \right)^{2k} \right) < \\ g_n(x) = \left(\frac{\sin(x)}{x} \right)^2 \left(1 - \frac{2 \left(\frac{2x}{\pi} \right)^{2n+2}}{1 - (\frac{2x}{\pi})^2} \right) + \frac{\tan(x)}{x} < \\ \left(\frac{\sin(x)}{x} \right)^2 \times \left(2 + \sum_{k=1}^p \frac{2^{2k}(2^{2k}-2) |B_{2k}|}{(2k)!} x^{2k} \right) < \left(\frac{\sin(x)}{x} \right)^2 + \frac{\tan(x)}{x}.$$

The function $g_n(x)$ is growing as n increasing. We have

$$g_2(x) = \left(\frac{\sin(x)}{x} \right)^2 \left(1 - \frac{2 \left(\frac{2x}{\pi} \right)^2}{1 - (\frac{2x}{\pi})^2} \right) + \frac{\tan(x)}{x} < g_n(x) < \\ \lim_{n \rightarrow \infty} g_n(x) = \left(\frac{\sin x}{x} \right)^2 + \frac{\tan x}{x}.$$

Moreover, we may compute the limit when x tends to $(\frac{\pi}{2})^-$

$$\lim_{x \rightarrow \frac{\pi}{2}^-} g_n(x) = \frac{2(3+4n)}{\pi^2},$$

and

$$g_n(x) - \frac{2(3+4n)}{\pi^2} = \frac{-24n^2 + 24n + 33 + 2\pi^2}{3\pi^3}(\pi - 2x) + \dots$$

Examples 2-9 Let $0 < x < \pi/2$.

- Taking $n = 3$ and $p = 2$ we find

$$\begin{aligned} 2 + \frac{8x^4}{45} &< g_3(x) = \left(\frac{\sin x}{x}\right)^2 + \frac{\tan x}{x} - \left(\frac{\sin x}{x}\right)^2 \left(\frac{2\left(\frac{2x}{\pi}\right)^8}{1 - \left(\frac{2x}{\pi}\right)^2}\right) < \\ \frac{2306x^{10}}{467775} - \frac{2x^8}{63} + \frac{16x^6}{315} + \frac{8x^4}{45} + 2 &< \frac{16x^6}{315} + \frac{8x^4}{45} + 2. \end{aligned}$$

- Taking $n = 4$ and $p = 3$ we find

$$\begin{aligned} 2 + \frac{8x^4}{45} + \frac{16x^6}{315} &< g_4(x) = \left(\frac{\sin(x)}{x}\right)^2 + \frac{\tan(x)}{x} - \left(\frac{\sin(x)}{x}\right)^2 \left(\frac{2\left(\frac{2x}{\pi}\right)^{10}}{1 - \left(\frac{2x}{\pi}\right)^2}\right) < \\ \frac{61232x^{12}}{30405375} - \frac{868x^{10}}{66825} + \frac{104x^8}{4725} + \frac{16x^6}{315} + \frac{8x^4}{45} + 2 &< \frac{104x^8}{4725} + \frac{16x^6}{315} + \frac{8x^4}{45} + 2. \end{aligned}$$

- Taking $n = 5$ and $p = 3$ we obtain

$$\begin{aligned} 2 + \frac{8x^4}{45} + \frac{16x^6}{315} + \frac{104x^8}{4725} &< g_5(x) = \left(\frac{\sin(x)}{x}\right)^2 + \frac{\tan(x)}{x} - \left(\frac{\sin(x)}{x}\right)^2 \left(\frac{2\left(\frac{2x}{\pi}\right)^{12}}{1 - \left(\frac{2x}{\pi}\right)^2}\right) < \\ \frac{1566172x^{14}}{1915538625} - \frac{480604x^{12}}{91216125} + \frac{592x^{10}}{66825} + \frac{104x^8}{4725} + \frac{16x^6}{315} + \frac{8x^4}{45} + 2 &< \\ \frac{592x^{10}}{66825} + \frac{104x^8}{4725} + \frac{16x^6}{315} + \frac{8x^4}{45} + 2. \end{aligned}$$

We then improve by another way statement 1 (i) ([4, p.9]) since by Lemma 2-4

$$\begin{aligned} \left(\frac{8}{45}x^4 + \frac{16}{315}x^6 + \frac{104}{4725}x^8 + \frac{592}{66825}x^{10}\right) \cos(x) &< \frac{8}{45}x^4 - \frac{4}{105}x^6 + \frac{19}{4725}x^8 \\ \left(\frac{8}{45}x^4 + \frac{16}{315}x^6 + \frac{104}{4725}x^8 + \frac{592}{66825}x^{10} + \frac{152912}{42567525}x^{12}\right) \cos(x) &> \\ \frac{8}{45}x^4 - \frac{4}{105}x^6 + \frac{19}{4725}x^8 - \frac{37}{133650}x^{10} + \frac{283}{20638800}x^{12}. \end{aligned}$$

- Taking $n = 6$ and $p = 3$ we obtain

$$\begin{aligned} 2 + \frac{8x^4}{45} + \frac{16x^6}{315} + \frac{104x^8}{4725} + \frac{592}{66825}x^{10} &< g_6(x) = \left(\frac{\sin(x)}{x}\right)^2 + \frac{\tan(x)}{x} - \left(\frac{\sin(x)}{x}\right)^2 \left(\frac{2\left(\frac{2x}{\pi}\right)^{14}}{1 - \left(\frac{2x}{\pi}\right)^2}\right) < \\ \frac{161934166x^{16}}{488462349375} - \frac{123992x^{14}}{58046625} + \frac{152912x^{12}}{42567525} + \frac{592x^{10}}{66825} + \frac{104x^8}{4725} + \frac{16x^6}{315} + \frac{8x^4}{45} + 2 &< \end{aligned}$$

$$\frac{152912x^{12}}{42567525} + \frac{592x^{10}}{66825} + \frac{104x^8}{4725} + \frac{16x^6}{315} + \frac{8x^4}{45} + 2$$

The last estimate improves statement 1 (ii) ([4, p.10]).

Etc...

3 Second Wilker inequality

Wu and Srivastava [23, Lemma 3] proved the following dual inequality for $0 < x < \pi/2$ also called second Wilker inequality

$$\left(\frac{x}{\sin(x)}\right)^2 + \frac{x}{\tan(x)} > 2, \quad 0 < x < \frac{\pi}{2}$$

Mortici [17] improved it and gave

$$\begin{aligned} \left(\frac{x}{\sin(x)}\right)^2 + \frac{x}{\tan(x)} &> 2 + \frac{2x^4}{45}. \\ \left(\frac{x}{\sin(x)}\right)^2 + \frac{x}{\tan(x)} &> \frac{2\sin(x)}{x} + \frac{\tan(x)}{x}. \end{aligned}$$

Malesevic and al. [12, Theorem 5] gave an improvement of that and provided the following bounds for $0 < x < \pi/2$ and any integer $m \geq 2$

$$\begin{aligned} 2 + \sum_{k=2}^m \frac{(2k-2)2^{2k} |B_{2k}|}{(2k)!} x^{2k} &< \left(\frac{x}{\sin(x)}\right)^2 + \frac{x}{\tan(x)} < \\ 2 + \sum_{k=2}^{m-1} \frac{(2k-2)2^{2k} |B_{2k}|}{(2k)!} x^{2k} + \left(\frac{2x}{\pi}\right)^{2n} \left(\frac{\pi^2}{4} - 2 - 2 + \sum_{k=2}^{m-1} \frac{(2k-2)2^{2k} |B_{2k}|}{(2k)!} \left(\frac{\pi}{2}\right)^{2k}\right). \end{aligned}$$

It seems that Theorem 3-1 below improves that result.

Theorem 3-1 For $0 < x < \pi/2$ and any $p \geq 1$ the following inequalities hold

$$\begin{aligned} \left(1 + \sum_{k=1}^{2p} (-1)^k \frac{(2x)^{2k}}{(2k+1)!}\right) \left(1 + \sum_{k=1}^p \frac{(2k-1)2^{2k} |B_{2k}|}{(2k)!} x^{2k} + \sum_{k=p+1}^{\infty} \frac{(2k-1)2^{2k+1}}{\pi^{2k}(2^{2k}-1)} x^{2k}\right) < \\ \left(\frac{x}{\sin(x)}\right)^2 + \frac{x}{\tan(x)} < \\ \left(1 + \sum_{k=1}^{2p+1} (-1)^k \frac{(2x)^{2k}}{(2k+1)!}\right) \left(1 + \sum_{k=1}^p \frac{(2k-1)2^{2k} |B_{2k}|}{(2k)!} x^{2k} + \sum_{k=p+1}^{\infty} \frac{(2k-1)2^{2k+1}}{\pi^{2k}(2^{2k}-2^\beta)} x^{2k}\right), \end{aligned}$$

where B_{2k} are the Bernoulli numbers and $\beta = 2 + \frac{\ln(1 - \frac{6}{\pi^2})}{\ln 2} = 0.6491\dots$ is the Alzer constant.

Proof of Theorem 3-1

Recall the following series expansions which can be found in [11] or [10]

$$\cot x = \frac{1}{x} - \sum_{k=1}^{\infty} \frac{2^{2k} |B_{2k}|}{(2k)!} x^{2k-1}, \quad \frac{\sin x}{x} = \sum_{k=0}^{\infty} (-1)^k \frac{x^{2k}}{(2k+1)!}$$

Then we derive

$$\left(\frac{x}{\sin x}\right)^2 = -x^2 \frac{d \cot x}{dx} = 1 + \sum_{k=1}^{\infty} \frac{(2k-1)2^{2k} |B_{2k}|}{(2k)!} x^{2k}.$$

Notice that

$$\begin{aligned} \left(\frac{x}{\sin(x)}\right)^2 + \frac{x}{\tan(x)} &= \left(\frac{x}{\sin x}\right)^2 \left(1 + \frac{\sin 2x}{2x}\right) = \\ &\left(1 + \sum_{k=1}^{\infty} \frac{(2k-1)2^{2k} |B_{2k}|}{(2k)!} x^{2k}\right) \left(1 + \sum_{k=0}^{\infty} (-1)^k \frac{2^{2k} x^{2k}}{(2k+1)!}\right). \end{aligned}$$

By Taylor expansions we may deduce

$$\sum_{k=0}^{2p} (-1)^k \frac{x^{2k}}{(2k+1)!} < \frac{\sin x}{x} < \sum_{k=0}^{2p+1} (-1)^k \frac{x^{2k}}{(2k+1)!}.$$

On the other hand, writing

$$\sum_{k=1}^{\infty} \frac{(2k-1)2^{2k} |B_{2k}|}{(2k)!} x^{2k} = \sum_{k=1}^p \frac{(2k-1)2^{2k} |B_{2k}|}{(2k)!} x^{2k} + \sum_{k=p+1}^{\infty} \frac{(2k-1)2^{2k} |B_{2k}|}{(2k)!} x^{2k}.$$

Combining with inequalities (2)

$$\frac{2(2k)!}{\pi^{2k}(2^{2k}-1)} < |B_{2k}| < \frac{2^{2k+1}(2k)!}{\pi^{2k}(2^{2k}-2^\beta)} < \frac{2^{2k+1}(2k)!}{\pi^{2k}(2^{2k}-2)}$$

it follows for $0 < x < \pi/2$ and any $p \geq 1$

$$\begin{aligned} \left(\frac{x}{\sin(x)}\right)^2 + \frac{x}{\tan(x)} &> \left(1 + \sum_{k=1}^{2p} (-1)^k \frac{(2x)^{2k}}{(2k+1)!}\right) \times \\ &\left(1 + \sum_{k=1}^p \frac{(2k-1)2^{2k} |B_{2k}|}{(2k)!} x^{2k} + \sum_{k=p+1}^{\infty} \frac{(2k-1)2^{2k+1}}{\pi^{2k}(2^{2k}-1)} x^{2k}\right), \end{aligned}$$

as well as

$$\begin{aligned} \left(\frac{x}{\sin(x)} \right)^2 + \frac{x}{\tan(x)} &< \left(1 + \sum_{k=1}^{2p+1} (-1)^k \frac{(2x)^{2k}}{(2k+1)!} \right) \times \\ &\left(1 + \sum_{k=1}^p \frac{(2k-1)2^{2k} |B_{2k}|}{(2k)!} x^{2k} + \sum_{k=p+1}^{\infty} \frac{(2k-1)2^{2k+1}}{\pi^{2k}(2^{2k}-2^{\beta})} x^{2k} \right) < \\ &\left(1 + \sum_{k=1}^{2p+1} (-1)^k \frac{(2x)^{2k}}{(2k+1)!} \right) \left(1 + \sum_{k=1}^p \frac{(2k-1)2^{2k} |B_{2k}|}{(2k)!} x^{2k} + \sum_{k=p+1}^{\infty} \frac{(2k-1)2^{2k+1}}{\pi^{2k}(2^{2k}-2)} x^{2k} \right). \end{aligned}$$

Corollary 3-2 For $0 < x < \pi/2$ and any $n \geq p \geq 1$ the following inequalities hold

$$\begin{aligned} a_{p,n}(x) &= \left(1 + \sum_{k=1}^{2p} (-1)^k \frac{(2x)^{2k}}{(2k+1)!} \right) \left(1 + \sum_{k=1}^p \frac{(2k-1)2^{2k} |B_{2k}|}{(2k)!} x^{2k} + \sum_{k=p+1}^n \frac{(2k-1)2^{2k+1}}{\pi^{2k}(2^{2k}-1)} x^{2k} \right) \\ &< \left(\frac{x}{\sin(x)} \right)^2 + \frac{x}{\tan(x)} < b_p(x) = \left(1 + \sum_{k=1}^{2p+1} (-1)^k \frac{(2x)^{2k}}{(2k+1)!} \right) \left(1 + \sum_{k=1}^p \frac{(2k-1)2^{2k} |B_{2k}|}{(2k)!} x^{2k} + \right. \\ &\quad \left. \frac{2 \left(\frac{x}{\pi} \right)^{2p+2}}{\left(1 - \left(\frac{x}{\pi} \right)^2 \right)^2} \left[(1-2p) \left(\frac{x}{\pi} \right)^2 + 2p+1 \right] + \frac{2 \left(\frac{x}{2\pi} \right)^{2p+2}}{\left(1 - \left(\frac{x}{2\pi} \right)^2 \right)^2} \left[(1-2p) \left(\frac{x}{2\pi} \right)^2 + 2p+1 \right] \right). \end{aligned}$$

Proof

Let us consider the function

$$\frac{1}{1 - 2^{1-2x}}, \quad x \geq 1.$$

For $1 \leq x$ this function can be majored

Lemma 3-3 For $1 \leq x$ the following inequality holds

$$\frac{1}{1 - 2^{1-2x}} \leq (1 + 2^{2-2x}).$$

Indeed, consider the difference

$$\alpha(x) = \frac{1}{1 - 2^{1-2x}} < (1 + 2^{2-2x}).$$

Its derivative is

$$\frac{d\alpha(x)}{dx} = -2 \frac{2^{1-2x} \ln(2)}{\left(1 - 2^{1-2x} \right)^2} + 4 2^{1-2x} \ln(2) = 2 \frac{2^{1-2x} \ln(2) \left(1 - 4 \cdot 2^{1-2x} + 2 \left(2^{1-2x} \right)^2 \right)}{\left(-1 + 2^{1-2x} \right)^2}.$$

The study suggest us that this function is non positive for $x \neq 1$. It is such that $\alpha(1) = 0$, $\lim_{x \rightarrow \infty} \alpha(x) = 0$ and increases between 1 and ∞ . Thus, we get for $1 \leq x$, $\frac{1}{1-2^{1-2x}} \leq (1 + 4.2^{-2x})$.

By Lemma 3-3 we have for any $k \geq 1$

$$\begin{aligned} \frac{(2k-1)2^{2k+1}}{\pi^{2k}(2^{2k}-2)}x^{2k} &= 2(2k-1)\frac{1}{1-2^{1-2x}}\left(\frac{x}{\pi}\right)^{2k} \leq \\ 2(2k-1)(1+4.2^{-2k})\left(\frac{x}{\pi}\right)^{2k} &= 2(2k-1)\left(\frac{x}{\pi}\right)^{2k} + 8(2k-1)\left(\frac{x}{2\pi}\right)^{2k}. \end{aligned}$$

We then deduce the sum since $0 < x < \pi/2$

$$\begin{aligned} \sum_{k=p+1}^{\infty} \frac{(2k-1)2^{2k+1}}{\pi^{2k}(2^{2k}-2)}x^{2k} &\leq \sum_{k=p+1}^{\infty} 2(2k-1)\left(\frac{x}{\pi}\right)^{2k} + 8(2k-1)\left(\frac{x}{2\pi}\right)^{2k} = \\ \frac{2\left(\frac{x}{\pi}\right)^{2p+2}}{\left(1-\left(\frac{x}{\pi}\right)^2\right)^2} \left[(1-2p)\left(\frac{x}{\pi}\right)^2 + 2p+1 \right] &+ \frac{2\left(\frac{x}{2\pi}\right)^{2p+2}}{\left(1-\left(\frac{x}{2\pi}\right)^2\right)^2} \left[(1-2p)\left(\frac{x}{2\pi}\right)^2 + 2p+1 \right]. \end{aligned}$$

Replacing in Theorem 3-1 we get Corollary 3-2.

Examples 3-4 Let $0 < x < \pi/2$ we will use *Maple*

- Taking $n=3$, $p=2$ one obtains

$$\begin{aligned} a_{2,3}(x) &= 2 + \frac{2x^4}{45} + \frac{8x^6}{945} < \left(\frac{x}{\sin(x)}\right)^2 + \frac{x}{\tan(x)} < \\ b_2(x) &= \left(2 - \frac{2x^2}{3} + \frac{2x^4}{15} - \frac{4x^6}{315}\right) \left(1 + \frac{x^2}{3} + \frac{x^4}{15} + \frac{85}{8} \frac{x^6}{\pi^6}\right) < 2 + \frac{2x^4}{45} + \left(\frac{85}{4\pi^6} - \frac{4}{315}\right)x^6 \end{aligned}$$

The last expression is lower than

$$2 + \frac{2x^4}{45} + \frac{64}{\pi^6} \left(-2 + \frac{\pi^2}{4} - \frac{\pi^4}{360}\right) x^6$$

since $\left(\frac{85}{4\pi^6} - \frac{4}{315}\right) - \frac{64}{\pi^6}(-2 + \frac{\pi^2}{4} - \frac{\pi^4}{360}) \approx -0.003697$.
Then, this case is finer than statement 2(i).

- Taking $n=4$, $p=3$ one obtains

$$\begin{aligned} a_{3,4}(x) &= 2 + \frac{2x^4}{45} + \frac{8x^6}{945} + \frac{2x^8}{1575} < \left(\frac{x}{\sin(x)}\right)^2 + \frac{x}{\tan(x)} < b_3(x) = \\ \left(2 - \frac{2x^2}{3} + \frac{2x^4}{15} - \frac{4x^6}{315}\right) \left(1 + \frac{x^2}{3} + \frac{x^4}{15} + \frac{2}{189}x^6 + \frac{16x^8\pi^2 - 12x^{10}}{\pi^6(x^2 - \pi^2)^2} + \right. & \\ \left. \frac{1}{4} \frac{16x^8\pi^2 - 3x^{10}}{\pi^6(x^2 - 4\pi^2)^2} - 2 \frac{x^8}{\pi^6(-x^2 + \pi^2)} + \frac{x^8}{-32\pi^8 + 8x^2\pi^6} \right) &< \end{aligned}$$

$$2 + \frac{2}{45} x^4 + \frac{8}{945} x^6 + \left(-\frac{34}{14175} + \frac{455}{16} \pi^{-8} \right) x^8.$$

The last expression is lower than

$$2 + \frac{2}{45} x^4 + \frac{8}{945} x^6 + \frac{256}{\pi^8} \left(-2 + \frac{\pi^2}{4} - \frac{\pi^4}{360} - \frac{\pi^6}{7560} \right) x^8$$

$$\text{since } -\frac{34}{14175} + \frac{455}{16} \pi^{-8} - \frac{256}{\pi^8} \left(-2 + \frac{\pi^2}{4} - \frac{\pi^4}{360} - \frac{\pi^6}{7560} \right) \approx -0.0012804.$$

This case is also finer than statement 2(ii).

- Taking n=5, p=4 one obtains (details omitted)

$$\begin{aligned} a_{3,4}(x) &= 2 + \frac{2x^4}{45} + \frac{8x^6}{945} + \frac{2x^8}{1575} + \frac{16x^{10}}{93555} < \left(\frac{x}{\sin(x)} \right)^2 + \frac{x}{\tan(x)} < b_3(x) < \\ &2 + \frac{2}{45} x^4 + \frac{8}{945} x^6 + \frac{2}{1575} x^8 + \left(-\frac{4}{18711} + \frac{2313}{64} \pi^{-10} \right) x^{10}. \end{aligned}$$

The last expression is lower than

$$2 + \frac{2x^4}{45} + \frac{8x^6}{945} + \frac{2x^8}{1575} + \left(\frac{2}{\pi} \right)^{10} \left(-2 + \frac{\pi^2}{4} - \frac{\pi^4}{360} - \frac{\pi^6}{7560} - \frac{\pi^8}{201600} \right) x^{10}$$

$$\text{since } \left(-\frac{4}{18711} + \frac{2313}{64} \right) - \left(-2 + \frac{\pi^2}{4} - \frac{\pi^4}{360} - \frac{\pi^6}{7560} - \frac{\pi^8}{201600} \right) \approx -0.00007469.$$

This case is also finer than statement 2(iii).

4 C

oncluding remarks

1 - Examples 2-5 and Examples 2-9 above suggest us that Corollary 2-7 is finer than Theorem 4 of [12]. Therefore, we may ask if the following is valid for $0 < x < \pi/2$ and $2 \leq n$:

$$(i) \quad 2 + \frac{1}{\cos x} \sum_{k=2}^{2n+1} (-1)^k D_k x^{2k} < g_n(x) = \left(\frac{\sin(x)}{x} \right)^2 \left(1 - \frac{2 \left(\frac{2x}{\pi} \right)^{2n+2}}{1 - \left(\frac{2x}{\pi} \right)^2} \right) + \frac{\tan(x)}{x}.$$

$$\begin{aligned} (ii) \quad 2 + \frac{1}{\cos x} \sum_{k=2}^{2n+1} (-1)^k D_k x^{2k} &< \left(\frac{\sin(x)}{x} \right)^2 \left(2 + \sum_{k=1}^p \frac{2^{2k} (2^{2k} - 2) |B_{2k}|}{(2k)!} x^{2k} + \right. \\ &\left. \frac{2 \left(\frac{2x}{\pi} \right)^{2n+2}}{1 - \left(\frac{2x}{\pi} \right)^2} - 2 \sum_{k=1}^n \frac{1}{2^k - 1} \left(\frac{2x}{\pi} \right)^{2k} \right) \end{aligned}$$

and

$$(iii) \quad \left(\frac{\sin(x)}{x} \right)^2 \left(2 + \sum_{k=1}^p \frac{2^{2k} (2^{2k} - 2) |B_{2k}|}{(2k)!} x^{2k} + \frac{2 \left(\frac{2x}{\pi} \right)^{2n+2}}{1 - \left(\frac{2x}{\pi} \right)^2} \right) < 2 + \frac{1}{\cos x} \sum_{k=2}^{2n} (-1)^k D_k x^{2k},$$

where $D_k = \frac{(-9+3^{2k+2}-40k-32k^2)}{4(2k+2)!}$.

2 - Examples 3-4 suggest us that Corollary 3-2 is finer than Theorem 5 of [12] and we may naturally ask if more generally the following inequality

$$b_m(x) < 2 + \sum_{k=2}^{m-1} \frac{|B_{2k}|(2k-2)4^k}{(2k)!} x^{2k} + \left(\frac{2x}{\pi} \right)^{2n} \left(\frac{\pi^2}{4} - 2 - \sum_{k=2}^{m-1} \frac{|B_{2k}|(2k-2)4^k}{(2k)!} \left(\frac{\pi}{2} \right)^{2k} \right),$$

holds for any $m \geq 2$, where

$$\begin{aligned} b_p(x) = & \left(1 + \sum_{k=1}^{2p+1} (-1)^k \frac{(2x)^{2k}}{(2k+1)!} \right) \left(1 + \sum_{k=1}^p \frac{(2k-1)2^{2k}|B_{2k}|}{(2k)!} x^{2k} + \right. \\ & \left. \frac{2\left(\frac{x}{\pi}\right)^{2p+2}}{\left(1-\left(\frac{x}{\pi}\right)^2\right)^2} \left[(1-2p)\left(\frac{x}{\pi}\right)^2 + 2p+1 \right] + \frac{2\left(\frac{x}{2\pi}\right)^{2p+2}}{\left(1-\left(\frac{x}{2\pi}\right)^2\right)^2} \left[(1-2p)\left(\frac{x}{2\pi}\right)^2 + 2p+1 \right] \right). \end{aligned}$$
