## ABSTRACT

The data presented here are related to the article entitled "New contributions to the drug profile of TNF $\alpha$  inhibitor SPD304: affinity, selectivity ADMET considerations" published in the European Journal of pharmacology. As DMSO is usually used as a co-solvent to dissolve low aqueous soluble small molecules, such as SPD304, we have investigated the influence of its concentration on the kinetic of interaction between tumor necrosis factor  $\alpha$  (TNF- $\alpha$ ) and its inhibitor, SPD304. The presented data, acquired using a surface acoustic wave sensor, can be used in further biological studies to compare the kinetic of interaction between proteins/small molecules in general and TNF $\alpha$ /inhibitors in particular. The estimated dissociation constant can be compared to other ones to statute on the degree of affinity between a protein and a given molecule.

## Specifications Table

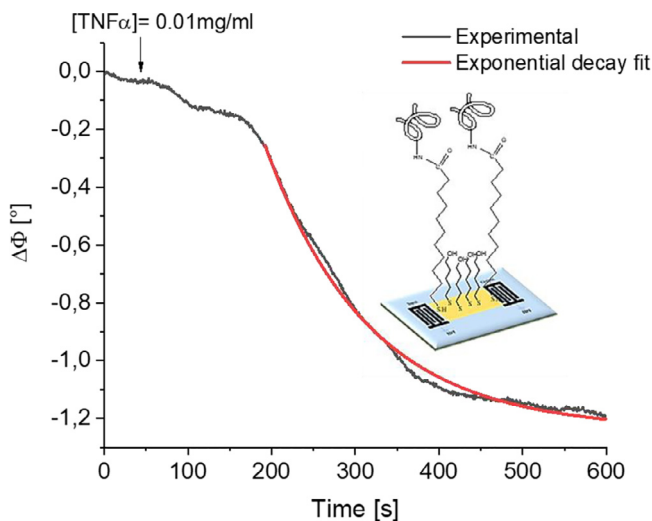

Subject	Physical and Theoretical Chemistry
Specific subject area	Effects of DMSO cosolvent on TNF $\alpha$ /SPD304 interaction
Type of data	Figures
How data were acquired	The data were acquired using a surface acoustic wave sensor which consists in dual delay lines fabricated on 36°rot lithium tantalate piezoelectric substrate. The interdigital transducers, realized by evaporation of (20/80) nm Cr/Au layers, were photolithographically patterned with a periodicity of $\lambda = 40 \mu\text{m}$ which corresponds to an operating frequency of about 103 MHz. The measurement setup consists of a TNF $\alpha$ grafted SAW sensor, a Kalrez <sup>®</sup> flow cell, a PMMA cover including inlets and outlets connected to a Gilson <sup>®</sup> 3 peristaltic pump, and a HP8214 network analyser.
Data format	Raw and analysed graphs. The presented results are average of triplicate sample analysis.
Parameters for data collection	A HP8214 Network analyser was used to monitor phase output signals versus time at a fixed frequency.
Description of data collection	Temporal phase and amplitude output signals' variations, after functionalization steps and further analytes' injections, were monitored by a HP8214 network analyzer piloted by a home-made software <i>Conservatoire National des Arts et Métiers (Cnam), Paris, France</i> .
Data source location	Data are available with the article
Data accessibility	for co-submission manuscripts
Related research article	Aida Mascret, Hadley Mouhsine, Ghada Attia, Damien Cabrera, Mohamed Benchekroun, Patrick Gizzi, Chouki Zerrouki, Najla Fourati, Jean-François Zagury, Maité Sylla-Iyarreta Veitia Sylla, Marc Port. ## Value of the Data

- Dimethyl sulfoxide (DMSO) is a cosolvent often used for biological or biophysical characterization. In this context, it is important to know whether its presence can affect the interaction between small molecules inhibiting TNF $\alpha$  and the latter.
- Research is currently underway to find small molecules that inhibit TNF $\alpha$  to overcome the limits of biomolecules currently on the market. To develop this research, it is essential to be able to accurately measure the affinity of these small molecules towards TNF $\alpha$ . Alongside conventional devices, surface acoustic wave (SAW) sensors prove to be an accurate and powerful tool to support such investigations.
- Due to their high sensitivity and versatility, SAW sensors can be considered for reliable and rapid screening of many molecules before considering only the promising ones for biological tests.
- The (6,7-dimethyl-3-[[methyl[2-[methyl[[1-[3-(trifluoromethyl)phenyl]-1H-indol-3-yl]methyl]amino]ethyl]amino]methyl]-(4H-1-benzopyran-4-one dihydrochloride) in a salt form (SPD304) molecule is considered as a reference molecule in almost all publications describing direct inhibitors of TNF $\alpha$ . He *et al* in 2005, using a fluorescence homoquenching-based assay, postulated that the mechanism was described by a predissociation-independent model where SPD304 interacts with TNF $\alpha$  trimer to form an intermediate complex which promotes TNF $\alpha$  monomer dissociation.

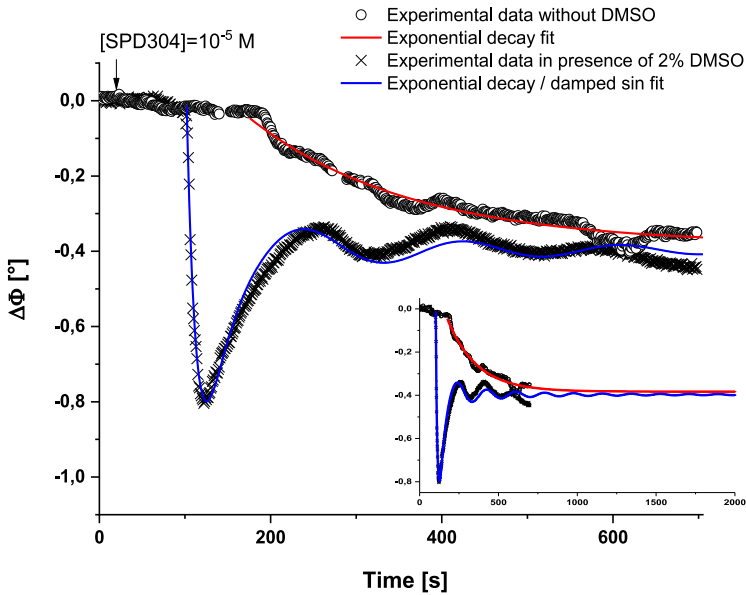

**Fig. 2.** Schematic representation and phase variations versus time after the injection of TNF $\alpha$  protein.

## 1. Data Description

The following figures are related to the design of the SAW biosensor and SPD304 detection in absence and in presence of dimethyl sulfoxide (DMSO). Representations of temporal phase variations after the grafting of the 11-mercapto-1-undecanoic acid (MUDA) / 6-mercapto-1-hexanol (MHOH) (1/9, v/v) self-assembled monolayers (SAMs) and further activation of the carboxylic acid groups with 1-ethyl-3-[3-dimethylaminopropyl] carbodiimide hydrochloride (EDC) / N-hydroxysuccinimide (NHS) are presented in Fig. 1a and 1b, respectively. This functionalisation step is followed by TNF $\alpha$  protein anchoring. The corresponding phase variation versus time graph is depicted in Fig. 2.

Figs. 3 and 4 are related to the effect of DMSO cosolvent concentration on the kinetic of interaction between TNF $\alpha$  and SPD304. In this study, we have chosen to investigate three concentrations of DMSO: 2%, 5% and 10% after the injection of the same concentration of SPD304 ( $10^{-5}$  M) in the flow cell.

**Fig. 3.** Phase shift variation versus time after the injection of  $10^{-5}$  M of SPD304 in absence and in presence of 2% of DMSO and their further modelling with exponential decay function (in the absence of DMSO) and a combined decay / exponential decay-damped sine functions (in presence of 2% DMSO). Inset: extrapolation of the two models over a sufficiently long period for the disappearance/reduction of the DMSO effect.

**Fig. 4.** Phase variations versus time after the injections of SPD304 dissolved in PBS solutions containing a) 5% of DMSO, b) 10% of DMSO.

## 2. Primary Data

All the raw data corresponding to these figures are gathered in the Supplementary Information.

Table S1a and b contain the primary data related to the functionalization of the SAW sensing area with MUDA/MHOH and further activation with EDC/NHS.

Primary data concerning TNF $\alpha$  grafting are gathered in Table S2. Those related to the detection of SPD304 in the absence and in the presence of 2% DMSO are collected in the Tables S3a and 3b, respectively.

The primary data collected after the injection of SPD304 in DMSO at a concentration of 5% and 10% are collected in Table S4.

### 3. Experimental Design, Materials and Methods

#### 3.1. Validation of surface functionalization of biosensor

The surface functionalization step was validated carefully to ensure reproducibility of the biosensor. Phase variations versus time after mixed SAMs grafting and their further activation with EDC/NHS are gathered in Fig. 1. Fig. 1a show that the phase output signal decreases slowly after SAMs injection and that it stabilizes after 40,000 s. Almost 11 h are thus needed for the organization and the formation of the mixed self-assembled monolayers of (MUDA/MHOH) on SAW gold surface. This duration is in phase with those reported in literature [1,2].

The device was after that rinsed with ethanol, to remove un-grafted molecules, and then with PBS. When phase stability was reached, a continuous flow of EDC/NHS was injected on the SAW sensing area. Results presented in Fig. 1b show that the formation of NHS ester was completed in approximately 5 min. A further fitting of phase variations versus time with an exponential decay function indicates that the characteristic time was of order of  $(27 \pm 1)$  s confirming that the kinetics of activation reaction is fast. Besides the large difference in terms of reaction duration, Fig. 1a and b also reveal that the phase shift variations are much higher for SAMs grafting than for EDC/NHS activation. This can be explained by the fact that the self-assembled layers cover the entire sensitive area and they are directly linked to it.

TNF $\alpha$  protein was after that grafted on the SAMs via a carbodiimide coupling reaction. The corresponding temporal phase variations curve (presented in Fig. 2.) indicate that the phase signal was stabilized approximately 600 s after TNF $\alpha$  injection. The characteristic time constant  $\tau_c$ , estimated with a modelling with an exponential decay function, was of order of  $(123 \pm 1)$  s.

#### 3.2. The effect of DMSO cosolvent concentration

The effect of DMSO cosolvent concentration on the kinetic of interaction between TNF $\alpha$  and SPD304 was then investigated. Experiments were performed in the absence and in presence of 2%, 5% and 10% of DMSO. For all these experiments, we have chosen to inject the same concentration of SPD304 ( $10^{-5}$  M) in the flow cell, so that only the effect of DMSO is highlighted. Temporal phase shifts variations after the injection of the ligand in the absence and in the presence of 2% of DMSO are plotted in Fig. 3. Results show that the injection of SPD304 dissolved in a PBS solution engenders only a phase decrease, while, we have recorded, in presence of 2% of DMSO, a large phase decrease, followed first by phase increase and then by damped oscillations, prior to phase output signal stabilization at almost the same value as that of SPD304 in PBS. The shapes of the two graphs are clearly different, but the phase shifts following the injection of the same concentration of SPD304 are quasi-comparable, once the stability reached.

For better comprehension of DMSO effect, we have fitted both gravimetric curves with exponential decay functions (first order for PBS solution, and first order to which we added a damped sine for 2% DMSO solution) to extract their corresponding time constants  $\tau$ . Results indicate that  $\tau_{\text{SPD304 in 2\% DMSO}} = (17.5 \pm 0.5)$  s is largely inferior to that of  $\tau_{\text{SPD304 in PBS}} = (176 \pm 7)$  s. Adding 2% of DMSO cosolvent permits thus to accelerate the kinetic of interaction between TNF $\alpha$  and SPD304. Extrapolation of the two models over a sufficiently long period, until the disappearance/reduction of the effect of DMSO, shows the same frequency shift within uncertainties (the relative difference is lower than 4%).

Phase variations versus time after the injection of SPD304 dissolved in PBS solutions, containing 5% and 10% of DMSO are presented in Fig. 4.

Fig. 4a shows that the phase decreases drastically to  $1.4^\circ$ , and then increases slowly with damped oscillations till  $\approx 1^\circ$ . A further rinsing with PBS permits to eliminate the excess of co-

solvent molecules, and the phase reaches after that the same value as that of SPD304 in PBS. Here also, we can conclude that adding 5% of DMSO cosolvent permits only to accelerate the kinetic of interaction between TNF $\alpha$  and SPD304. On the other hand, this was not the case for SPD304 dissolved in 10% of DMSO, as the phase signal returns to its initial value after rinsing with PBS. At this high value of DMSO concentration, we have probably destabilized and dissociated TNF $\alpha$  protein, confirming thus the results of Corti et al [3].

DMSO, added at moderate concentrations (< 5%), permitted to accelerate the kinetic of binding between the protein and the ligand. However, at higher concentrations (10%) the protein is denatured leading to the inhibition of TNF $\alpha$ /SPD304 interaction.
