## Cross-linguistic gender congruency effects during lexical access in novice L2 learners: Evidence from ERPs

Ana Zappa, Daniel Mestre, Jean-Marie Pergandi, Deirdre Bolger & Cheryl Frenck-Mestre

*Herein we present electrophysiological evidence of extremely rapid learning of new labels in an L2 (Brazilian Portuguese) for existing concepts, via computerized games. However, the effect was largely constrained by cross-linguistic grammatical gender congruency. We recorded ERPs both prior to exposure with the second language and following a 4-day training session. Results showed rapid changes in cortical activity, associated with learning. Prior to exposure, no modulation of the N400 component was found as a function of the correct match vs. mismatch of audio presentation of words and their associated images. Post-training, a large N400 effect was found for mismatch trials compared to correctly matched audio-visual trials. However, for learners these results were only obtained for trials on which the L2 words shared grammatical gender in the learners L1 (French). For trials on which the L2 words had the opposite gender in French, no N400 mismatch effect was found post-training. In contrast, behavioral results showed that all L2 words were learned equally as well, independent of gender congruency across Portuguese and French. For control participants who were native speakers of Portuguese, a clear N400 effect was found for mismatch compared to match trials, which was independent of gender congruency. The results demonstrate that grammatical gender overlap in the L1 and L2 influences lexical activation during the initial stages of establishing a new L2 lexicon.*

1  
2  
3 In Brazilian Portuguese, a mouse, no matter which biological sex, is  
4 grammatically masculine ( $o_{\text{masc}}$  *camundongo*<sub>masc</sub>) whereas a cockroach is grammatically  
5 feminine ( $a_{\text{fem}}$  *barata*<sub>fem</sub>). The opposite is true in standard French, with grammatically  
6 feminine mice ( $la_{\text{fem}}$  *souris*<sub>fem</sub>) and masculine cockroaches ( $le_{\text{masc}}$  *cafard*<sub>masc</sub>). This  
7 arbitrary assignment of grammatical gender is even more apparent for inanimate objects,  
8 with opposite gender assignment for trash cans, brooms and chalk across Portuguese  
9 and French, despite both languages being derived from Latin. The present study  
10 examined how cross-linguistic gender congruency, i.e. the overlap in grammatical  
11 gender for nouns across languages, might affect both the acquisition and online  
12 processing of a second language (L2) in novice adult learners. Although numerous  
13 online studies have provided evidence that speakers of gendered languages are sensitive  
14 to gender congruency across languages, during both L2 comprehension and production  
15 (cf. Sá-Leite, Fraga & Comesaña, 2019, for a meta analysis) these studies have almost  
16 exclusively examined learners who had extensive experience with the L2. We propose a  
17 novel approach to this question by starting from the initial stages of exposure to the L2.  
18 In addition, we provide both behavioral and electrophysiological measures of  
19 performance, which indeed revealed different patterns of the effect of gender  
20 congruency.

44 Numerous psycholinguistic studies have examined the effect of gender  
45 congruency (GCE), both within languages in monolinguals and across languages in  
46 bilinguals. Monolingual studies have been conducted in the framework of speech  
47 production models, which generally assume that grammatical gender is represented  
48 independently from other levels of lexical representation, i.e. phonological and semantic,  
49 but differ as concerns when and how gender is retrieved (Caramazza, 1997; Cubelli et al.  
50 2005; Foucart et al., 2010; Levelt et al., 1999; Schiller & Caramazza, 2006). Several

1  
2  
3 bilingual studies, discussed below, have also been conducted within this framework. As  
4  
5 concerns comprehension, bilingual studies that have examined cross-linguistic GCE  
6  
7 have looked at both the interactive nature of bilingual lexical access (Morales et al.,  
8  
9 2016; Paolieri et al., 2020) and late bilinguals' ability to use grammatical gender to  
10  
11 predict upcoming elements (Hopp & Lemmerth, 2016; Lemmerth & Hopp, 2019). The  
12  
13 latter have addressed processing at the lexical level. However, a handful of  
14  
15 comprehension studies have also investigated the influence of cross-linguistic gender  
16  
17 congruency on syntactic processing (Foucart & Frenck-Mestre, 2011, 2012; Sabourin et  
18  
19 al., 2006). We shall address these topics in turn.

20  
21  
22  
23  
24 Cross-linguistic GCEs have been examined at the lexical level during production,  
25  
26 in naming (Bordag, 2004; Bordag & Pechmann, 2007; Costa et al., 2003; Lemhöfer et  
27  
28 al., 2008; Morales et al., 2011; Paolieri et al., 2010) and translation (Bordag &  
29  
30 Pechmann, 2008; Paolieri et al., 2010; Salamoura & Williams, 2007), as well as in  
31  
32 comprehension (Lemhöfer et al., 2008; Paolieri et al., 2020). The pattern of results  
33  
34 across studies is both complex and inconsistent. In two independent experiments with  
35  
36 German L1-Dutch L2 late bilinguals, Lemhöfer et al. (2008) examined the effects of  
37  
38 cognate status and gender congruency on lexical decision times and naming latencies in  
39  
40 the L2. They reported robust effects of both factors in both tasks, with no interaction  
41  
42 effects. Participants showed faster lexical decision times and naming latencies for L2  
43  
44 Dutch words that shared gender in German and for cognates (cf. Sá-Leite et al., 2019, as  
45  
46 well as Costa et al., 2000, for a discussion of cognate effects). In addition, in the naming  
47  
48 task, no effect of syntactic structure was found, such that GCE were reported  
49  
50 independent of whether participants produced determiner phrases or bare nouns. Similar  
51  
52 results were reported by Bordag & Pechman (2007) for relatively inexperienced Czech  
53  
54 L1-German L2 late learners, who found GCE in 2 experiments independent of whether  
55  
56  
57  
58  
59  
60

1  
2  
3 participants named bare nouns or nouns preceded by gender-marked adjectives in the L2.  
4  
5 In like fashion, Paolieri and colleagues reported faster naming latencies in the L2  
6  
7 (Spanish) for line drawings that shared the same gender in the bilingual participants' L1  
8  
9 (Italian) (eg "falda" and "gonna" *skirt*) compared to those that had opposite gender (e.g.,  
10  
11 "mesa" and "tavolo" *table*) and this was true for both bare nouns and determiner noun  
12  
13 phrases (Paolieri et al., 2010). Paolieri et al. (2010) replicated their results for bilingual  
14  
15 participants across 2 experiments; however, in their second experiment both the effect  
16  
17 of gender congruency and the critical interaction with Group (bilingual vs. monolingual)  
18  
19 were only reliable by participants, suggesting that the GCE was not restricted to the  
20  
21 bilingual group and may have been partially driven by characteristics of the items  
22  
23 unrelated to gender congruency. Klassen (2016) examined GCE in naming across  
24  
25 Spanish and German, which differ concerning the number of gender categories (2 vs. 3),  
26  
27 the phonetic regularity of gender marking (overt and highly consistent in Spanish vs. not  
28  
29 phonetically salient in German) and complexity (case interacts with gender in German  
30  
31 but not Spanish). Results showed facilitated processing for gender congruent nouns  
32  
33 compared to incongruent nouns, for both bare nouns and determiner phrases in the  
34  
35 group of L1 Spanish-L2 German learners but not L1 German controls. Yet, this was true  
36  
37 for nouns that were either masculine or feminine in German but not for neuter gender,  
38  
39 which, although indeed incongruent with either gender in Spanish led to faster naming  
40  
41 latencies. Hence, the GCE also appears to be constrained by the overlap of gender  
42  
43 categories across languages. All of these studies argue in favor of an interactive  
44  
45 activation model of processing (Dell, 1986) in which both the L1 gender and  
46  
47 phonological form of lexical entries influence L2 processing, and according to which  
48  
49 grammatical gender is not stored as an independent feature at the lemma level (i.e.  
50  
51 Levelt et al., 1999).

3 In contrast, Costa and colleagues failed to find GCE across 5 independent  
4 experiments in which participants produced NPs in their L2, even when with gender-  
5 marked determiners (Costa et al., 2003). This was true independent of whether the

In contrast, Costa and colleagues failed to find GCE across 5 independent experiments in which participants produced NPs in their L2, even when with gender-marked determiners (Costa et al., 2003). This was true independent of whether the bilinguals' two languages had similar gender systems. Costa and colleagues (2003) argued that while semantic representations are shared across languages and commonly activated by lexical entries of either language, the specific grammatical features of a lexical entry, such as its gender, are inherent properties of that entry. Hence, these features would not be shared across languages. Costa et al. (2003) noted nonetheless that they tested highly proficient bilinguals and suggested that less proficient L2 speakers might show greater interaction between their two gender systems, as was indeed reported by subsequent studies (Bordag & Pechmann, 2007; Lemhöfer et al., 2008; Paolieri et al., 2010). In addition, as highlighted by Sá-Leite et al. (2009), other mitigating factors that were not considered by Costa et al. (2003) may have played a role and could explain why this study seems to be the odd man out as concerns finding GCE.

In translation tasks, the results are also mixed. At one extreme, Bordag & Pechmann (2008) reported no cross-linguistic GCE across three translation tasks with Czech-German participants who translated either bare nouns or adjective-noun phrases into the L2. It is of particular interest that the absence of a GCE was reported in translation for the same materials and participant population that produced a robust GCE in production (Bordag & Pechmann, 2007). Bordag and Pechmann (2008) account for the discrepancy in results across tasks as concerns GCE in terms of time course. During picture naming, activation would spread from the concept to the L1 and L2 lemmas in parallel, hence leading to the simultaneous activation of L1 and L2 gender nodes and competition when the two do not match. In translation, the time course would

1  
2  
3 be shifted, such that L1 word forms would activate their lemmas which in turn would  
4  
5 activate the L2 lemma and word form. As such, the L2 gender node would only be  
6  
7 activated subsequent to the L1 gender node and no direct competition would arise.  
8  
9  
10 Salamoura & Williams (2007) reported a different pattern of results, whereby proficient  
11  
12 Greek-German bilinguals showed cross-linguistic GCE when they translated gender-  
13  
14 marked adjectives along with the noun, but not for bare nouns. The authors argued that  
15  
16 gender retrieval occurs only when gender concord must be computed, i.e. within the  
17  
18 determiner phrase, in line with certain monolingual models of production (Caramazza,  
19  
20 1997, but see Cubelli et al., 2005). Last, Paolieri et al. (2010) reported GCE during a  
21  
22 translation task with advanced Italian-Spanish bilinguals, independent of whether  
23  
24 participants produced the bare noun or a determiner phrase. Based on this pattern of  
25  
26 results, the authors proposed that lexical selection necessarily entails the activation of  
27  
28 gender, in parallel. Lexical items that share gender across languages would enjoy a  
29  
30 higher level of activation, hence facilitating both naming and translation. The three  
31  
32 competing sets of results and theoretical accounts leave ample room for discussion.  
33  
34  
35  
36

37  
38 The effect of gender congruency across languages has also been examined  
39  
40 during online comprehension. Several studies have approached this topic in the  
41  
42 framework of whether bilinguals can use grammatical gender to predict upcoming  
43  
44 elements in their L2 (Hopp & Lemmerth, 2016; Lemmerth & Hopp, 2019; Morales et  
45  
46 al., 2016). The results from two visual world paradigm studies with Russian-German  
47  
48 bilinguals, which used the same design and materials, failed to produce statistically  
49  
50 conclusive evidence that gender congruency plays a significant role in the ability of  
51  
52 either adults (Hopp & Lemmerth, 2016) or children (Lemmerth & Hopp, 2019) to  
53  
54 process gender online in the L2. Another visual world paradigm study, conducted with  
55  
56 proficient Italian-Spanish bilingual adults, showed interference from a distracter image  
57  
58  
59  
60

1  
2  
3 when its gender was incongruent with the L1 equivalent, suggesting gender-induced  
4 competition (Morales et al., 2016). However, the effects were not significant until after  
5 the onset of the target noun, suggesting that co-activation of gender across languages  
6 during comprehension may not occur until a certain amount of information has been  
7 processed.  
8  
9

10  
11  
12  
13  
14  
15 Event-related potentials (ERPs) have also been used to measure the effects of  
16 cross-linguistic gender congruency on language processing. The most common of these  
17 are the N400, the P600 and the LAN, generally elicited by semantic and syntactic  
18 violations respectively. The N400, a negative deflection in the waveform with a central-  
19 parietal distribution usually observed between 300-500 msec after stimulus onset, is  
20 generally thought to reflect semantic integration such that increased N400 amplitude is  
21 attributed to processing difficulty that results from attempting to integrate a new  
22 element within an existing semantic context (Holcomb, 1993; Kutas & Federmeier,  
23 2011; Kutas & Hillyard, 1980). The N400 component has also been associated with  
24 retrieval/access, with increased N400 amplitude reflecting the effort of retrieving  
25 semantic/conceptual information from long-term memory. In this case a reduced N400  
26 is interpreted as signaling facilitated access to lexical information (Delogu et al., 2019).  
27  
28 Recently, Bornkessel-Schlesewsky & Schlewsky (2019) re-examined N400 results in  
29 a predictive coding perspective. Accordingly, the N400 (along with other language-  
30 related negativities) could reflect precision-weighted prediction errors rather than  
31 linguistic processing per se. Another ERP component commonly used in language  
32 studies is the P600, which is a positive-deflection in the wave form with a centro-  
33 parietal distribution thought to show difficulty in syntactic integration (Kaan et al.,  
34 2000; Meltzer & Braun, 2013), as well as the cost of “revising, repairing or reanalyzing  
35 an existing (morpho-) syntactic structure” (Delogu et al., 2019, p.2). The P600 is  
36

1  
2  
3 sometimes associated with the Left Anterior Negativity (LAN) (for a debate on the  
4 significance of the LAN, cf. Fraga et al., 2021; Molinaro et al., 2015; Tanner, 2015).  
5  
6 The P600/LAN has also been associated with conflict/monitoring resolution  
7 (Bornkessel-Schlesewsky & Schlewsky, 2008; Kim & Osterhout, 2005) as well as  
8 semantic integration (Brouwer et al., 2017). Finally, the nogo N200 response occurs  
9 roughly 200 msec post-stimulus when there is conflict and/or inhibition as concerns  
10 processing and the participant's response (Enriquez-Guppert et al., 2010). While not  
11 specific to language processing, the N200 can be used to measure response conflict  
12 during language processing such as in the study described below.

24       Rodriguez-Fornells & Münte (2016) recorded ERPs in a Go/Nogo paradigm to  
25 probe the effect of grammatical gender congruency (and language switching) across  
26 German and Spanish in fluent bilinguals. Compared to monolingual controls, bilinguals  
27 showed greater negativity (N200) for incongruent compared to congruent gender trials.  
28 While this result may indicate the automatic activation of gender across languages, there  
29 are several caveats. First, the task explicitly required participants to retrieve  
30 grammatical gender and both languages were actively recruited. Second, participants  
31 could potentially predict the incongruent gender trials based on the structure of the  
32 experiment. Last, gender incongruence elicited a late ERP component (P600/LPC).  
33 Hence, these results do not provide clear evidence for the automatic, early retrieval of  
34 gender. Paolieri et al. (2020) also recorded ERPs to examine the effect of gender  
35 congruency during the processing of translation equivalents in Spanish and Catalan.  
36 Only bare nouns were presented. A small but reliable increase in N400 amplitude was  
37 found at central-midline sites for translation pairs that did not share grammatical gender  
38 across languages in comparison to those that did, along with increased response times  
39 for incongruent pairs, leading the authors to claim that gender is automatically activated

1  
2  
3 during lexical retrieval and elicits competition when different genders are activated  
4  
5 across languages. As with Rodriguez-Fornells & Münte (2016), however, participants  
6  
7 were actively processing both languages; a stronger demonstration would have  
8  
9 consisted in comparing N400 amplitude for bare nouns in the L2 alone as a function of  
10  
11 gender congruency. Moreover, no L1 control group was included such that it is not  
12  
13 possible to determine whether the effect was driven solely by gender congruency or  
14  
15 perhaps by extraneous factors specific to the gender-incongruent pairs. Nevertheless, in  
16  
17 a semantic categorization task conducted exclusively in English with Spanish-English  
18  
19 late bilinguals and monolingual controls, Boutonnet et al. (2012) reported a late  
20  
21 negative ERP component (starting at roughly 400 msec) for trials that did not share  
22  
23 gender in Spanish (the L1) with the two preceding items. This effect was specific to the  
24  
25 bilingual group. No effects were found for the behavioral measures, in contrast to  
26  
27 Paolieri et al. (2020), although the absence of an effect for behavioral measures in the  
28  
29 presence of electrophysiological evidence is rather common. The authors argued for the  
30  
31 automatic activation of L1 gender in speakers of gendered languages, even when  
32  
33 processing exclusively the L2 and in a non-gendered language such as English.  
34  
35  
36  
37  
38  
39

40 Gender congruency effects have also been examined at the syntactic level during  
41  
42 sentence processing, using ERPs. Several monolingual studies have shown that gender  
43  
44 agreement violations in sentential context systematically elicit the P600 component  
45  
46 (Alencar de Resende et al., 2019; Barber & Carreiras, 2005; Beatty-Martinez et al.,  
47  
48 2021; Hagoort, 2003; Frenck-Mestre, 2005; Fraga et al., 2021; Gunter et al., 2000;  
49  
50 Popov & Bastiaansen, 2018; Popov et al., 2020; Wicha et al., 2004) and can also  
51  
52 produce a LAN (Alencar de Resende et al., 2019; Barber & Carreiras, 2005; Beatty-  
53  
54 Martinez et al., 2021; Fraga et al., 2021; Gunter et al., 2000; Popov et al., 2020). The  
55  
56 electrophysiological signature of gender concord during sentence processing is  
57  
58  
59  
60

1  
2  
3 nonetheless modulated by various factors, both linguistic (Alencar de Resende et al.,  
4 2019; Beatty-Martinez et al., 2021) and task-related (Schacht et al., 2014). In Brazilian  
5 Portuguese, Alencar de Resende and colleagues (2019) compared ERP signatures  
6 elicited by gender concord violations within the determiner phrase, either between the  
7 determiner and noun or the adjective and noun, for nouns with either regular or irregular  
8 gender assignment in Brazilian Portuguese. Results showed a biphasic LAN/P600 in  
9 response to concord violations, independent of the regularity of gender assignment.  
10 However, the amplitude of the P600 evoked by concord violations was greater for  
11 regular nouns. The authors suggested that both regular and irregular forms are stored  
12 and accessed in similar fashion, i.e. via a single lexical route, but that repair processes  
13 are facilitated for regular forms. Beatty-Martinez et al. (2021) reported differences as a  
14 function of gender category in Spanish, whereby determiner-noun violations in sentence  
15 contexts elicited a biphasic LAN/P600 response for masculine nouns in contrast to the  
16 same violations for feminine nouns, which did not elicit a LAN and showed a wider  
17 P600 distribution in comparison to masculine nouns. This difference in the  
18 electrophysiological response was interpreted as being linked to systematic differences  
19 in the representation of the two gender categories.

40  
41

42 The P600 is also elicited during L2 sentential processing of gender concord  
43 violations for L2 learners whose L1 has grammatical gender (Foucart & Frenck-Mestre,  
44 2011; Sabourin et al., 2006) but also for those who do not (Foucart & Frenck-Mestre,  
45 2012; Dowens et al., 2011; Morgan-Short et al., 2010; Tokowicz & MacWhinney,  
46 2005). Moreover, P600 amplitude for gender concord violations in an L2 is contingent  
47 on proficiency and age of acquisition (Nichols & Joanisse, 2016). ERP studies that  
48 focused on cross-language gender congruency have provided evidence that the overlap  
49 of both syntactic rules, as concerns gender concord (Foucart & Frenck-Mestre, 2011;  
50

60

1  
2  
3 Sabourin & Stowe, 2008), and lexical gender across languages (Foucart & Frenck-  
4  
5 Mestre, 2011) affect whether gender concord violations in the L2 elicit an  
6  
7 electrophysiological response, the type of response (Foucart & Frenck-Mestre, 2012)  
8  
9 and its magnitude.  
10

11  
12 The body of studies cited above has examined L2 gender processing and gender  
13  
14 congruency in participants who had several years of experience with and exposure to  
15  
16 the L2. Various authors have used learning paradigms with either an artificial language  
17  
18 or miniature versions of natural languages to explore how different factors affect gender  
19  
20 acquisition after short training periods. Arnon and Ramscar (2012) used an artificial  
21  
22 language to test whether acquiring the gender and new lexical labels of known concepts  
23  
24 was affected by the sequence of explicit training. Participants who first learned novel  
25  
26 words preceded by their gender-marked article within an auditory sentential context,  
27  
28 followed by paired associate learning with bare nouns had better learning outcomes,  
29  
30 both for gender assignment and noun labels, than those who learned in the opposite  
31  
32 order. The authors argued that learning new lexical labels for concepts first via bare  
33  
34 nouns blocked the later acquisition of gender assignment in sentential context due to the  
35  
36 redundancy of gender in relation to meaning. Brooks and Kempe (2013) examined the  
37  
38 implicit learning of nominal gender agreement and case marking in a subset of Russian  
39  
40 following a 6-day training session. Results showed that while learners relied on  
41  
42 metalinguistic knowledge to acquire case marking, for gender concord they relied on the  
43  
44 consistent and transparent morphological cues (feminine being systematically indicated  
45  
46 by a final vowel on the noun and agreeing adjective, and masculine by a final  
47  
48 consonant) and knowledge of nominal morphology in another known L2. Indeed, the  
49  
50 best predictor of acquiring Russian gender agreement was whether the learners had  
51  
52 already acquired a Latin language with the same rule for feminine gender. Morgan-

56  
57  
58  
59  
60

1  
2  
3 Short and colleagues (2010) compared the processing of gender concord in early  
4 learning stages, after implicit versus explicit training in an artificial language. During  
5 early stages of acquisition, the ERP signature to gender concord violations differed  
6 according to the type of training. Notwithstanding, both implicit and explicit learning  
7 groups ultimately attained similar levels of proficiency and exhibited similar patterns of  
8 cortical response to gender concord violations at the final stage of acquisition.  
9

10  
11 To our knowledge, no studies have measured the effect of cross-language gender  
12 congruency during the early stages of L2 lexical acquisition in a natural language. The  
13 current study aimed to fill this void by examining how cross-linguistic gender  
14 congruency might influence processing in an L2 from the very initial stages of learning.  
15 We examined French L1 speakers' acquisition of Brazilian Portuguese via interactive  
16 computer games, in which L2 Portuguese was presented aurally in full sentences and  
17 segmented format, in which grammatical gender within determiner phrases was taught  
18 implicitly. Both French and Portuguese have two classes of grammatical gender  
19 (masculine and feminine) and require gender concord within the determiner phrase.  
20 Whereas French uses the singular definite article  $le[lə]_{\text{masc}}$  to mark the masculine gender  
21 and Portuguese uses  $o_{\text{masc}}$  (realized as /o/ or /u/), in both languages the singular feminine  
22 definite article carries the final phoneme [a] (French:  $la_{\text{fem}}$  [la], Portuguese  $a_{\text{fem}}$  [a]). In  
23 addition, in Portuguese, the vowel of the definite determiner is generally consistent with  
24 the final vowel of the noun (e.g., “a faca” “the knife” and “o garfo” the fork). It is  
25 therefore probable that, even without formal instruction concerning the gender of the  
26 Portuguese nouns or the determiner system, French native speakers are able to extract  
27 this information from the phonological word forms (Brooks & Kempe, 2013;  
28 Denhovska & Seratrice, 2017). Indeed, following the seminal work by Karmiloff-Smith  
29 (1979), various experimental studies have shown that native French speakers are  
30

1  
2  
3 sensitive to the regularities present in noun endings and reliably use them as early as age  
4  
5 3 to process and/or assign grammatical gender (cf. Seigneuric et al., 2007 for a  
6  
7 discussion and further work with children, and Pérez-Pereira (1991) for similar work in  
8  
9 Spanish). In Brazilian Portuguese, incongruent grammatical gender marking within the  
10  
11 determiner phrase between adjacent elements (notably the determiner and noun) affects  
12  
13 children's ability to process gender assignment as young as age 2 (Corréa & Name,  
14  
15 2003), in support of the hypothesis that young children are sensitive to grammatical  
16  
17 information conveyed by the determiner and process gender concord in the DP (cf.  
18  
19 Corrêa et al., 2011 for further work). Thus, native speakers of gendered languages show  
20  
21 rapid acquisition of the phonological features associated with grammatical gender  
22  
23 categories, when present, and the syntactic reflexes of elements that are controlled by  
24  
25 the noun. Our French learners undoubtedly exploited these capacities when acquiring  
26  
27 the L2 Brazilian Portuguese vocabulary.  
28  
29  
30  
31  
32

33 We created 4 computer games to teach French native speakers a small lexicon in  
34  
35 Brazilian Portuguese. All auditory materials were presented exclusively in Brazilian  
36  
37 Portuguese. The games involved both full sentences and individual lexical items, which  
38  
39 comprised noun phrases (definite determiner and noun) and verbs. We manipulated  
40  
41 gender congruency such that the nouns were either gender congruent or incongruent  
42  
43 across the learners' L1 and L2 (cf. Table 1). No instruction was provided concerning  
44  
45 grammatical gender, however; nouns were always preceded by the singular definite  
46  
47 determiner, i.e. the overtly marked vowel (e.g., a<sub>fem</sub> faca<sub>fem</sub> [the knife], o<sub>masc</sub> garfo<sub>masc</sub>  
48  
49 [the fork]). Participants with no prior knowledge of (Brazilian) Portuguese took part in a  
50  
51 3-day training program, during which they learned a vocabulary of 36 words overall,  
52  
53 divided into 12 sentences comprised of 3 verbs and 4 nouns each day via the games.  
54  
55 ERPs were recorded both pre- and post-training in a match/mismatch paradigm in which  
56  
57  
58  
59  
60

auditory nouns were paired with visual images that either depicted the noun (match) or another learned noun (mismatch). Thus, we were able to follow progression from zero knowledge to the recognition of newly learned L2 phonological word forms.

We hypothesized that learners should be able to fully acquire the L2 vocabulary. Performance was measured both by their accuracy scores pre- and post-training and, crucially, the change in electrophysiological response pre to post-training. Concerning the latter, we expected variation in the N400 component, whereby prior to training match and mismatch trials should not differ in the N400 response, but post-training mismatch trials should evoke an increased N400 response compared to match trials due to difficulties in lexical processing. In relation to the congruency of grammatical gender across the L1 and L2, we hypothesized that it should not affect the ERP response pre-training. In contrast, at the post-training session, it should affect the size of the N400 effect if indeed grammatical gender is automatically activated for speakers of gendered languages (Boutonnet et al., 2012; Dahan et al., 2000; Lew-Williams & Fernald, 2007) and if inhibition results from gender inconsistency across languages (Morales et al., 2016; Rodriguez-Fornells & Münte, 2016).

	L2fem	L2masc
L1fem	a saia (la jupe)	o cachimbo (la pipe)
L1masc	a vassoura (le balai)	o casaco (le manteau)

*Table 1. Examples of gender congruency/incranguency across Brazilian portuguese and French*

## Methods

**Participants.** Eighteen right-handed French native speakers (10 women), enrolled as undergraduate students at Aix-Marseille Université, aged 20 to 26 years old ( $M = 22.8$  years,  $SD = 2.4$ ), who had no knowledge of Brazilian Portuguese, and 18 right-handed

1  
2  
3 native speakers of Brazilian Portuguese (16 women) aged 22 to 28 ( $M = 25.3$ ,  $SD = 3.4$ )  
4 who were enrolled at AMU in a one year abroad program were recruited for the study.  
5  
6 One French participant's data was excluded due to displaying knowledge of the L2  
7 vocabulary (an N400 effect for mismatched pairs) prior to training. All French  
8 participants had learned English as a second language throughout secondary school;  
9  
10 eight had also learned Spanish as a third language while seven had learned German.  
11  
12 None considered themselves fluent in Spanish. The Brazilian participants had all  
13 learned English in secondary school; 12 considered themselves novice in French and 6  
14 intermediate. Participants had no history of neurological insult and received monetary  
15 compensation in exchange for their participation. All participants gave their written  
16 informed consent prior to the experiment and were debriefed about its purpose at its end.  
17  
18 The study was approved by the local university ethics committee.

32

33 **Materials.** Thirty-six concrete nouns and 9 transitive verbs were presented orally in  
34 Brazilian Portuguese (BP), in sentences and in isolation, across 3 training sessions, with  
35 3 verbs and 12 nouns learned in each session. All materials are presented in the  
36 appendix. The items were selected based on their ease of imageability, cognate status  
37 with the learners' L1 (French) as well as other Latin languages commonly learned in  
38 France (Italian, Spanish) and English, and congruency of grammatical gender across  
39 Portuguese and French. Half of the nouns had the same gender across French and  
40 Portuguese and French. Half of the nouns had the same gender across French and  
41 Brazilian Portuguese ( $[a_f \text{ panela}_f]$  /  $la_f \text{ casserole}_f$  "the pot") and the other half had the  
42 opposite gender ( $[a_f \text{ faca}_f]$  /  $le_m \text{ couteau}_m$  "the knife"). Of the 36 nouns, 32 were  
43 phonetically marked for gender (16 ending with /a/ and 16 ending with /o/) while 4 were  
44 phonetically opaque (2 feminine and 2 masculine nouns). As an added precaution, the  
45 overlap in gender between Portuguese and Spanish was also checked for the set of 36  
46  
47  
48  
49  
50  
51

59  
60

1  
2  
3 nouns. For the 18 nouns that had the same gender in French and Portuguese, 14 also  
4  
5 matched between Portuguese and Spanish and 14 between French and Spanish. For the  
6  
7 18 nouns that had opposite gender across French and Portuguese, 7 had opposite gender  
8  
9 between Portuguese and Spanish and 11 had opposite gender between French and  
10  
11 Spanish. Nouns were systematically preceded by the definite determiner (/a/<sub>f</sub> or /o/<sub>m</sub>).  
12  
13 Nouns that shared gender (SG) and those that had opposite gender (OG) across French  
14  
15 and Portuguese were equated across numerous lexical variables: printed mean frequency  
16  
17 per million in French (M = 19.71, sd = 21.19) vs. (M = 18.04, sd = 16.05) for SG and  
18  
19 OG, respectively (New, Pallier Brysbaert & Ferrand, 2004), mean number of letters SG  
20  
21 (M = 6.17, sd = 1.70) vs. OG (M = 5.53, sd = 1.62), mean number of phonemes SG (M =  
22  
23 5.50, sd = 1.62) vs. OG (M = 5.47, sd = 1.51) and mean number of syllables SG (M =  
24  
25 2.58, sd = 0.79) vs. OG (M = 2.47, sd = 0.80), grammatical gender SG (9fem/6masc,  
26  
27 tested in the Match/mismatch task) vs. OG (8fem/7masc, tested in the Match/mismatch  
28  
29 task) and Levenshtein distance SG (M = 5.5, sd = 1.4) vs. OG (M = 6.0, sd = 1.62).  
30  
31  
32  
33  
34

35 Each of the 9 verbs was paired with 4 different nouns to create 36 declarative  
36  
37 sentences in canonical SVO order preceded by a lead in phrase e.g., Esfregar / Scrub  
38  
39 [Ele está esfregando a janela / a lareira com a escova / o trapo] / He is scrubbing the  
40  
41 window/fireplace with the brush/rag). Three additional partially transparent verbs (e.g.,  
42  
43 “pintar” “peindre” paint) and 12 additional partially transparent nouns (e.g., “esponja”,  
44  
45 “éponge”, sponge) were selected to familiarize participants with the games and for EEG  
46  
47 training. All auditory materials were recorded by a native Brazilian female speaker at 48  
48  
49 kHz (32-bit float) in a professional sound booth, in a single session. The onset of each  
50  
51 word within auditory sentences was detected automatically using SPPAS (Bigi, 2015)  
52  
53 and manually verified using PRAAT (Boersma & Weenink, 2018). The materials were  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 spliced into individual syntactic units (pronoun + copula, determiner + noun, lexical  
4 verb) and individual sentences using Audacity 2.2.1 software.  
5  
6

7  
8 A subset of the materials was selected for pre- and post-training in a  
9  
10 Match/mismatch task (see appendix). Thirty auditory nouns were presented in a  
11  
12 2x2 factorial design defined by the congruency of the auditory noun and line  
13  
14 drawing (match vs. mismatch) and gender congruency across languages (same vs.  
15  
16 opposite gender). Auditory nouns were paired with 30 line drawings selected from  
17  
18 the Snodgrass & Vanderwart (1980) and Alario and Ferrand (1999) standardized image  
19  
20 databases (with the exception of two images which were taken from line-drawing  
21  
22 internet databases). These images were different from those used for the computerized  
23  
24 games (described below), which were selected from internet databases. Each auditory  
25  
26 noun was presented twice, once paired with the correct line drawing (match) and once  
27  
28 with a line drawing that corresponded to another (to be) learned noun (mismatch). For  
29  
30 each Condition (Match vs. Mismatch) half of the trials had the same grammatical  
31  
32 gender across Portuguese and French and half had opposite gender: Gender (Same vs.  
33  
34 Opposite). Hence, a full factorial design was used: Gender (Same vs. Opposite) x  
35  
36 Condition (Match vs. Mismatch). For Match trials, where the presented image  
37  
38 matched the auditory word, only the gender of the auditory word was in play,  
39  
40 which was either the same in Portuguese and French (e.g., *a janlea* / *la fenêtre* [the  
41  
42 window]) or opposite across languages (e.g., *o garfo* / *la fourchette* [the fork]). For  
43  
44 mismatch trials, where the image *did not* correspond to the auditory word, we  
45  
46 controlled for the coherency of gender across the distractor image and auditory  
47  
48 target word in Portuguese. For example, the auditory word *o cachimbo* (*la pipe* [the  
49  
50 pipe]) was paired with the distractor image of a masculine Portuguese word *o lixo*  
51  
52 (*la poubelle* [the trashcan]). This prevented participants from noting a mismatch  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 based on the determiner alone if they accessed the name of the distractor image  
4  
5 prior to the auditory target word. Three pseudo-randomized lists were created for pre-  
6  
7 training EEG testing including 30 "match" pairs and 30 "mismatch" pairs, with 15 same  
8  
9 gender and 15 opposite gender pairs for each. Three other pseudo-randomized lists were  
10  
11 created for post-training EEG testing, which included the same 30 Match and 30  
12  
13 Mismatch pairs and an additional 30 Semantically related and 30 Semantically unrelated  
14  
15 pairs (data reported elsewhere). Participants saw different lists at pre- and post-training  
16  
17 testing, with complete counter-balancing of lists across participants such that all lists  
18  
19 were seen at both pre- and at post-training sessions.  
20  
21  
22  
23  
24  
25

## 26 **Procedure**

27  
28 **Games.** Four computerized games were created in collaboration with the Mediterranean  
29  
30 Virtual Reality Center (CRVM). All 4 games involved the auditory presentation via  
31  
32 headphones of materials in Brazilian Portuguese accompanied by either static line  
33  
34 drawings or animated GIF on a flat screen. Participants' responses and playing behavior  
35  
36 (mouse clicks, timing) were recorded throughout each game and feedback was provided.  
37  
38 Trials that were not completed successfully were repeated at the end of each game. All  
39  
40 participants played the 4 games in the same order and were required to successfully  
41  
42 complete a given game prior to engaging in the next. This ensured that all participants  
43  
44 had acquired the vocabulary presented throughout the games on each day. In all 4  
45  
46 games, participants initiated a trial by clicking on an audio button image to hear an  
47  
48 auditory stimulus. In the first, "exposure" game, participants clicked to hear the 12  
49  
50 sentences, one at a time, which were presented simultaneously with an animated GIF of  
51  
52 the action and accompanying objects. In the second "segmentation" game, participants  
53  
54 clicked to hear a sentence, which was accompanied by the visual presentation of 5 blank  
55  
56  
57  
58  
59  
60

1  
2  
3 squares at the bottom and 3 in the center of the computer screen. Participants clicked on  
4  
5 any of the 5 bottom squares to display a static image and hear the audio file  
6  
7 corresponding to it (4 nouns and 1 verb were depicted). Participants had to recreate the  
8  
9 auditory sentence by clicking and dragging the 3 correct syntactic elements in order  
10  
11 (verb, NP1, NP2) to the center of the screen. Upon correct completion, an animated GIF  
12  
13 played along with the auditory sentence. In the third, “verb identity” game, participants  
14  
15 clicked to hear a verb and saw three different animated GIFs in the center of the screen,  
16  
17 the task being to select the animation that corresponded to the audio file. In the final  
18  
19 “memory” game, participants clicked to hear a sentence, then had to find the pair of  
20  
21 cards, among 8 presented face down on the screen, that matched the auditory sentence  
22  
23 by clicking on the cards individually (a card reverted to blank when another card was  
24  
25 selected). The vocabulary depicted across the 8 cards involved a single verb and 4  
26  
27 nouns. When the correct pair was selected, the auditory sentence was replayed along  
28  
29 with an animated GIF. Across games 2, 3 and 4, participants were allowed to click on a  
30  
31 given item (audio button or card) a maximum of 3 times and time-out was 30 seconds  
32  
33 on any given trial. They were encouraged to repeat the materials out loud while playing.  
34  
35 Participants were not permitted to take notes during training sessions and were asked  
36  
37 not to review what they had learned between sessions. All participants successfully  
38  
39 completed all games on each of the three training days, as revealed by their recorded  
40  
41 scores.  
42  
43  
44  
45  
46  
47  
48  
49  
50

51 **Training.** Participants learned how to play the 4 computer games, prior to actual  
52  
53 training, using a miniature auditory vocabulary. This initiation to the games took place  
54  
55 directly after the first EEG session. During the initiation and subsequent training,  
56  
57 participants were comfortably seated in a sound-attenuated room where they played the  
58  
59  
60

1  
2  
3 games on a 15-inch-screen laptop computer while wearing headphones. Training  
4  
5 occurred over 4 consecutive days. On each of the first three days, participants were  
6  
7 exposed to 3 verbs and 12 nouns, comprised in 12 auditory sentences, via the 4 games,  
8  
9 with the vocabulary repeated across the games. Each session lasted roughly 25 minutes,  
10  
11 with each game taking 5-10 minutes. The fourth day consisted of a 40-minute review  
12  
13 day, where participants played all the games with the entire new lexicon (9 verbs and 36  
14  
15 nouns).  
16  
17  
18  
19  
20

21 **EEG Match-Mismatch task.** A trial began with the presentation of a centered fixation  
22  
23 cross for 250 msec that was replaced by a centered black and white line drawing for 1  
24  
25 second followed by an auditory word presented over speakers. At the offset of the  
26  
27 auditory word, a visual “yes/no” prompt was presented and participants were requested  
28  
29 to judge whether the auditory word matched the visual image or not on a button box. A  
30  
31 visual blink prompt was presented for 2s following the response. During the pre-training  
32  
33 session, 2 blocks of 30 trials, with 15 “match” and 15 “mismatch” pairs in each, were  
34  
35 presented, preceded by three warm-up pairs. During the post-training session, an  
36  
37 additional 30 trials were presented per session, comprising 15 semantically related and  
38  
39 15 unrelated pairs (data reported elsewhere), for a total of 60 trials per session. Short  
40  
41 rest periods were allowed between blocks. Participants were asked to remain still and to  
42  
43 blink at the prompt. Behavioral responses to the questions were recorded. The session  
44  
45 lasted roughly 30 minutes.  
46  
47  
48  
49  
50  
51

52  
53 **ERP Data acquisition and analysis.** Electroencephalographic (EEG) activity was  
54  
55 recorded continuously from 64 scalp locations over frontal, temporal, central, posterior  
56  
57 temporal, parietal and occipital areas of the left and right hemispheres and midline.  
58  
59  
60

Individual electrodes were adjusted to a stable offset lower than  $20\mu\text{V}$ . EEG data were sampled online at 512 Hz. Blinks and horizontal eye-movements were monitored by means of electrodes placed beneath the left eye and at the outer canthus of the right eye. Electrodes were placed on the left and right mastoids for referencing offline. Periods spanning from -100 pre- stimulus onset to 1100 msec post stimulus onset were used post-recording for analyses. A low pass digital filter of 30 Hz was applied post-recording. Trials contaminated by ocular-motor or muscular artifacts were excluded using automated routines that were manually checked. The percentage of trials retained for analyses was 88% for the same gender condition and 87% for the opposite gender condition.

## Results.

To determine the pattern of data, we ran a series of comparisons for both behavioral and electrophysiological measures. On the one hand, we compared the data for the L2 learner group across sessions. In addition, we compared the L2 learners' data post-training to that of the Brazilian control group. When indicated, we ran subsequent independent models (in each session, for the L2 learners and for each group).

### *Behavioral measures.*

#### Game-playing accuracy

Errors took the shape of time-outs. Accuracy was at ceiling (over 96% across all games) for all participants. The low level of variability during game play in the review session did not warrant further analyses (cf. Table 2a).

Verb game	Segmentation game	Memory game
22/648 (3.4%)	3/864 trials (0.3%)	3/864 trials (0.3%)

**Table 2a.** *Total number and percentage of time-outs across the different games for all L2 participants*

Accuracy in the EEG match-mismatch task.

The percentages of correct responses are presented in Table 2b and d prime scores are presented in Figure 1 for the L2 learners at the pre- and post-training session, and for the Brazilian control group. The data were modeled using linear mixed effect regressions, with the *LmerTest* package (Kuznetsova & Christensen, 2017) implemented in R (R Core Team, 2017). For both measures, we first modeled the data for L2 learners, pre- and post-training. The model for the percentage of correct responses included the sum coded fixed factors Training session (Pre vs. Post), Gender (Same vs. Opposite), Condition (Match vs. Mismatch) and their interactions, with random intercepts for Participant and Item and a random slope for Condition:Gender. The model for d prime included the sum coded fixed factors Training session (Pre- vs. Post), Gender (Same vs. Opposite) and their interaction, with random intercept for Participant. We subsequently compared L2 learners to Brazilian controls at the post training session. For accuracy, the model included the sum coded fixed factors Group (Control vs. L2), Gender (Same vs. Opposite), Condition (Match vs. Mismatch) and their interactions, with random intercepts for Participant and Item. The same model was applied for d prime, without the factor Condition.

Accuracy.

For L2 learners, the first model, comparing pre- and post-training sessions revealed an effect of Session ( $\beta = 1.35$ ,  $se = 0.07$ ,  $z = 18.85$ ,  $p < .001$ ), the interaction between Gender and Condition ( $\beta = 0.19$ ,  $se = 0.08$ ,  $z = -2.25$ ,  $p < .001$ ) and the interaction between Gender, Condition and Session ( $\beta = 0.14$   $se = 0.07$ ,  $z = 2.02$ ,  $p$

< .05). Subsequently, models were run on the L2 data for the pre- and post-training session independently. Pre-training, the treatment coded model, revealed an interaction between Gender and Condition ( $\beta = -1.32$  se = 0.28,  $z = -4.74$ ,  $p < .001$ ), and a simple effect of Condition for Opposite gender trials ( $\beta = 0.51$ , se = 0.19,  $z = 2.74$ ,  $p < .01$ ). The re-leveled treatment coded model showed a simple effect of Condition for Same gender trials ( $\beta = -0.81$  se = 0.21,  $z = -3.92$ ,  $p < .001$ ). Pre-training, L2 participants showed a bias to respond positively for Same gender trials and negatively for Opposite gender trials, although accuracy remained at chance levels. Post-training, the sum coded model revealed only an effect of the Intercept for L2 learners ( $\beta = 2.78$ , se = 0.26,  $z = 10.68$ ,  $p < .001$ ), due to accuracy being higher than chance. No other effects were significant.

Last, the model comparing L2 learners' performance at the post-training session to the native Brazilian control group failed to converge due to the extremely low variability and high level of accuracy.

	Match	Mismatch
<b>L2: Pre-training</b>		
Same Gender	57% (49)	38% (48)
Opposite Gender	36% (48)	47% (50)
<b>L2: Post-training</b>		
Same Gender	92% (27)	92% (29)
Opposite Gender	92% (27)	90% (27)
<b>Brazilian control group</b>		
Same Gender	95% (21)	100% (0)
Opposite Gender	98% (26)	100% (0)

**Table 2b.** Percentage of correct answers (standard deviations in parentheses) in the Match-Mismatch task for L2 learners pre- and post- learning, and for Brazilian controls, as a function of Gender (same vs. opposite) and Condition (Match vs. Mismatch)

D-prime.

The model comparing L2 learners' data pre- and post-training revealed only an effect of Session ( $\beta = 1.76$ , se = 0.105,  $t = 16.90$ ,  $p < .001$ ). Participants' d prime scores

(i.e. their ability to correctly discriminate between Match and Mismatch trials) increased significantly from pre- to post-training and this did not depend on the gender congruency of trials.

The model comparing *d* prime scores for L2 learners post-training and the native Brazilian control group revealed an effect of Group ( $\beta = 0.59$ ,  $se = 0.102$ ,  $t = 5.80$ ,  $p < .001$ ), due to Brazilian controls showing higher *d* prime scores. No other effects were significant.

## ERP analysis

The ERP data were modeled using linear mixed effect regressions, with the *LmerTest* package (Kuznetsova & Christensen, 2017) implemented in R (R Core Team, 2017) for the mean voltage amplitudes in the N400 time window, calculated 300-600 msec post onset of the auditory noun for correct trials. This window was based on prior literature and confirmed by permutation tests conducted across the entire epoch (see below). Data were trimmed in R to remove outliers (1% of the data were excluded). Models were performed independently over midline sites (Fz, FCz, Cz, CPz, Pz), frontal-central sites (FC1, FC3, FC5, FC2, FC4, FC6, C1, C3, C5, C2, C4, C6) and centro-parietal sites (CP1, CP3, CP5, CP2, CP4, CP6, P1, P3, P5, P2, P4, P6). Below we report the results from the maximal random-effects structure (Barr, et al., 2013).

In addition to the LMER models, to test the hypothesis of a significant difference in the ERP amplitude between conditions, a two-tailed permutation test (1000 random partitions) was carried out over the 1-second post-stimulus time window for all electrodes entered into the models. Statistically significant

1  
2  
3 differences were taken into consideration only if they persisted for 10 msec or more,  
4 which corresponds to an interval of 5 samples, given a sampling rate of 512Hz. The  
5 results of these tests are visible in Figures 2a through 4b for 9 central electrodes  
6 commonly associated with the N400 effect and voltage maps that included a larger array  
7 of electrodes.

14  
15 *Pre vs. Post-training: L2 learners*

16  
17 To examine the effect of training, we ran a first model, summarized in Table 3a,  
18 which included the sum-coded fixed factors Session (Pre vs. Post), Gender (Same vs.  
19 Opposite), Condition (Match vs. Mismatch) and their interactions, with random  
20 intercepts for Participant and Item. Condition included a random slope for Participant  
21 and for Item. The model revealed a three-way interaction of Condition:Gender:Session  
22 at all electrode sites. The data were modeled independently thereafter for each training  
23 session. Pre-training, no effects were found for any factor at any ROI (cf. Table 3b).  
24 Figures 2a and 2b show the mean Match-Mismatch ERP response for Same and  
25 Opposite gender conditions, respectively, for illustrative purposes.

**Figure 2b.** Mean voltage ERPs (and SD) for 9 central electrodes in the pre-training session for L2 learners as a function of Condition (Match vs. Mismatch) for nouns with opposite gender across languages. Permutation tests revealed no significant differences.

Post-training, sum coded models performed independently at all 3 ROI revealed a significant interaction of Condition x Gender at all sites (cf. Table 3c). Models of simple effects (cf. Tables 3d and 3e) revealed a significant effect of Condition for same gender trials at all ROI (midline:  $\beta = -3.40$ ,  $se = 0.770$ ,  $t = -4.42$ ,  $p < .001$ ; frontal-central:  $\beta = -2.60$ ,  $se = 0.682$ ,  $t = -3.82$ ,  $p < .002$ ; central-parietal:  $\beta = -2.91$ ,  $se = 0.577$ ,  $t = -5.05$ ,  $p < .001$ ) but no effect of Condition for opposite gender trials (midline:  $\beta = -0.27$ ,  $se = 0.757$ ,  $t = -0.36$ ,  $p < 0.73$ ; frontal-central:  $\beta = -0.52$ ,  $se = 0.644$ ,  $t = -0.81$ ,  $p < .43$ ; central-parietal:  $\beta = -0.59$ ,  $se = 0.613$ ,  $t = -0.97$ ,  $p < .35$ ). These effects are shown in Figures 3a and 3b.

**Figure 3b.** Mean voltage ERPs (and SD) in the post-training session for L2 learners for 9 central electrodes as a function of Condition (Match vs. Mismatch) for nouns with opposite gender across languages. Permutation tests revealed no significant effects.

In addition, for Match trials there was an effect of Gender at all three ROI (cf. Table 3e) (midline:  $\beta = 2.08$ ,  $se = 0.422$ ,  $t = 4.92$ ,  $p < .001$ ; frontal-central:  $\beta = 1.69$ ,  $se = 0.584$ ,  $t = 2.89$ ,  $p < .01$ ; central-parietal:  $\beta = 1.27$ ,  $se = 0.257$ ,  $t = 4.96$ ,  $p < .001$ ), while for Mismatch trials the effect of Gender was only present at midline (midline:  $\beta = -0.91$ ,  $se = 0.434$ ,  $t = -2.09$ ,  $p < .04$ ; frontal-central:  $\beta = -0.38$ ,  $se = 0.805$ ,  $t = -0.48$ ,  $p < 0.64$ ; central-parietal:  $\beta = 1.06$ ,  $se = 0.89$ ,  $t = -1.19$ ,  $p < .025$ ). These effects are depicted in Figures 3c and 3d.

*Figure 3c about here*

**Figure 3c.** Mean voltage ERPs (and SD) for 9 central electrodes in the post-training session for L2 learners as a function of Gender across languages (same vs. opposite) for Match trials. Permutation tests are shown in red ( $p = .05$ ) and green ( $p < .05$ ) across the entire epoch.

*Figure 3d about here*

**Figure 3d.** Mean voltage ERPs (and SD) for 9 central electrodes in the post-training session for L2 learners as a function of Gender across languages (same vs. opposite) for Mismatch trials. Permutation tests revealed no significant effects.

*Post-training: Native controls vs. L2*

The first model, summarized in Table 4a, included the sum-coded factors Group (Native vs. L2), Gender (Same vs. Opposite), Condition (Match vs. Mismatch) and their interactions. Condition included a random slope for Participant and for Item. The model revealed an interaction of Condition:Gender:Group at all sites. For native controls, there was an N400 effect, with Mismatch trials producing a larger N400 amplitude than Match trials, which was independent of Gender congruency across languages. For L2

1  
2  
3 learners, the N400 effect interacted with Gender congruency. The data were modeled  
4 independently thereafter for the Brazilian control group, using the same model structure  
5 as above without the fixed factor Group. For native speakers, the effect of Condition  
6 was significant at all sites due to greater mean N400 amplitude for mismatch than match  
7 trials. At frontal central sites, there was also an effect of Gender, due to a larger N400  
8 for same gender trials. Crucially, Condition did not interact with Gender at any site (see  
9 Table 4b and Figures 4a and 4b, for same and opposite gender respectively).

39  
40  
41 Correlation between D prime score and N400 effect

42  
43 Pearson's correlations were performed in order to determine whether there was any  
44 correlation between the ability to correctly identify match trials (d prime) and the  
45 magnitude of the N400 effect (cf. Tanner et al., 2013). We found no correlation between  
46 d prime scores and the magnitude of the N400 effect for either the L2 learners (same  
47 gender  $r(16)=0.07$ ,  $p = .72$ , opposite gender  $r(16) = 0.36$ ,  $p = .15$ ) or the Brazilian  
48 control group (same gender  $r(16) = 0.04$ ,  $p = .84$ , opposite gender  $r(16) = 0.18$ ,  $p =$

## Discussion

Our study revealed clear cross-linguistic gender congruency effects (GCE), from the earliest stages of acquiring a second language. This was apparent in the electrophysiological trace of lexical access, as measured by the N400. L2 learners demonstrated a clear N400 effect for mismatched visual-auditory pairs post-training, but only for newly learned nouns that shared grammatical gender across their native (French) and newly acquired language (Portuguese). No modulation of the ERP response was found as a function of the match between auditory words and visual stimuli for nouns that had opposite gender across the two languages for these learners. In addition, the effect of gender congruency was visible in the N400 modulation for match trials, for which the N400 response was increased for nouns that had opposite gender across the L2 and French compared to nouns that shared grammatical gender across languages. Hence, cross-linguistic GCE were clearly reflected in the automatic cortical response associated with lexical processing (Kutas & Federmeier, 2011). It is important to note that in the control group of native Brazilian Portuguese speakers, who on average were novice French speakers, only a robust N400 mismatch effect was found, which was independent of gender congruency. Otherwise stated, the cross-linguistic GCE revealed by the N400 was specific to the L2 learners processing nouns in the newly learned language. Importantly, this effect was found following only 4 days of training using interactive computerized games.

Previous studies on the effect of cross-linguistic gender congruency have examined this question in populations that had several years of formal learning of the

1  
2  
3 second language (Bordag, 2004; Bordag & Pechmann, 2007, 2008; Costa et al., 2003;  
4  
5 Lemhöfer et al., 2008; Morales et al., 2011; Rodriguez-Fornells & Münte, 2016;  
6  
7 Salamoura & Williams, 2007). Our training study allowed us to examine this question  
8  
9 from the earliest stages of acquisition. In addition, our design has the distinct advantage  
10  
11 of presenting only the newly learned language. In several studies that have shown cross-  
12  
13 linguistic GCE, participants had to actively process their native and second language  
14  
15 simultaneously due to task requirements (switching between languages, translating, or  
16  
17 ignoring embedded L1 words during L2 production; Bordag & Pechmann, 2007, 2008;  
18  
19 Costa et al., 2003; Rodriguez-Fornells & Münte, 2016; Salamoura & Williams, 2007).  
20  
21 The necessity to maintain both languages active may have played a role in evoking  
22  
23 gender congruency effects in these studies. This cannot be claimed for the present  
24  
25 results. Indeed, our study did not require L2 participants to overtly produce or  
26  
27 consciously activate their L1. Nonetheless, that the L1 lexicon, and more specifically  
28  
29 the grammatical features of L1 candidates, became active during L2 processing was  
30  
31 readily apparent in the ERP data. Our results are in line with those reported by  
32  
33 Boutonnet et al. (2012) who showed modulation of a late negative component as a  
34  
35 function of whether triplets of words, presented in English, all shared the same lexical  
36  
37 gender in the participants' native language, Spanish. Thus, as in the current study, even  
38  
39 in conditions where the L1 was physically absent, it played a significant role in  
40  
41 processing. More specifically, native speakers of "gendered" languages automatically  
42  
43 and irrepressibly activate the L1 gender of nouns, even when processing words  
44  
45 exclusively in the L2.  
46  
47  
48  
49  
50  
51  
52

53  
54 In many studies, gender congruency effects have been reported both within a  
55  
56 given language and across languages when participants were required to produce a  
57  
58 definite article prior to the noun (Costa et al., 2003; Salamoura & Williams, 2007);  
59  
60

1  
2  
3 although others have shown GCE when participants produced bare nouns (Bordag &  
4 Pechmann, 2007; Cubelli et al., 2005). In light of this, it is of interest to note that, while  
5 our participants did not produce the lexical items, all auditory nouns were preceded by  
6 the definite determiner (e.g., /oparafuzo/ “the screw” and /aluva/ “the glove”). It is an  
7 empirical question whether the gender congruency effects that we obtained would occur  
8 in the absence of the determiner. Given that our participants showed evidence that they  
9 had acquired the gender of the L2 nouns, it is possible that they may have retrieved this  
10 information during processing, either from a stored representation of the noun or from  
11 the morphology of the word form itself, which may then have been the source of  
12 interference (cf. Gollan and Frost, 2001, for a discussion of different routes to stored  
13 gender information). Further work is necessary to determine the locus of the  
14 interference we found.

15  
16  
17 Our results show rapid learning of the L2 vocabulary, as demonstrated by both  
18 the establishment of an N400 response to newly learned words and by ceiling level  
19 accuracy post-training. Concerning the cortical response, modulations of the N400 have  
20 been noted in association with L2 learning and/or artificial languages in several studies.  
21 This has been demonstrated in L2 studies that have used longitudinal designs to  
22 investigate changes in cortical activity over the course of learning (Chun, Choi, & Kim,  
23 2012; McLaughlin, Osterhout, & Kim, 2004; Stein et al., 2006; Yum, Midgley,  
24 Holcomb & Grainger, 2014). In a seminal study, McLaughlin and colleagues (2004)  
25 found that L2 pseudowords elicited a larger N400 than learned L2 words following 14  
26 hours of classroom instruction (McLaughlin et al., 2004). Crucially, these effects were  
27 not seen behaviorally; when making overt lexical decisions, learners performed at  
28 chance. Hence, L2 learners were sensitive to the prior exposure to word forms, as  
29 shown by the N400 effect, even when they could not consciously identify these forms.

1  
2  
3 In contrast, the semantic integration of these newly learned lexical items only occurred  
4 following 60 hours of instruction, as indexed by reduced N400 amplitude for L2 target  
5 words preceded by semantically related primes. Similarly, Soskey and colleagues  
6 (Soskey et al., 2016) reported the gradual instantiation of L2 words, as indexed by  
7 modulation of the N400, across a semester of learning. It is important to note, however,  
8 that these studies reported cortical changes due to L2 meaning integration following  
9 extended L2 training whereas we found that participants accessed the meaning of newly  
10 acquired L2 words after only 3 hours of learning.

19  
20

21 Artificial language paradigms have been used to ascertain whether novel L2  
22 words can be associated quickly with meaning. Breitenstein and colleagues  
23 (Breitenstein et al., 2007) used associative learning, where a spoken word was paired  
24 with the image of an object with increasing statistical probability over multiple trials  
25 and found that after 5 days of training, newly learned words facilitated (in the form of  
26 shorter response latencies) the processing of related pictures, indicating integration into  
27 existing lexical networks. A similar magnetoencephalography (MEG) study by Dobel et  
28 al. (2010) showed a reduction in the mN400 (the MEG component comparable to the  
29 ERP N400 component) to correct images preceded by trained spoken words from pre-  
30 to post-training, indicating that trained words had become associated with existing  
31 conceptual representations. Our results corroborate these findings, showing the  
32 acquisition of a small L2 vocabulary following three 25-minute training sessions and  
33 one 40-minute review session over the course of 4 days, as manifested by the  
34 establishment of an N400 response from pre- to post-training and increased accuracy,  
35 from chance to ceiling level.

54

55 Our study clearly demonstrates that learners were sensitive to the grammatical  
56 gender of the newly learned words, despite there having been no formal or explicit  
57  
58  
59  
60

1  
2  
3 instruction concerning gender and even though the stimuli were only presented aurally.  
4  
5 This implies that our participants segmented the auditory stimuli into the determiner and  
6  
7 noun and inferred gender information from the properties of the speech signal.  
8  
9 Segmenting the audio signal into its syntactic elements is notoriously difficult during  
10  
11 second language acquisition (Altenberg, 2005), which is why we created a game that  
12  
13 specifically segmented the auditory sentences and required participants to recognize the  
14  
15 meanings of the different elements and assemble them in the correct order to recreate  
16  
17 the auditory sentence. However, while determiner phrases and verbal phrases were  
18  
19 explicitly segmented, the determiner phrases were presented as a single unit (e.g.,  
20  
21 /okaSimbo/ “the pipe” and /asaia/ “the skirt”). Learners could, in theory, have  
22  
23 interpreted the determiner phrase as a whole rather than segment it into the determiner  
24  
25 and noun, as indeed there is evidence for in young children. For example, in early stages  
26  
27 of acquisition French children may produce forms that reveal segmentation errors (e.g.,  
28  
29 “*le loiseau*” and “*le noiseau*” stemming from the speech signal “*l’oiseau*” and “*un*  
30  
31 *oiseau*” «the bird / a bird» Clark, 2009). Even so, the regularity of the morphological  
32  
33 form for the determiner (/a/ or /o/) preceding the noun and the concurring final phoneme  
34  
35 of nouns reduces this possibility, as discussed below. Moreover, the majority of  
36  
37 participants had formally learned Spanish as a third language throughout secondary  
38  
39 school, which may well have prompted them to capitalize on the partial overlap of  
40  
41 gender concord rules in Spanish and Portuguese (cf. Brooks & Kempe, 2013).  
42  
43  
44  
45  
46  
47  
48

49 Various studies with either natural or artificial languages have shown that  
50  
51 following implicit training, adult learners rapidly deduce the rules that govern  
52  
53 grammatical gender assignment (Öttl & Behne, 2017) and gender concord (Denhovska  
54  
55 & Serratrice, 2017; Morgan-Short et al., 2010). Concerning gender assignment, our  
56  
57 materials provided a clear phonetic cue, as outlined above, but no semantic information  
58  
59  
60

1  
2  
3 was associated with the gender of nouns. This differs from the materials learned in an  
4 artificial language (Öttl & Behne, 2017) in which gender suffixes on the noun were  
5 determined by the biological gender of stimuli. Concerning gender concord, Morgan-  
6 Short et al. (2010) found no difference in learning as measured by behavioral (d prime)  
7 or cortical sensitivity (P600 response) to determiner-noun gender concord violations as  
8 a function of the type of training (implicit or explicit) at the end of training. Using a  
9 miniature set of Russian nouns and adjectives, in which adult learners were exposed to  
10 noun-adjective gender concord in short written sentences, Denhovska and Seratrice  
11 (2017) showed that even under implicit learning, where emphasis was placed on  
12 learning the meanings of the sentences and no mention was made of the underlying  
13 grammatical rules, participants readily acquired these rules. Moreover, no difference in  
14 behavioral accuracy was found for grammatical judgments as a function of the type of  
15 instruction (implicit or explicit), although only those who received explicit instruction  
16 were able to produce the grammatical rules governing gender concord above chance  
17 level. The present results are in line with those found in the above studies, showing that  
18 participants rapidly acquire grammatical gender concord rules in a newly learned  
19 language following short training sessions, even in the absence of formal instruction.

40  
41

42 The pattern of results we obtained suggests that gender congruency effects play  
43 an early role during lexical access. This question, i.e. whether grammatical gender  
44 exerts an early influence on lexical access or only later, during lexical selection, has  
45 been examined in various monolingual studies. Eye-tracking experiments have  
46 demonstrated that both children and adults use gender agreement to predict nouns when  
47 they are preceded by a gender-marked determiner (Brouwer et al., 2017; Cholewa et al.,  
48 2019; Lew-Williams & Fernald, 2007). Far less evidence of this has been found in the  
49 second language (Hopp & Lemmerth, 2016; Lemmerth & Hopp, 2019). In a primed  
50  
51  
52

56  
57  
58  
59  
60

1  
2  
3 lexical decision task using auditory homophone primes and orthographic targets,  
4  
5 Spinelli and Alario (2002) found that gender-marked determiners constrained lexical  
6  
7 access to the gender compatible candidate for French homophones. However,  
8  
9 subsequent work provided evidence that grammatical gender does not in fact constrain  
10  
11 lexical access but acts at a later stage during the selection of the appropriate candidate  
12  
13 (Spinelli et al., 2006). Our results clearly demonstrate that the L1 gender of stored  
14  
15 words was activated and interacted with the L2 gender of actually presented words. It  
16  
17 remains to be determined whether such was due to the presence of the salient and  
18  
19 reliable morphological marking carried in the determiner (i.e. whether participants  
20  
21 computed gender based on morpho-phonological cues) or due to the activation of the L2  
22  
23 gender from the auditory noun itself (i.e. retrieval of gender from a newly stored  
24  
25 representation). Nevertheless, our results suggest that gender congruency across  
26  
27 languages affected lexical access for newly learned L2 nouns, which was hindered when  
28  
29 competing gender features from the L1 were activated.  
30  
31  
32  
33  
34

35 Our results, showing a clear interaction between the established L1 and a newly  
36  
37 acquired L2 vocabulary, add to the ample body of experimental evidence showing that  
38  
39 the interaction between languages is ubiquitous and found at all levels of processing  
40  
41 (see Kroll & Bialystok, 2013, for a review of experimental studies). Indeed, the  
42  
43 automatic activation across languages has been demonstrated during both auditory and  
44  
45 written processing at the phonological level (Carrasco et al., 2012; Friesen et al., 2020),  
46  
47 the lexical level (Dijkstra et al., 2000; Lagrou et al., 2011; Sunderman & Kroll, 2006)  
48  
49 and the syntactic level (Dussias & Sagarra, 2007; Foucart & Frenck-Mestre, 2011).  
50  
51 Moreover, parallel activation across languages is found despite distinct writing systems  
52  
53 (Thierry & Wu, 2012; Wu & Thierry, 2010). Our results present further evidence that  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 even in monolingual contexts and even for novice learners, the two languages are  
4  
5 activated in parallel.  
6  
7

8  
9 Differences between ERP and behavioral results are likely due to discrepancies in  
10 timing and granularity. Whereas the N400 is time-locked to stimuli in such a way as to  
11 provide information regarding early aspects of lexical-semantic processing, behavioral  
12 measures can encompass both early and late effects during processing. Otherwise stated,  
13 by the time low-temporal resolution behavioral data, such as accuracy or reaction time,  
14 are measured, other, later, cognitive processes have plausibly occurred (ex. working and  
15 episodic memory processes, response selection, mental imagery, c.f. Hauk, 2016).  
16 Specifically pertaining to gender congruency effects during a semantic categorization  
17 task in the L2, previous ERP results showed a negative (LAN) modulation for cross-  
18 language gender incongruent words but no differences in reaction time between  
19 conditions (Boutonnet et al., 2012). Similarly, in our study, an N400 effect was seen for  
20 Match vs. Mismatch trials but only for cross-language gender congruent words,  
21 suggesting that cross-language gender congruency had a direct effect on semantic  
22 processing. Once again, this effect was not seen in behavioral results (d prime or  
23 accuracy). We posit that in both our and Boutonnet et al.'s (2012) studies, cross-  
24 language gender interference effects happen too early in lexical processing to be  
25 evidenced behaviorally, which explains why the GCE as measured by EEG (N400) was  
26 not echoed by a behavioral effect. Our results are also in line with those reported by  
27 McLaughlin and colleagues (2004) who found cortical sensitivity to the lexical status of  
28 newly learned L2 items in the absence of behavioral capacity to distinguish between  
29 words and non-words. In similar fashion our results show cortical sensitivity to gender  
30 congruency across languages that was not reflected in the behavioral response.

1  
2  
3 Last, we can note that our design did not allow us to examine the effect of  
4 gender concord or gender congruency within the L2. Several studies are warranted to  
5 delve further into this question. It would be of interest, for example, to test whether we  
6 could establish gender congruency effects within the newly learned L2 by adopting a  
7 paradigm similar to that used by Boutonnet et al. (2012), in which successive trials  
8 carried the same L2 gender, or a visual world paradigm (Hopp & Lemmerth, 2016) in  
9 which the gender of the items is varied both across languages and within the L2.  
10 Concerning gender concord, a typical violation paradigm could be added to the current  
11 design, whereby the learned L2 nouns are preceded by either the correct determiner or  
12 the incorrect determiner (Foucart & Frenck-Mestre, 2011, 2012; Morgan-Short et al.,  
13 2010). We demonstrated previously that the overlap of grammatical features between  
14 the learners' L1 and L2, the specific syntactic structure and the level of proficiency in  
15 the L2 all play a role in the pattern of ERP components elicited by gender concord  
16 violations in sentential contexts for L2 speakers (Foucart & Frenck-Mestre, 2011, 2012).  
17 In similar fashion, recent work that manipulated gender concord in sentential contexts  
18 found that the ERP signature for these violations – generally the LAN/P600 – can vary  
19 even in native speakers as a function of stimulus characteristics (Beatty- Martínez, et al.,  
20 2021). This challenges the notion that ERP signatures associated with syntactic  
21 processing (error detection) are tied to a specific level of processing and/or are more  
22 systematic in native speakers than in L2 learners. Hence, in novice learners of a  
23 gendered language, whether we would find an ERP response to gender concord errors  
24 within the newly learned language and, if so, what component would be elicited is an  
25 open question.

26  
27  
28 To conclude, we have provided clear electrophysiological evidence of gender  
29 congruency effects in an L2, from the very beginning of acquisition. The clear N400  
30

1  
2  
3 effect elicited by mismatched compared to matched audio-visual pairs for gender  
4  
5 congruent trials was basically annulled for gender incongruent trials. To our knowledge,  
6  
7 no prior work has provided evidence of GCE, either behaviorally or via the cortical  
8  
9 response to newly learned L2 words. It is important to note that our behavioral results  
10  
11 clearly demonstrate that participants learned the correct association between auditory  
12  
13 words and images and that this was independent of both the gender in the second  
14  
15 language vocabulary and, importantly, of the congruency of gender across the L2 and  
16  
17 the participants' L1. Hence, we have also provided evidence of the importance of a  
18  
19 multi-disciplinary approach to bring the effects of cross-linguistic gender congruency to  
20  
21 light, at least in the early stages of acquisition.

13  
14 *Herein we present electrophysiological evidence of extremely rapid learning*  
15 *of new labels in an L2 (Brazilian Portuguese) for existing concepts, via*  
16 *computerized games. However, the effect was largely constrained by cross-*  
17 *linguistic grammatical gender congruency. We recorded ERPs both prior to*  
18 *exposure with the second language and following a 4-day training session.*  
19 *Results showed rapid changes in cortical activity, associated with learning.*  
20 *Prior to exposure, no modulation of the N400 component was found as a*  
21 *function of the correct match vs. mismatch of audio presentation of words and*  
22 *their associated images. Post-training, a large N400 effect was found for*  
23 *mismatch trials compared to correctly matched audio-visual trials. However,*  
24 *for learners these results were only obtained for trials on which the L2 words*  
25 *shared grammatical gender in the learners L1 (French). For trials on which*  
26 *the L2 words had the opposite gender in French, no N400 mismatch effect*  
27 *was found post-training. In contrast, behavioral results showed that all L2*  
28 *words were learned equally as well, independent of gender congruency*  
29 *across Portuguese and French. For control participants who were native*  
30 *speakers of Portuguese, a clear N400 effect was found for mismatch*  
31 *compared to match trials, which was independent of gender congruency. The*  
32 *results demonstrate that grammatical gender overlap in the L1 and L2*  
33 *influences lexical activation during the initial stages of establishing a new L2*  
34 *lexicon.*

1  
2  
3 In Brazilian Portuguese, a mouse, no matter which biological sex, is  
4 grammatically masculine ( $o_{\text{masc}}$  *camundongo*<sub>masc</sub>) whereas a cockroach is grammatically  
5 feminine ( $a_{\text{fem}}$  *barata*<sub>fem</sub>). The opposite is true in standard French, with grammatically  
6 feminine mice ( $la_{\text{fem}}$  *souris*<sub>fem</sub>) and masculine cockroaches ( $le_{\text{masc}}$  *cafard*<sub>masc</sub>). This  
7 arbitrary assignment of grammatical gender is even more apparent for inanimate objects,  
8 with opposite gender assignment for trash cans, brooms and chalk across Portuguese  
9 and French, despite both languages being derived from Latin. The present study  
10 examined how cross-linguistic gender congruency, i.e. the overlap in grammatical  
11 gender for nouns across languages, might affect both the acquisition and online  
12 processing of a second language (L2) in novice adult learners. Although numerous  
13 online studies have provided evidence that speakers of gendered languages are sensitive  
14 to gender congruency across languages, during both L2 comprehension and production  
15 (cf. Sá-Leite, Fraga & Comesaña, 2019, for a meta analysis) these studies have almost  
16 exclusively examined learners who had extensive experience with the L2. We propose a  
17 novel approach to this question by starting from the initial stages of exposure to the L2.  
18 In addition, we provide both behavioral and electrophysiological measures of  
19 performance, which indeed revealed different patterns of the effect of gender  
20 congruency.

Numerous psycholinguistic studies have examined the effect of gender  
congruency (GCE), both within languages in monolinguals and across languages in  
bilinguals. Monolingual studies have been conducted in the framework of speech  
production models, which generally assume that grammatical gender is represented  
independently from other levels of lexical representation, i.e. phonological and semantic,  
but differ as concerns when and how gender is retrieved (Caramazza, 1997; Cubelli et al.  
2005; Foucart et al., 2010; Levelt et al., 1999; Schiller & Caramazza, 2006). Several

1  
2  
3 bilingual studies, discussed below, have also been conducted within this framework. As  
4  
5 concerns comprehension, bilingual studies that have examined cross-linguistic GCE  
6  
7 have looked at both the interactive nature of bilingual lexical access (Morales et al.,  
8  
9 2016; Paolieri et al., 2020) and late bilinguals' ability to use grammatical gender to  
10  
11 predict upcoming elements (Hopp & Lemmerth, 2016; Lemmerth & Hopp, 2019). The  
12  
13 latter have addressed processing at the lexical level. However, a handful of  
14  
15 comprehension studies have also investigated the influence of cross-linguistic gender  
16  
17 congruency on syntactic processing (Foucart & Frenck-Mestre, 2011, 2012; Sabourin et  
18  
19 al., 2006). We shall address these topics in turn.

20  
21  
22  
23  
24 Cross-linguistic GCEs have been examined at the lexical level during production,  
25  
26 in naming (Bordag, 2004; Bordag & Pechmann, 2007; Costa et al., 2003; Lemhöfer et  
27  
28 al., 2008; Morales et al., 2011; Paolieri et al., 2010) and translation (Bordag &  
29  
30 Pechmann, 2008; Paolieri et al., 2010; Salamoura & Williams, 2007), as well as in  
31  
32 comprehension (Lemhöfer et al., 2008; Paolieri et al., 2020). The pattern of results  
33  
34 across studies is both complex and inconsistent. In two independent experiments with  
35  
36 German L1-Dutch L2 late bilinguals, Lemhöfer et al. (2008) examined the effects of  
37  
38 cognate status and gender congruency on lexical decision times and naming latencies in  
39  
40 the L2. They reported robust effects of both factors in both tasks, with no interaction  
41  
42 effects. Participants showed faster lexical decision times and naming latencies for L2  
43  
44 Dutch words that shared gender in German and for cognates (cf. Sá-Leite et al., 2019, as  
45  
46 well as Costa et al., 2000, for a discussion of cognate effects). In addition, in the naming  
47  
48 task, no effect of syntactic structure was found, such that GCE were reported  
49  
50 independent of whether participants produced determiner phrases or bare nouns. Similar  
51  
52 results were reported by Bordag & Pechman (2007) for relatively inexperienced Czech  
53  
54 L1-German L2 late learners, who found GCE in 2 experiments independent of whether  
55  
56  
57  
58  
59  
60

1  
2  
3 participants named bare nouns or nouns preceded by gender-marked adjectives in the L2.  
4  
5 In like fashion, Paolieri and colleagues reported faster naming latencies in the L2  
6  
7 (Spanish) for line drawings that shared the same gender in the bilingual participants' L1  
8  
9 (Italian) (eg "falda" and "gonna" *skirt*) compared to those that had opposite gender (e.g.,  
10  
11 "mesa" and "tavolo" *table*) and this was true for both bare nouns and determiner noun  
12  
13 phrases (Paolieri et al., 2010). Paolieri et al. (2010) replicated their results for bilingual  
14  
15 participants across 2 experiments; however, in their second experiment both the effect  
16  
17 of gender congruency and the critical interaction with Group (bilingual vs. monolingual)  
18  
19 were only reliable by participants, suggesting that the GCE was not restricted to the  
20  
21 bilingual group and may have been partially driven by characteristics of the items  
22  
23 unrelated to gender congruency. Klassen (2016) examined GCE in naming across  
24  
25 Spanish and German, which differ concerning the number of gender categories (2 vs. 3),  
26  
27 the phonetic regularity of gender marking (overt and highly consistent in Spanish vs. not  
28  
29 phonetically salient in German) and complexity (case interacts with gender in German  
30  
31 but not Spanish). Results showed facilitated processing for gender congruent nouns  
32  
33 compared to incongruent nouns, for both bare nouns and determiner phrases in the  
34  
35 group of L1 Spanish-L2 German learners but not L1 German controls. Yet, this was true  
36  
37 for nouns that were either masculine or feminine in German but not for neuter gender,  
38  
39 which, although indeed incongruent with either gender in Spanish led to faster naming  
40  
41 latencies. Hence, the GCE also appears to be constrained by the overlap of gender  
42  
43 categories across languages. All of these studies argue in favor of an interactive  
44  
45 activation model of processing (Dell, 1986) in which both the L1 gender and  
46  
47 phonological form of lexical entries influence L2 processing, and according to which  
48  
49 grammatical gender is not stored as an independent feature at the lemma level (i.e.  
50  
51 Levelt et al., 1999).  
52

54  
55  
56  
57  
58  
59  
60

1  
2  
3 In contrast, Costa and colleagues failed to find GCE across 5 independent  
4 experiments in which participants produced NPs in their L2, even when with gender-  
5 marked determiners (Costa et al., 2003). This was true independent of whether the  
6 bilinguals' two languages had similar gender systems. Costa and colleagues (2003)  
7 argued that while semantic representations are shared across languages and commonly  
8 activated by lexical entries of either language, the specific grammatical features of a  
9 lexical entry, such as its gender, are inherent properties of that entry. Hence, these  
10 features would not be shared across languages. Costa et al. (2003) noted nonetheless  
11 that they tested highly proficient bilinguals and suggested that less proficient L2  
12 speakers might show greater interaction between their two gender systems, as was  
13 indeed reported by subsequent studies (Bordag & Pechmann, 2007; Lemhöfer et al.,  
14 2008; Paolieri et al., 2010). In addition, as highlighted by Sá-Leite et al. (2009), other  
15 mitigating factors that were not considered by Costa et al. (2003) may have played a  
16 role and could explain why this study seems to be the odd man out as concerns finding  
17 GCE.

34  
35  
36

37 In translation tasks, the results are also mixed. At one extreme, Bordag &  
38 Pechmann (2008) reported no cross-linguistic GCE across three translation tasks with  
39 Czech-German participants who translated either bare nouns or adjective-noun phrases  
40 into the L2. It is of particular interest that the absence of a GCE was reported in  
41 translation for the same materials and participant population that produced a robust  
42 GCE in production (Bordag & Pechmann, 2007). Bordag and Pechmann (2008) account  
43 for the discrepancy in results across tasks as concerns GCE in terms of time course.  
44 During picture naming, activation would spread from the concept to the L1 and L2  
45 lemmas in parallel, hence leading to the simultaneous activation of L1 and L2 gender  
46 nodes and competition when the two do not match. In translation, the time course would  
47  
48

1  
2  
3 be shifted, such that L1 word forms would activate their lemmas which in turn would  
4  
5 activate the L2 lemma and word form. As such, the L2 gender node would only be  
6  
7 activated subsequent to the L1 gender node and no direct competition would arise.  
8  
9 Salamoura & Williams (2007) reported a different pattern of results, whereby proficient  
10  
11 Greek-German bilinguals showed cross-linguistic GCE when they translated gender-  
12  
13 marked adjectives along with the noun, but not for bare nouns. The authors argued that  
14  
15 gender retrieval occurs only when gender concord must be computed, i.e. within the  
16  
17 determiner phrase, in line with certain monolingual models of production (Caramazza,  
18  
19 1997, but see Cubelli et al., 2005). Last, Paolieri et al. (2010) reported GCE during a  
20  
21 translation task with advanced Italian-Spanish bilinguals, independent of whether  
22  
23 participants produced the bare noun or a determiner phrase. Based on this pattern of  
24  
25 results, the authors proposed that lexical selection necessarily entails the activation of  
26  
27 gender, in parallel. Lexical items that share gender across languages would enjoy a  
28  
29 higher level of activation, hence facilitating both naming and translation. The three  
30  
31 competing sets of results and theoretical accounts leave ample room for discussion.  
32  
33  
34  
35  
36

37 The effect of gender congruency across languages has also been examined  
38  
39 during online comprehension. Several studies have approached this topic in the  
40  
41 framework of whether bilinguals can use grammatical gender to predict upcoming  
42  
43 elements in their L2 (Hopp & Lemmerth, 2016; Lemmerth & Hopp, 2019; Morales et  
44  
45 al., 2016). The results from two visual world paradigm studies with Russian-German  
46  
47 bilinguals, which used the same design and materials, failed to produce statistically  
48  
49 conclusive evidence that gender congruency plays a significant role in the ability of  
50  
51 either adults (Hopp & Lemmerth, 2016) or children (Lemmerth & Hopp, 2019) to  
52  
53 process gender online in the L2. Another visual world paradigm study, conducted with  
54  
55 proficient Italian-Spanish bilingual adults, showed interference from a distracter image  
56  
57  
58  
59  
60

1  
2  
3 when its gender was incongruent with the L1 equivalent, suggesting gender-induced  
4 competition (Morales et al., 2016). However, the effects were not significant until after  
5 the onset of the target noun, suggesting that co-activation of gender across languages  
6 during comprehension may not occur until a certain amount of information has been  
7 processed.  
8  
9

10  
11  
12  
13  
14  
15 Event-related potentials (ERPs) have also been used to measure the effects of  
16 cross-linguistic gender congruency on language processing. The most common of these  
17 are the N400, the P600 and the LAN, generally elicited by semantic and syntactic  
18 violations respectively. The N400, a negative deflection in the waveform with a central-  
19 parietal distribution usually observed between 300-500 msec after stimulus onset, is  
20 generally thought to reflect semantic integration such that increased N400 amplitude is  
21 attributed to processing difficulty that results from attempting to integrate a new  
22 element within an existing semantic context (Holcomb, 1993; Kutas & Federmeier,  
23 2011; Kutas & Hillyard, 1980). The N400 component has also been associated with  
24 retrieval/access, with increased N400 amplitude reflecting the effort of retrieving  
25 semantic/conceptual information from long-term memory. In this case a reduced N400  
26 is interpreted as signaling facilitated access to lexical information (Delogu et al., 2019).  
27  
28 Recently, Bornkessel-Schlesewsky & Schlewsky (2019) re-examined N400 results in  
29 a predictive coding perspective. Accordingly, the N400 (along with other language-  
30 related negativities) could reflect precision-weighted prediction errors rather than  
31 linguistic processing per se. Another ERP component commonly used in language  
32 studies is the P600, which is a positive-deflection in the wave form with a centro-  
33 parietal distribution thought to show difficulty in syntactic integration (Kaan et al.,  
34 2000; Meltzer & Braun, 2013), as well as the cost of “revising, repairing or reanalyzing  
35 an existing (morpho-) syntactic structure” (Delogu et al., 2019, p.2). The P600 is  
36  
37  
38

59  
60

1  
2  
3 sometimes associated with the Left Anterior Negativity (LAN) (for a debate on the  
4 significance of the LAN, cf. Fraga et al., 2021; Molinaro et al., 2015; Tanner, 2015).  
5  
6 The P600/LAN has also been associated with conflict/monitoring resolution  
7  
8 (Bornkessel-Schlesewsky & Schlewsky, 2008; Kim & Osterhout, 2005) as well as  
9  
10 semantic integration (Brouwer et al., 2017). Finally, the nogo N200 response occurs  
11  
12 roughly 200 msec post-stimulus when there is conflict and/or inhibition as concerns  
13  
14 processing and the participant's response (Enriquez-Guppert et al., 2010). While not  
15  
16 specific to language processing, the N200 can be used to measure response conflict  
17  
18 during language processing such as in the study described below.  
19  
20  
21  
22  
23

24         Rodriguez-Fornells & Münte (2016) recorded ERPs in a Go/Nogo paradigm to  
25  
26 probe the effect of grammatical gender congruency (and language switching) across  
27  
28 German and Spanish in fluent bilinguals. Compared to monolingual controls, bilinguals  
29  
30 showed greater negativity (N200) for incongruent compared to congruent gender trials.  
31  
32 While this result may indicate the automatic activation of gender across languages, there  
33  
34 are several caveats. First, the task explicitly required participants to retrieve  
35  
36 grammatical gender and both languages were actively recruited. Second, participants  
37  
38 could potentially predict the incongruent gender trials based on the structure of the  
39  
40 experiment. Last, gender incongruence elicited a late ERP component (P600/LPC).  
41  
42 Hence, these results do not provide clear evidence for the automatic, early retrieval of  
43  
44 gender. Paolieri et al. (2020) also recorded ERPs to examine the effect of gender  
45  
46 congruency during the processing of translation equivalents in Spanish and Catalan.  
47  
48 Only bare nouns were presented. A small but reliable increase in N400 amplitude was  
49  
50 found at central-midline sites for translation pairs that did not share grammatical gender  
51  
52 across languages in comparison to those that did, along with increased response times  
53  
54 for incongruent pairs, leading the authors to claim that gender is automatically activated  
55  
56  
57  
58  
59  
60

1  
2  
3 during lexical retrieval and elicits competition when different genders are activated  
4 across languages. As with Rodriguez-Fornells & Münte (2016), however, participants  
5 were actively processing both languages; a stronger demonstration would have  
6 consisted in comparing N400 amplitude for bare nouns in the L2 alone as a function of  
7 gender congruency. Moreover, no L1 control group was included such that it is not  
8 possible to determine whether the effect was driven solely by gender congruency or  
9 perhaps by extraneous factors specific to the gender-incongruent pairs. Nevertheless, in  
10 a semantic categorization task conducted exclusively in English with Spanish-English  
11 late bilinguals and monolingual controls, Boutonnet et al. (2012) reported a late  
12 negative ERP component (starting at roughly 400 msec) for trials that did not share  
13 gender in Spanish (the L1) with the two preceding items. This effect was specific to the  
14 bilingual group. No effects were found for the behavioral measures, in contrast to  
15 Paolieri et al. (2020), although the absence of an effect for behavioral measures in the  
16 presence of electrophysiological evidence is rather common. The authors argued for the  
17 automatic activation of L1 gender in speakers of gendered languages, even when  
18 processing exclusively the L2 and in a non-gendered language such as English.

38  
39  
40 Gender congruency effects have also been examined at the syntactic level during  
41 sentence processing, using ERPs. Several monolingual studies have shown that gender  
42 agreement violations in sentential context systematically elicit the P600 component  
43 (Alencar de Resende et al., 2019; Barber & Carreiras, 2005; Beatty-Martinez et al.,  
44 2021; Hagoort, 2003; Frenck-Mestre, 2005; Fraga et al., 2021; Gunter et al., 2000;  
45 Popov & Bastiaansen, 2018; Popov et al., 2020; Wicha et al., 2004) and can also  
46 produce a LAN (Alencar de Resende et al., 2019; Barber & Carreiras, 2005; Beatty-  
47 Martinez et al., 2021; Fraga et al., 2021; Gunter et al., 2000; Popov et al., 2020). The  
48 electrophysiological signature of gender concord during sentence processing is  
49

2  
3 nonetheless modulated by various factors, both linguistic (Alencar de Resende et al.,  
4 2019; Beatty-Martinez et al., 2021) and task-related (Schacht et al., 2014). In Brazilian  
5 Portuguese, Alencar de Resende and colleagues (2019) compared ERP signatures  
6 elicited by gender concord violations within the determiner phrase, either between the  
7 determiner and noun or the adjective and noun, for nouns with either regular or irregular  
8 gender assignment in Brazilian Portuguese. Results showed a biphasic LAN/P600 in  
9 response to concord violations, independent of the regularity of gender assignment.  
10 However, the amplitude of the P600 evoked by concord violations was greater for  
11 regular nouns. The authors suggested that both regular and irregular forms are stored  
12 and accessed in similar fashion, i.e. via a single lexical route, but that repair processes  
13 are facilitated for regular forms. Beatty-Martinez et al. (2021) reported differences as a  
14 function of gender category in Spanish, whereby determiner-noun violations in sentence  
15 contexts elicited a biphasic LAN/P600 response for masculine nouns in contrast to the  
16 same violations for feminine nouns, which did not elicit a LAN and showed a wider  
17 P600 distribution in comparison to masculine nouns. This difference in the  
18 electrophysiological response was interpreted as being linked to systematic differences  
19 in the representation of the two gender categories.  
20

37  
38  
39  
40  
41

42 The P600 is also elicited during L2 sentential processing of gender concord  
43 violations for L2 learners whose L1 has grammatical gender (Foucart & Frenck-Mestre,  
44 2011; Sabourin et al., 2006) but also for those who do not (Foucart & Frenck-Mestre,  
45 2012; Dowens et al., 2011; Morgan-Short et al., 2010; Tokowicz & MacWhinney,  
46 2005). Moreover, P600 amplitude for gender concord violations in an L2 is contingent  
47 on proficiency and age of acquisition (Nichols & Joanisse, 2016). ERP studies that  
48 focused on cross-language gender congruency have provided evidence that the overlap  
49 of both syntactic rules, as concerns gender concord (Foucart & Frenck-Mestre, 2011;  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 Sabourin & Stowe, 2008), and lexical gender across languages (Foucart & Frenck-  
4  
5 Mestre, 2011) affect whether gender concord violations in the L2 elicit an  
6  
7 electrophysiological response, the type of response (Foucart & Frenck-Mestre, 2012)  
8  
9 and its magnitude.  
10

11  
12 The body of studies cited above has examined L2 gender processing and gender  
13  
14 congruency in participants who had several years of experience with and exposure to  
15  
16 the L2. Various authors have used learning paradigms with either an artificial language  
17  
18 or miniature versions of natural languages to explore how different factors affect gender  
19  
20 acquisition after short training periods. Arnon and Ramscar (2012) used an artificial  
21  
22 language to test whether acquiring the gender and new lexical labels of known concepts  
23  
24 was affected by the sequence of explicit training. Participants who first learned novel  
25  
26 words preceded by their gender-marked article within an auditory sentential context,  
27  
28 followed by paired associate learning with bare nouns had better learning outcomes,  
29  
30 followed by paired associate learning with bare nouns had better learning outcomes,  
31  
32 both for gender assignment and noun labels, than those who learned in the opposite  
33  
34 order. The authors argued that learning new lexical labels for concepts first via bare  
35  
36 nouns blocked the later acquisition of gender assignment in sentential context due to the  
37  
38 redundancy of gender in relation to meaning. Brooks and Kempe (2013) examined the  
39  
40 implicit learning of nominal gender agreement and case marking in a subset of Russian  
41  
42 following a 6-day training session. Results showed that while learners relied on  
43  
44 metalinguistic knowledge to acquire case marking, for gender concord they relied on the  
45  
46 consistent and transparent morphological cues (feminine being systematically indicated  
47  
48 by a final vowel on the noun and agreeing adjective, and masculine by a final  
49  
50 consonant) and knowledge of nominal morphology in another known L2. Indeed, the  
51  
52 best predictor of acquiring Russian gender agreement was whether the learners had  
53  
54 already acquired a Latin language with the same rule for feminine gender. Morgan-  
55

1  
2  
3 Short and colleagues (2010) compared the processing of gender concord in early  
4 learning stages, after implicit versus explicit training in an artificial language. During  
5 early stages of acquisition, the ERP signature to gender concord violations differed  
6 according to the type of training. Notwithstanding, both implicit and explicit learning  
7 groups ultimately attained similar levels of proficiency and exhibited similar patterns of  
8 cortical response to gender concord violations at the final stage of acquisition.  
9

10  
11 To our knowledge, no studies have measured the effect of cross-language gender  
12 congruency during the early stages of L2 lexical acquisition in a natural language. The  
13 current study aimed to fill this void by examining how cross-linguistic gender  
14 congruency might influence processing in an L2 from the very initial stages of learning.  
15 We examined French L1 speakers' acquisition of Brazilian Portuguese via interactive  
16 computer games, in which L2 Portuguese was presented aurally in full sentences and  
17 segmented format, in which grammatical gender within determiner phrases was taught  
18 implicitly. Both French and Portuguese have two classes of grammatical gender  
19 (masculine and feminine) and require gender concord within the determiner phrase.  
20 Whereas French uses the singular definite article le[lə]<sub>masc</sub> to mark the masculine gender  
21 and Portuguese uses o<sub>masc</sub> (realized as /o/ or /u/), in both languages the singular feminine  
22 definite article carries the final phoneme [a] (French: la<sub>fem</sub> [la], Portuguese a<sub>fem</sub> [a]). In  
23 addition, in Portuguese, the vowel of the definite determiner is generally consistent with  
24 the final vowel of the noun (e.g., “a faca” “the knife” and “o garfo” the fork). It is  
25 therefore probable that, even without formal instruction concerning the gender of the  
26 Portuguese nouns or the determiner system, French native speakers are able to extract  
27 this information from the phonological word forms (Brooks & Kempe, 2013;  
28 Denhovska & Seratrice, 2017). Indeed, following the seminal work by Karmiloff-Smith  
29 (1979), various experimental studies have shown that native French speakers are  
30

1  
2  
3 sensitive to the regularities present in noun endings and reliably use them as early as age  
4  
5 3 to process and/or assign grammatical gender (cf. Seigneuric et al., 2007 for a  
6  
7 discussion and further work with children, and Pérez-Pereira (1991) for similar work in  
8  
9 Spanish). In Brazilian Portuguese, incongruent grammatical gender marking within the  
10  
11 determiner phrase between adjacent elements (notably the determiner and noun) affects  
12  
13 children's ability to process gender assignment as young as age 2 (Corréa & Name,  
14  
15 2003), in support of the hypothesis that young children are sensitive to grammatical  
16  
17 information conveyed by the determiner and process gender concord in the DP (cf.  
18  
19 Corrêa et al., 2011 for further work). Thus, native speakers of gendered languages show  
20  
21 rapid acquisition of the phonological features associated with grammatical gender  
22  
23 categories, when present, and the syntactic reflexes of elements that are controlled by  
24  
25 the noun. Our French learners undoubtedly exploited these capacities when acquiring  
26  
27 the L2 Brazilian Portuguese vocabulary.  
28  
29  
30  
31  
32

33 We created 4 computer games to teach French native speakers a small lexicon in  
34  
35 Brazilian Portuguese. All auditory materials were presented exclusively in Brazilian  
36  
37 Portuguese. The games involved both full sentences and individual lexical items, which  
38  
39 comprised noun phrases (definite determiner and noun) and verbs. We manipulated  
40  
41 gender congruency such that the nouns were either gender congruent or incongruent  
42  
43 across the learners' L1 and L2 (cf. Table 1). No instruction was provided concerning  
44  
45 grammatical gender, however; nouns were always preceded by the singular definite  
46  
47 determiner, i.e. the overtly marked vowel (e.g., a<sub>fem</sub> faca<sub>fem</sub> [the knife], o<sub>masc</sub> garfo<sub>masc</sub>  
48  
49 [the fork]). Participants with no prior knowledge of (Brazilian) Portuguese took part in a  
50  
51 3-day training program, during which they learned a vocabulary of 36 words overall,  
52  
53 divided into 12 sentences comprised of 3 verbs and 4 nouns each day via the games.  
54  
55 ERPs were recorded both pre- and post-training in a match/mismatch paradigm in which  
56  
57  
58  
59  
60

auditory nouns were paired with visual images that either depicted the noun (match) or another learned noun (mismatch). Thus, we were able to follow progression from zero knowledge to the recognition of newly learned L2 phonological word forms.

We hypothesized that learners should be able to fully acquire the L2 vocabulary. Performance was measured both by their accuracy scores pre- and post-training and, crucially, the change in electrophysiological response pre to post-training. Concerning the latter, we expected variation in the N400 component, whereby prior to training match and mismatch trials should not differ in the N400 response, but post-training mismatch trials should evoke an increased N400 response compared to match trials due to difficulties in lexical processing. In relation to the congruency of grammatical gender across the L1 and L2, we hypothesized that it should not affect the ERP response pre-training. In contrast, at the post-training session, it should affect the size of the N400 effect if indeed grammatical gender is automatically activated for speakers of gendered languages (Boutonnet et al., 2012; Dahan et al., 2000; Lew-Williams & Fernald, 2007) and if inhibition results from gender inconsistency across languages (Morales et al., 2016; Rodriguez-Fornells & Münte, 2016).

	L2fem	L2masc
L1fem	a saia (la jupe)	o cachimbo (la pipe)
L1masc	a vassoura (le balai)	o casaco (le manteau)

*Table 1. Examples of gender congruency/incranguency across Brazilian portuguese and French*

## Methods

**Participants.** Eighteen right-handed French native speakers (10 women), enrolled as undergraduate students at Aix-Marseille Université, aged 20 to 26 years old ( $M = 22.8$  years,  $SD = 2.4$ ), who had no knowledge of Brazilian Portuguese, and 18 right-handed

1  
2  
3 native speakers of Brazilian Portuguese (16 women) aged 22 to 28 ( $M = 25.3$ ,  $SD = 3.4$ )  
4  
5 who were enrolled at AMU in a one year abroad program were recruited for the study.  
6  
7 One French participant's data was excluded due to displaying knowledge of the L2  
8  
9 vocabulary (an N400 effect for mismatched pairs) prior to training. All French  
10  
11 participants had learned English as a second language throughout secondary school;  
12  
13 eight had also learned Spanish as a third language while seven had learned German.  
14  
15 None considered themselves fluent in Spanish. The Brazilian participants had all  
16  
17 learned English in secondary school; 12 considered themselves novice in French and 6  
18  
19 intermediate. Participants had no history of neurological insult and received monetary  
20  
21 compensation in exchange for their participation. All participants gave their written  
22  
23 informed consent prior to the experiment and were debriefed about its purpose at its end.  
24  
25 The study was approved by the local university ethics committee.  
26  
27  
28  
29  
30  
31  
32

33 **Materials.** Thirty-six concrete nouns and 9 transitive verbs were presented orally in  
34  
35 Brazilian Portuguese (BP), in sentences and in isolation, across 3 training sessions, with  
36  
37 3 verbs and 12 nouns learned in each session. All materials are presented in the  
38  
39 appendix. The items were selected based on their ease of imageability, cognate status  
40  
41 with the learners' L1 (French) as well as other Latin languages commonly learned in  
42  
43 France (Italian, Spanish) and English, and congruency of grammatical gender across  
44  
45 Portuguese and French. Half of the nouns had the same gender across French and  
46  
47 Brazilian Portuguese ( $[a_f \text{ panela}_f]$  /  $la_f \text{ casserole}_f$  "the pot") and the other half had the  
48  
49 opposite gender ( $[a_f \text{ faca}_f]$  /  $le_m \text{ couteau}_m$  "the knife"). Of the 36 nouns, 32 were  
50  
51 phonetically marked for gender (16 ending with /a/ and 16 ending with /o/) while 4 were  
52  
53 phonetically opaque (2 feminine and 2 masculine nouns). As an added precaution, the  
54  
55 overlap in gender between Portuguese and Spanish was also checked for the set of 36  
56  
57  
58  
59  
60

1  
2  
3 nouns. For the 18 nouns that had the same gender in French and Portuguese, 14 also  
4  
5 matched between Portuguese and Spanish and 14 between French and Spanish. For the  
6  
7 18 nouns that had opposite gender across French and Portuguese, 7 had opposite gender  
8  
9 between Portuguese and Spanish and 11 had opposite gender between French and  
10  
11 Spanish. Nouns were systematically preceded by the definite determiner (/a/<sub>f</sub> or /o/<sub>m</sub>).  
12  
13 Nouns that shared gender (SG) and those that had opposite gender (OG) across French  
14  
15 and Portuguese were equated across numerous lexical variables: printed mean frequency  
16  
17 per million in French (M = 19.71, sd = 21.19) vs. (M = 18.04, sd = 16.05) for SG and  
18  
19 OG, respectively (New, Pallier Brysbaert & Ferrand, 2004), mean number of letters SG  
20  
21 (M = 6.17, sd = 1.70) vs. OG (M = 5.53, sd = 1.62), mean number of phonemes SG (M =  
22  
23 5.50, sd = 1.62) vs. OG (M = 5.47, sd = 1.51) and mean number of syllables SG (M =  
24  
25 2.58, sd = 0.79) vs. OG (M = 2.47, sd = 0.80), grammatical gender SG (9fem/6masc,  
26  
27 tested in the Match/mismatch task) vs. OG (8fem/7masc, tested in the Match/mismatch  
28  
29 task) and Levenshtein distance SG (M = 5.5, sd = 1.4) vs. OG (M = 6.0, sd = 1.62).  
30  
31  
32  
33  
34

35 Each of the 9 verbs was paired with 4 different nouns to create 36 declarative  
36  
37 sentences in canonical SVO order preceded by a lead in phrase e.g., Esfregar / Scrub  
38  
39 [Ele está esfregando a janela / a lareira com a escova / o trapo] / He is scrubbing the  
40  
41 window/fireplace with the brush/rag)). Three additional partially transparent verbs (e.g.,  
42  
43 “pintar” “peindre” paint) and 12 additional partially transparent nouns (e.g., “esponja”,  
44  
45 “éponge”, sponge) were selected to familiarize participants with the games and for EEG  
46  
47 training. All auditory materials were recorded by a native Brazilian female speaker at 48  
48  
49 kHz (32-bit float) in a professional sound booth, in a single session. The onset of each  
50  
51 word within auditory sentences was detected automatically using SPPAS (Bigi, 2015)  
52  
53 and manually verified using PRAAT (Boersma & Weenink, 2018). The materials were  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 spliced into individual syntactic units (pronoun + copula, determiner + noun, lexical  
4  
5 verb) and individual sentences using Audacity 2.2.1 software.  
6  
7

8 A subset of the materials was selected for pre- and post-training in a  
9  
10 Match/mismatch task (see appendix). Thirty auditory nouns were presented in a  
11  
12 2x2 factorial design defined by the congruency of the auditory noun and line  
13  
14 drawing (match vs. mismatch) and gender congruency across languages (same vs.  
15  
16 opposite gender). Auditory nouns were paired with 30 line drawings selected from  
17  
18 the Snodgrass & Vanderwart (1980) and Alario and Ferrand (1999) standardized image  
19  
20 databases (with the exception of two images which were taken from line-drawing  
21  
22 internet databases). These images were different from those used for the computerized  
23  
24 games (described below), which were selected from internet databases. Each auditory  
25  
26 noun was presented twice, once paired with the correct line drawing (match) and once  
27  
28 with a line drawing that corresponded to another (to be) learned noun (mismatch). For  
29  
30 each Condition (Match vs. Mismatch) half of the trials had the same grammatical  
31  
32 gender across Portuguese and French and half had opposite gender: Gender (Same vs.  
33  
34 Opposite). Hence, a full factorial design was used: Gender (Same vs. Opposite) x  
35  
36 Condition (Match vs. Mismatch). For Match trials, where the presented image  
37  
38 matched the auditory word, only the gender of the auditory word was in play,  
39  
40 which was either the same in Portuguese and French (e.g., *a janlea / la fenêtre* [the  
41  
42 window]) or opposite across languages (e.g., *o garfo / la fourchette* [the fork]). For  
43  
44 mismatch trials, where the image *did not* correspond to the auditory word, we  
45  
46 controlled for the coherency of gender across the distractor image and auditory  
47  
48 target word in Portuguese. For example, the auditory word *o cachimbo (la pipe* [the  
49  
50 pipe]) was paired with the distractor image of a masculine Portuguese word *o lixo*  
51  
52 (*la poubelle* [the trashcan]). This prevented participants from noting a mismatch  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 based on the determiner alone if they accessed the name of the distractor image  
4  
5 prior to the auditory target word. Three pseudo-randomized lists were created for pre-  
6  
7 training EEG testing including 30 "match" pairs and 30 "mismatch" pairs, with 15 same  
8  
9 gender and 15 opposite gender pairs for each. Three other pseudo-randomized lists were  
10  
11 created for post-training EEG testing, which included the same 30 Match and 30  
12  
13 Mismatch pairs and an additional 30 Semantically related and 30 Semantically unrelated  
14  
15 pairs (data reported elsewhere). Participants saw different lists at pre- and post-training  
16  
17 testing, with complete counter-balancing of lists across participants such that all lists  
18  
19 were seen at both pre- and at post-training sessions.  
20  
21  
22  
23  
24  
25

## 26 **Procedure**

27  
28 **Games.** Four computerized games were created in collaboration with the Mediterranean  
29  
30 Virtual Reality Center (CRVM). All 4 games involved the auditory presentation via  
31  
32 headphones of materials in Brazilian Portuguese accompanied by either static line  
33  
34 drawings or animated GIF on a flat screen. Participants' responses and playing behavior  
35  
36 (mouse clicks, timing) were recorded throughout each game and feedback was provided.  
37  
38 Trials that were not completed successfully were repeated at the end of each game. All  
39  
40 participants played the 4 games in the same order and were required to successfully  
41  
42 complete a given game prior to engaging in the next. This ensured that all participants  
43  
44 had acquired the vocabulary presented throughout the games on each day. In all 4  
45  
46 games, participants initiated a trial by clicking on an audio button image to hear an  
47  
48 auditory stimulus. In the first, "exposure" game, participants clicked to hear the 12  
49  
50 sentences, one at a time, which were presented simultaneously with an animated GIF of  
51  
52 the action and accompanying objects. In the second "segmentation" game, participants  
53  
54 clicked to hear a sentence, which was accompanied by the visual presentation of 5 blank  
55  
56  
57  
58  
59  
60

1  
2  
3 squares at the bottom and 3 in the center of the computer screen. Participants clicked on  
4  
5 any of the 5 bottom squares to display a static image and hear the audio file  
6  
7 corresponding to it (4 nouns and 1 verb were depicted). Participants had to recreate the  
8  
9 auditory sentence by clicking and dragging the 3 correct syntactic elements in order  
10  
11 (verb, NP1, NP2) to the center of the screen. Upon correct completion, an animated GIF  
12  
13 played along with the auditory sentence. In the third, “verb identity” game, participants  
14  
15 clicked to hear a verb and saw three different animated GIFs in the center of the screen,  
16  
17 the task being to select the animation that corresponded to the audio file. In the final  
18  
19 “memory” game, participants clicked to hear a sentence, then had to find the pair of  
20  
21 cards, among 8 presented face down on the screen, that matched the auditory sentence  
22  
23 by clicking on the cards individually (a card reverted to blank when another card was  
24  
25 selected). The vocabulary depicted across the 8 cards involved a single verb and 4  
26  
27 nouns. When the correct pair was selected, the auditory sentence was replayed along  
28  
29 with an animated GIF. Across games 2, 3 and 4, participants were allowed to click on a  
30  
31 given item (audio button or card) a maximum of 3 times and time-out was 30 seconds  
32  
33 on any given trial. They were encouraged to repeat the materials out loud while playing.  
34  
35 Participants were not permitted to take notes during training sessions and were asked  
36  
37 not to review what they had learned between sessions. All participants successfully  
38  
39 completed all games on each of the three training days, as revealed by their recorded  
40  
41 scores.  
42  
43  
44  
45  
46  
47  
48  
49  
50

51 **Training.** Participants learned how to play the 4 computer games, prior to actual  
52  
53 training, using a miniature auditory vocabulary. This initiation to the games took place  
54  
55 directly after the first EEG session. During the initiation and subsequent training,  
56  
57 participants were comfortably seated in a sound-attenuated room where they played the  
58  
59  
60

1  
2  
3 games on a 15-inch-screen laptop computer while wearing headphones. Training  
4  
5 occurred over 4 consecutive days. On each of the first three days, participants were  
6  
7 exposed to 3 verbs and 12 nouns, comprised in 12 auditory sentences, via the 4 games,  
8  
9 with the vocabulary repeated across the games. Each session lasted roughly 25 minutes,  
10  
11 with each game taking 5-10 minutes. The fourth day consisted of a 40-minute review  
12  
13 day, where participants played all the games with the entire new lexicon (9 verbs and 36  
14  
15 nouns).  
16  
17  
18  
19  
20

21 **EEG Match-Mismatch task.** A trial began with the presentation of a centered fixation  
22  
23 cross for 250 msec that was replaced by a centered black and white line drawing for 1  
24  
25 second followed by an auditory word presented over speakers. At the offset of the  
26  
27 auditory word, a visual “yes/no” prompt was presented and participants were requested  
28  
29 to judge whether the auditory word matched the visual image or not on a button box. A  
30  
31 visual blink prompt was presented for 2s following the response. During the pre-training  
32  
33 session, 2 blocks of 30 trials, with 15 “match” and 15 “mismatch” pairs in each, were  
34  
35 presented, preceded by three warm-up pairs. During the post-training session, an  
36  
37 additional 30 trials were presented per session, comprising 15 semantically related and  
38  
39 15 unrelated pairs (data reported elsewhere), for a total of 60 trials per session. Short  
40  
41 rest periods were allowed between blocks. Participants were asked to remain still and to  
42  
43 blink at the prompt. Behavioral responses to the questions were recorded. The session  
44  
45 lasted roughly 30 minutes.  
46  
47  
48  
49  
50  
51  
52

53 **ERP Data acquisition and analysis.** Electroencephalographic (EEG) activity was  
54  
55 recorded continuously from 64 scalp locations over frontal, temporal, central, posterior  
56  
57 temporal, parietal and occipital areas of the left and right hemispheres and midline.  
58  
59  
60

Individual electrodes were adjusted to a stable offset lower than  $20\mu\text{V}$ . EEG data were sampled online at 512 Hz. Blinks and horizontal eye-movements were monitored by means of electrodes placed beneath the left eye and at the outer canthus of the right eye. Electrodes were placed on the left and right mastoids for referencing offline. Periods spanning from -100 pre- stimulus onset to 1100 msec post stimulus onset were used post-recording for analyses. A low pass digital filter of 30 Hz was applied post-recording. Trials contaminated by ocular-motor or muscular artifacts were excluded using automated routines that were manually checked. The percentage of trails retained for analyses was 88% for the same gender condition and 87% for the opposite gender condition.

## Results.

To determine the pattern of data, we ran a series of comparisons for both behavioral and electrophysiological measures. On the one hand, we compared the data for the L2 learner group across sessions. In addition, we compared the L2 learners' data post-training to that of the Brazilian control group. When indicated, we ran subsequent independent models (in each session, for the L2 learners and for each group).

### *Behavioral measures.*

#### Game-playing accuracy

Errors took the shape of time-outs. Accuracy was at ceiling (over 96% across all games) for all participants. The low level of variability during game play in the review session did not warrant further analyses (cf. Table 2a).

Verb game	Segmentation game	Memory game
22/648 (3.4%)	3/864 trials (0.3%)	3/864 trials (0.3%)

**Table 2a.** *Total number and percentage of time-outs across the different games for all L2 participants*

Accuracy in the EEG match-mismatch task.

The percentages of correct responses are presented in Table 2b and d prime scores are presented in Figure 1 for the L2 learners at the pre- and post-training session, and for the Brazilian control group. The data were modeled using linear mixed effect regressions, with the *LmerTest* package (Kuznetsova & Christensen, 2017) implemented in R (R Core Team, 2017). For both measures, we first modeled the data for L2 learners, pre- and post-training. The model for the percentage of correct responses included the sum coded fixed factors Training session (Pre vs. Post), Gender (Same vs. Opposite), Condition (Match vs. Mismatch) and their interactions, with random intercepts for Participant and Item and a random slope for Condition:Gender. The model for d prime included the sum coded fixed factors Training session (Pre- vs. Post), Gender (Same vs. Opposite) and their interaction, with random intercept for Participant. We subsequently compared L2 learners to Brazilian controls at the post training session. For accuracy, the model included the sum coded fixed factors Group (Control vs. L2), Gender (Same vs. Opposite), Condition (Match vs. Mismatch) and their interactions, with random intercepts for Participant and Item. The same model was applied for d prime, without the factor Condition.

Accuracy.

For L2 learners, the first model, comparing pre- and post-training sessions revealed an effect of Session ( $\beta = 1.35$ ,  $se = 0.07$ ,  $z = 18.85$ ,  $p < .001$ ), the interaction between Gender and Condition ( $\beta = 0.19$ ,  $se = 0.08$ ,  $z = -2.25$ ,  $p < .001$ ) and the interaction between Gender, Condition and Session ( $\beta = 0.14$   $se = 0.07$ ,  $z = 2.02$ ,  $p$

< .05). Subsequently, models were run on the L2 data for the pre- and post-training session independently. Pre-training, the treatment coded model, revealed an interaction between Gender and Condition ( $\beta = -1.32$  se = 0.28,  $z = -4.74$ ,  $p < .001$ ), and a simple effect of Condition for Opposite gender trials ( $\beta = 0.51$ , se = 0.19,  $z = 2.74$ ,  $p < .01$ ). The re-leveled treatment coded model showed a simple effect of Condition for Same gender trials ( $\beta = -0.81$  se = 0.21,  $z = -3.92$ ,  $p < .001$ ). Pre-training, L2 participants showed a bias to respond positively for Same gender trials and negatively for Opposite gender trials, although accuracy remained at chance levels. Post-training, the sum coded model revealed only an effect of the Intercept for L2 learners ( $\beta = 2.78$ , se = 0.26,  $z = 10.68$ ,  $p < .001$ ), due to accuracy being higher than chance. No other effects were significant.

Last, the model comparing L2 learners' performance at the post-training session to the native Brazilian control group failed to converge due to the extremely low variability and high level of accuracy.

	Match	Mismatch
<b>L2: Pre-training</b>		
Same Gender	57% (49)	38% (48)
Opposite Gender	36% (48)	47% (50)
<b>L2: Post-training</b>		
Same Gender	92% (27)	92% (29)
Opposite Gender	92% (27)	90% (27)
<b>Brazilian control group</b>		
Same Gender	95% (21)	100% (0)
Opposite Gender	98% (26)	100% (0)

**Table 2b.** Percentage of correct answers (standard deviations in parentheses) in the Match-Mismatch task for L2 learners pre- and post- learning, and for Brazilian controls, as a function of Gender (same vs. opposite) and Condition (Match vs. Mismatch)

D-prime.

The model comparing L2 learners' data pre- and post-training revealed only an effect of Session ( $\beta = 1.76$ , se = 0.105,  $t = 16.90$ ,  $p < .001$ ). Participants' d prime scores

(i.e. their ability to correctly discriminate between Match and Mismatch trials) increased significantly from pre- to post-training and this did not depend on the gender congruency of trials.

The model comparing d prime scores for L2 learners post-training and the native Brazilian control group revealed an effect of Group ( $\beta = 0.59$ ,  $se = 0.102$ ,  $t = 5.80$ ,  $p < .001$ ), due to Brazilian controls showing higher d prime scores. No other effects were significant.

**Figure 1.** *D prime scores for Brazilian controls and for L2 learners at pre- and post-training sessions*

### ERP analysis

The ERP data were modeled using linear mixed effect regressions, with the *LmerTest* package (Kuznetsova & Christensen, 2017) implemented in R (R Core Team, 2017) for the mean voltage amplitudes in the N400 time window, calculated 300-600

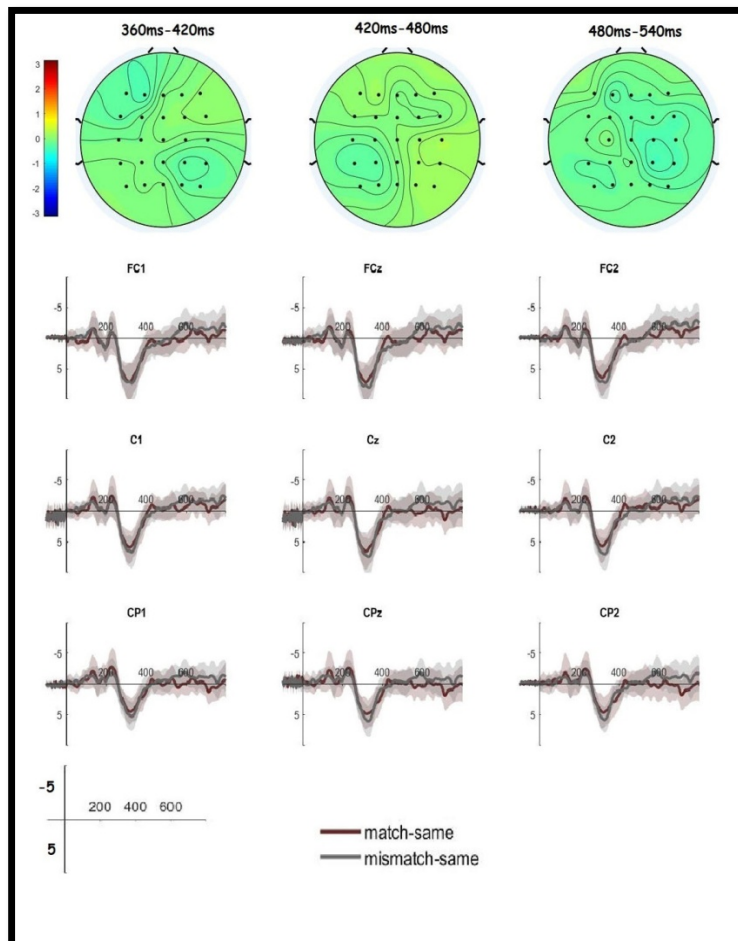

1  
2  
3 msec post onset of the auditory noun for correct trials. This window was based on prior  
4 literature and confirmed by permutation tests conducted across the entire epoch (see  
5 below). Data were trimmed in R to remove outliers (1% of the data were excluded).  
6  
7  
8  
9  
10 Models were performed independently over midline sites (Fz, FCz Cz, CPz, Pz),  
11  
12 frontal-central sites (FC1, FC3, FC5, FC2, FC4, FC6, C1, C3, C5, C2, C4, C6) and  
13  
14 centro-parietal sites (CP1, CP3, CP5, CP2, CP4, CP6, P1, P3, P5, P2, P4, P6). Below  
15  
16 we report the results from the maximal random-effects structure (Barr, et al., 2013).  
17  
18

19 In addition to the LMER models, to test the hypothesis of a  
20 significant difference in the ERP amplitude between conditions, a two-tailed  
21 permutation test (1000 random partitions) was carried out over the 1-second post-  
22 stimulus time window for all electrodes entered into the models. Statistically significant  
23 differences were taken into consideration only if they persisted for 10 msec or more,  
24 which corresponds to an interval of 5 samples, given a sampling rate of 512Hz. The  
25 results of these tests are visible in Figures 2a through 4b for 9 central electrodes  
26 commonly associated with the N400 effect and voltage maps that included a larger array  
27 of electrodes.

#### 39 *Pre vs. Post-training: L2 learners*

40  
41  
42 To examine the effect of training, we ran a first model, summarized in Table 3a,  
43 which included the sum-coded fixed factors Session (Pre vs. Post), Gender (Same vs.  
44 Opposite), Condition (Match vs. Mismatch) and their interactions, with random  
45 intercepts for Participant and Item. Condition included a random slope for Participant  
46 and for Item. The model revealed a three-way interaction of Condition:Gender:Session  
47 at all electrode sites. The data were modeled independently thereafter for each training  
48 session. Pre-training, no effects were found for any factor at any ROI (cf. Table 3b).

Figures 2a and 2b show the mean Match-Mismatch ERP response for Same and Opposite gender conditions, respectively, for illustrative purposes.

**Figure 2a.** Mean voltage ERPs (and SD) for 9 central electrodes in the pre-training session for L2 learners as a function of Condition (Match vs. Mismatch) for nouns with same gender across languages. Permutation tests revealed no significant differences.

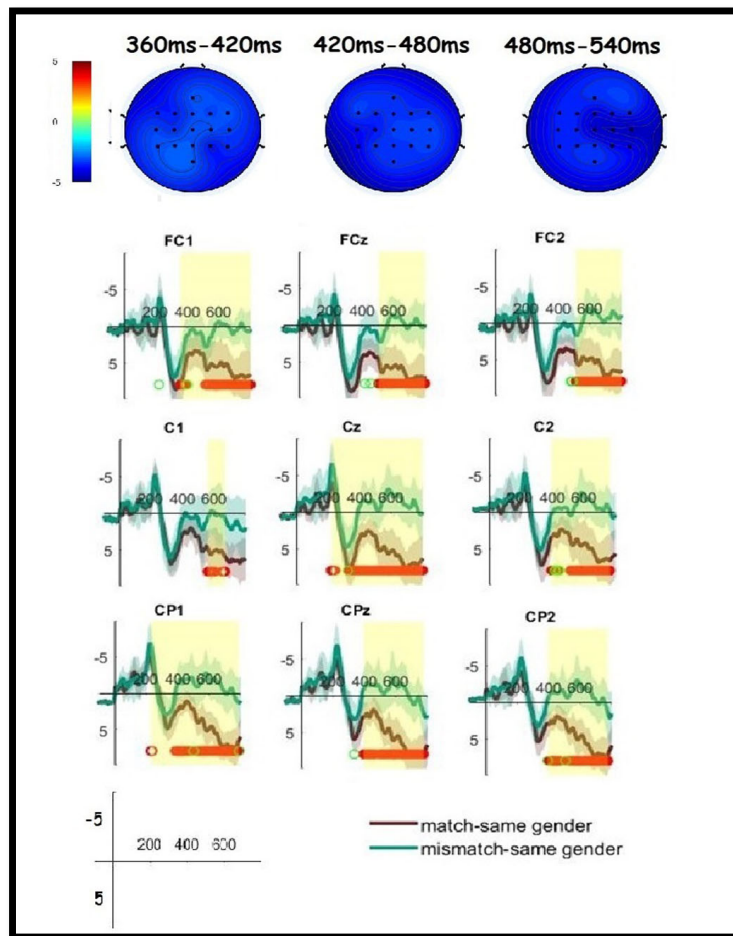

**Figure 2b.** Mean voltage ERPs (and SD) for 9 central electrodes in the pre-training session for L2 learners as a function of Condition (Match vs. Mismatch) for nouns with opposite gender across languages. Permutation tests revealed no significant differences.

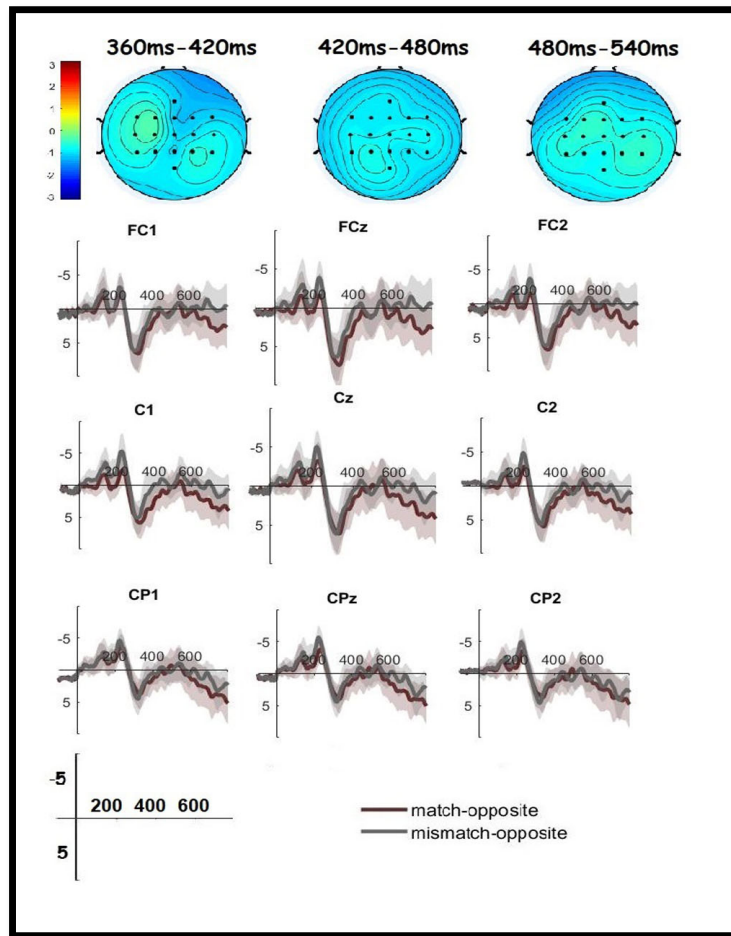

Post-training, sum coded models performed independently at all 3 ROI revealed a significant interaction of Condition x Gender at all sites (cf. Table 3c). Models of simple effects (cf. Tables 3d and 3e) revealed a significant effect of Condition for same gender trials at all ROI (midline:  $\beta = -3.40$ ,  $se = 0.770$ ,  $t = -4.42$ ,  $p < .001$ ; frontal-central:  $\beta = -2.60$ ,  $se = 0.682$ ,  $t = -3.82$ ,  $p < .002$ ; central-parietal:  $\beta = -2.91$ ,  $se = 0.577$ ,  $t = -5.05$ ,  $p < .001$ ) but no effect of Condition for opposite gender trials (midline:  $\beta = -0.27$ ,  $se = 0.757$ ,  $t = -0.36$ ,  $p < 0.73$ ; frontal-central:  $\beta = -0.52$ ,  $se = 0.644$ ,  $t = -0.81$ ,  $p < 0.42$ ).

< .43; central-parietal:  $\beta = -0.59$ ,  $se = 0.613$ ,  $t = -0.97$ ,  $p < .35$ ). These effects are shown in Figures 3a and 3b.

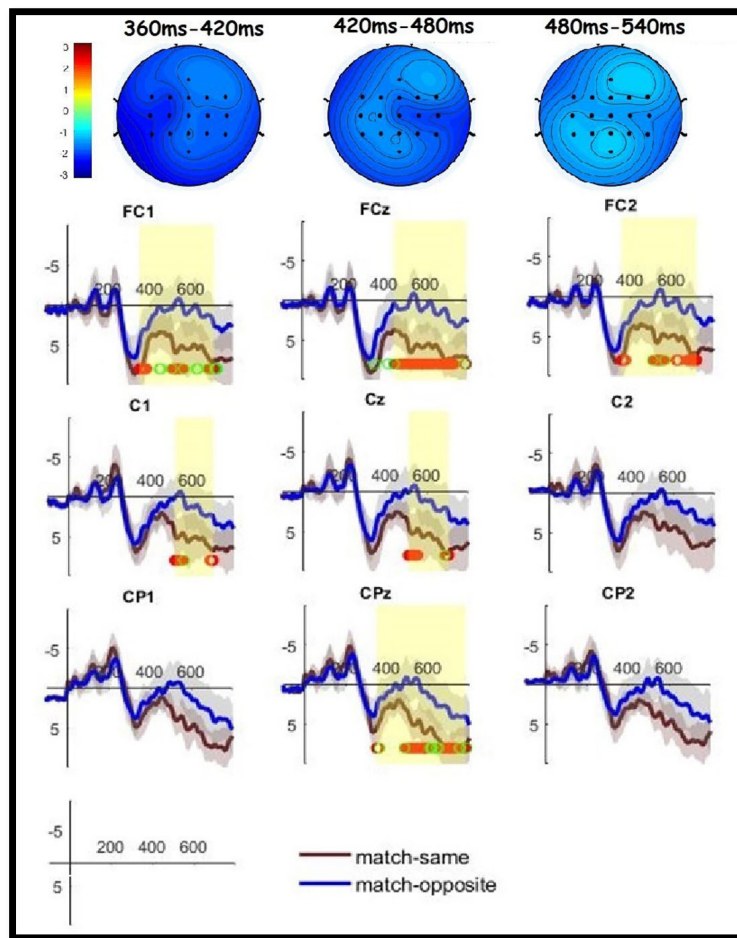

**Figure 3a.** Mean voltage ERPs (and SD ) for 9 central electrodes in the post-training session for L2 learners as a function of Condition (Match vs. Mismatch) for nouns with same gender across languages. Permutation tests are shown in red ( $p = .05$ ) and green ( $p < .05$ ) across the entire epoch.

**Figure 3b.** Mean voltage ERPs (and SD) in the post-training session for L2 learners for 9 central electrodes as a function of Condition (Match vs. Mismatch) for nouns with opposite gender across languages. Permutation tests revealed no significant effects.

In addition, for Match trials there was an effect of Gender at all three ROI (cf. Table 3e) (midline:  $\beta = 2.08$ ,  $se = 0.422$ ,  $t = 4.92$ ,  $p < .001$ ; frontal-central:  $\beta = 1.69$ ,  $se = 0.584$ ,  $t = 2.89$ ,  $p < .01$ ; central-parietal:  $\beta = 1.27$ ,  $se = 0.257$ ,  $t = 4.96$ ,  $p < .001$ ), while for Mismatch trials the effect of Gender was only present at midline (midline:  $\beta = -0.91$ ,  $se = 0.434$ ,  $t = -2.09$ ,  $p < .04$ ; frontal-central:  $\beta = -0.38$ ,  $se = 0.805$ ,  $t = -0.48$ ,  $p < 0.64$ ; central-parietal:  $\beta = 1.06$ ,  $se = 0.89$ ,  $t = -1.19$ ,  $p < .025$ ). These effects are depicted in Figures 3c and 3d.

**Figure 3c.** Mean voltage ERPs (and SD) for 9 central electrodes in the post-training session for L2 learners as a function of Gender across languages (same vs. opposite) for Match trials. Permutation tests are shown in red ( $p=.05$ ) and green ( $p<.05$ ) across the entire epoch.

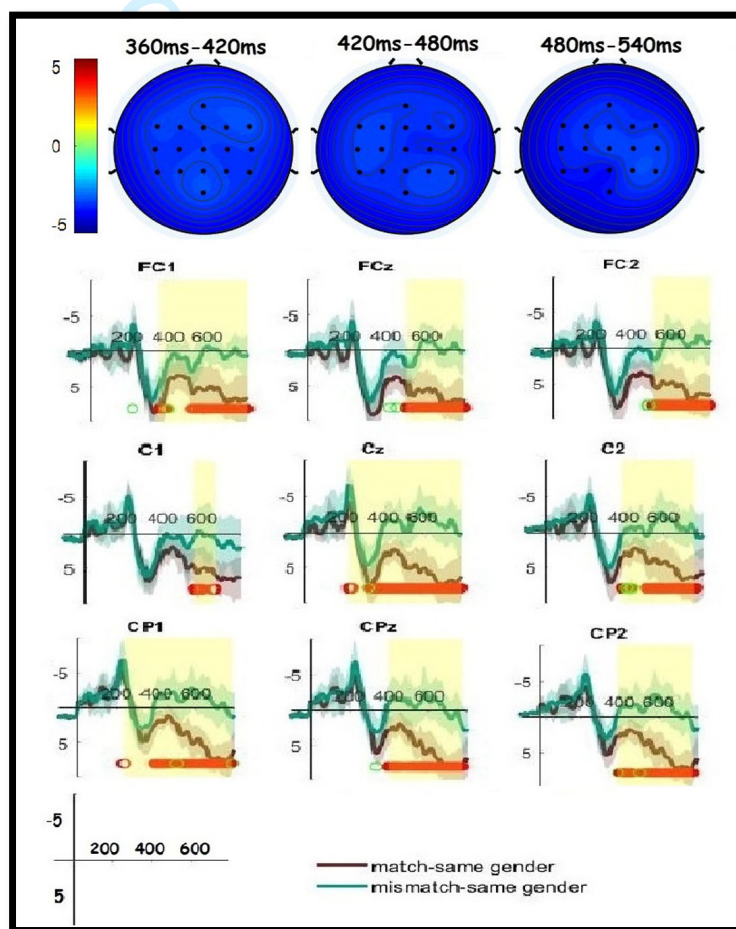

**Figure 3d.** Mean voltage ERPs (and SD) for 9 central electrodes in the post-training session for L2 learners as a function of Gender across languages (same vs. opposite) for Mismatch trials. Permutation tests revealed no significant effects.

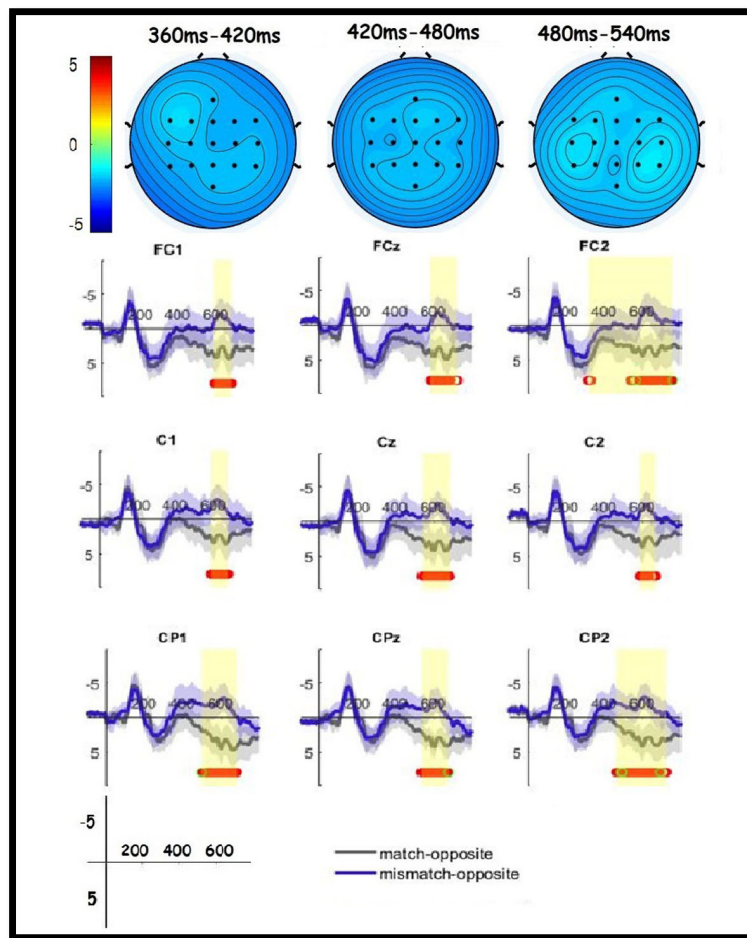

#### *Post-training: Native controls vs. L2*

The first model, summarized in Table 4a, included the sum-coded factors Group (Native vs. L2), Gender (Same vs. Opposite), Condition (Match vs. Mismatch) and their interactions. Condition included a random slope for Participant and for Item. The model revealed an interaction of Condition:Gender:Group at all sites. For native controls, there was an N400 effect, with Mismatch trials producing a larger N400 amplitude than Match trials, which was independent of Gender congruency across languages. For L2 learners, the N400 effect interacted with Gender congruency. The data were modeled

independently thereafter for the Brazilian control group, using the same model structure as above without the fixed factor Group. For native speakers, the effect of Condition was significant at all sites due to greater mean N400 amplitude for mismatch than match trials. At frontal central sites, there was also an effect of Gender, due to a larger N400 for same gender trials. Crucially, Condition did not interact with Gender at any site (see Table 4b and Figures 4a and 4b, for same and opposite gender respectively).

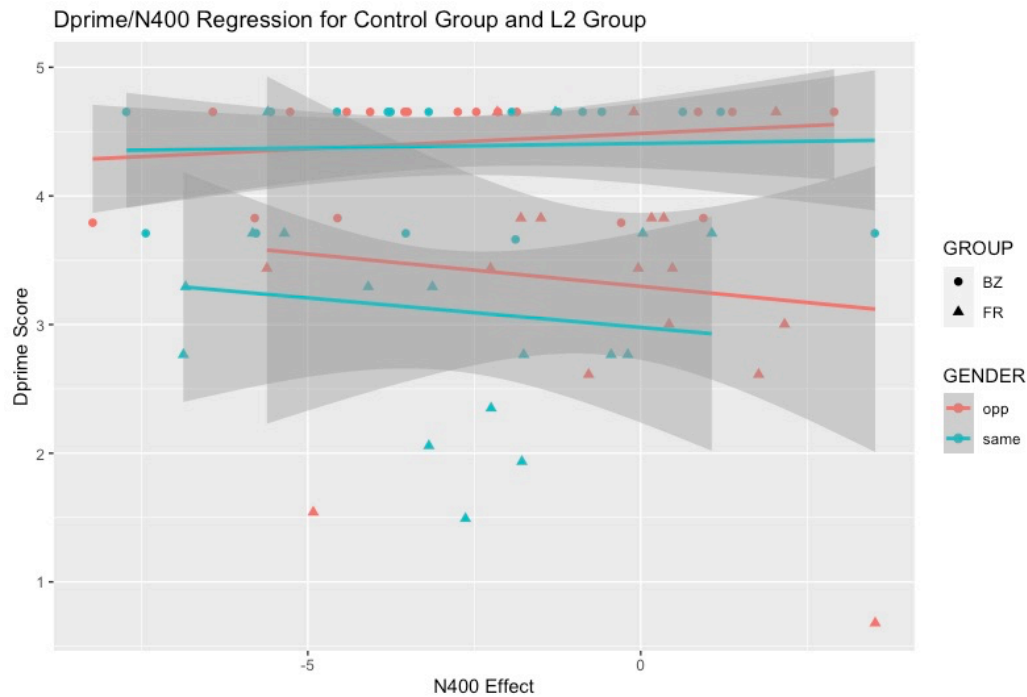

**Figure 4a.** Mean voltage ERPs (and SD) for native Brazilians for 9 central electrodes as a function of Condition (Match vs. Mismatch) for nouns with same gender across languages. Permutation tests are indicated in red ( $p=.05$ ) and green ( $p<.05$ ) across the entire epoch.

**Figure 4b.** Mean voltage ERPs (and SD) for native Brazilians for 9 central electrodes as a function of Condition (Match vs. Mismatch) for nouns with opposite gender across languages. Permutation tests are indicated in red ( $p=.05$ ) and green ( $p<.05$ ) across the entire epoch.

#### Correlation between D prime score and N400 effect

Pearson's correlations were performed in order to determine whether there was any correlation between the ability to correctly identify match trials (d prime) and the magnitude of the N400 effect (cf. Tanner et al., 2013). We found no correlation between d prime scores and the magnitude of the N400 effect for either the L2 learners (same gender  $r(16)=0.07$ ,  $p = .72$ , opposite gender  $r(16) = 0.36$ ,  $p = .15$ ) or the Brazilian control group (same gender  $r(16) = 0.04$ ,  $p = .84$ , opposite gender  $r(16) = 0.18$ ,  $p = .46$ ). These results are depicted in Figure 5.

**Figure 5.** Regression of N400 effect as a function of D prime score for Brazilian control group and L2 learners

## Discussion

Our study revealed clear cross-linguistic gender congruency effects (GCE), from the earliest stages of acquiring a second language. This was apparent in the electrophysiological trace of lexical access, as measured by the N400. L2 learners demonstrated a clear N400 effect for mismatched visual-auditory pairs post-training, but only for newly learned nouns that shared grammatical gender across their native (French) and newly acquired language (Portuguese). No modulation of the ERP response was found as a function of the match between auditory words and visual stimuli for nouns that had opposite gender across the two languages for these learners. In addition, the effect of gender congruency was visible in the N400 modulation for match trials, for which the N400 response was increased for nouns that had opposite gender across the L2 and French compared to nouns that shared grammatical gender across languages. Hence, cross-linguistic GCE were clearly reflected in the automatic

1  
2  
3 cortical response associated with lexical processing (Kutas & Federmeier, 2011). It is  
4 important to note that in the control group of native Brazilian Portuguese speakers, who  
5 on average were novice French speakers, only a robust N400 mismatch effect was found,  
6 which was independent of gender congruency. Otherwise stated, the cross-linguistic  
7 GCE revealed by the N400 was specific to the L2 learners processing nouns in the  
8 newly learned language. Importantly, this effect was found following only 4 days of  
9 training using interactive computerized games.

12  
13  
14  
15  
16  
17  
18

19 Previous studies on the effect of cross-linguistic gender congruency have  
20 examined this question in populations that had several years of formal learning of the  
21 second language (Bordag, 2004; Bordag & Pechmann, 2007, 2008; Costa et al., 2003;  
22 Lemhöfer et al., 2008; Morales et al., 2011; Rodriguez-Fornells & Münte, 2016;  
23 Salamoura & Williams, 2007). Our training study allowed us to examine this question  
24 from the earliest stages of acquisition. In addition, our design has the distinct advantage  
25 of presenting only the newly learned language. In several studies that have shown cross-  
26 linguistic GCE, participants had to actively process their native and second language  
27 simultaneously due to task requirements (switching between languages, translating, or  
28 ignoring embedded L1 words during L2 production; Bordag & Pechmann, 2007, 2008;  
29 Costa et al., 2003; Rodriguez-Fornells & Münte, 2016; Salamoura & Williams, 2007).  
30 The necessity to maintain both languages active may have played a role in evoking  
31 gender congruency effects in these studies. This cannot be claimed for the present  
32 results. Indeed, our study did not require L2 participants to overtly produce or  
33 consciously activate their L1. Nonetheless, that the L1 lexicon, and more specifically  
34 the grammatical features of L1 candidates, became active during L2 processing was  
35 readily apparent in the ERP data. Our results are in line with those reported by  
36 Boutonnet et al. (2012) who showed modulation of a late negative component as a  
37

1  
2  
3 function of whether triplets of words, presented in English, all shared the same lexical  
4 gender in the participants' native language, Spanish. Thus, as in the current study, even  
5  
6 in conditions where the L1 was physically absent, it played a significant role in  
7  
8 processing. More specifically, native speakers of "gendered" languages automatically  
9  
10 and irrepressibly activate the L1 gender of nouns, even when processing words  
11  
12 exclusively in the L2.  
13  
14  
15

16  
17 In many studies, gender congruency effects have been reported both within a  
18  
19 given language and across languages when participants were required to produce a  
20  
21 definite article prior to the noun (Costa et al., 2003; Salamoura & Williams, 2007);  
22  
23 although others have shown GCE when participants produced bare nouns (Bordag &  
24  
25 Pechmann, 2007; Cubelli et al., 2005). In light of this, it is of interest to note that, while  
26  
27 our participants did not produce the lexical items, all auditory nouns were preceded by  
28  
29 the definite determiner (e.g., /oparafuzo/ "the screw" and /aluva/ "the glove"). It is an  
30  
31 empirical question whether the gender congruency effects that we obtained would occur  
32  
33 in the absence of the determiner. Given that our participants showed evidence that they  
34  
35 had acquired the gender of the L2 nouns, it is possible that they may have retrieved this  
36  
37 information during processing, either from a stored representation of the noun or from  
38  
39 the morphology of the word form itself, which may then have been the source of  
40  
41 interference (cf. Gollan and Frost, 2001, for a discussion of different routes to stored  
42  
43 gender information). Further work is necessary to determine the locus of the  
44  
45 interference we found.  
46  
47  
48  
49

50  
51 Our results show rapid learning of the L2 vocabulary, as demonstrated by both  
52  
53 the establishment of an N400 response to newly learned words and by ceiling level  
54  
55 accuracy post-training. Concerning the cortical response, modulations of the N400 have  
56  
57 been noted in association with L2 learning and/or artificial languages in several studies.  
58  
59  
60

1  
2  
3 This has been demonstrated in L2 studies that have used longitudinal designs to  
4 investigate changes in cortical activity over the course of learning (Chun, Choi, & Kim,  
5 2012; McLaughlin, Osterhout, & Kim, 2004; Stein et al., 2006; Yum, Midgley,  
6 Holcomb & Grainger, 2014). In a seminal study, McLaughlin and colleagues (2004)  
7 found that L2 pseudowords elicited a larger N400 than learned L2 words following 14  
8 hours of classroom instruction (McLaughlin et al., 2004). Crucially, these effects were  
9 not seen behaviorally; when making overt lexical decisions, learners performed at  
10 chance. Hence, L2 learners were sensitive to the prior exposure to word forms, as  
11 shown by the N400 effect, even when they could not consciously identify these forms.  
12 In contrast, the semantic integration of these newly learned lexical items only occurred  
13 following 60 hours of instruction, as indexed by reduced N400 amplitude for L2 target  
14 words preceded by semantically related primes. Similarly, Soskey and colleagues  
15 (Soskey et al., 2016) reported the gradual instantiation of L2 words, as indexed by  
16 modulation of the N400, across a semester of learning. It is important to note, however,  
17 that these studies reported cortical changes due to L2 meaning integration following  
18 extended L2 training whereas we found that participants accessed the meaning of newly  
19 acquired L2 words after only 3 hours of learning.

41  
42 Artificial language paradigms have been used to ascertain whether novel L2  
43 words can be associated quickly with meaning. Breitenstein and colleagues  
44 (Breitenstein et al., 2007) used associative learning, where a spoken word was paired  
45 with the image of an object with increasing statistical probability over multiple trials  
46 and found that after 5 days of training, newly learned words facilitated (in the form of  
47 shorter response latencies) the processing of related pictures, indicating integration into  
48 existing lexical networks. A similar magnetoencephalography (MEG) study by Dobel et  
49 al. (2010) showed a reduction in the mN400 (the MEG component comparable to the

2  
3 ERP N400 component) to correct images preceded by trained spoken words from pre-  
4 to post-training, indicating that trained words had become associated with existing  
5 conceptual representations. Our results corroborate these findings, showing the  
6 acquisition of a small L2 vocabulary following three 25-minute training sessions and  
7 one 40-minute review session over the course of 4 days, as manifested by the  
8 establishment of an N400 response from pre- to post-training and increased accuracy,  
9 from chance to ceiling level.

11  
12  
13  
14  
15  
16  
17  
18

19 Our study clearly demonstrates that learners were sensitive to the grammatical  
20 gender of the newly learned words, despite there having been no formal or explicit  
21 instruction concerning gender and even though the stimuli were only presented aurally.  
22 This implies that our participants segmented the auditory stimuli into the determiner and  
23 noun and inferred gender information from the properties of the speech signal.  
24 Segmenting the audio signal into its syntactic elements is notoriously difficult during  
25 second language acquisition (Altenberg, 2005), which is why we created a game that  
26 specifically segmented the auditory sentences and required participants to recognize the  
27 meanings of the different elements and assemble them in the correct order to recreate  
28 the auditory sentence. However, while determiner phrases and verbal phrases were  
29 explicitly segmented, the determiner phrases were presented as a single unit (e.g.,  
30 /okaSimbo/ “the pipe” and /asaia/ “the skirt”). Learners could, in theory, have  
31 interpreted the determiner phrase as a whole rather than segment it into the determiner  
32 and noun, as indeed there is evidence for in young children. For example, in early stages  
33 of acquisition French children may produce forms that reveal segmentation errors (e.g.,  
34 “*le loiseau*” and “*le noiseau*” stemming from the speech signal “*l’oiseau*” and “*un*  
35 *oiseau*” «the bird / a bird» Clark, 2009). Even so, the regularity of the morphological  
36 form for the determiner (/a/ or /o/) preceding the noun and the concurring final phoneme

3 of nouns reduces this possibility, as discussed below. Moreover, the majority of  
4 participants had formally learned Spanish as a third language throughout secondary  
5 school, which may well have prompted them to capitalize on the partial overlap of  
6 gender concord rules in Spanish and Portuguese (cf. Brooks & Kempe, 2013).  
7  
8  
9  
10

11  
12 Various studies with either natural or artificial languages have shown that  
13 following implicit training, adult learners rapidly deduce the rules that govern  
14 grammatical gender assignment (Öttl & Behne, 2017) and gender concord (Denhovska  
15 & Serratrice, 2017; Morgan-Short et al., 2010). Concerning gender assignment, our  
16 materials provided a clear phonetic cue, as outlined above, but no semantic information  
17 was associated with the gender of nouns. This differs from the materials learned in an  
18 artificial language (Öttl & Behne, 2017) in which gender suffixes on the noun were  
19 determined by the biological gender of stimuli. Concerning gender concord, Morgan-  
20 Short et al. (2010) found no difference in learning as measured by behavioral ( $d$  prime)  
21 or cortical sensitivity (P600 response) to determiner-noun gender concord violations as  
22 a function of the type of training (implicit or explicit) at the end of training. Using a  
23 miniature set of Russian nouns and adjectives, in which adult learners were exposed to  
24 noun-adjective gender concord in short written sentences, Denhovska and Serratrice  
25 (2017) showed that even under implicit learning, where emphasis was placed on  
26 learning the meanings of the sentences and no mention was made of the underlying  
27 grammatical rules, participants readily acquired these rules. Moreover, no difference in  
28 behavioral accuracy was found for grammatical judgments as a function of the type of  
29 instruction (implicit or explicit), although only those who received explicit instruction  
30 were able to produce the grammatical rules governing gender concord above chance  
31 level. The present results are in line with those found in the above studies, showing that

3 participants rapidly acquire grammatical gender concord rules in a newly learned  
4  
5 language following short training sessions, even in the absence of formal instruction.  
6

7  
8 The pattern of results we obtained suggests that gender congruency effects play  
9  
10 an early role during lexical access. This question, i.e. whether grammatical gender  
11  
12 exerts an early influence on lexical access or only later, during lexical selection, has  
13  
14 been examined in various monolingual studies. Eye-tracking experiments have  
15  
16 demonstrated that both children and adults use gender agreement to predict nouns when  
17  
18 they are preceded by a gender-marked determiner (Brouwer et al., 2017; Cholewa et al.,  
19  
20 2019; Lew-Williams & Fernald, 2007). Far less evidence of this has been found in the  
21  
22 second language (Hopp & Lemmerth, 2016; Lemmerth & Hopp, 2019). In a primed  
23  
24 lexical decision task using auditory homophone primes and orthographic targets,  
25  
26 Spinelli and Alario (2002) found that gender-marked determiners constrained lexical  
27  
28 access to the gender compatible candidate for French homophones. However,  
29  
30 subsequent work provided evidence that grammatical gender does not in fact constrain  
31  
32 lexical access but acts at a later stage during the selection of the appropriate candidate  
33  
34 (Spinelli et al., 2006). Our results clearly demonstrate that the L1 gender of stored  
35  
36 words was activated and interacted with the L2 gender of actually presented words. It  
37  
38 remains to be determined whether such was due to the presence of the salient and  
39  
40 reliable morphological marking carried in the determiner (i.e. whether participants  
41  
42 computed gender based on morpho-phonological cues) or due to the activation of the L2  
43  
44 gender from the auditory noun itself (i.e. retrieval of gender from a newly stored  
45  
46 representation). Nevertheless, our results suggest that gender congruency across  
47  
48 languages affected lexical access for newly learned L2 nouns, which was hindered when  
49  
50 competing gender features from the L1 were activated.

2  
3 Our results, showing a clear interaction between the established L1 and a newly  
4 acquired L2 vocabulary, add to the ample body of experimental evidence showing that  
5 the interaction between languages is ubiquitous and found at all levels of processing  
6 (see Kroll & Bialystok, 2013, for a review of experimental studies). Indeed, the  
7 automatic activation across languages has been demonstrated during both auditory and  
8 written processing at the phonological level (Carrasco et al., 2012; Friesen et al., 2020),  
9 the lexical level (Dijkstra et al., 2000; Lagrou et al., 2011; Sunderman & Kroll, 2006)  
10 and the syntactic level (Dussias & Sagarra, 2007; Foucart & Frenck-Mestre, 2011).  
11 Moreover, parallel activation across languages is found despite distinct writing systems  
12 (Thierry & Wu, 2012; Wu & Thierry, 2010). Our results present further evidence that  
13 even in monolingual contexts and even for novice learners, the two languages are  
14 activated in parallel.

32 Differences between ERP and behavioral results are likely due to discrepancies in  
33 timing and granularity. Whereas the N400 is time-locked to stimuli in such a way as to  
34 provide information regarding early aspects of lexical-semantic processing, behavioral  
35 measures can encompass both early and late effects during processing. Otherwise stated,  
36 by the time low-temporal resolution behavioral data, such as accuracy or reaction time,  
37 are measured, other, later, cognitive processes have plausibly occurred (ex. working and  
38 episodic memory processes, response selection, mental imagery, c.f. Hauk, 2016).  
39 Specifically pertaining to gender congruency effects during a semantic categorization  
40 task in the L2, previous ERP results showed a negative (LAN) modulation for cross-  
41 language gender incongruent words but no differences in reaction time between  
42 conditions (Boutonnet et al., 2012). Similarly, in our study, an N400 effect was seen for  
43 Match vs. Mismatch trials but only for cross-language gender congruent words,  
44 suggesting that cross-language gender congruency had a direct effect on semantic  
45

2  
3 processing. Once again, this effect was not seen in behavioral results (d prime or  
4 accuracy). We posit that in both our and Boutonnet et al.'s (2012) studies, cross-  
5 language gender interference effects happen too early in lexical processing to be  
6 evidenced behaviorally, which explains why the GCE as measured by EEG (N400) was  
7 not echoed by a behavioral effect. Our results are also in line with those reported by  
8 McLaughlin and colleagues (2004) who found cortical sensitivity to the lexical status of  
9 newly learned L2 items in the absence of behavioral capacity to distinguish between  
10 words and non-words. In similar fashion our results show cortical sensitivity to gender  
11 congruency across languages that was not reflected in the behavioral response.

23

24 Last, we can note that our design did not allow us to examine the effect of  
25 gender concord or gender congruency within the L2. Several studies are warranted to  
26 delve further into this question. It would be of interest, for example, to test whether we  
27 could establish gender congruency effects within the newly learned L2 by adopting a  
28 paradigm similar to that used by Boutonnet et al. (2012), in which successive trials  
29 carried the same L2 gender, or a visual world paradigm (Hopp & Lemmerth, 2016) in  
30 which the gender of the items is varied both across languages and within the L2.  
31 Concerning gender concord, a typical violation paradigm could be added to the current  
32 design, whereby the learned L2 nouns are preceded by either the correct determiner or  
33 the incorrect determiner (Foucart & Frenck-Mestre, 2011, 2012; Morgan-Short et al.,  
34 2010). We demonstrated previously that the overlap of grammatical features between  
35 the learners' L1 and L2, the specific syntactic structure and the level of proficiency in  
36 the L2 all play a role in the pattern of ERP components elicited by gender concord  
37 violations in sentential contexts for L2 speakers (Foucart & Frenck-Mestre, 2011, 2012).  
38 In similar fashion, recent work that manipulated gender concord in sentential contexts  
39 found that the ERP signature for these violations – generally the LAN/P600 – can vary  
40

1  
2  
3 even in native speakers as a function of stimulus characteristics (Beatty- Martínez, et al.,  
4 2021). This challenges the notion that ERP signatures associated with syntactic  
5 processing (error detection) are tied to a specific level of processing and/or are more  
6 systematic in native speakers than in L2 learners. Hence, in novice learners of a  
7 gendered language, whether we would find an ERP response to gender concord errors  
8 within the newly learned language and, if so, what component would be elicited is an  
9 open question.

10  
11  
12 To conclude, we have provided clear electrophysiological evidence of gender  
13 congruency effects in an L2, from the very beginning of acquisition. The clear N400  
14 effect elicited by mismatched compared to matched audio-visual pairs for gender  
15 congruent trials was basically annulled for gender incongruent trials. To our knowledge,  
16 no prior work has provided evidence of GCE, either behaviorally or via the cortical  
17 response to newly learned L2 words. It is important to note that our behavioral results  
18 clearly demonstrate that participants learned the correct association between auditory  
19 words and images and that this was independent of both the gender in the second  
20 language vocabulary and, importantly, of the congruency of gender across the L2 and  
21 the participants' L1. Hence, we have also provided evidence of the importance of a  
22 multi-disciplinary approach to bring the effects of cross-linguistic gender congruency to  
23 light, at least in the early stages of acquisition.

Appendix: Nouns that were learned in the training sessions. The nouns included in the pre- and post-training Match/Mismatch task are indicated with an asterisk.

BR Portuguese	French	English
<u>Same Gender (Portuguese/French)</u>		
*janela (f)	fenêtre(f)	window
*lareira (f)	cheminée(f)	fireplace
*casaco (m)	manteau(m)	coat
*saia (f)	jupe(f)	skirt
*isqueiro	briquet(m)	lighter
*chaleira(f)	bouilloire(f)	kettle
*panela(f)	poêle(f)	pan
*linguiça(f)	saucisse(f)	sausage
*chão(m)	sol(m)	floor
*estante(f)	étagère(f)	bookcase
*peneira(f)	passoire(f)	colander
*pau(m)	bâton(m)	stick
*gancho(m)	crochet(m)	hook
*escova(f)	brosse(f)	brush
*trapo(m)	chiffon(m)	rag
barata(f)	blatte(f)	cockroach
frango(m)	poulet(m)	chicken (food)
capacho(m)	tapis(m)	rug
<u>Opposite Gender (Portuguese/French)</u>		
*vagem(f)	haricot vert(m)	greenbean
*alface(m)	laitue(f)	lettuce
*brinco(m)	boucle d'oreille(f)	earring
*garfo(m)	fourchette(f)	fork
*vassoura (f)	balai(m)	broom
*calça(f)	pantalón(m)	pants
*tigela(f)	bol(m)	bowl
*caneta(f)	stylo(m)	pen
*lixo(m)	poubelle(f)	tashcan
*giz(m)	craie(f)	chalk
*faca(f)	couteau(m)	knife
*luva(f)	manique(f)	oven mitt
*gaveta(f)	tiroir(m)	drawer
*parafuso(m)	tournevis(m)	screw
*cachimbo(m)	pipe(f)	pipe
pasta(f)	classeur(m)	folder
camundongo(m)	souris(f)	mouse
guardanapo(m)	serviette(f)	napkin
