Abstract

In a recent work [10], we have introduced a pressure-robust Hybrid High-Order method for the numerical solution of the incompressible Navier–Stokes equations on matching simplicial meshes. Pressure-robust methods are characterized by error estimates for the velocity that are fully independent of the pressure. A crucial question was left open in that work, namely whether the proposed construction could be extended to general polytopal meshes. In this paper we provide a positive answer to this question. Specifically, we introduce a novel divergence-preserving velocity reconstruction that hinges on the solution inside each element of a mixed problem on a subtriangulation, then use it to design discretizations of the body force and convective terms that lead to pressure robustness. An in-depth theoretical study of the properties of this velocity reconstruction, and their reverberation on the scheme, is carried out for polynomial degrees $k \in \{0, 1\}$ and meshes composed of general convex polytopes. The theoretical convergence estimates and the pressure robustness of the method are confirmed by an extensive panel of numerical examples.

Key words: Hybrid High-Order methods, incompressible Navier–Stokes equations, general meshes, pressure robustness

MSC 2010: 65N08, 65N30, 65N12, 35Q30, 76D05

1 Introduction

This paper focuses on numerical approximations of the Navier–Stokes equations robust with respect to large irrotational body forces. Specifically, we address a nontrivial question left open in the previous work [10], namely whether robustness can be achieved on general polyhedral meshes such as the ones supported by the Hybrid High-Order (HHO) method [15, 21].

Let $\Omega \subset \mathbb{R}^3$ denote an open, bounded, simply connected polyhedral domain with Lipschitz boundary $\partial\Omega$. Let $\nu > 0$ be the kinematic viscosity of the fluid and $\mathbf{f} \in L^2(\Omega)^3$ a given vector field representing a body force. Setting $\mathbf{U} := H_0^1(\Omega)^3$ and $P := L_0^2(\Omega) = \{q \in L^2(\Omega) : \int_{\Omega} q = 0\}$, we consider the Navier–Stokes problem: Find $(\mathbf{u}, p) \in \mathbf{U} \times P$ such that

$$\nu \int_{\Omega} \nabla \mathbf{u} : \nabla \mathbf{v} + \int_{\Omega} ((\nabla \times \mathbf{u}) \times \mathbf{u}) \cdot \mathbf{v} - \int_{\Omega} (\nabla \cdot \mathbf{v}) p = \int_{\Omega} \mathbf{f} \cdot \mathbf{v} \quad \forall \mathbf{v} \in \mathbf{U}, \quad (1a)$$

$$\int_{\Omega} (\nabla \cdot \mathbf{u}) q = 0 \quad \forall q \in L^2(\Omega). \quad (1b)$$

*danielcq.mathematics@gmail.com

†daniele.di-pietro@umontpellier.fr

Above, $\nabla \cdot$ and $\nabla \times$ denote, respectively, the divergence and curl operators, while \times is the cross product of two vectors. The convective term in (1a) is expressed in rotational form, so p is here the Bernoulli pressure, which is related to the kinematic pressure p_{kin} by the equation $p = p_{\text{kin}} + \frac{1}{2}|\mathbf{u}|^2$.

The domain Ω being simply connected, we have the following Hodge decomposition of the body force (see, e.g., [2, Section 4.3]):

$$\mathbf{f} = \mathbf{g} + \lambda \nabla \psi, \quad (2)$$

where \mathbf{g} is the curl of a function in $\mathbf{H}(\mathbf{curl}; \Omega)$ the tangent trace of which vanishes on $\partial\Omega$, $\psi \in H^1(\Omega)$ is such that $\|\nabla \psi\|_{L^2(\Omega)^3} = 1$, and $\lambda \in \mathbb{R}^+$. It is well-known that, at the continuous level, the velocity field is entirely determined by the first component in the decomposition (2). This property, however, does not carry out automatically to the discrete level. The development of numerical methods that possess this property, and which are sometimes referred to in the literature as *pressure-robust*, has been an active field of research over the last few years; see, e.g., [1, 24, 30, 36, 37] concerning finite element methods on standard meshes.

Recently, the mathematical community have become interested in the development of arbitrary-order approximation methods that support more general meshes than standard finite elements and which can include, e.g., polyhedral elements and non-matching interfaces. A representative but by far non exhaustive list of references concerning incompressible flow problems includes [4, 5, 7, 17, 18, 22, 26, 47]; see also the recent works [9, 11] concerning non-Newtonian fluids. Pressure-robust variations of the HHO method on matching simplicial meshes for the Stokes and Navier–Stokes problem have been proposed, respectively, in [10, 19].

The development of pressure-robust methods on polyhedral meshes is, however, a challenging task. Some of the first genuinely pressure-robust polyhedral methods for the Stokes equations have been proposed in [38, 46, 48]. These methods handle the lowest order case using a velocity reconstruction in $\mathbf{H}(\text{div}; \Omega)$ introduced in [12] and relying on Wachspress (generalized barycentric) coordinates. This approach has two shortcomings: first, the faces of each (convex) polyhedral element must be either triangles or parallelograms; second, error estimates for the approximated velocity would require gradient bounds for the Wachspress coordinates on an arbitrary convex polyhedron, the derivation of which remains, to the best of our knowledge, an open problem. Regarding arbitrary-order methods on general meshes, a pressure-robust Virtual Element method has been recently proposed in [25] for the Stokes equations. The extension of this method to the Navier–Stokes equations remains, to the best of our knowledge, an open problem. A pressure-robust discretization scheme for the full Navier–Stokes equations has been proposed in [32] based on the staggered Discontinuous Galerkin method. This method solves for three unknowns (the pressure, the velocity, and its gradient), thus leading to larger algebraic systems. Recently, a novel HHO method for which pressure-robustness has been numerically demonstrated has been proposed in [8]. This method uses a larger pressure space than the one considered in the present work, and the derivation of rigorous pressure-robust error estimates is still to be done. An entirely different approach to pressure-robustness on polyhedral meshes has also been recently pursued in [44], hinging on the compatibility features of Discrete de Rham [14, 16] and Virtual Element methods. While this approach leads to a fully pressure-robust, arbitrary-order method, it is based on a curl-curl formulation of the viscous term, which does not lend itself to the treatment of standard boundary conditions.

In the present work, we propose a novel fully pressure-robust HHO method for the Navier–Stokes problem (1) that works in space dimension two and three and supports general meshes composed of convex polytopal elements. For the versions of the proposed method corresponding to a polynomial degrees $k \in \{0, 1\}$, we prove pressure-robust estimates for both the velocity and the discrete portion of the error on the pressure. The cornerstone of the method is a local divergence-preserving reconstruction of the velocity built inside each mesh element T by solving a mixed problem

inspired by [34, 35] on a subtriangulation of T ; see also [45]. The convexity assumption on T enables us to derive the required continuity and approximation bounds for this reconstruction. Robustness with respect to large irrotational body forces is achieved by leveraging the divergence-preserving velocity reconstruction in the discretisation of both the convective term and the body force, so that similar properties as the ones discussed in [10, Section 4.3 and Lemma 7] are obtained for these terms.

The rest of the paper is organised as follows. In Section 2 we introduce the discrete setting, including mesh assumptions, notation, and the novel divergence-preserving velocity reconstruction. Section 3 contains the discrete problem and the main results of the analysis, with particular focus on the definition and properties of the discrete convective trilinear form. A complete panel of two-dimensional numerical tests on a variety of polygonal meshes is provided in Section 4, including a comparison with the standard HHO scheme of [7].

2 Discrete setting

The following exposition focuses on the three-dimensional case $d = 3$, the two-dimensional case $d = 2$ being a special instance of the latter as detailed in Remark 10 below.

2.1 Mesh

Following [15, Definition 1.4], we consider a polyhedral mesh defined as a couple $\mathcal{M}_h := (\mathcal{T}_h, \mathcal{F}_h)$, where \mathcal{T}_h is a finite collection of polyhedral elements which we additionally assume to be convex, while \mathcal{F}_h is a finite collection of planar faces F . For any mesh element or face $X \in \mathcal{T}_h \cup \mathcal{F}_h$, we denote by $|X|$ its Hausdorff measure and by h_X its diameter, so that the meshsize satisfies $h = \max_{T \in \mathcal{T}_h} h_T$. Boundary faces lying on $\partial\Omega$ and internal faces contained in Ω are collected in the sets \mathcal{F}_h^b and \mathcal{F}_h^i , respectively. For each mesh element $T \in \mathcal{T}_h$, we denote by \mathcal{F}_T the set collecting the faces that lie on the boundary ∂T of T and, for all $F \in \mathcal{F}_T$, we denote by \mathbf{n}_{TF} the (constant) unit vector normal to F and pointing out of T .

It is assumed that \mathcal{M}_h belongs to a regular mesh sequence $(\mathcal{M}_h)_h$ in the sense of [15, Definition 1.9]. This assumption entails the existence of a matching simplicial submesh $\mathfrak{M}_h := (\mathfrak{T}_h, \mathfrak{F}_h)$ of \mathcal{M}_h with the following properties: \mathfrak{T}_h is a finite collection of simplicial elements; for any simplex $\tau \in \mathfrak{T}_h$, there is a unique mesh element $T \in \mathcal{T}_h$ such that $\tau \subset T$; for any simplicial face $\sigma \in \mathfrak{F}_h$ and any mesh face $F \in \mathcal{F}_h$, either $\sigma \cap F = \emptyset$ or $\sigma \subset F$. For $T \in \mathcal{T}_h$, we define \mathfrak{T}_T as the set of all simplices of \mathfrak{T}_h contained in T (see Figure 1a) and \mathfrak{F}_T^i as the set of faces of \mathfrak{F}_h that lie in the interior of T . For $F \in \mathcal{F}_h$, \mathfrak{F}_F denotes the set of simplicial faces σ for which $\sigma \subset F$, and we let $\mathbf{n}_\sigma := \mathbf{n}_{TF}$, and $\mathbf{n}_{\tau\sigma} := \mathbf{n}_\sigma$ for the unique element $\tau \in \mathfrak{T}_T$, $T \in \mathcal{T}_h$, which contains σ . For future use, we notice that mesh regularity implies the existence of an integer $N \geq 0$ depending only on the mesh regularity parameter such that

$$\max_h \max_{T \in \mathcal{T}_h} \text{card}(\mathfrak{T}_T) \leq N \quad \text{and} \quad \max_h \max_{T \in \mathcal{T}_h} \text{card}(\mathfrak{F}_T) \leq N. \quad (3)$$

In order to prevent the proliferation of generic constants we write, whenever possible, $a \lesssim b$ in place of $a \leq Cb$ with $C > 0$ independent of ν , λ , h and, for local inequalities, also on the mesh element or face. The dependencies of the hidden constant will be further specified when relevant. Moreover, we write $a \simeq b$, when both $a \lesssim b$ and $b \lesssim a$ hold.

2.2 Local and broken spaces and projectors

Let X denote a mesh element or face and, for an integer $l \geq 0$, denote by $\mathcal{P}^l(X)$ the space spanned by the restrictions to X of polynomials in the space variables of total degree $\leq l$. The L^2 -orthogonal

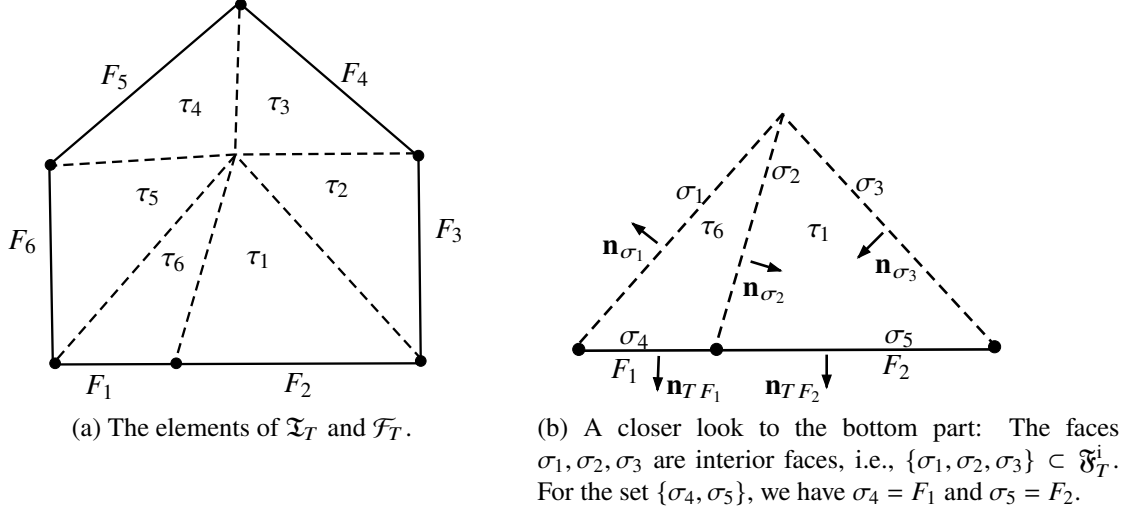

Figure 1: An illustration of the sets \mathfrak{T}_T , \mathcal{F}_T and \mathfrak{F}_T^i for a given element $T \in \mathcal{T}_h$ in \mathbb{R}^2 .

projector $\pi_X^l : L^1(X) \rightarrow \mathcal{P}^l(X)$ is such that, for all $\zeta \in L^1(X)$,

$$\int_X (\zeta - \pi_X^l \zeta) w = 0 \quad \forall w \in \mathcal{P}^l(X). \quad (4)$$

Vector and matrix versions of the L^2 -orthogonal projector are obtained by applying π_X^l component-wise, and are both denoted with the bold symbol $\boldsymbol{\pi}_X^l$ in what follows. Optimal approximation properties for the L^2 -orthogonal projector are proved in [20, Appendix A.2]; see also [15, Chapter 1], where these estimates are extended to non-star shaped elements. Specifically, let $s \in \{0, \dots, l+1\}$ and $r \in [1, +\infty]$. Then, it holds, with hidden constant only depending on l, s, r , and the mesh regularity parameter: For all $T \in \mathcal{T}_h$, all $\zeta \in W^{s,r}(T)$, and all $m \in \{0, \dots, s\}$,

$$|\zeta - \pi_T^l \zeta|_{W^{m,r}(T)} \lesssim h_T^{s-m} |\zeta|_{W^{s,r}(T)}, \quad (5a)$$

and, if $s \geq 1$ and $m \leq s-1$,

$$h_T^{\frac{1}{r}} |\zeta - \pi_T^l \zeta|_{W^{m,r}(\mathcal{F}_T)} \lesssim h_T^{s-m} |\zeta|_{W^{s,r}(T)}, \quad (5b)$$

where $W^{m,r}(\mathcal{F}_T)$ is the space spanned by functions that are in $W^{m,r}(F)$ for all $F \in \mathcal{F}_T$, endowed with the corresponding broken norm.

At the global level, the space of broken polynomial functions on \mathcal{T}_h of total degree $\leq l$ is denoted by $\mathcal{P}^l(\mathcal{T}_h)$, and π_h^l is the corresponding L^2 -orthogonal projector such that, for all $\zeta \in L^1(\Omega)$, $(\pi_h^l \zeta)|_T := \pi_T^l \zeta|_T$ for all $T \in \mathcal{T}_h$. Regularity requirements in error estimates will be expressed in terms of the broken Sobolev spaces $W^{s,r}(\mathcal{T}_h)$ spanned by functions in $L^r(\Omega)$ the restriction of which to every $T \in \mathcal{T}_h$ is in $W^{s,r}(T)$. We additionally set, as usual, $H^s(\mathcal{T}_h) := W^{s,2}(\mathcal{T}_h)$.

2.3 Discrete spaces and norms

Let a polynomial degree $k \geq 0$ be fixed. We define the HHO space as usual setting

$$\underline{U}_h^k := \{ \underline{v}_h = ((v_T)_{T \in \mathcal{T}_h}, (v_F)_{F \in \mathcal{F}_h}) : v_T \in \mathcal{P}^k(T)^3 \text{ for all } T \in \mathcal{T}_h \text{ and } v_F \in \mathcal{P}^k(F)^3 \text{ for all } F \in \mathcal{F}_h \}.$$

The restrictions of \underline{U}_h^k and $\underline{v}_h \in \underline{U}_h^k$ to a generic mesh element $T \in \mathcal{T}_h$ are respectively denoted by \underline{U}_T^k and $\underline{v}_T = (v_T, (v_F)_{F \in \mathcal{F}_T})$. The vector of polynomials corresponding to a smooth function over Ω is obtained via the global interpolation operator $\underline{I}_h^k : H^1(\Omega)^3 \rightarrow \underline{U}_h^k$ such that, for all $\mathbf{v} \in H^1(\Omega)^3$,

$$\underline{I}_h^k \mathbf{v} := ((\boldsymbol{\pi}_T^k \mathbf{v}|_T)_{T \in \mathcal{T}_h}, (\boldsymbol{\pi}_F^k \mathbf{v}|_F)_{F \in \mathcal{F}_h}). \quad (6)$$

Its restriction to a generic mesh element $T \in \mathcal{T}_h$, collecting the components on T and its faces, is denoted by $\underline{\mathbf{I}}_T^k$. We furnish $\underline{\mathbf{U}}_h^k$ with the discrete H^1 -like seminorm such that, for all $\underline{\mathbf{v}}_h \in \underline{\mathbf{U}}_h^k$,

$$\|\underline{\mathbf{v}}_h\|_{1,h} := \left(\sum_{T \in \mathcal{T}_h} \|\underline{\mathbf{v}}_T\|_{1,T}^2 \right)^{1/2},$$

where, for all $T \in \mathcal{T}_h$,

$$\|\underline{\mathbf{v}}_T\|_{1,T} := \left(\|\nabla \mathbf{v}_T\|_{L^2(T)^{3 \times 3}}^2 + |\underline{\mathbf{v}}_T|_{1,\partial T}^2 \right)^{1/2} \quad \text{with} \quad |\underline{\mathbf{v}}_T|_{1,\partial T} := \left(\sum_{F \in \mathcal{F}_T} h_F^{-1} \|\mathbf{v}_F - \mathbf{v}_T\|_{L^2(F)^3}^2 \right)^{1/2}. \quad (7)$$

The discrete spaces for the velocity and the pressure, respectively accounting for the wall boundary condition and the zero-average condition, are

$$\underline{\mathbf{U}}_{h,0}^k := \{ \underline{\mathbf{v}}_h = ((\mathbf{v}_T)_{T \in \mathcal{T}_h}, (\mathbf{v}_F)_{F \in \mathcal{F}_h}) \in \underline{\mathbf{U}}_h^k : \mathbf{v}_F = \mathbf{0} \quad \forall F \in \mathcal{F}_h^b \}, \quad P_h^k := \mathcal{P}^k(\mathcal{T}_h) \cap P.$$

For all $\underline{\mathbf{v}}_h \in \underline{\mathbf{U}}_h^k$, we denote by $\mathbf{v}_h \in \mathcal{P}^k(\mathcal{T}_h)^3$ the vector-valued broken polynomial function obtained patching element-based unknowns, that is $(\mathbf{v}_h)|_T := \mathbf{v}_T$ for all $T \in \mathcal{T}_h$. The following discrete Sobolev embeddings in $\underline{\mathbf{U}}_{h,0}^k$ have been proved in [20, Proposition 5.4]: For all $r \in [1, 6]$ it holds, for all $\underline{\mathbf{v}}_h \in \underline{\mathbf{U}}_{h,0}^k$,

$$\|\mathbf{v}_h\|_{L^r(\Omega)^3} \lesssim \|\underline{\mathbf{v}}_h\|_{1,h}. \quad (8)$$

where the hidden constant is independent of both h and $\underline{\mathbf{v}}_h$, but possibly depends on Ω , k , r , and the mesh regularity parameter. It follows from (8) that the map $\|\cdot\|_{1,h}$ defines a norm on $\underline{\mathbf{U}}_{h,0}^k$. Classically, the corresponding dual norm of a linear form $\mathcal{L}_h : \underline{\mathbf{U}}_{h,0}^k \rightarrow \mathbb{R}$ is given by

$$\|\mathcal{L}_h\|_{1,h,*} := \sup_{\underline{\mathbf{v}}_h \in \underline{\mathbf{U}}_{h,0}^k, \|\underline{\mathbf{v}}_h\|_{1,h}=1} |\mathcal{L}_h(\underline{\mathbf{v}}_h)|. \quad (9)$$

2.4 Divergence-preserving local velocity reconstruction

Following [21], for any element $T \in \mathcal{T}_h$ we define the discrete divergence operator $D_T^k : \underline{\mathbf{U}}_T^k \rightarrow \mathcal{P}^k(T)$ such that, for all $\underline{\mathbf{v}}_T \in \underline{\mathbf{U}}_T^k$ and all $q \in \mathcal{P}^k(T)$,

$$\int_T D_T^k \underline{\mathbf{v}}_T q = - \int_T \mathbf{v}_T \cdot \nabla q + \sum_{F \in \mathcal{F}_T} \int_F (\mathbf{v}_F \cdot \mathbf{n}_{TF}) q. \quad (10)$$

Crucially, the operator D_T^k satisfies the following commutation property (see [15, Eq. (8.21)]):

$$D_T^k \underline{\mathbf{I}}_T^k \mathbf{v} = \pi_T^k(\nabla \cdot \mathbf{v}) \quad \forall \mathbf{v} \in H^1(T)^3. \quad (11)$$

To achieve pressure robustness in the sense made precise by Remark 12 below, we reconstruct divergence-preserving velocity test functions, which are used for the discretization of the body force and the nonlinear term. Let an element $T \in \mathcal{T}_h$ be fixed and, for $\tau \in \mathfrak{T}_T$, denote by $\mathcal{RT}^k(\tau) := \mathcal{P}^k(\tau)^3 + \mathbf{x}\mathcal{P}^k(\tau)$ the local Raviart–Thomas–Nédélec space of degree k [40, 42]. We recall that a function in $\mathcal{RT}^k(\tau)$ is uniquely determined by its polynomial moments of degree up to $(k-1)$ inside τ and the polynomial moments of degree k of its normal component on each face $\sigma \in \mathfrak{F}_\tau$ (with \mathfrak{F}_τ denoting the subset of \mathfrak{F}_h collecting the simplicial faces of τ). We additionally note the following local norm equivalence uniform in h :

$$\|\mathbf{w}\|_{L^2(\tau)^3}^2 \simeq \|\pi_\tau^{k-1} \mathbf{w}\|_{L^2(\tau)^3}^2 + \sum_{\sigma \in \mathfrak{F}_\tau} h_\sigma \|\mathbf{w} \cdot \mathbf{n}_{\tau\sigma}\|_{L^2(\sigma)}^2 \quad \forall \mathbf{w} \in \mathcal{RT}^k(\tau). \quad (12)$$

We introduce the Raviart–Thomas–Nédélec space of degree k on the matching simplicial submesh \mathfrak{T}_T of T defined as follows:

$$\mathcal{RT}^k(\mathfrak{T}_T) := \{ \mathbf{w} \in \mathbf{H}_{\text{div}}(T) : \mathbf{w}|_{\tau} \in \mathcal{RT}^k(\tau) \text{ for all } \tau \in \mathfrak{T}_T \},$$

where $\mathbf{H}_{\text{div}}(T) := \{ \mathbf{w} \in L^2(T)^3 : \nabla \cdot \mathbf{w} \in L^2(T) \}$. We also introduce the subspace of $\mathcal{RT}^k(\mathfrak{T}_T)$ spanned by functions with zero normal trace on the boundary of T :

$$\mathcal{RT}_0^k(\mathfrak{T}_T) := \{ \mathbf{w} \in \mathcal{RT}^k(\mathfrak{T}_T) : \mathbf{w} \cdot \mathbf{n}_{\sigma} = 0 \text{ for all } \sigma \in \mathfrak{F}_F \text{ and all } F \in \mathcal{F}_T \}.$$

The *divergence-preserving velocity reconstruction* $\mathbf{R}_T^k : \underline{\mathbf{U}}_T^k \rightarrow \mathcal{RT}^k(\mathfrak{T}_T)$ is defined, for all $\underline{\mathbf{v}}_T \in \underline{\mathbf{U}}_T^k$, as the first component of the solution of the following mixed problem: Find $(\mathbf{R}_T^k \underline{\mathbf{v}}_T, \psi) \in \mathcal{RT}^k(\mathfrak{T}_T) \times \mathcal{P}^k(\mathfrak{T}_T)$ such that

$$(\mathbf{R}_T^k \underline{\mathbf{v}}_T)|_{\sigma} \cdot \mathbf{n}_{\sigma} = (\mathbf{v}_F \cdot \mathbf{n}_{TF})|_{\sigma} \quad \forall \sigma \in \mathfrak{F}_F, \forall F \in \mathcal{F}_T, \quad (13a)$$

$$\int_T (\nabla \cdot \mathbf{R}_T^k \underline{\mathbf{v}}_T) \phi = \int_T (D_T^k \underline{\mathbf{v}}_T) \phi \quad \forall \phi \in \mathcal{P}^k(\mathfrak{T}_T), \quad (13b)$$

$$\int_T \mathbf{R}_T^k \underline{\mathbf{v}}_T \cdot \mathbf{w} + \int_T (\nabla \cdot \mathbf{w}) \psi = \int_T \mathbf{v}_T \cdot \mathbf{w} \quad \forall \mathbf{w} \in \mathcal{RT}_0^k(\mathfrak{T}_T). \quad (13c)$$

Lemma 1 (Properties of \mathbf{R}_T^k). *It holds:*

(i) Well-posedness. *For a given $\underline{\mathbf{v}}_T \in \underline{\mathbf{U}}_T^k$, there exists a unique $\mathbf{R}_T^k \underline{\mathbf{v}}_T \in \mathcal{RT}^k(\mathfrak{T}_T)$ that satisfies problem (13), and it holds that*

$$\| \mathbf{v}_T - \mathbf{R}_T^k \underline{\mathbf{v}}_T \|_{L^2(T)^3} \lesssim h_T |\underline{\mathbf{v}}_T|_{1, \partial T}. \quad (14)$$

(ii) Approximation. *For all $\mathbf{v} \in \mathbf{H}^{k+1}(T)^3$ such that $\nabla \cdot \mathbf{v} = 0$ in T , it holds*

$$\| \mathbf{v} - \mathbf{R}_T^k(\underline{\mathbf{I}}_T^k \mathbf{v}) \|_{L^2(T)^3} \lesssim h_T^{k+1} |\mathbf{v}|_{H^{k+1}(T)^3}. \quad (15)$$

(iii) Consistency. *For a given $\underline{\mathbf{v}}_T \in \underline{\mathbf{U}}_T^1$, it holds*

$$\pi_T^0(\mathbf{R}_T^1 \underline{\mathbf{v}}_T) = \mathbf{v}_T. \quad (16)$$

Proof. (i) *Well-posedness.* We prove this item in three parts starting with the existence and uniqueness of $\mathbf{R}_T^k \underline{\mathbf{v}}_T$.

(i.A) *Existence, uniqueness, and decomposition of $\mathbf{R}_T^k \underline{\mathbf{v}}_T$.* The existence and uniqueness of $\mathbf{R}_T^k \underline{\mathbf{v}}_T$ follows from the classical theory of mixed problems given the compatibility of the selected couple of spaces; see, e.g., [13, Section 14]. In order to prove the a priori estimate (14), we decompose $\mathbf{R}_T^k \underline{\mathbf{v}}_T$ as follows:

$$\mathbf{R}_T^k \underline{\mathbf{v}}_T = \mathbf{v}' + \mathbf{v}_0, \quad (17)$$

where:

• $\mathbf{v}' \in \mathcal{RT}^k(\mathfrak{T}_T)$ is a lifting of the boundary values defined by prescribing its DOFs as follows:

$$\forall \tau \in \mathfrak{T}_T, \quad \int_{\tau} \mathbf{v}' \cdot \mathbf{w} = 0, \quad \forall \mathbf{w} \in \mathcal{P}^{k-1}(\tau)^3, \quad (18a)$$

$$\forall \sigma \in \mathfrak{F}_T^i, \quad \int_{\sigma} (\mathbf{v}' \cdot \mathbf{n}_{\sigma}) \phi = 0 \quad \forall \phi \in \mathcal{P}^k(\sigma), \quad (18b)$$

$$\forall \sigma \in \mathfrak{F}_F, \forall F \in \mathcal{F}_T, \quad \mathbf{v}'|_{\sigma} \cdot \mathbf{n}_{\sigma} = (\mathbf{v}_F \cdot \mathbf{n}_{TF})|_{\sigma}; \quad (18c)$$

- Letting $\mathcal{P}_0^k(\mathfrak{T}_T) := \{\phi \in \mathcal{P}^k(\mathfrak{T}_T) : \int_T \phi = 0\}$, \mathbf{v}_0 is the first component of the unique solution to the following mixed problem: Find $(\mathbf{v}_0, \psi) \in \mathcal{RT}_0^k(\mathfrak{T}_T) \times \mathcal{P}_0^k(\mathfrak{T}_T)$ such that

$$\int_T (\nabla \cdot \mathbf{v}_0) \phi = \int_T (D_T^k \underline{\mathbf{v}}_T - \nabla \cdot \mathbf{v}') \phi \quad \forall \phi \in \mathcal{P}_0^k(\mathfrak{T}_T), \quad (19a)$$

$$\int_T \mathbf{v}_0 \cdot \mathbf{w} + \int_T (\nabla \cdot \mathbf{w}) \psi = \int_T (\mathbf{v}_T - \mathbf{v}') \cdot \mathbf{w} \quad \forall \mathbf{w} \in \mathcal{RT}_0^k(\mathfrak{T}_T). \quad (19b)$$

(i.B) Boundedness. We begin by proving the following estimate:

$$\|\mathcal{RT}_0^k \underline{\mathbf{v}}_T\|_{L^2(T)^3} \lesssim \|\mathbf{v}_T\|_{L^2(T)^3} + h_T \|\underline{\mathbf{v}}_T\|_{1,T} + \sum_{F \in \mathcal{F}_T} h_F^{\frac{1}{2}} \|\mathbf{v}_F\|_{L^2(F)^3}. \quad (20)$$

Let $L_0^2(T) := \{\xi \in L^2(T) : \int_T \xi = 0\}$, denote by $\theta \in H^1(T) \cap L_0^2(T)$ the solution of the Neumann problem

$$\int_T \nabla \theta \cdot \nabla \xi = \int_T (D_T^k \underline{\mathbf{v}}_T - \nabla \cdot \mathbf{v}') \xi \quad \forall \xi \in H^1(T) \cap L_0^2(T). \quad (21)$$

We recall that problem (21) is the weak form of the following strong problem

$$-\Delta \theta = (D_T^k \underline{\mathbf{v}}_T - \nabla \cdot \mathbf{v}') \quad \text{in } T, \quad (22a)$$

$$\frac{\partial \theta}{\partial n} = 0 \quad \text{on } \partial T. \quad (22b)$$

Since $(D_T^k \underline{\mathbf{v}}_T - \nabla \cdot \mathbf{v}') \in \mathcal{P}_0^k(\mathfrak{T}_T)$, the compatibility condition $\int_T (D_T^k \underline{\mathbf{v}}_T - \nabla \cdot \mathbf{v}') = 0$ for problem (22) is satisfied, yielding existence and uniqueness of θ . Moreover, since T is a convex polyhedron and the forcing term is in $L^2(T)$, $\theta \in H^2(T) \cap L_0^2(T)$ (see [28, Section 8.2]) with

$$|\theta|_{H^2(T)} \lesssim \|D_T^k \underline{\mathbf{v}}_T - \nabla \cdot \mathbf{v}'\|_{L^2(T)}, \quad (23)$$

where it can be checked following the argument in the reference that the hidden constant does not depend on T . Setting $\xi = \theta$ in (21) and using the Cauchy–Schwarz inequality followed by the Poincaré–Wirtinger inequality $\|\zeta\|_{L^2(T)} \leq \frac{h_T}{\pi} |\zeta|_{H^1(T)}$ valid for all $\zeta \in H^1(T)$ such that $\int_T \zeta = 0$ (see [3, 41]), we estimate

$$|\theta|_{H^1(T)} \lesssim h_T \|D_T^k \underline{\mathbf{v}}_T - \nabla \cdot \mathbf{v}'\|_{L^2(T)}. \quad (24)$$

Let now $\mathbf{z} := -\nabla \theta \in H^1(T)^3$. Defining $\hat{\mathbf{z}} \in \mathcal{RT}_0^k(\mathfrak{T}_T)$ as the interpolate of \mathbf{z} onto $\mathcal{RT}^k(\mathfrak{T}_T)$, and using the commutation property $\nabla \cdot \hat{\mathbf{z}} = \pi_{\mathfrak{T}_T}^k(\nabla \cdot \mathbf{z})$ with $\pi_{\mathfrak{T}_T}^k$ denoting the L^2 -orthogonal projector onto $\mathcal{P}^k(\mathfrak{T}_T)$ (see, e.g., [6, Section 2.5.2]), it is inferred that $\nabla \cdot \hat{\mathbf{z}} = \pi_{\mathfrak{T}_T}^k(\nabla \cdot \mathbf{z}) = (D_T^k \underline{\mathbf{v}}_T - \nabla \cdot \mathbf{v}')$, where we have used (22a) in the last step. Therefore, by (19a), $\nabla \cdot (\mathbf{v}_0 - \hat{\mathbf{z}}) = 0$ and, taking $\mathbf{w} = \mathbf{v}_0 - \hat{\mathbf{z}}$ as a test function in (19b), we obtain

$$\int_T \mathbf{v}_0 \cdot (\mathbf{v}_0 - \hat{\mathbf{z}}) = \int_T (\mathbf{v}_T - \mathbf{v}') \cdot (\mathbf{v}_0 - \hat{\mathbf{z}}). \quad (25)$$

Thus, it is readily seen that

$$\begin{aligned}
\|\mathbf{v}_0 - \hat{\mathbf{z}}\|_{L^2(T)^3}^2 &= \int_T (\mathbf{v}_0 - \hat{\mathbf{z}}) \cdot (\mathbf{v}_0 - \hat{\mathbf{z}}) \\
&= \int_T (\mathbf{v}_T - \mathbf{v}' - \hat{\mathbf{z}}) \cdot (\mathbf{v}_0 - \hat{\mathbf{z}}) \\
&\leq \left(\|\mathbf{v}_T - \hat{\mathbf{z}}\|_{L^2(T)^3} + \|\mathbf{v}'\|_{L^2(T)^3} \right) \|\mathbf{v}_0 - \hat{\mathbf{z}}\|_{L^2(T)^3} \\
&\leq \left(\|\mathbf{v}_T - \mathbf{z}\|_{L^2(T)^3} + \|\mathbf{z} - \hat{\mathbf{z}}\|_{L^2(T)^3} + \|\mathbf{v}'\|_{L^2(T)^3} \right) \|\mathbf{v}_0 - \hat{\mathbf{z}}\|_{L^2(T)^3} \\
&=: (\mathfrak{I}_1 + \mathfrak{I}_2 + \mathfrak{I}_3) \|\mathbf{v}_0 - \hat{\mathbf{z}}\|_{L^2(T)^3},
\end{aligned} \tag{26}$$

where we have used equation (25) in the second step, the Cauchy–Schwarz and triangle inequalities in the third step, and again a triangle inequality after inserting $\pm\hat{\mathbf{z}}$ into the first norm in the fourth step. To estimate \mathfrak{I}_1 , we begin using the triangle inequality twice to obtain

$$\begin{aligned}
\mathfrak{I}_1 &\leq \|\mathbf{v}_T - \pi_T^0 \mathbf{v}_T\|_{L^2(T)^3} + \|\pi_T^0 \mathbf{v}_T - \pi_T^0 \mathbf{z}\|_{L^2(T)^3} + \|\pi_T^0 \mathbf{z} - \mathbf{z}\|_{L^2(T)^3} \\
&=: \mathfrak{I}_{11} + \mathfrak{I}_{12} + \mathfrak{I}_{13}.
\end{aligned} \tag{27}$$

Using the approximation properties (5a) of π_T^0 with $(r, m, s) = (2, 0, 1)$, we get

$$\mathfrak{I}_{11} \lesssim h_T |\mathbf{v}_T|_{H^1(T)^3} \lesssim h_T \|\nabla \mathbf{v}_T\|_{L^2(T)^{3 \times 3}} \leq h_T \|\underline{\mathbf{v}}_T\|_{1,T}, \tag{28}$$

where, in the last step, we have used the definition (7) of $\|\cdot\|_{1,T}$. To estimate \mathfrak{I}_{12} , we first observe that, using the equation (21) with $\xi = q \in \mathcal{P}_0^1(T) \subset H^1(T) \cap L_0^2(T)$, we get

$$-\int_T \mathbf{z} \cdot \nabla q = \int_T (D_T^k \underline{\mathbf{v}}_T - \nabla \cdot \mathbf{v}') q \quad \forall q \in \mathcal{P}_0^1(T).$$

Using the definition (10) of the operator D_T^k , the relations (18b) and (18c) prescribing the normal components of \mathbf{v}' on the faces of the subtriangulation along with an integration by parts, and the fact that $\mathcal{P}^0(T)^3 = \nabla \mathcal{P}_0^1(T)$, it is proved that

$$\int_T \mathbf{z} \cdot \mathbf{w} = \int_T \mathbf{v}_T \cdot \mathbf{w} \quad \forall \mathbf{w} \in \mathcal{P}^0(T)^3,$$

thus $\pi_T^0 \mathbf{z} = \pi_T^0 \mathbf{v}_T$, and the quantity \mathfrak{I}_{12} in (27) vanishes. To bound \mathfrak{I}_{13} , we first recall that $\mathbf{z} := -\nabla \theta$, then use the approximation properties (5a) of π_T^0 with $(r, m, s) = (2, 0, 1)$ and (23) to write

$$\mathfrak{I}_{13} \lesssim h_T |\theta|_{H^2(T)} \lesssim h_T \|D_T^k \underline{\mathbf{v}}_T - \nabla \cdot \mathbf{v}'\|_{L^2(T)} \leq h_T \left(\|D_T^k \underline{\mathbf{v}}_T\|_{L^2(T)} + \|\nabla \cdot \mathbf{v}'\|_{L^2(T)} \right). \tag{29}$$

For the first term in parentheses, integrating by parts the right-hand side of (10), applying Cauchy–Schwarz and discrete trace inequalities, and taking the supremum over $q \in \mathcal{P}^k(T)$, we obtain

$$\|D_T^k \underline{\mathbf{v}}_T\|_{L^2(T)} \lesssim \|\underline{\mathbf{v}}_T\|_{1,T}. \tag{30}$$

To bound the second term in parentheses, we use a discrete inverse inequality to write

$$\|\nabla \cdot \mathbf{v}'\|_{L^2(T)}^2 \lesssim \sum_{\tau \in \mathfrak{T}_T} |\mathbf{v}'|_{H^1(\tau)}^2 \lesssim h_\tau^{-2} \sum_{\tau \in \mathfrak{T}_T} \|\mathbf{v}'\|_{L^2(\tau)}^2 \lesssim h_T^{-2} \|\mathbf{v}'\|_{L^2(T)^3}^2, \tag{31}$$

where the fact that $h_\tau^{-1}h_T \lesssim 1$ for regular mesh sequences (see [15, Eq. (1.4)]) has been used in the last step. Now, to estimate $\|\mathbf{v}'\|_{L^2(T)^3}$, we combine (12) and (18) to obtain

$$\|\mathbf{v}'\|_{L^2(T)^3}^2 \simeq \sum_{\sigma \in \mathfrak{F}_F, F \in \mathcal{F}_T} h_\sigma \|\mathbf{v}_F \cdot \mathbf{n}_{TF}\|_{L^2(\sigma)}^2 \lesssim \sum_{F \in \mathcal{F}_T} h_F \|\mathbf{v}_F\|_{L^2(F)^3}^2, \quad (32)$$

where we have used the fact that $\sigma \subset F$, the inequality $h_\sigma \leq h_F$ valid for any $\sigma \in \mathfrak{F}_F$ and any $F \in \mathcal{F}_T$, and the Hölder inequality with exponents $(2, \infty)$ along with $\|\mathbf{n}_{TF}\|_{L^\infty(F)^d} = 1$ for the third step. Therefore plugging (30), (31), and (32) into (29), we obtain

$$\mathfrak{I}_{13} \lesssim h_T \|\underline{\mathbf{v}}_T\|_{1,T} + \sum_{F \in \mathcal{F}_T} h_F^{\frac{1}{2}} \|\mathbf{v}_F\|_{L^2(F)^3},$$

where we have also used the equivalence $h_F \simeq h_T$ valid for regular mesh sequences (see [15, Eq. (1.4)]), along with the bound $\sum_i a_i^2 \leq (\sum_i a_i)^2$ valid for non-negative real numbers a_i for the second addend. Plugging the above bounds for \mathfrak{I}_{11} , \mathfrak{I}_{12} , and \mathfrak{I}_{13} into (27), it is readily seen that

$$\mathfrak{I}_1 \lesssim h_T \|\underline{\mathbf{v}}_T\|_{1,T} + \sum_{F \in \mathcal{F}_T} h_F^{\frac{1}{2}} \|\mathbf{v}_F\|_{L^2(F)^3}. \quad (33)$$

To bound the term \mathfrak{I}_2 in (26), we use (23) followed by standard interpolation estimates for $\hat{\mathbf{z}}$ (see, e.g., [6, Proposition 2.5.4]) to write

$$\mathfrak{I}_2 \lesssim h_T |\theta|_{H^2(T)} \lesssim h_T \|D_T^k \underline{\mathbf{v}}_T - \nabla \cdot \mathbf{v}'\|_{L^2(T)^3} \lesssim h_T \|\underline{\mathbf{v}}_T\|_{1,T} + \sum_{F \in \mathcal{F}_T} h_F^{\frac{1}{2}} \|\mathbf{v}_F\|_{L^2(F)^3}, \quad (34)$$

where we have used a triangle inequality followed by (30), (31), and (32) to conclude.

Plugging (33) and (34) into (26), using (32) to estimate \mathfrak{I}_3 , and simplifying, we obtain

$$\|\mathbf{v}_0 - \hat{\mathbf{z}}\|_{L^2(T)^3} \lesssim h_T \|\underline{\mathbf{v}}_T\|_{1,T} + \sum_{F \in \mathcal{F}_T} h_F^{\frac{1}{2}} \|\mathbf{v}_F\|_{L^2(F)^3}. \quad (35)$$

Using the decomposition (17) followed by a triangle inequality, we finally get

$$\begin{aligned} \|\mathbf{v}_T - \mathbf{R}_T^k \underline{\mathbf{v}}_T\|_{L^2(T)^3} &\leq \|\mathbf{v}_T - \hat{\mathbf{z}}\|_{L^2(T)^3} + \|\hat{\mathbf{z}} - \mathbf{v}_0\|_{L^2(T)^3} + \|\mathbf{v}'\|_{L^2(T)^3} \\ &\leq \|\mathbf{v}_T - \mathbf{z}\|_{L^2(T)^3} + \|\mathbf{z} - \hat{\mathbf{z}}\|_{L^2(T)^3} + \|\hat{\mathbf{z}} - \mathbf{v}_0\|_{L^2(T)^3} + \|\mathbf{v}'\|_{L^2(T)^3} \\ &\lesssim h_T \|\underline{\mathbf{v}}_T\|_{1,T} + \sum_{F \in \mathcal{F}_T} h_F^{\frac{1}{2}} \|\mathbf{v}_F\|_{L^2(F)^3}, \end{aligned}$$

where we have used the bounds (32)–(35) in the last step. Inserting $\pm \mathbf{R}_T^k \underline{\mathbf{v}}_T$ into the left-hand side of (20) and using a triangle inequality followed by the above estimate, (20) follows.

(i.C) *Proof of the bound (14)*. Recalling that $\underline{\mathbf{I}}_T^k$ is obtained restricting the global interpolator (6) to an element T , letting $\hat{\mathbf{v}} := \mathbf{R}_T^k(\underline{\mathbf{I}}_T^k \mathbf{v}_T)$, and using the triangle inequality, we get that

$$\|\mathbf{v}_T - \mathbf{R}_T^k \underline{\mathbf{v}}_T\|_{L^2(T)^3} \leq \|\mathbf{v}_T - \hat{\mathbf{v}}\|_{L^2(T)^3} + \|\hat{\mathbf{v}} - \mathbf{R}_T^k \underline{\mathbf{v}}_T\|_{L^2(T)^3} =: \mathfrak{I}_1 + \mathfrak{I}_2. \quad (36)$$

By condition (13b), we have that $\nabla \cdot \hat{\mathbf{v}} = D_T^k(\underline{\mathbf{I}}_T^k \mathbf{v}_T) \in \mathcal{P}^k(T) \subset \mathcal{P}^k(\mathfrak{T}_T)$. But, since $\mathbf{v}_T \in \mathcal{P}^k(T)$, the commutation property (11) gives $D_T^k(\underline{\mathbf{I}}_T^k \mathbf{v}_T) = \pi_T^k(\nabla \cdot \mathbf{v}_T) = \nabla \cdot \mathbf{v}_T$, so that $\nabla \cdot (\hat{\mathbf{v}} - \mathbf{v}_T) = 0$. In addition, observing that $\hat{\mathbf{v}} - \mathbf{v}_T \in \mathcal{RT}_0^k(\mathfrak{T}_T)$ and taking $\mathbf{w} = \hat{\mathbf{v}} - \mathbf{v}_T$ in (13c), it is inferred that $\|\hat{\mathbf{v}} - \mathbf{v}_T\|_{L^2(T)^3}^2 = 0$, hence $\mathfrak{I}_1 = 0$.

Let us now estimate the term \mathfrak{I}_2 . By linearity of \mathbf{R}_T^k , we can write $\mathfrak{I}_2 = \|\mathbf{R}_T^k(\underline{\mathbf{I}}_T^k \mathbf{v}_T - \underline{\mathbf{v}}_T)\|_{L^2(T)^3}$. Hence, using the bound (20), the fact that $(\underline{\mathbf{I}}_T^k \mathbf{v}_T - \underline{\mathbf{v}}_T)_T = 0$ and $(\underline{\mathbf{I}}_T^k \mathbf{v}_T - \underline{\mathbf{v}}_T)_F = (\mathbf{v}_T - \mathbf{v}_F)$ for all $F \in \mathcal{F}_T$, and recalling the definition (7), we can write

$$\begin{aligned} \mathfrak{I}_2 &\lesssim h_T \|\underline{\mathbf{I}}_T^k \mathbf{v}_T - \underline{\mathbf{v}}_T\|_{1,T} + \sum_{F \in \mathcal{F}_T} h_F^{\frac{1}{2}} \|\mathbf{v}_T - \mathbf{v}_F\|_{L^2(F)^3} \\ &= h_T |\underline{\mathbf{v}}_T|_{1,\partial T} + \sum_{F \in \mathcal{F}_T} h_F h_F^{-\frac{1}{2}} \|\mathbf{v}_T - \mathbf{v}_F\|_{L^2(F)^3} \leq h_T |\underline{\mathbf{v}}_T|_{1,\partial T}, \end{aligned}$$

where we have used the inequality $h_F \leq h_T$ in the last step. Plugging this last bound along with $\mathfrak{I}_1 = 0$ into (36), the conclusion follows.

(ii) *Approximation.* To prove the approximation estimate (15), let $T \in \mathcal{T}_h$ and denote, for the sake of brevity, by $\hat{\mathbf{v}}$ the interpolate of \mathbf{v} on $\mathcal{RT}^k(\mathfrak{I}_T)$. We begin using the triangle inequality to write

$$\|\mathbf{v} - \mathbf{R}_T^k(\underline{\mathbf{I}}_T^k \mathbf{v})\|_{L^2(T)^3} \leq \|\mathbf{v} - \hat{\mathbf{v}}\|_{L^2(T)^3} + \|\hat{\mathbf{v}} - \mathbf{R}_T^k(\underline{\mathbf{I}}_T^k \mathbf{v})\|_{L^2(T)^3} =: \mathfrak{I}_1 + \mathfrak{I}_2.$$

From the interpolation estimates of [6, Proposition 2.5.4] along with the mesh regularity assumption, it immediately follows that

$$\mathfrak{I}_1 \lesssim h^{k+1} |\mathbf{v}|_{H^{k+1}(T)^3}. \quad (37)$$

Let us now estimate \mathfrak{I}_2 . By definition of the interpolator on $\mathcal{RT}^k(\mathfrak{I}_T)$ along with (13a), we have that $\mathbf{w} := \hat{\mathbf{v}} - \mathbf{R}_T^k(\underline{\mathbf{I}}_T^k \mathbf{v}) \in \mathcal{RT}_0^k(\mathfrak{I}_T)$. Moreover, using the assumption that $\nabla \cdot \mathbf{v} = 0$ and the commuting diagram property, we infer that $\nabla \cdot \hat{\mathbf{v}} = \pi_{\mathfrak{I}_T}^k(\nabla \cdot \mathbf{v}) = 0$. On the other hand, we have

$$\nabla \cdot \mathbf{R}_T^k(\underline{\mathbf{I}}_T^k \mathbf{v}) = D_T^k(\underline{\mathbf{I}}_T^k \mathbf{v}) = \pi_T^k(\nabla \cdot \mathbf{v}) = 0,$$

where we have used (13b) in the second step, and the commutation property (11) in the third step. Therefore, $\nabla \cdot \mathbf{w} = 0$ and, by (13c), it is inferred that

$$\int_T \mathbf{R}_T^k(\underline{\mathbf{I}}_T^k \mathbf{v}) \cdot \mathbf{w} = \int_T \pi_T^k \mathbf{v} \cdot \mathbf{w} = \int_T (\pi_T^k \mathbf{v} - \hat{\mathbf{v}} + \hat{\mathbf{v}}) \cdot \mathbf{w} = \int_T (\pi_T^k \mathbf{v} - \hat{\mathbf{v}}) \cdot \mathbf{w} + \int_T \hat{\mathbf{v}} \cdot \mathbf{w}.$$

Rearranging and recalling the definition of \mathbf{w} , we get

$$\|\mathbf{w}\|_{L^2(T)^3}^2 = \int_T (\hat{\mathbf{v}} - \pi_T^k \mathbf{v}) \cdot \mathbf{w} \leq \|\hat{\mathbf{v}} - \pi_T^k \mathbf{v}\|_{L^2(T)^3} \|\mathbf{w}\|_{L^2(T)^3},$$

where we have use the Cauchy–Schwarz inequality to conclude. After simplifying, we can write

$$\mathfrak{I}_2 = \|\mathbf{w}\|_{L^2(T)^3} \leq \|\hat{\mathbf{v}} - \pi_T^k \mathbf{v}\|_{L^2(T)^3} \leq \|\hat{\mathbf{v}} - \mathbf{v}\|_{L^2(T)^3} + \|\mathbf{v} - \pi_T^k \mathbf{v}\|_{L^2(T)^3}.$$

Using, respectively, (37) and (5a) with $(l, m, r, s) = (k, 0, 2, k+1)$ to bound the terms in the right-hand side, the conclusion follows.

(iii) *Consistency.* Observe that $\mathcal{P}^0(T)^3 = \nabla \mathcal{P}^1(T)$, i.e., every constant polynomial in \mathbb{R}^3 inside T can be expressed as the gradient of a scalar polynomial of degree one. Thus, for all $\mathbf{\Phi} \in \mathcal{P}^0(T)^3$, there exists $\phi \in \mathcal{P}^1(T)$ such that $\mathbf{\Phi} = \nabla \phi$. Then, using (13b) along with an integration by parts and the boundary condition (13a), we infer that

$$-\int_T \mathbf{R}_T^1 \underline{\mathbf{v}}_T \cdot \nabla \phi + \sum_{F \in \mathcal{F}_T} \int_F (\mathbf{v}_F \cdot \mathbf{n}_{TF}) \phi = \int_T (D_T^1 \underline{\mathbf{v}}_T) \phi = -\int_T \mathbf{v}_T \cdot \nabla \phi + \sum_{F \in \mathcal{F}_T} \int_F (\mathbf{v}_F \cdot \mathbf{n}_{TF}) \phi,$$

where in the last step we have used the definition (10) of D_T^1 . This shows that $\int_T \mathbf{\Phi} \cdot (\mathbf{R}_T^1 \underline{\mathbf{v}}_T - \mathbf{v}_T) = 0$ for all $\mathbf{\Phi} \in \mathcal{P}^0(T)^3$, and (16) follows. \square

Let $\mathcal{RT}^k(\mathfrak{T}_h)$ denote the global ($\mathbf{H}_{\text{div}}(\Omega)$ -conforming) Raviart–Thomas–Nédélec space on \mathfrak{T}_h . We define the *global velocity reconstruction* $\mathbf{R}_h^k : \underline{\mathbf{U}}_h^k \rightarrow \mathcal{RT}^k(\mathfrak{T}_h)$ patching the local contributions: For all $\underline{\mathbf{v}}_h \in \underline{\mathbf{U}}_h^k$,

$$(\mathbf{R}_h^k \underline{\mathbf{v}}_h)|_T := \mathbf{R}_T^k \underline{\mathbf{v}}_T \quad \forall T \in \mathcal{T}_h.$$

Note that $\mathbf{R}_h^k \underline{\mathbf{v}}_h$ is well-defined, since its normal components across each mesh interface are continuous as a consequence of (13a) combined with the single-valuedness of interface unknowns.

Proposition 2 (Sobolev inequalities for the velocity reconstruction). *It holds, for all $r \in [1, 6]$ and all $\underline{\mathbf{v}}_h \in \underline{\mathbf{U}}_{h,0}^k$*

$$\|\mathbf{R}_h^k \underline{\mathbf{v}}_h\|_{L^r(\Omega)^3} \lesssim \|\underline{\mathbf{v}}_h\|_{1,h}, \quad (38)$$

where the hidden constant is independent of both h and $\underline{\mathbf{v}}_h$, but possibly depends on Ω , k , r , and the mesh regularity parameter.

Proof. Let a mesh element $T \in \mathcal{T}_h$ be fixed. Inserting $\pm \mathbf{v}_T$ into the norm and using a triangle inequality, we can write

$$\begin{aligned} \|\mathbf{R}_T^k \underline{\mathbf{v}}_T\|_{L^r(T)^3} &\leq \|\mathbf{R}_T^k \underline{\mathbf{v}}_T - \mathbf{v}_T\|_{L^r(T)^3} + \|\mathbf{v}_T\|_{L^r(T)^3} \\ &= \left(\sum_{\tau \in \mathfrak{T}_T} \|\mathbf{R}_T^k \underline{\mathbf{v}}_T - \mathbf{v}_T\|_{L^r(\tau)^3}^r \right)^{\frac{1}{r}} + \|\mathbf{v}_T\|_{L^r(T)^3}. \end{aligned} \quad (39)$$

From the discrete Lebesgue embeddings proved in [15, Lemma 1.25], it follows that, for all $(\alpha, \beta) \in [1, +\infty]$, all $X \in \mathcal{T}_h \cup \mathfrak{T}_h$, and all $\zeta \in \mathcal{P}^l(X)$ for $l \geq 0$,

$$\|\zeta\|_{L^\alpha(X)} \lesssim h_X^{\frac{3}{\alpha} - \frac{3}{\beta}} \|\zeta\|_{L^\beta(X)}, \quad (40)$$

with hidden constant independent of h , X , and ζ , but possibly depending on l , α , β , and the mesh regularity parameter. Since $(\mathbf{R}_T^k \underline{\mathbf{v}}_T - \mathbf{v}_T)|_\tau \in \mathcal{P}^{k+1}(\tau)^3$, we use (40) for $(X, \alpha, \beta) = (\tau, r, 2)$ in the term in parentheses of (39) to write

$$\begin{aligned} \sum_{\tau \in \mathfrak{T}_T} \|\mathbf{R}_T^k \underline{\mathbf{v}}_T - \mathbf{v}_T\|_{L^2(\tau)^r}^r &\lesssim \sum_{\tau \in \mathfrak{T}_T} h_\tau^{r(\frac{3}{r} - \frac{3}{2})} \|\mathbf{R}_T^k \underline{\mathbf{v}}_T - \mathbf{v}_T\|_{L^2(\tau)^3}^r \\ &\lesssim h_T^{r(\frac{3}{r} - \frac{3}{2})} \|\mathbf{R}_T^k \underline{\mathbf{v}}_T - \mathbf{v}_T\|_{L^2(T)^3}^r \lesssim h_T^{r(\frac{3}{r} - \frac{1}{2})} |\underline{\mathbf{v}}_T|_{1,\partial T}^r, \end{aligned} \quad (41)$$

where we have used $\tau \subset T$ and $h_\tau \leq h_T$ for all $\tau \in \mathfrak{T}_T$ along with the uniform bound (3) on $\text{card}(\mathfrak{T}_T)$ in the second step, and the estimate (14) to conclude. Plugging (41) into (39), raising the resulting inequality to the r -th power, using the inequality $(a + b)^r \lesssim a^r + b^r$ valid for any nonnegative real numbers a and b , and summing over $T \in \mathcal{T}_h$, we get

$$\|\mathbf{R}_h^k \underline{\mathbf{v}}_h\|_{L^r(\Omega)^3}^r \lesssim \sum_{T \in \mathcal{T}_h} h_T^{\frac{6-r}{2}} |\underline{\mathbf{v}}_T|_{1,\partial T}^r + \|\underline{\mathbf{v}}_h\|_{L^r(\Omega)^3}^r.$$

The proof now continues as that of [10, Proposition 3]. The details are omitted for the sake of conciseness. \square

2.5 Gradient reconstruction on a submesh

Let an element $T \in \mathcal{T}_h$ be fixed. For every face $\sigma \in \mathfrak{F}_T^i$, we introduce an arbitrary but fixed ordering of the elements τ_1 and τ_2 such that $\sigma \subset \partial\tau_1 \cap \partial\tau_2$, and let $\mathbf{n}_\sigma := \mathbf{n}_{\tau_1\sigma} = -\mathbf{n}_{\tau_2\sigma}$, where $\mathbf{n}_{\tau_i\sigma}, i \in \{1, 2\}$, denotes the unit vector normal to σ pointing out of τ_i (see Figure 1b). With this convention, for every scalar-valued function ζ admitting a possibly two-valued trace on σ , we define the jump of ζ across σ as

$$[[\zeta]]_\sigma := \zeta|_{\tau_1} - \zeta|_{\tau_2}. \quad (42)$$

When applied to vector- or tensor-valued functions, the jump operator acts component-wise.

For any polynomial degree $l \geq 0$, we then define the local gradient reconstruction $\mathbf{G}_{\mathfrak{X}_T}^l : \underline{\mathbf{U}}_T^k \rightarrow \mathcal{P}^l(\mathfrak{X}_T)^{3 \times 3}$ such that, for all $\underline{\mathbf{v}}_T \in \underline{\mathbf{U}}_T^k$ and all $\boldsymbol{\tau} \in \mathcal{P}^l(\mathfrak{X}_T)^{3 \times 3}$,

$$\int_T \mathbf{G}_{\mathfrak{X}_T}^l \underline{\mathbf{v}}_T : \boldsymbol{\tau} = \int_T \nabla \mathbf{v}_T : \boldsymbol{\tau} + \sum_{F \in \mathcal{F}_T} \int_F (\mathbf{v}_F - \mathbf{v}_T) \cdot \boldsymbol{\tau} \mathbf{n}_{TF} \quad (43a)$$

$$= - \int_T \mathbf{v}_T \cdot (\nabla \cdot \boldsymbol{\tau}) + \sum_{\sigma \in \mathfrak{F}_T^i} \int_\sigma \mathbf{v}_T \cdot [[\boldsymbol{\tau}]]_\sigma \mathbf{n}_\sigma + \sum_{F \in \mathcal{F}_T} \int_F \mathbf{v}_F \cdot \boldsymbol{\tau} \mathbf{n}_{TF}, \quad (43b)$$

where we have used integration by parts to pass to the second line. The above definition is an extension of the operator $\mathbf{G}_T^l : \underline{\mathbf{U}}_T^k \rightarrow \mathcal{P}^l(T)^{3 \times 3}$ introduced in [10, 22], which is defined using $\mathcal{P}^l(T)^{3 \times 3}$ instead of $\mathcal{P}^l(\mathfrak{X}_T)^{3 \times 3}$ as a test space, and thus we have $\boldsymbol{\pi}_T^l \mathbf{G}_{\mathfrak{X}_T}^l = \mathbf{G}_T^l$. The gradient reconstruction \mathbf{G}_T^l will be used with $l = k$ in the viscous term, while the enriched gradient reconstruction $\mathbf{G}_{\mathfrak{X}_T}^l$ will be used with $l = 2(k + 1)$ in the convective term (see Section 3.3).

Lemma 3 (Properties of $\mathbf{G}_{\mathfrak{X}_T}^l$). *The operator $\mathbf{G}_{\mathfrak{X}_T}^l$ has the following properties:*

1. Boundedness. For all $\underline{\mathbf{v}}_T \in \underline{\mathbf{U}}_T^k$, it holds

$$\|\mathbf{G}_{\mathfrak{X}_T}^l \underline{\mathbf{v}}_T\|_{L^2(T)^{3 \times 3}} \lesssim \|\underline{\mathbf{v}}_T\|_{1,T}. \quad (44)$$

2. Consistency. For all $\mathbf{v} \in H^{k+1}(T)^3$ and all $l > k$, it holds,

$$\|\mathbf{G}_{\mathfrak{X}_T}^l \underline{\mathbf{I}}_T^k \mathbf{v} - \nabla \mathbf{v}\|_{L^2(T)^{3 \times 3}} \lesssim h_T^k |\mathbf{v}|_{H^{k+1}(T)^3}. \quad (45)$$

Proof. (i) *Boundedness.* The proof is the same as that of [22, Proposition 1].

(ii) *Consistency.* Let $\mathbf{v} \in H^{k+1}(T)^3$. For all $T \in \mathcal{T}_h$, using $\underline{\mathbf{I}}_T^k \mathbf{v} = (\boldsymbol{\pi}_T^k \mathbf{v}, (\boldsymbol{\pi}_F^k \mathbf{v}|_F)_{F \in \mathcal{F}_T})$ into (43b) for the first term and an integration by parts for the second term, we obtain, for all $\boldsymbol{\tau} \in \mathcal{P}^k(\mathfrak{X}_T)^{3 \times 3}$,

$$\begin{aligned} \int_T (\mathbf{G}_{\mathfrak{X}_T}^l \underline{\mathbf{I}}_T^k \mathbf{v} - \nabla \mathbf{v}) : \boldsymbol{\tau} &= - \int_T (\boldsymbol{\pi}_T^k \mathbf{v} - \mathbf{v}) \cdot (\nabla \cdot \boldsymbol{\tau}) + \sum_{F \in \mathcal{F}_T} \int_F (\boldsymbol{\pi}_F^k \mathbf{v} - \mathbf{v}) \cdot \boldsymbol{\tau} \mathbf{n}_{TF} \\ &+ \sum_{\sigma \in \mathfrak{F}_T^i} \int_\sigma (\boldsymbol{\pi}_T^k \mathbf{v} - \mathbf{v}) \cdot [[\boldsymbol{\tau}]]_\sigma \mathbf{n}_\sigma =: \mathfrak{I}_1 + \mathfrak{I}_2 + \mathfrak{I}_3. \end{aligned} \quad (46)$$

We now proceed to bound the terms in the right-hand side.

Using Cauchy–Schwarz and discrete inverse inequalities along with the approximation properties (5a) of $\boldsymbol{\pi}_T^k$ with $(l, r, m, s) = (k, 2, 0, k + 1)$ we obtain, for the first term,

$$|\mathfrak{I}_1| \lesssim h_T^k |\mathbf{v}|_{H^{k+1}(T)^3} \|\boldsymbol{\tau}\|_{L^2(T)^{3 \times 3}}. \quad (47)$$

For the second term, we use a Hölder inequality with exponents $(2, 2, \infty)$ along with $\|\mathbf{n}_{TF}\|_{L^\infty(F)^3} = 1$ to write

$$\begin{aligned} |\mathfrak{I}_2| &\leq \sum_{F \in \mathcal{F}_T} \|\pi_F^k \mathbf{v} - \mathbf{v}\|_{L^2(F)^3} \|\boldsymbol{\tau}\|_{L^2(F)^{3 \times 3}} \\ &\lesssim h_T^{-1/2} \left(\sum_{F \in \mathcal{F}_T} \|\pi_F^k \mathbf{v} - \mathbf{v}\|_{L^2(F)^3}^2 \right)^{1/2} \|\boldsymbol{\tau}\|_{L^2(T)^{3 \times 3}} \lesssim h_T^k |\mathbf{v}|_{H^{k+1}(T)^3} \|\boldsymbol{\tau}\|_{L^2(T)^{3 \times 3}}, \end{aligned} \quad (48)$$

where we have used the fact that $\|\pi_F^k \mathbf{v} - \mathbf{v}\|_{L^2(F)^3}^2 = \inf_{\mathbf{w} \in \mathcal{P}^k(F)^3} \|\mathbf{w} - \mathbf{v}\|_{L^2(F)^3}^2 \leq \|\pi_T^k \mathbf{v} - \mathbf{v}\|_{L^2(F)^3}^2$ together with a discrete trace inequality in the second step and the trace approximation properties (5b) of π_T^k with $(l, r, m, s) = (k, 2, 0, k+1)$ to conclude.

Let us now consider the third term. Recalling the definition (42) of the jump operator, we bound each integral over $\sigma \in \mathfrak{F}_T^i$ as follows:

$$\begin{aligned} \left| \int_{\sigma} (\pi_T^k \mathbf{v} - \mathbf{v}) \cdot \llbracket \boldsymbol{\tau} \rrbracket_{\sigma} \mathbf{n}_{\sigma} \right| &\leq \sum_{i=1}^2 \left| \int_{\sigma} (\pi_T^k \mathbf{v} - \mathbf{v}) \cdot (\boldsymbol{\tau}|_{\tau_i} \mathbf{n}_{\tau_i \sigma}) \right| \\ &\leq \sum_{i=1}^2 \|\pi_T^k \mathbf{v} - \mathbf{v}\|_{L^2(\sigma)^3} \|\boldsymbol{\tau}|_{\tau_i}\|_{L^2(\sigma)^{3 \times 3}} \\ &\lesssim \sum_{i=1}^2 \left(h_{\sigma}^{-1} \|\pi_T^k \mathbf{v} - \mathbf{v}\|_{L^2(\tau_i)^3} + |\pi_T^k \mathbf{v} - \mathbf{v}|_{1, \tau_i} \right) \|\boldsymbol{\tau}\|_{L^2(\tau_i)^{3 \times 3}} \\ &\lesssim \left(h_T^{-1} \|\pi_T^k \mathbf{v} - \mathbf{v}\|_{L^2(T)^3} + |\pi_T^k \mathbf{v} - \mathbf{v}|_{1, T} \right) \|\boldsymbol{\tau}\|_{L^2(T)^{3 \times 3}} \\ &\lesssim h_T^k |\mathbf{v}|_{H^{k+1}(T)^3} \|\boldsymbol{\tau}\|_{L^2(T)^{3 \times 3}}, \end{aligned}$$

where we have started with a triangle inequality, used Cauchy–Schwarz and Hölder inequalities (the latter with exponents $(2, \infty)$) along with $\|\mathbf{n}_{\tau_i \sigma}\|_{L^\infty(\sigma)^3} = 1$ in the second step, local continuous and discrete trace inequalities on the submesh for the first and second factor, respectively, in the third step, and the fact that $\tau_i \subset T$ for $i \in \{1, 2\}$ along with the first geometric bound in (3) and $h_{\sigma}^{-1} \lesssim h_T^{-1}$ (consequence of mesh regularity) in the fourth step. The conclusion follows using the approximation properties (5a) of π_T^k with $(l, r, m, s) = (k, 2, 0, k+1)$ for the first term in parenthesis and $(l, r, m, s) = (k, 2, 1, k+1)$ for the second one. Gathering the above estimates and observing that $\text{card}(\mathfrak{F}_T^i) \leq 4 \text{card}(\mathfrak{I}_T) \lesssim N$ by (3), we obtain

$$|\mathfrak{I}_3| \lesssim h_T^k |\mathbf{v}|_{H^{k+1}(T)^3} \|\boldsymbol{\tau}\|_{L^2(T)^{3 \times 3}}, \quad (49)$$

Setting $\boldsymbol{\tau} = \mathbf{G}_{\mathfrak{I}_T}^l \mathbf{I}_T^k \mathbf{v} - \boldsymbol{\pi}_{\mathfrak{I}_T}^l \nabla \mathbf{v}$ in (46), using the bounds (47)–(49), and simplifying yields

$$\|\mathbf{G}_{\mathfrak{I}_T}^l \mathbf{I}_T^k \mathbf{v} - \boldsymbol{\pi}_{\mathfrak{I}_T}^l \nabla \mathbf{v}\|_{L^2(T)^{3 \times 3}} \lesssim h_T^k |\mathbf{v}|_{H^{k+1}(T)^3}.$$

Therefore, using the triangle inequality and the approximation properties (5a), valid as well for $\boldsymbol{\pi}_{\tau}^l$, with $(l, r, m, s) = (k, 2, 0, k+1)$ along with $h_{\tau} \leq h_T$, we infer

$$\|\mathbf{G}_{\mathfrak{I}_T}^l \mathbf{I}_T^k \mathbf{v} - \nabla \mathbf{v}\|_{L^2(T)^{3 \times 3}} \leq \|\mathbf{G}_{\mathfrak{I}_T}^l \mathbf{I}_T^k \mathbf{v} - \boldsymbol{\pi}_{\mathfrak{I}_T}^l \nabla \mathbf{v}\|_{L^2(T)^{3 \times 3}} + \|\boldsymbol{\pi}_{\mathfrak{I}_T}^l \nabla \mathbf{v} - \nabla \mathbf{v}\|_{L^2(T)^{3 \times 3}} \lesssim h_T^k |\mathbf{v}|_{H^{k+1}(T)^3}. \quad \square$$

3 Discrete problem

3.1 Viscous term and pressure-velocity coupling

The viscous term and the pressure-velocity coupling are the same as in the standard HHO method; see, e.g., [7, 22]. We briefly recall them here to make the exposition self-contained.

The viscous bilinear form $a_h: \underline{U}_h^k \times \underline{U}_h^k \rightarrow \mathbb{R}$ is such that, for all $\underline{w}_h, \underline{v}_h \in \underline{U}_h^k$,

$$a_h(\underline{w}_h, \underline{v}_h) := \sum_{T \in \mathcal{T}_h} \int_T \mathbf{G}_T^k \underline{w}_T : \mathbf{G}_T^k \underline{v}_T + \sum_{T \in \mathcal{T}_h} s_T(\underline{w}_T, \underline{v}_T),$$

where, for any $T \in \mathcal{T}_h$, $s_T: \underline{U}_T^k \times \underline{U}_T^k \rightarrow \mathbb{R}$ denotes a local stabilization bilinear form designed according to the principles of [15, Assumption 2.4], so that, in particular, there exists $C_a > 0$ independent of h (and, clearly, also of ν and λ) such that, for all $\underline{v}_h \in \underline{U}_h^k$,

$$C_a \|\underline{v}_h\|_{1,h}^2 \leq a_h(\underline{v}_h, \underline{v}_h) \leq C_a^{-1} \|\underline{v}_h\|_{1,h}^2. \quad (50)$$

Recalling the definition (10) of the local divergence D_T^k , the global pressure-velocity coupling bilinear form $b_h: \underline{U}_{h,0}^k \times \mathcal{P}^k(\mathcal{T}_h) \rightarrow \mathbb{R}$ is such that, for all $(\underline{v}_h, q_h) \in \underline{U}_{h,0}^k \times \mathcal{P}^k(\mathcal{T}_h)$,

$$b_h(\underline{v}_h, q_h) := - \sum_{T \in \mathcal{T}_h} \int_T D_T^k \underline{v}_T q_T,$$

where $q_T := q_h|_T$. The properties of b_h relevant for the analysis can be found in [15, Lemma 8.12].

3.2 Body force

The discretization of the body force leverages the new divergence-preserving velocity reconstruction introduced in Section 2.4. Specifically, we introduce the bilinear form $\ell_h: L^2(\Omega)^3 \times \underline{U}_h^k \rightarrow \mathbb{R}$ such that, for any $\boldsymbol{\phi} \in L^2(\Omega)^3$ and any $\underline{v}_h \in \underline{U}_h^k$,

$$\ell_h(\boldsymbol{\phi}, \underline{v}_h) := \int_{\Omega} \boldsymbol{\phi} \cdot \mathbf{R}_h^k \underline{v}_h.$$

Lemma 4 (Properties of ℓ_h). *The bilinear form ℓ_h has the following properties:*

(i) Velocity invariance. *Recalling the Hodge decomposition (2) of \mathbf{f} , it holds*

$$\ell_h(\mathbf{g} + \lambda \nabla \psi, \underline{v}_h) = \ell_h(\mathbf{g}, \underline{v}_h) + b_h(\underline{v}_h, \lambda \pi_h^k \psi) \quad \forall \underline{v}_h \in \underline{U}_{h,0}^k. \quad (51)$$

(ii) Consistency. *For $k \in \{0, 1\}$ and all $\boldsymbol{\phi} \in L^2(\Omega)^3 \cap H^k(\mathcal{T}_h)^3$,*

$$\|\mathcal{E}_{\ell,h}(\boldsymbol{\phi}; \cdot)\|_{1,h,*} \lesssim h^{k+1} |\boldsymbol{\phi}|_{H^k(\mathcal{T}_h)^3}, \quad (52)$$

where the linear form $\mathcal{E}_{\ell,h}(\boldsymbol{\phi}; \cdot): \underline{U}_h^k \rightarrow \mathbb{R}$, representing the consistency error, is such that

$$\mathcal{E}_{\ell,h}(\boldsymbol{\phi}; \underline{v}_h) := \ell_h(\boldsymbol{\phi}, \underline{v}_h) - \int_{\Omega} \boldsymbol{\phi} \cdot \mathbf{v}_h = \sum_{T \in \mathcal{T}_h} \int_T \boldsymbol{\phi} \cdot (\mathbf{R}_T^k \underline{v}_T - \mathbf{v}_T). \quad (53)$$

Proof. (i) *Velocity invariance.* The proof is the same as in [10, Section 4.3], using the fact that $(\nabla \cdot \mathbf{R}_h^k \underline{v}_h)|_T = D_T^k \underline{v}_T \in \mathcal{P}^k(T)$, which is enforced by (13b).

(ii) *Consistency.* We prove the cases $k = 0$ and $k = 1$ separately.

(ii.A) *The case $k = 0$.* Taking absolute values in (53) and using Cauchy–Schwarz inequalities along with (14) and $h_T \leq h$ for all $T \in \mathcal{T}_h$, we can write $|\mathcal{E}_{\ell,h}(\boldsymbol{\phi}; \underline{\mathbf{v}}_h)| \leq h \|\boldsymbol{\phi}\|_{L^2(\Omega)^3} \|\underline{\mathbf{v}}_T\|_{1,h}$. Passing to the supremum over $\underline{\mathbf{v}}_h \in \underline{\mathbf{U}}_h^k$ such that $\|\underline{\mathbf{v}}_h\|_{1,h} = 1$, we obtain (52).

(ii.B) *The case $k = 1$.* Using (16) in (53) and continuing with Cauchy–Schwarz inequalities, we obtain

$$|\mathcal{E}_{\ell,h}(\boldsymbol{\phi}; \underline{\mathbf{v}}_h)| = \left| \sum_{T \in \mathcal{T}_h} \int_T (\boldsymbol{\phi} - \boldsymbol{\pi}^0 \boldsymbol{\phi}) \cdot (\mathbf{R}_T^1 \underline{\mathbf{v}}_T - \mathbf{v}_T) \right| \leq \sum_{T \in \mathcal{T}_h} \|\boldsymbol{\phi} - \boldsymbol{\pi}^0 \boldsymbol{\phi}\|_{L^2(T)^3} \|\mathbf{R}_T^k \underline{\mathbf{v}}_T - \mathbf{v}_T\|_{L^2(T)^3}.$$

Using then the approximation properties (5a) of the L^2 -projector with $(l, m, r, s) = (0, 0, 2, 1)$ for the first factor and the bound (14) for the second, applying discrete Cauchy–Schwarz inequalities to the sums, and passing to the supremum over $\underline{\mathbf{v}}_h \in \underline{\mathbf{U}}_h^k$ such that $\|\underline{\mathbf{v}}_h\|_{1,h} = 1$, (52) follows. \square

Remark 5 (Role of the assumption on k). The proof of Point (ii.B) in Proposition 4 uses (16), which relies, in turn, on the fact that every function in $\mathcal{P}^0(T)^3$ can be written as the gradient of a function in $\mathcal{P}^1(T)$. This property no longer holds for higher polynomial degrees, hence the proof breaks down.

3.3 Convective term

To discretize the convective term, we introduce the global trilinear form $t_h : \underline{\mathbf{U}}_h^k \times \underline{\mathbf{U}}_h^k \times \underline{\mathbf{U}}_h^k \rightarrow \mathbb{R}$ such that

$$t_h(\underline{\mathbf{w}}_h, \underline{\mathbf{v}}_h, \underline{\mathbf{z}}_h) := \sum_{T \in \mathcal{T}_h} t_T(\underline{\mathbf{w}}_T, \underline{\mathbf{v}}_T, \underline{\mathbf{z}}_T), \quad (54a)$$

where, for any $T \in \mathcal{T}_h$, $t_T : \underline{\mathbf{U}}_T^k \times \underline{\mathbf{U}}_T^k \times \underline{\mathbf{U}}_T^k \rightarrow \mathbb{R}$ is defined as

$$t_T(\underline{\mathbf{w}}_T, \underline{\mathbf{v}}_T, \underline{\mathbf{z}}_T) := \int_T \mathbf{G}_{\underline{\mathbf{x}}_T}^{2(k+1)} \underline{\mathbf{w}}_T \mathbf{R}_T^k \underline{\mathbf{v}}_T \cdot \mathbf{R}_T^k \underline{\mathbf{z}}_T - \int_T \mathbf{G}_{\underline{\mathbf{x}}_T}^{2(k+1)} \underline{\mathbf{w}}_T \mathbf{R}_T^k \underline{\mathbf{z}}_T \cdot \mathbf{R}_T^k \underline{\mathbf{v}}_T. \quad (54b)$$

Remark 6 (Reformulation of t_h). In practice, it is not necessary to compute the piecewise gradient reconstruction operators $\mathbf{G}_{\underline{\mathbf{x}}_T}^{2(k+1)}$ to evaluate t_T and t_h . As a matter of fact, expanding the piecewise gradient operator in (54) according to its definition (43a), we have that

$$\begin{aligned} t_h(\underline{\mathbf{w}}_h, \underline{\mathbf{v}}_h, \underline{\mathbf{z}}_h) &= \sum_{T \in \mathcal{T}_h} \left[\int_T \nabla \underline{\mathbf{w}}_T \mathbf{R}_T^k \underline{\mathbf{v}}_T \cdot \mathbf{R}_T^k \underline{\mathbf{z}}_T - \int_T \nabla \underline{\mathbf{w}}_T \mathbf{R}_T^k \underline{\mathbf{z}}_T \cdot \mathbf{R}_T^k \underline{\mathbf{v}}_T \right] \\ &\quad + \sum_{T \in \mathcal{T}_h} \sum_{F \in \mathcal{F}_T} \int_F (\underline{\mathbf{w}}_F - \underline{\mathbf{w}}_T) \cdot \mathbf{R}_T^k \underline{\mathbf{z}}_T (\mathbf{R}_T^k \underline{\mathbf{v}}_T \cdot \mathbf{n}_{TF}) \\ &\quad - \sum_{T \in \mathcal{T}_h} \sum_{F \in \mathcal{F}_T} \int_F (\underline{\mathbf{w}}_F - \underline{\mathbf{w}}_T) \cdot \mathbf{R}_T^k \underline{\mathbf{v}}_T (\mathbf{R}_T^k \underline{\mathbf{z}}_T \cdot \mathbf{n}_{TF}). \end{aligned}$$

The properties of t_h relevant for the analysis are contained in the following lemma.

Lemma 7 (Properties of t_h). *The trilinear form t_h has the following properties:*

1. *Non-dissipativity. For all $\underline{\mathbf{w}}_h, \underline{\mathbf{v}}_h \in \underline{\mathbf{U}}_h^k$, it holds that*

$$t_h(\underline{\mathbf{w}}_h, \underline{\mathbf{v}}_h, \underline{\mathbf{v}}_h) = 0. \quad (55)$$

2. *Boundedness. There exists a real number $C_t > 0$ independent of h (and, clearly, also of ν and λ) such that, for all $\underline{\mathbf{w}}_h, \underline{\mathbf{v}}_h, \underline{\mathbf{z}}_h \in \underline{\mathbf{U}}_h^k$,*

$$|t_h(\underline{\mathbf{w}}_h, \underline{\mathbf{v}}_h, \underline{\mathbf{z}}_h)| \leq C_t \|\underline{\mathbf{w}}_h\|_{1,h} \|\underline{\mathbf{v}}_h\|_{1,h} \|\underline{\mathbf{z}}_h\|_{1,h}. \quad (56)$$

3. Consistency. It holds, for all $\mathbf{w} \in \mathbf{U} \cap W^{k+1,4}(\mathcal{T}_h)^3$ such that $\nabla \cdot \mathbf{w} = 0$ a.e. in Ω ,

$$\|\mathcal{E}_{t,h}(\mathbf{w}; \cdot)\|_{1,h,*} \lesssim h^{k+1} |\mathbf{w}|_{W^{k+1,4}(\mathcal{T}_h)^3} \|\mathbf{w}\|_{W^{1,4}(\Omega)^3}, \quad (57)$$

where the linear form $\mathcal{E}_{t,h}(\mathbf{w}; \cdot) : \underline{\mathbf{U}}_h^k \rightarrow \mathbb{R}$ representing the consistency error is such that, for all $\underline{\mathbf{z}}_h \in \underline{\mathbf{U}}_h^k$,

$$\mathcal{E}_{t,h}(\mathbf{w}; \underline{\mathbf{z}}_h) := \ell_h((\nabla \times \mathbf{w}) \times \mathbf{w}, \underline{\mathbf{z}}_h) - t_h(\underline{\mathbf{I}}_h^k \mathbf{w}, \underline{\mathbf{I}}_h^k \mathbf{w}, \underline{\mathbf{z}}_h).$$

Proof. (i) *Non-dissipativity.* Immediate consequence of the definition (54) of t_h .

(ii) *Boundedness.* The proof is similar as in [10, Lemma 7.ii] using the Hölder inequalities with exponent (2,4,4), the bound (44), and the discrete Sobolev embedding (38) with $r = 4$. The details are omitted for the sake of conciseness.

(iii) *Consistency.* Let $\hat{\mathbf{w}}_h := \underline{\mathbf{I}}_h^k \mathbf{w}$. Proceeding as in [10, Lemma 7.iii], we obtain the following decomposition:

$$\begin{aligned} \mathcal{E}_{t,h}(\mathbf{w}; \underline{\mathbf{z}}_h) &= \underbrace{\sum_{T \in \mathcal{T}_h} \int_T (\mathbf{G}_{\mathfrak{I}_T}^{2(k+1)} \hat{\mathbf{w}}_T - \nabla \mathbf{w}) \mathbf{R}_T^k \underline{\mathbf{z}}_T \cdot \mathbf{w}}_{\mathfrak{I}_1} + \underbrace{\sum_{T \in \mathcal{T}_h} \int_T (\nabla \mathbf{w} - \mathbf{G}_{\mathfrak{I}_T}^{2(k+1)} \hat{\mathbf{w}}_T) \mathbf{w} \cdot \mathbf{R}_T^k \underline{\mathbf{z}}_T}_{\mathfrak{I}_2} \\ &\quad + \underbrace{\sum_{T \in \mathcal{T}_h} \int_T \mathbf{G}_{\mathfrak{I}_T}^{2(k+1)} \hat{\mathbf{w}}_T (\mathbf{w} - \mathbf{R}_T^k \hat{\mathbf{w}}_T) \cdot \mathbf{R}_T^k \underline{\mathbf{z}}_T}_{\mathfrak{I}_3} + \underbrace{\sum_{T \in \mathcal{T}_h} \int_T \mathbf{G}_{\mathfrak{I}_T}^{2(k+1)} \hat{\mathbf{w}}_T \mathbf{R}_T^k \underline{\mathbf{z}}_T \cdot (\mathbf{R}_T^k \hat{\mathbf{w}}_T - \mathbf{w})}_{\mathfrak{I}_4}. \end{aligned} \quad (58)$$

We next proceed to estimate the terms $\mathfrak{I}_1, \dots, \mathfrak{I}_4$.

(iii.A) *Estimate of \mathfrak{I}_1 .* Following similar steps as in [10, Lemma 7.iii.A] along with the approximation properties (45) of $\mathbf{G}_{\mathfrak{I}_T}^{2(k+1)}$ and its definition (43), we get that

$$|\mathfrak{I}_1| \leq h^{k+1} |\mathbf{w}|_{H^{k+1}(\mathcal{T}_h)^3} \|\mathbf{w}\|_{W^{1,4}(\Omega)^3} \|\underline{\mathbf{z}}_h\|_{1,h}. \quad (59)$$

(iii.B) *Estimate of \mathfrak{I}_2 .* For the term \mathfrak{I}_2 in (58), inserting $\pm \pi_T^0 \mathbf{w}$ into the second factor, we get

$$\begin{aligned} \mathfrak{I}_2 &= \sum_{T \in \mathcal{T}_h} \int_T (\nabla \mathbf{w} - \mathbf{G}_{\mathfrak{I}_T}^{2(k+1)} \hat{\mathbf{w}}_T) (\mathbf{w} - \pi_T^0 \mathbf{w}) \cdot \mathbf{R}_T^k \underline{\mathbf{z}}_T + \sum_{T \in \mathcal{T}_h} \int_T (\nabla \mathbf{w} - \mathbf{G}_{\mathfrak{I}_T}^{2(k+1)} \hat{\mathbf{w}}_T) \pi_T^0 \mathbf{w} \cdot \mathbf{R}_T^k \underline{\mathbf{z}}_T \\ &=: \mathfrak{I}_{2,1} + \mathfrak{I}_{2,2}. \end{aligned} \quad (60)$$

We bound $\mathfrak{I}_{2,1}$ using Hölder inequalities with exponents (2, 4, 4), then the approximation properties (45) of $\mathbf{G}_{\mathfrak{I}_T}^{2(k+1)}$ and (5a) of π_T^0 with $(l, m, r, s) = (0, 0, 4, 1)$, and the bound (38) with $r = 4$:

$$|\mathfrak{I}_{2,1}| \lesssim h^{k+1} |\mathbf{w}|_{H^{k+1}(\mathcal{T}_h)^3} |\mathbf{w}|_{W^{1,4}(\Omega)^3} \|\underline{\mathbf{z}}_T\|_{1,h}. \quad (61)$$

To estimate $\mathfrak{I}_{2,2}$ in (60), we integrate by parts the term involving $\nabla \mathbf{w}$ and we use, for each element $T \in \mathcal{T}_h$, the definition (43b) of $\mathbf{G}_{\mathfrak{I}_T}^{2(k+1)}$ with $(\mathbf{v}_T, \boldsymbol{\tau}) = (\hat{\mathbf{w}}_T, \mathbf{R}_T^k \underline{\mathbf{z}}_T \otimes \pi_T^0 \mathbf{w})$ (notice that $\mathbf{R}_T^k \underline{\mathbf{z}}_T \otimes \pi_T^0 \mathbf{w} \in$

$\mathcal{P}^{k+1}(\mathfrak{T}_T)^{3 \times 3} \subset \mathcal{P}^{2(k+1)}(\mathfrak{T}_T)^{3 \times 3}$ to write

$$\begin{aligned}
\mathfrak{I}_{2,2} &= - \sum_{T \in \mathcal{T}_h} \sum_{\tau \in \mathfrak{I}_T} \int_{\tau} (\mathbf{w} - \boldsymbol{\pi}_T^k \mathbf{w}) \cdot \nabla \cdot (\mathbf{R}_T^k \underline{\mathbf{z}}_T \otimes \boldsymbol{\pi}_T^0 \mathbf{w}) \\
&\quad + \sum_{T \in \mathcal{T}_h} \sum_{\tau \in \mathfrak{I}_T} \sum_{\sigma \in \mathfrak{F}_T^i} \int_{\sigma} (\mathbf{w} - \boldsymbol{\pi}_T^k \mathbf{w}) \cdot \llbracket \mathbf{R}_T^k \underline{\mathbf{z}}_T \otimes \boldsymbol{\pi}_T^0 \mathbf{w} \rrbracket_{\sigma} \mathbf{n}_{\sigma} \\
&\quad + \sum_{T \in \mathcal{T}_h} \sum_{F \in \mathcal{F}_T} \int_F (\mathbf{w} - \boldsymbol{\pi}_F^k \mathbf{w}) \cdot (\mathbf{R}_T^k \underline{\mathbf{z}}_T \otimes \boldsymbol{\pi}_T^0 \mathbf{w}) \mathbf{n}_{TF}, \\
&=: \mathfrak{I}_{2,2,1} + \mathfrak{I}_{2,2,2} + \mathfrak{I}_{2,2,3}.
\end{aligned} \tag{62}$$

For $\mathfrak{I}_{2,2,1}$, we first observe that $\nabla \cdot (\mathbf{R}_T^k \underline{\mathbf{z}}_T \otimes \boldsymbol{\pi}_T^0 \mathbf{w}) = \nabla \mathbf{R}_T^k \underline{\mathbf{z}}_T \boldsymbol{\pi}_T^0 \mathbf{w} + \mathbf{R}_T^k \underline{\mathbf{z}}_T (\nabla \cdot \boldsymbol{\pi}_T^0 \mathbf{w}) \in \mathcal{P}^k(\mathfrak{T}_T)^3$. Hence, using Hölder inequalities with exponents $(4, 2, 4)$, we infer that

$$\begin{aligned}
|\mathfrak{I}_{2,2,1}| &\leq \sum_{T \in \mathcal{T}_h} \sum_{\tau \in \mathfrak{I}_T} \|\mathbf{w} - \boldsymbol{\pi}_T^k \mathbf{w}\|_{L^4(\tau)^3} \|\nabla \mathbf{R}_T^k \underline{\mathbf{z}}_T\|_{L^2(\tau)^{3 \times 3}} \|\boldsymbol{\pi}_T^0 \mathbf{w}\|_{L^4(\tau)^3} \\
&\leq \sum_{T \in \mathcal{T}_h} \|\mathbf{w} - \boldsymbol{\pi}_T^k \mathbf{w}\|_{L^4(T)^3} \|\boldsymbol{\pi}_T^0 \mathbf{w}\|_{L^4(T)^3} \sum_{\tau \in \mathfrak{I}_T} \|\nabla \mathbf{R}_T^k \underline{\mathbf{z}}_T\|_{L^2(\tau)^{3 \times 3}} \\
&\lesssim \sum_{T \in \mathcal{T}_h} h_T^{k+1} |\mathbf{w}|_{W^{k+1,4}(T)^3} \|\mathbf{w}\|_{W^{1,4}(T)^3} \sum_{\tau \in \mathfrak{I}_T} \|\nabla \mathbf{R}_T^k \underline{\mathbf{z}}_T\|_{L^2(\tau)^{3 \times 3}},
\end{aligned} \tag{63}$$

where in the second step we have used the fact that $\tau \subset T$ for all $\tau \in \mathfrak{I}_T$, while, in the third step, we have used the approximation properties (5a) of the L^2 -orthogonal projector with $(l, m, r, s) = (k, 0, 4, k+1)$ for the first factor and its boundedness for the second factor. To bound $\|\nabla \mathbf{R}_T^k \underline{\mathbf{z}}_T\|_{L^2(\tau)^{3 \times 3}}$, we first observe that $(\mathbf{R}_T^k \underline{\mathbf{z}}_T)|_{\tau}$ is in the space $\mathcal{P}^{k+1}(\tau)^3$, and it holds that

$$\begin{aligned}
\|\nabla \mathbf{R}_T^k \underline{\mathbf{z}}_T\|_{L^2(\tau)^{3 \times 3}} &\leq \|\nabla(\mathbf{R}_T^k \underline{\mathbf{z}}_T - \mathbf{z}_T)\|_{L^2(\tau)^3} + \|\nabla \mathbf{z}_T\|_{L^2(\tau)^3} \\
&\lesssim h_{\tau}^{-1} \|\mathbf{R}_T^k \underline{\mathbf{z}}_T - \mathbf{z}_T\|_{L^2(\tau)^3} + \|\nabla \mathbf{z}_T\|_{L^2(\tau)^3} \\
&\lesssim h_{\tau}^{-1} \|\mathbf{R}_T^k \underline{\mathbf{z}}_T - \mathbf{z}_T\|_{L^2(T)^3} + \|\nabla \mathbf{z}_T\|_{L^2(T)^3} \\
&\lesssim h_{\tau}^{-1} h_T |\underline{\mathbf{z}}_T|_{1, \partial T} + \|\nabla \mathbf{z}_T\|_{L^2(T)^3} \lesssim \|\underline{\mathbf{z}}_T\|_{1, T},
\end{aligned}$$

where we have started with a triangle inequality after inserting $\pm \nabla \mathbf{z}_T$, used a local discrete inverse inequality on τ in the second step, the fact that $\tau \subset T$ for all $\tau \in \mathfrak{I}_T$ in the third step, the bound (14) in the fourth step, and the inequality $h_{\tau}^{-1} h_T \lesssim 1$ valid for regular mesh sequences (see [15, Eq. (1.4)]), along with the definition (7) of the $\|\cdot\|_{1, T}$ -norm to conclude. Plugging this last inequality into (63) and using the geometric bound (3) along with a discrete Hölder inequality, we arrive at

$$|\mathfrak{I}_{2,2,1}| \lesssim h^{k+1} |\mathbf{w}|_{W^{k+1,4}(\mathcal{T}_h)^3} \|\mathbf{w}\|_{W^{1,4}(\Omega)^3} \|\underline{\mathbf{z}}_h\|_{1, h}. \tag{64}$$

To estimate $\mathfrak{I}_{2,2,2}$ in (62), we insert $\pm \mathbf{z}_T$ into the first factor inside the jump operator to write

$$\begin{aligned}
\mathfrak{I}_{2,2,2} &= \sum_{T \in \mathcal{T}_h} \sum_{\tau \in \mathfrak{I}_T} \sum_{\sigma \in \mathfrak{F}_T^i} \int_{\sigma} (\mathbf{w} - \boldsymbol{\pi}_T^k \mathbf{w}) \cdot \llbracket (\mathbf{R}_T^k \underline{\mathbf{z}}_T - \mathbf{z}_T) \otimes \boldsymbol{\pi}_T^0 \mathbf{w} \rrbracket_{\sigma} \mathbf{n}_{\sigma} \\
&\quad - \sum_{T \in \mathcal{T}_h} \sum_{\tau \in \mathfrak{I}_T} \sum_{\sigma \in \mathfrak{F}_T^i} \int_{\sigma} (\mathbf{w} - \boldsymbol{\pi}_T^k \mathbf{w}) \cdot \llbracket \mathbf{z}_T \otimes \boldsymbol{\pi}_T^0 \mathbf{w} \rrbracket_{\sigma} \mathbf{n}_{\sigma},
\end{aligned}$$

where the second addend cancels since $\mathbf{z}_T \otimes \boldsymbol{\pi}_T^0$ is continuous across the interior faces of \mathfrak{I}_T . Setting $\mathfrak{F}_h^i := \{\sigma \in \mathfrak{F}_T^i : T \in \mathcal{T}_h\}$ and exchanging the order of the sums, we can now express $\mathfrak{I}_{2,2,2}$ in the

following equivalent form:

$$\mathfrak{I}_{2,2,2} = \sum_{\sigma \in \mathfrak{F}_h^i} \sum_{i=1}^2 \int_{\sigma} (\mathbf{w} - \pi_T^k \mathbf{w}) \cdot [(\mathbf{R}_T^k \underline{z}_T - z_T) \otimes \pi_T^0 \mathbf{w}]|_{\tau_i} \mathbf{n}_{\tau_i \sigma}, \quad (65)$$

where, for a given $\sigma \in \mathfrak{F}_h^i$, τ_1 and τ_2 denote the simplices sharing σ . To bound the right-hand side of the above expression, we apply Hölder inequalities with exponents $(4, 2, 4, \infty)$ along with $\|\mathbf{n}_{\tau \sigma}\|_{L^\infty(\sigma)^3} = 1$ to write

$$\begin{aligned} |\mathfrak{I}_{2,2,2}| &\leq \sum_{\sigma \in \mathfrak{F}_h^i} \sum_{i=1}^2 \|\mathbf{w} - \pi_T^k \mathbf{w}\|_{L^4(\sigma)^3} \|(\mathbf{R}_T^k \underline{z}_T)|_{\tau_i} - z_T\|_{L^2(\sigma)^3} \|\pi_T^0 \mathbf{w}\|_{L^4(\sigma)^3} \\ &\lesssim \sum_{\sigma \in \mathfrak{F}_h^i} \sum_{i=1}^2 \|\mathbf{w} - \pi_T^k \mathbf{w}\|_{L^4(\sigma)^3} h_{\tau_i}^{-\frac{1}{2}} \|\mathbf{R}_T^k \underline{z}_T - z_T\|_{L^2(\tau_i)^3} h_{\tau_i}^{-\frac{1}{4}} \|\pi_T^0 \mathbf{w}\|_{L^4(\tau_i)^3} \\ &\lesssim \sum_{\sigma \in \mathfrak{F}_h^i} \left(h_T^{\frac{1}{4}} \|\mathbf{w} - \pi_T^k \mathbf{w}\|_{L^4(\sigma)^3} \right) \|\underline{z}_T\|_{1,T} \|\mathbf{w}\|_{W^{1,4}(T)^3}, \end{aligned} \quad (66)$$

where, in the second step, we have used local trace inequalities on the submesh for the second and third factors while, in the third step, we have used $\tau \subset T$ along with (14), (7), and $h_{\tau_i}^{-1} h_T \lesssim 1$ (consequence of mesh regularity) for the second factor while, for the third factor, we have used again $\tau \subset T$ along with the boundedness of the L^2 -orthogonal projector. Using trace inequalities on the submesh along with the approximation properties of the L^2 -orthogonal projector, we infer $h_T^{\frac{1}{4}} \|\mathbf{w} - \pi_T^k \mathbf{w}\|_{L^4(\sigma)^3} \lesssim h_T^{k+1} |\mathbf{w}|_{W^{k+1,4}(T)^3}$ which, plugged into (66) and combined with the geometric bound (3), gives

$$|\mathfrak{I}_{2,2,2}| \lesssim h^{k+1} |\mathbf{w}|_{W^{k+1,4}(\mathcal{T}_h)^3} \|\mathbf{w}\|_{W^{1,4}(\Omega)^3} \|\underline{z}_h\|_{1,h}. \quad (67)$$

To bound the term $\mathfrak{I}_{2,2,3}$ in (62), we first insert $\pm z_T$ into its second factor to write

$$\begin{aligned} \mathfrak{I}_{2,2,3} &= \sum_{T \in \mathcal{T}_h} \sum_{F \in \mathcal{F}_T} \int_F (\mathbf{w} - \pi_F^k \mathbf{w}) \cdot [(\mathbf{R}_T^k \underline{z}_T - z_T) \otimes \pi_T^0 \mathbf{w}] \mathbf{n}_{TF} \\ &\quad + \sum_{T \in \mathcal{T}_h} \sum_{F \in \mathcal{F}_T} \int_F \cancel{(\mathbf{w} - \pi_F^k \mathbf{w}) \cdot (z_T \otimes \pi_T^0 \mathbf{w})} \mathbf{n}_{TF}, \end{aligned}$$

where the second addend cancels by the definition (4) of the L^2 -orthogonal projector π_F^k since $(z_T \otimes \pi_T^0)|_F \mathbf{n}_{TF} \in \mathcal{P}^k(F)^3$. Now, we rewrite the equation above as

$$\mathfrak{I}_{2,2,3} = \sum_{T \in \mathcal{T}_h} \sum_{F \in \mathcal{F}_T} \sum_{\sigma \in \mathfrak{F}_F} \int_{\sigma} (\mathbf{w} - \pi_F^k \mathbf{w}) \cdot [(\mathbf{R}_T^k \underline{z}_T - z_T) \otimes \pi_T^0 \mathbf{w}] \mathbf{n}_{TF},$$

thus, using a similiary procedure as for (65)–(66), but for $\sigma \in \mathfrak{F}_F$ and $\tau_i = \tau_\sigma$ where $\tau_\sigma \in \mathcal{T}$ is the simplicial subelement containing σ , we infer that

$$|\mathfrak{I}_{2,2,3}| \lesssim \sum_{T \in \mathcal{T}_h} \sum_{F \in \mathcal{F}_T} \sum_{\sigma \in \mathfrak{F}_F} \left(h_T^{\frac{1}{4}} \|\mathbf{w} - \pi_F^k \mathbf{w}\|_{L^4(\sigma)^3} \right) \|\underline{z}_T\|_{1,T} \|\mathbf{w}\|_{W^{1,4}(T)^3},$$

in addition, using the fact that

$$\begin{aligned}
\|\mathbf{w} - \pi_F^k \mathbf{w}\|_{L^4(\sigma)^3} &\leq \|\mathbf{w} - \pi_F^k \mathbf{w}\|_{L^4(F)^3} \\
&\leq \|\pi_T^k \mathbf{w} - \pi_F^k \mathbf{w}\|_{L^4(F)^3} + \|\mathbf{w} - \pi_T^k \mathbf{w}\|_{L^4(F)^3} \\
&\leq \|\pi_F^k (\pi_T^k \mathbf{w} - \mathbf{w})\|_{L^4(F)^3} + \|\mathbf{w} - \pi_T^k \mathbf{w}\|_{L^4(F)^3} \lesssim \|\mathbf{w} - \pi_T^k \mathbf{w}\|_{L^4(F)^3},
\end{aligned}$$

the approximation properties (5b) of the L^2 -orthogonal projector with $(l, m, r, s) = (k, 0, 4, k + 1)$, and the bound (3), we obtain

$$|\mathfrak{I}_{2,2,3}| \lesssim h^{k+1} |\mathbf{w}|_{W^{k+1,4}(\mathcal{T}_h)^3} \|\mathbf{w}\|_{W^{1,4}(\Omega)^3} \|\underline{\mathbf{z}}_h\|_{1,h}. \quad (68)$$

Plugging the estimates (64), (67), and (68) into (62), we conclude that

$$|\mathfrak{I}_{2,2}| \lesssim h^{k+1} |\mathbf{w}|_{W^{k+1,4}(\mathcal{T}_h)^3} \|\mathbf{w}\|_{W^{1,4}(\Omega)^3} \|\underline{\mathbf{z}}_h\|_{1,h},$$

which, combined with (61), finally gives

$$|\mathfrak{I}_2| \lesssim h^{k+1} |\mathbf{w}|_{W^{k+1,4}(\mathcal{T}_h)^3} \|\mathbf{w}\|_{W^{1,4}(\Omega)^3} \|\underline{\mathbf{z}}_h\|_{1,h}. \quad (69)$$

(iii.C) Estimate of \mathfrak{I}_3 and \mathfrak{I}_4 . To bound \mathfrak{I}_3 , we follow the same steps as in [10, Lemma 7.iii.C] along with the boundedness (44) of $\mathbf{G}_{\mathfrak{I}_T}^{2(k+1)}$ to obtain

$$|\mathfrak{I}_3| \lesssim |\mathbf{w}|_{H^1(\Omega)^3} \left(\sum_{T \in \mathcal{T}_h} \|\mathbf{w} - \mathbf{R}_T^k \hat{\mathbf{w}}_T\|_{L^4(T)^3}^4 \right)^{\frac{1}{4}} \|\underline{\mathbf{z}}_h\|_{1,h}.$$

To estimate the addends in the second factor, we first insert $\pm \pi_T^k \mathbf{w}$ and then use a triangle inequality to write

$$\begin{aligned}
\|\mathbf{w} - \mathbf{R}_T^k \hat{\mathbf{w}}_T\|_{L^4(T)^3} &\leq \|\mathbf{w} - \pi_T^k \mathbf{w}\|_{L^4(T)^3} + \|\pi_T^k \mathbf{w} - \mathbf{R}_T^k \hat{\mathbf{w}}_T\|_{L^4(T)^3} \\
&\lesssim h_T^{k+1} |\mathbf{w}|_{W^{k+1,4}(T)^3} + \|\pi_T^k \mathbf{w} - \mathbf{R}_T^k \hat{\mathbf{w}}_T\|_{L^4(T)^3},
\end{aligned} \quad (70)$$

where we have used the approximation properties (5a) of π_T^k with $(l, m, r, s) = (k, 0, 4, k + 1)$ to conclude. To estimate the second term in the right-hand side of (70), we proceed as follows:

$$\begin{aligned}
\|\pi_T^k \mathbf{w} - \mathbf{R}_T^k \hat{\mathbf{w}}_T\|_{L^4(T)^3}^4 &= \sum_{\tau \in \mathfrak{I}_T} \|\pi_T^k \mathbf{w} - \mathbf{R}_T^k \hat{\mathbf{w}}_T\|_{L^4(\tau)^3}^4 \\
&\lesssim \sum_{\tau \in \mathfrak{I}_T} \left(h_\tau^{-\frac{3}{4}} \|\pi_T^k \mathbf{w} - \mathbf{R}_T^k \hat{\mathbf{w}}_T\|_{L^2(\tau)^3} \right)^4 \\
&\leq \sum_{\tau \in \mathfrak{I}_T} h_\tau^{-3} \left(\|\pi_T^k \mathbf{w} - \mathbf{w}\|_{L^2(T)^3} + \|\mathbf{w} - \mathbf{R}_T^k \hat{\mathbf{w}}_T\|_{L^2(T)^3} \right)^4 \\
&\lesssim \sum_{\tau \in \mathfrak{I}_T} h_\tau^{-3} h_T^{4(k+1)} |\mathbf{w}|_{H^{k+1}(T)^3}^4 \lesssim h_T^{4(k+1)} |\mathbf{w}|_{W^{k+1,4}(T)^3}^4,
\end{aligned}$$

where: to pass to the second line we have used the reverse Lebesgue embedding (40) for $(X, \alpha, \beta) = (T, 4, 2)$; to pass to the third line, we have inserted $\pm \mathbf{w}$ and used a triangle inequality along with $\tau \subset T$; to pass to the fourth line, we have used the approximation properties (5a) of the L^2 -orthogonal projector with $(l, m, r, s) = (k, 0, 2, k + 1)$ for the first addend and the approximation property

(15) along with the assumption $\nabla \cdot \mathbf{w} = 0$ a.e in T for the second addend; the conclusion follows from $h_T^{-1} h_T \lesssim 1$ (consequence of mesh regularity), the bound (3), and the Lebesgue embedding $\|\zeta\|_{L^2(T)} \lesssim h_T^{\frac{3}{4}} \|\zeta\|_{L^4(T)}$ valid for all $\zeta \in L^4(T)$. Plugging the above bound into (70), we get

$$\|\mathbf{w} - \mathbf{R}_T^k \hat{\mathbf{w}}_T\|_{L^4(T)^3} \lesssim h_T^{k+1} |\mathbf{w}|_{W^{k+1,4}(T)^3}.$$

In conclusion, we have that

$$|\mathfrak{I}_3| \lesssim h^{k+1} |\mathbf{w}|_{H^1(\Omega)^3} |\mathbf{w}|_{W^{k+1,4}(\mathcal{T}_h)^3} \|\underline{\mathbf{z}}_h\|_{1,h}. \quad (71)$$

Using similar arguments as for \mathfrak{I}_3 , we have for the last term

$$|\mathfrak{I}_4| \lesssim h^{k+1} |\mathbf{w}|_{H^1(\Omega)^3} |\mathbf{w}|_{W^{k+1,4}(\mathcal{T}_h)^3} \|\underline{\mathbf{z}}_h\|_{1,h}. \quad (72)$$

(iv.D) *Conclusion.* Taking absolute values in (58), recalling the definition (9) of the dual norm, and using the estimates (59), (69), (71), and (72), and additionally noticing that $|\mathbf{w}|_{H^1(\Omega)^3} \lesssim |\mathbf{w}|_{W^{1,4}(\Omega)^3}$, the conclusion follows. \square

3.4 Discrete problem and main results

The HHO discretization of problem (1) reads: Find $(\underline{\mathbf{u}}_h, p_h) \in \underline{\mathbf{U}}_{h,0}^k \times P_h^k$ such that

$$va_h(\underline{\mathbf{u}}_h, \underline{\mathbf{v}}_h) + t_h(\underline{\mathbf{u}}_h, \underline{\mathbf{u}}_h, \underline{\mathbf{v}}_h) + b_h(\underline{\mathbf{v}}_h, p_h) = \ell_h(\mathbf{f}, \underline{\mathbf{v}}_h) \quad \forall \underline{\mathbf{v}}_h \in \underline{\mathbf{U}}_{h,0}, \quad (73a)$$

$$-b_h(\underline{\mathbf{u}}_h, q_h) = 0 \quad \forall q_h \in \mathbb{P}^k(\mathcal{T}_h). \quad (73b)$$

The existence of a solution to (73) for any $\mathbf{f} \in L^2(\Omega)^3$ can be proved using a topological degree argument as in [22, Theorem 1]. Similarly, uniqueness can be proved along the lines of Theorem 2 therein under a smallness condition on \mathbf{f} .

Recalling the Hodge decomposition (2) and denoting by C_P a Poincaré constant in Ω , Proposition 8 below is the discrete equivalent of the a priori continuous bound (see [10, Section 2.3])

$$|\mathbf{u}|_{H^1(\Omega)^3} \leq \nu^{-1} C_P \|\mathbf{g}\|_{L^2(\Omega)^3}. \quad (74)$$

Proposition 8 (Uniform a priori bound on the discrete velocity). *Let $(\underline{\mathbf{u}}_h, p_h) \in \underline{\mathbf{U}}_{h,0}^k \times P_h^k$ be a solution to (73). Then, given the Hodge decomposition (2) of \mathbf{f} , we have the following uniform a priori bound for the velocity:*

$$\|\underline{\mathbf{u}}_h\|_{1,h} \lesssim \nu^{-1} \|\mathbf{g}\|_{L^2(\Omega)^3}.$$

Proof. The proof follows the same reasoning as [10, Proposition 8] with Lemmas 4 and 7 replacing, respectively, [10, Eqs. (41)–(42) and Lemma 7]. \square

Remark 9 (Efficient implementation). When solving the algebraic problem corresponding to (73) by a first order iterative algorithm, all element-based velocity unknowns and all but one pressure unknowns per element can be statically condensed at each iteration in the spirit of [19, Section 6.2].

Remark 10 (The two-dimensional case). The two-dimensional version of the method (73) will be considered numerically in Section 4. Denoting by u_i , $i = 1, \dots, 3$, the component of the velocity field along the Cartesian axis x_i , the two-dimensional plane velocity problem can be recovered from (1) setting $u_3 = 0$ and assuming that u_1 and u_2 do not depend on x_3 .

We next consider the discretization error defined as the difference between the solution to the HHO scheme and the interpolate of the exact solution. Specifically, the following theorem contains a pressure-robust estimate for $k \in \{0, 1\}$, for which (52) has been established (see Remark 5). The extension to higher-order versions of the method remains an open problem.

Theorem 11 (Error estimate for small data). *Recalling the Hodge decomposition (2) of the forcing term \mathbf{f} , we assume that it holds, for some $\alpha \in (0, 1)$,*

$$\|\mathbf{g}\|_{L^2(\Omega)^3} \leq \alpha \frac{\nu^2 C_a}{C_t C_I C_P},$$

where C_a and C_t are defined in (50) and (56), while C_I denotes the continuity constant of the HHO interpolator in the discrete H^1 -like norm (see [15, Proposition 2.2]) and C_P is the Poincaré constant in (74). Let $k \in \{0, 1\}$ and let $(\mathbf{u}, p) \in \mathbf{U} \times P$ and $(\underline{\mathbf{u}}_h, p_h) \in \underline{\mathbf{U}}_h^k \times P_h^k$ solve (1) and (73), respectively. Assuming the additional regularity $\mathbf{u} \in H^{k+2}(\mathcal{T}_h)^3$ and $p \in H^1(\Omega) \cap H^{k+1}(\mathcal{T}_h)$, it holds:

$$\begin{aligned} \|\underline{\mathbf{u}}_h - \underline{\mathbf{I}}_h^k \mathbf{u}\|_{1,h} + \nu^{-1} \|p_h - \pi_h^k p\|_{L^2(\Omega)} \\ \lesssim h^{k+1} (1 - \alpha)^{-1} \left(\|\mathbf{u}\|_{H^{k+2}(\mathcal{T}_h)^3} + \nu^{-1} \|\mathbf{u}\|_{W^{1,4}(\Omega)^3} \|\mathbf{u}\|_{W^{k+1,4}(\mathcal{T}_h)^3} \right). \end{aligned} \quad (75)$$

where the hidden constant is independent of ν , λ , h , as well as (\mathbf{u}, p) .

Proof. Analogous to that of [10, Theorem 11] up to the same substitutions as in Proposition 8. \square

Remark 12 (Pressure robustness). The error estimate (75) is pressure-robust since the right-hand side does not depend on λ in (2) nor on the pressure.

4 Numerical tests

In this section we verify numerically the proposed method for general meshes with convex elements for $\Omega \subset \mathbb{R}^2$. For each element $T \in \mathcal{T}_h$, we construct its simplicial submesh \mathfrak{T}_T in such a way that no additional internal nodes are introduced and that $\mathfrak{T}_T = \mathcal{F}_T$. For the sake of completeness, we also include comparisons with the original HHO method of [7]. Our implementation is based on the HARDCore library¹ and makes extensive use of the linear algebra Eigen open-source library [29]. All the steady-state computations presented hereafter are done by means of the pseudo-transient-continuation algorithm analyzed by [31] employing the Selective Evolution Relaxation (SER) strategy [39] for evolving the pseudo-time step according to the Newton's equations residual. Convergence to steady-state is achieved when the Euclidean norm of the residual for the momentum equation drops below 10^{-11} . At each pseudo-time step, the linearized equations are exactly solved by means of the direct solver Pardiso [43]. Accordingly, the Euclidean norm of the residual for the continuity equation is comparable to the machine epsilon at all pseudo-time steps.

4.1 Kovasznay flow

We start by assessing the convergence properties of the method using the well known analytical solution of Kovasznay [33] with $\nu = 0.025$; see [15, Section 6.1] for the expression of the velocity and pressure fields. We consider computations over three h -refined mesh families (Cartesian, hexagonal and Kershaw type). The Figure 2 shows the coarsest mesh for each family. We monitor the following quantities in Table 3: N_{dof} and N_{nz} denoting, respectively, the number of discrete unknowns and nonzero entries of the statically condensed linearized problem; $\|\underline{\mathbf{e}}_h\|_{\nu,h} := [\nu a_h(\underline{\mathbf{e}}_h, \underline{\mathbf{e}}_h)]^{1/2}$, the energy norm of the error $\underline{\mathbf{e}}_h := \underline{\mathbf{u}}_h - \underline{\mathbf{I}}_h^k \mathbf{u}$ on the velocity (using the global norm equivalence (50), an estimate in h^{k+1} for this quantity is readily inferred from (75)); $\|\mathbf{e}_h\|_{L^2(\Omega)^2}$ and $\|\epsilon_h\|_{L^2(\Omega)}$, the

¹<https://github.com/jdroniou/HARDCore>

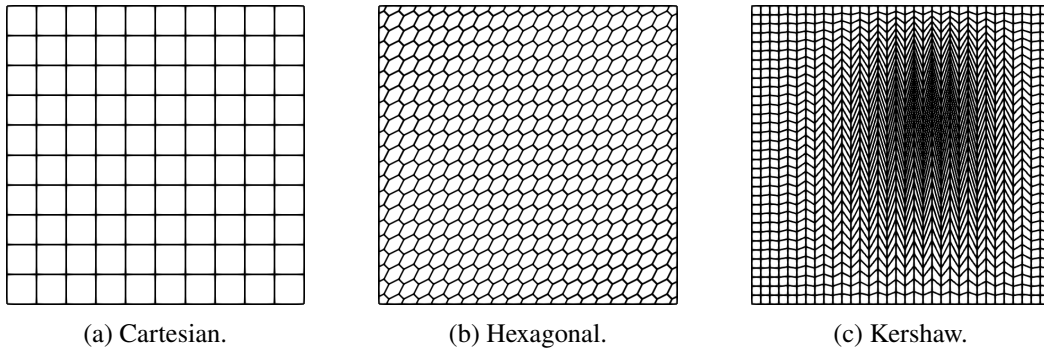

Figure 2: Coarsest meshes used in Section 4.1.

L^2 -errors on the velocity and the pressure, respectively. Each error measure is accompanied by the corresponding Estimated Order of Convergence (EOC) computed using successive refinement steps. The results collected in Table 3 show that both the energy norm of the error on the velocity and the L^2 -norm of error on the pressure converge as h^{k+1} as expected. Additionally, the L^2 -norm of the error of the velocity converges with rates close to h^{k+2} .

[Table 1 about here.]

4.2 Robustness of the velocity error estimate

The second numerical example, inspired by [36, Benchmark 3.3], is meant to demonstrate the robustness of the proposed method for large irrotational body forces. Specifically, we verify numerically the fact that the approximation of the velocity is independent of both λ and p . Letting $\Omega = (0, 1)^2$ and $\lambda \geq 0$, we solve the Dirichlet problem corresponding to the exact solution (\mathbf{u}, p) in (1) with velocity components given by $\mathbf{u}(\mathbf{x}) := \begin{pmatrix} -x_2 \\ x_1 \end{pmatrix}$ and pressure given by $p(\mathbf{x}) := \lambda x_1^3 + \frac{x_1^2 + x_2^2}{2} - \frac{1}{4}$. We set $\nu = 1$,

then observe that the force in (1a) is purely irrotational, i.e., $\mathbf{f}(\mathbf{x}) = \begin{pmatrix} 3\lambda x_1^2 \\ 0 \end{pmatrix}$. In the computations, we take $\lambda = 10^6$ and consider a sequence of uniformly h -refined meshes equivalent (by scaling and translation) to the three mesh families used in the previous section, see Figure 2. Table 1 collects the results for the Cartesian and hexagonal mesh families, and Table 2 for the Kershaw mesh family. For the sake of comparison, we also report in these tables the corresponding results obtained using the original HHO method of [7]. It can be noticed that the solution is exactly reproduced by the present method with $k = 1$ on all the meshes, while a quick convergence is observed for $k = 0$ on the hexagonal and Kershaw meshes, most likely due to the quadratic nature of the pressure. By contrast, the HHO method of [7] shows large errors on the velocity due to the lack of pressure-robustness.

4.3 Two-dimensional lid-driven cavity flow

The final numerical test is the classical two-dimensional lid-driven cavity problem. The computational domain is the unit square $\Omega = (0, 1)^2$ and we initially set $\mathbf{f} = \mathbf{0}$. Homogeneous (wall) boundary conditions are enforced at all but the top horizontal wall (at $x_2 = 1$), where we enforce a unit tangential velocity $\mathbf{u} = (1, 0)$ instead. In Figure 3 we report the horizontal component u_1 of the velocity along the vertical centerline $x_1 = \frac{1}{2}$ and the vertical component u_2 of the velocity along the horizontal centerline $x_2 = \frac{1}{2}$ for a global Reynolds number $\text{Re} := \frac{1}{\nu} = 1000$. The computation is carried out setting $k = 1$ for the finest meshes of the Cartesian, hexagonal, and Kershaw sequences used in the previous section. Reference solutions from the literature [23, 27] are also included for the sake of

Table 2: Convergence rates for the numerical test of Section 4.2 for $\lambda = 10^6$ using the Kershaw mesh family.

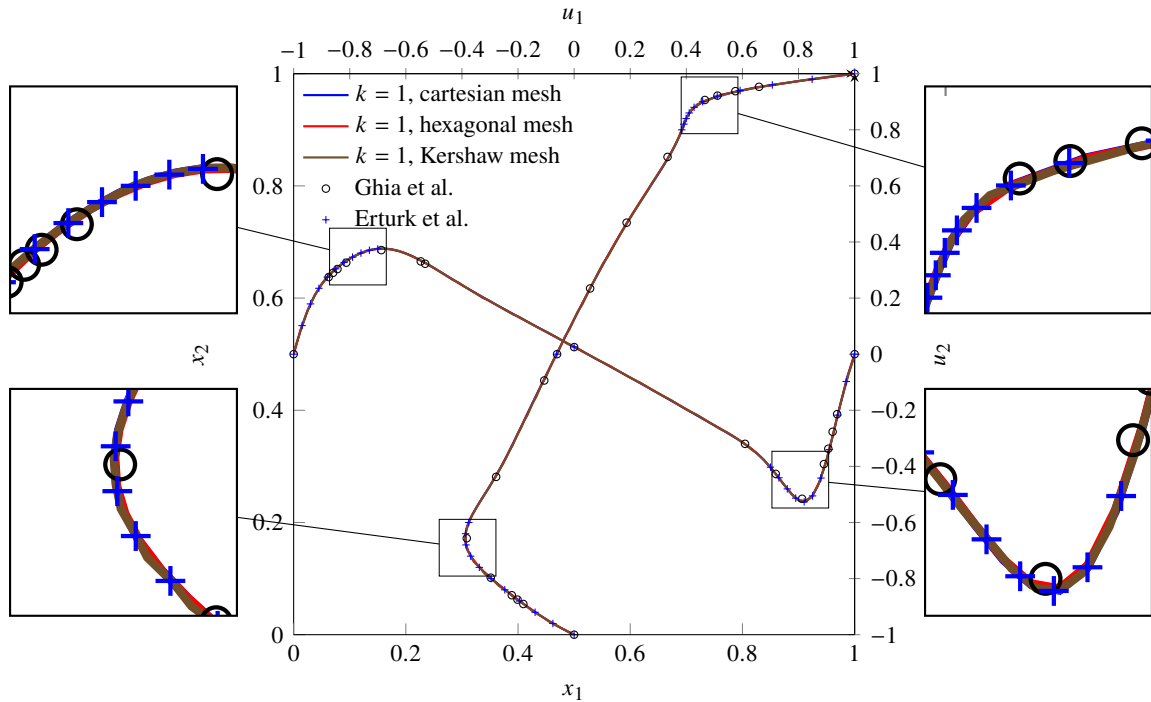

Figure 3: Two-dimensional lid-driven cavity flow, horizontal component u_1 of the velocity along the vertical centerline $x_1 = \frac{1}{2}$ and the vertical component u_2 of the velocity along the horizontal centerline $x_2 = \frac{1}{2}$ for $\text{Re} = 1,000$.

comparison. The numerical solution obtained using the proposed method is in agreement with the reference results for both values of the Reynolds number.

To check the robustness of the method with respect to irrotational body forces, we then run the same test case but with $\mathbf{f} = \lambda \nabla \psi$ where $\psi = \frac{1}{3}(x^3 + y^3)$. This body force is completely irrotational, so the velocity approximation obtained using the proposed method (73) should not be affected (and, therefore, should not depend on λ). To verify this, we report in Figure 4 computations for $\lambda = 10^6$, using $k = 1$ and the same meshes as before. As expected, the velocity profiles are not affected by the value of λ . The same plot also contains the results obtained with the original HHO formulation of [7], but only for the Cartesian mesh and $\lambda = 10^3$ (convergence was not achieved for $\lambda = 10^6$). It can be checked that the non-pressure-robust version of the method converges to a complete different solution.
