HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

LETTER TO THE EDITOR

Rare mutations in DNMT3A in myeloproliferative neoplasms and myelodysplastic syndromes

Blood Cancer Journal (2011), e18; doi:10.1038/bcj.2011.15;
published online 13 May 2011;

Alterations of epigenetic marks are thought to play an important role in myeloid malignancies. In particular, aberrant DNA methylation is a hallmark of these diseases. DNMT3A and DNMT3B methyltransferases have predominant role in *de novo* methylation of DNA. Mutations in DNMT3A have been found in roughly 20% of acute myeloid leukemia (AML).^{1–3} The precise mechanism by which DNMT3A may affect DNA methylation is not known. The *TET2* gene encodes an enzyme that favors the transformation of 5-methylcytosines in 5-hydroxymethylcytosines. *TET2* function requires alpha-ketoglutarate (α KG). *TET2* is frequently mutated in myeloid diseases. Mutation in *IDH1* and *IDH2* changes their enzymatic activity and induces an hypermethylation of AML DNA.³ Mutated *IDH1/2* enzymes catalyze α KG into 2-hydroxyglutarate (2HG). Production of 2HG impairs *TET2* function. This explains why mutations in *TET2* and in *IDH1/2* are mutually exclusive.⁴ In contrast, mutations in *IDH1/2* are more frequent in AML cases with DNMT3A mutations.²

We searched for mutations and deletions of *DNMT3A*, *TET2* and *IDH1/2* in a series of 201 chronic myeloid diseases including 135 myeloproliferative neoplasms (MPNs) and 66 myelodysplastic syndromes (MDSs). The MPN cases comprised 33 polycythemia vera (PV) and 5 post-PV myelofibrosis (MF), 56 essential thrombocythemia (ET) and 10 post-ET MF, 25 primary myelofibrosis (PMF), 3 MPN-unclassifiable and 3 MDS/MPN cases. The MDSs comprised 5 refractory anemia (RA), 13 RA with ring sideroblasts (RARS), 7 refractory cytopenia with multilineage dysplasia, 16 RA with excess blasts (RAEB) type 1, 20 RAEB type 2 and 5 MDS-unclassifiable cases.

We determined the sequence of all exons of *TET2*, exons 4 of *IDH1* and *IDH2*, and exons 15 to 23 of *DNMT3A* (which encode the C-terminal half of the protein, including the catalytic domain, where most mutations have been found so far), as described.^{2,5} High density array-comparative genomic hybridization⁵ provided information on the status of the respective loci.

In MPNs, we found 13 mutations in *TET2* in 12 patients (2 PV, 1 post-PV MF, 3 ET, 2 post-ET MF, 2 PMF, and 2 MDS/MPN one of which had two mutations), 0 mutations in *IDH1/2*, and 2 mutations in *DNMT3A* (1 in a JAK2 V617F-positive PV, 1 in a JAK2 V617F-negative PMF) (see Table 1). The two mutations in *DNMT3A* were missense (c.2245C>T, p.Arg749Cys in the PV;

c.2644G>A, p.Arg882Ser in the PMF). All mutations were heterozygous.

In MDSs, we found 12 mutations and 1 deletion of *TET2* (all heterozygous), 5 mutations of *IDH1/2*, and 4 mutations (6%) and 1 deletion of *DNMT3A* (all heterozygous) (see Table 1). Mutations in *DNMT3A* were 1 nonsense (c.1681G>T, p.Glu561Stop), 1 frameshift (c.1872del, p.Pro625LeufsX26) and 2 missense (c.1723G>C, p.Ala575Pro; c.2141C>G, p.Ser714Cys). Mutations in *TET2*, *IDH1/2* and *DNMT3A* were all mutually exclusive. Thus, 23 MDS cases out of 66 (roughly one-third) showed one alteration (mutation or deletion) in either DNA methylation-associated gene. Strikingly, the 4 *DNMT3A*-mutated cases were 1 RA and 3 RARS. One RARS case had a trisomy 8.

DNMT3A mutations were very recently reported in two series of MDSs, including 62 RAEB cases⁶ and 150 cases of various subclasses.⁷ In the RAEB series,⁶ 3 cases (4.8%) were mutated. In the second series,⁷ 12 patients had DNMT3A mutations (8%). These results show that, in chronic myeloid diseases, *TET2* mutations are prominent, whereas *IDH1/2* and *DNMT3A* are less frequent. In MPNs, we did not find any *IDH* mutation; previous works had found that only 4% of PMF cases and few PV and ET were mutated in *IDH1/2*.^{8,9} *IDH1/2* mutations are also rare in MDSs, except in some subclasses such as MDSs with del(5q) or trisomy 8.^{5,10,11} Only six cases were mutated in *DNMT3A* in our whole series of chronic cases. Overall, *IDH1/2* and *DNMT3A* mutations are therefore more a feature of AMLs, especially primary AMLs with normal karyotype and intermediate prognosis.^{2,3} This suggests that mutations in *TET2*, *IDH1/2* and *DNMT3A*, although potentially all functionally linked to DNA methylation, may not be equivalent events in the initiation of leukemogenesis; *TET2* mutation could be more efficient in triggering the process. In our series, mutations of the three genes were mutually exclusive, whereas *DNMT3A* mutations have been found to be associated with *TET2* or *IDH1/2* mutations in AMLs.² This may just be because of a low number of mutated samples in chronic cases. However, this may also suggest that *IDH1/2* and *DNMT3A* mutations may participate, although less frequently than *TET2*, to the initial phases of the disease. This may be in collaboration with specific cooperating alterations such as trisomy 8 or del(5q).

All our *DNMT3A*-mutated MDSs were low-risk RA/RARS cases. The *DNMT3A* Arg882 amino-acid residue, which is a mutation hotspot in AMLs,^{1–3} was only mutated once in our series of MPNs (in a PMF) and it was not mutated in our series of MDSs. In the reported RAEB series,⁶ the three mutations affected the Arg882 residue. In the other published series,⁷ three out of the four Arg882-mutated MDSs were RAEB/RAEB-T cases. The *DNMT3A* mutations can occur in the various subclasses of MDS. However, the Arg882 mutation may be more specific of RAEB and/or aggressive cases, whereas mutations at the other residues may have a different function and may be associated with a different (milder?) phenotype.

Table 1 Mutations in three DNA methylation-associated genes in patients with chronic myeloid diseases

	<i>TET2</i> ^a	<i>IDH1/2</i> ^a	<i>DNMT3A</i> ^a	Total ^a
MPNs (N = 135)	12 (8.9)	0	2 (1.5)	14 (10.4)
MDSs (N = 66)	12 (18.2)	5 (7.6)	4 (6)	21 (31.8)
Total (N = 201)	24 (11.9)	5 (2.5)	6 (3)	35 (17.4)

Abbreviations: *IDH1*, isocitrate dehydrogenase 1; MDS, myelodysplastic syndrome; MPN, myeloproliferative neoplasm.

^aPercentages are in parentheses.
