HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
Srianand et al. Reply: In the preceding Comment [1], Murphy, Webb, and Flambaum criticize the fitting procedure we used in two previous papers [2,3] and conclude that [2] offers no stringent test to previous evidence for varying \( \alpha \). We think this is a hasty conclusion as (a) our procedure is robust as shown in [3]; (b) the data used by Murphy et al. [1], in particular, the error array, is different from ours and there are differences in the fitting procedure; (c) despite these differences, 70\% of their individual measurements are consistent with that quoted in [3].

Point 1.—In [3], we explain our procedure in detail. In particular, we used \( \Delta \alpha / \alpha \) as an external parameter (as in [5]) when Murphy et al. used it as an additional fitting parameter. This choice has been tested extensively using simulations. To reiterate this point, we have refighted the systems in our sample using VPFIT keeping \( \Delta \alpha / \alpha \) as an external parameter (see Fig. 1). Our new results (closed circles) match our original results (squares) and Murphy et al.’s (open squares) within 1\( \sigma \). We point out that fluctuations in \( \chi^2 \) curves get indeed smoothed after a large number of iterations but the results from the first and last iterations are found to be very similar. We find significant differences in only two cases.

Point 2.—In the course of the analysis presented in [3] we define two errors for each pixel: one is the error calculated by the ESO-pipeline and one is calculated from the scatter of the different exposures. In principle the two errors should be of the same order but usually they are not because of the nontrivial observational procedure. This can be estimated by comparing the above errors with the scatter in the continuum. Murphy et al. used the data made available on the web with standard errors. In Fig. 2 we show the signal-to-noise ratio (SNR) (1/\( \sigma \)) used by Murphy et al. (dots) and by Srianand et al. (stars) versus the SNR as measured in the continuum around the absorption lines used in our analysis. Clearly the errors used by Murphy et al. are underestimated. Ours are consistent in the low SNR regime and slightly overestimated at high SNR. These measurements are done in the continuum and differences are more crucial in the lines (where we cannot perform this experiment). In addition, our procedure takes into account the differences in spectral resolution in different settings, while this is not the case with VPFIT.

\[ \Delta \alpha / \alpha (\text{in unit of } 10^{-6}) \]

![Fig. 1. Examples from our reanalysis (see point 1).](image)

Point 3.—Despite these differences, it is clear from Fig. 3 (left panel) and Table 1 of Murphy et al. [4] that their measurements match ours [3] at \( \leq 1 \sigma \) level for 16 systems. The corresponding weighted mean is \( \Delta \alpha / \alpha = (+0.06 \pm 0.18) \times 10^{-5} \). For the same systems Chand et al. find \( \Delta \alpha / \alpha = (+0.03 \pm 0.09) \times 10^{-5} \). It is also easy to recognize that only two \( >4 \sigma \) deviant systems (the \( z = 1.5419 \) system towards 0002–422 \( \Delta \alpha / \alpha = (-4.655 \pm 0.988) \times 10^{-5} \) and the \( z = 0.8593 \) system towards 0122–380 \( \Delta \alpha / \alpha = (-4.803 \pm 0.941) \times 10^{-5} \)), dominate the final result by Murphy et al.. Excluding these systems we get \( \Delta \alpha / \alpha = (-0.19 \pm 0.16) \times 10^{-5} \) for 21 points. Our reanalysis using VPFIT keeping constant resolution across the spectrum and with identical initial guess parameters leads to \( \Delta \alpha / \alpha = (0.01 \pm 0.15) \times 10^{-5} \) for 21 systems (excluding two systems that deviate at more than 3\( \sigma \) level) with very little scatter (\( \chi^2 \sim 1 \)) contrary to the claims by Murphy et al. [4]. Thus we believe, the results presented in [2,3] are robust (although errors are probably larger) and are not due to the failure in our fitting procedure.

Our result disagrees with earlier claims for a variation of \( \alpha \) by \( >3 \sigma \). We are awaiting results from the full independent analysis of ultraviolet and visual Echelle spectrograph data by Murphy et al..
