Dear Professor Jeffrey,

On behalf of all co-authors, I propose for publication in *Translational Research* an article entitled **“Inhibition of alkaline phosphatase impairs dyslipidemia and protects mice from atherosclerosis”**.

We recently published a review article in *Cardiovascular Research* explaining that alkaline phosphatase, the necessary enzyme in bone mineralization, is increasingly suspected to participate in cardiovascular calcification (Goettsch et al, *Cardiovasc Res* 2022). In the present experimental article, we report that alkaline phosphatase is locally associated with calcification in human and mouse atherosclerotic plaques, and that its pharmacological inhibition with the novel inhibitor SBI-425, prevents calcification in human vascular smooth muscle cell cultures *in vitro*, and *in vivo* in aortic plaques of mice with atherosclerosis. More unexpectedly and interestingly, we found that hepatic alkaline phosphatase is activated during the progression of liver steatosis, and that its inhibition reduces the release of triglycerides and cholesterol in the blood, and consequently impairs the whole development of atherosclerotic plaques. We identified phosphocholine as a new substrate of liver alkaline phosphatase, whose dephosphorylation normally participates in the release of lipids from the liver to the blood. Collectively, these data indicate that SBI-425 protects from atherosclerosis through the inhibition of both liver and arterial alkaline phosphatase. They moreover strengthen the notion that alkaline phosphatase inhibition may be a promising therapeutic option for atherosclerosis, especially since we observed that SBI-425 administration reduces inflammation and preserves the bone architecture.

This article is not under consideration for publication elsewhere. All co-authors have read and approved the manuscript.

Yours faithfully,

Background:

Our study provides the first demonstration that alkaline phosphatase inhibition prevents atherosclerotic plaque calcification and ameliorates atherosclerosis. Moreover, it identifies an unsuspected function of liver alkaline phosphatase, which is to participate in VLDL release through phosphocholine dephosphorylation.

Translational Significance:

Alkaline phosphatase inhibition has recently emerged as a promising option to block arterial calcification in patients with chronic kidney disease (CKD). Our study suggests that it will also ameliorates atherosclerosis, in patients with, and without CKD. Finally, it provides an unexpected function of liver alkaline phosphatase, whose release in the blood is clinically routinely measured in clinics, but whose function is obscure.

Short title: TNAP inhibition ameliorates atherosclerosis

List of abbreviations: Apo: apolipoprotein; bone volume to tissue volume ratio (BV/TV); HFD: high fat diet; LDLR: low density lipoprotein receptor; MetS: metabolic syndrome; NBT/BCIP: nitro blue tetrazolium/5-Bromo-4-chloro-3-indolyl phosphate; NIRF: near-infrared fluorescence; PCR: polymerase chain reaction; PET: positron emission tomography; PP_i: inorganic pyrophosphate; SUVR: standardized uptake value ratio; TNAP: tissue-nonspecific alkaline phosphatase; VSMC: vascular smooth muscle cell.

Abstract

1
2
3
4 Rationale: calcium accumulation in atherosclerotic plaques predicts cardiovascular mortality, but the
5
6 mechanisms responsible for plaque calcification and how calcification impacts plaque stability remain
7
8 debated. Tissue-nonspecific alkaline phosphatase (TNAP) recently emerged as a promising therapeutic
9
10 target to block cardiovascular calcification. In this study, we sought to investigate the effect of the
11
12 recently developed TNAP inhibitor SBI-425 on atherosclerosis plaque calcification and progression.
13
14
15

16
17
18 Methods: TNAP levels were investigated in *ApoE*-deficient mice fed a high fat diet from 10 weeks of
19
20 age and in plaques from the human ECLAGEN biocollection (101 calcified and 14 non-calcified carotid
21
22 plaques). TNAP was inhibited in mice using SBI-425 administered from 10 to 25 weeks of age, and in
23
24 human vascular smooth muscle cells (VSMCs) with MLS-0038949. Plaque calcification was imaged *in*
25
26 *vivo* with ¹⁸F-NaF-PET/CT, *ex vivo* with osteosense, and *in vitro* with alizarin red. Bone architecture was
27
28 determined with μ CT.
29
30
31

32
33
34
35 Results: TNAP activation preceded and predicted calcification in human and mouse plaques, and TNAP
36
37 inhibition prevented calcification in human VSMCs and in *ApoE*-deficient mice. Moreover, TNAP
38
39 inhibition reduced the blood levels of cholesterol and triglycerides, and protected mice from
40
41 atherosclerosis, without impacting the skeletal architecture. Metabolomics analysis of liver extracts
42
43 identified phosphocholine as a substrate of liver TNAP, whose decreased dephosphorylation upon
44
45 TNAP inhibition likely reduced the release of cholesterol and triglycerides into the blood.
46
47
48
49

50
51
52 Conclusion: systemic inhibition of TNAP protects from atherosclerosis, by ameliorating dyslipidemia,
53
54 and preventing plaque calcification.
55

Introduction

1
2
3
4 Cardiovascular diseases are responsible for 17.9 million deaths each year, which represents 31% of all
5 deaths worldwide (<https://www.who.int/health-topics/cardiovascular-diseases>). Rupture of an
6
7 atherosclerotic plaque is considered the primary reason for cardiovascular death, accounting for most
8
9 myocardial infarction cases and about 20% of ischemic strokes ¹. Acknowledged features of
10
11 vulnerability include a large lipid and necrotic core, a thin fibrous cap and intraplaque hemorrhage ².
12
13 In addition, recent data suggested that microcalcification, characterized by a size less than 10 μm , but
14
15 not macrocalcification, negatively impact plaque stability ³⁻⁵. Clinically, microcalcification can be
16
17 discriminated from macrocalcification with ¹⁸F-NaF positron emission tomography (PET) ⁶, because
18
19 fluoride ions can replace hydroxyl ions in newly formed apatite crystals, but not in more mature, inert
20
21 macrocalcification. To date, several *ex vivo* and *in vivo* studies have shown that ¹⁸F-NaF accumulates in
22
23 plaques with hallmarks of vulnerability, predicting future events ⁷⁻⁹. Microcalcification may destabilize
24
25 plaques through pro-inflammatory and mechanical mechanisms. In human macrophage cultures,
26
27 crystals measuring from 1 μm to 15 μm induce the release of tumor necrosis factor (TNF)- α at levels
28
29 inversely associated with crystal size ^{10,11}. Microcalcification can also exert a harmful mechanical stress
30
31 and favor plaque rupture, especially when it develops within the fibrous cap ¹²⁻¹⁴. Nonetheless, in the
32
33 absence of calcification inhibitors that could be used *in vivo*, the real impact of calcification on plaque
34
35 progression still remains debatable. In this regard, the recent development of an effective specific and
36
37 *in vivo* inhibitor of tissue-nonspecific alkaline phosphatase (TNAP) should help fill this gap in knowledge

TNAP, the enzyme necessary for physiologic bone and tooth mineralization ¹⁶, has emerged as a likely
suspect responsible for plaque calcification [reviewed in ¹⁷]. TNAP is normally expressed under the
control of the transcription factor RUNX2 in hypertrophic chondrocytes and osteoblasts, where it
hydrolyzes the constitutive mineralization inhibitor inorganic pyrophosphate (PP_i), to allow

1 progression of mineralization onto the extracellular matrix ^{18, 19}. Interestingly, in atherosclerotic
2 Apolipoprotein (Apo)E-deficient mice, vascular smooth muscle cells (VSMCs) transdifferentiate into
3
4 chondrocytes and express TNAP before calcification can be detected ²⁰⁻²². Moreover, VSMC-specific
5
6 deletion of RUNX2 in these mice ²³, or in atherosclerotic mice deficient for low density lipoprotein
7
8 receptor (*LDLr*^{-/-}) ²⁴, strongly reduces calcification, further suggesting that TNAP is a key player. In
9
10 humans, where plaque calcification does not seem to involve cartilage formation, and bone formation
11
12 within only a minority of plaques ²⁵, TNAP from the circulation is suspected to stimulate plaque
13
14 formation ^{26, 27}. As its name indicates, TNAP is indeed relatively ubiquitous. In humans, while
15
16 predominantly expressed in the skeleton and teeth during physiologic mineralization, it is also
17
18 expressed in the liver and released into the blood in increasing amounts with cholestasis and with the
19
20 development of metabolic syndrome (MetS) ^{26, 28-32}. Since genetic deficiency in PP_i generation leads to
21
22 vascular calcification ^{33, 34}, it is suspected that increased circulating TNAP in MetS exacerbates plaque
23
24 calcification.
25
26
27
28
29
30
31
32

33 In the present study, we explored the involvement of TNAP in plaque development and calcification in
34
35 different experimental designs: using ApoE-deficient mice, a biocollection of human carotid plaques as
36
37 well as cultured human VSMCs. To take into account the ubiquitous nature of TNAP, we also analyzed
38
39 the effects of its inhibition on the skeleton and liver. We report that systemic TNAP inhibition
40
41 decreased blood triglyceride and cholesterol levels, and hindered atherosclerosis development, as
42
43 demonstrated by reduced plaque growth, inflammation and calcification. Importantly, SBI-425
44
45 administration exerted these beneficial effects without producing any negative effect on mouse bone
46
47 architecture.

Materials and methods

Animal experiments

The present project received authorization from the ethics committee of the French Ministry of Education, Research and Innovation (APAFIS#15387-2018060708052279). Two cohorts of mice were used to characterize plaque calcification and TNAP activation (Suppl. Fig. 1A). Six-week-old *ApoE*-deficient male mice (Charles River, Lyon, France) were housed at the animal facility of INSA (Lyon, France; Cetil n°C2EA-102), and placed in conventional cages with 5 mice per cage. Mice were maintained on a 12-hrs light-dark cycle (7:00 am-7:00 pm) and were supplied with food and water *ad libitum*. From 10 weeks of age, they were fed *ad libitum* with a high fat diet (HFD, D12108C, Research Diets, New Brunswick, USA) containing 40% fat (kcal) and 1.25% cholesterol (weight). In cohort 1, 8 mice were sacrificed every 2 weeks between weeks 17 to 31, after overnight fasting, for histological and molecular analyses. Total body weight was measured weekly after starting the HFD. The sacrifice was done by CO₂ inhalation after anesthesia with isoflurane and intracardiac blood puncture. The abdominal aorta was used for quantitative polymerase chain reaction (PCR) analyses. We used mice from cohort 2 (n=5 per group) to analyze aortic calcification with ¹⁸F-NaF μPET and μCT and to compare the *in vivo* data with the *ex vivo* results obtained in cohort 1. According to the results obtained in cohorts 1 and 2, in the next cohorts (cohorts 3 and 4), we administered the TNAP inhibitor SBI-425 (30 mg/kg/day, formulated as a food admixture in the HFD) from 10 weeks of age³⁵. Treatment was stopped at 25 weeks of age, when microcalcification is detected in all mice analyzed in cohorts 1 and 2. Mice in cohort 3 (2 groups of 13 mice) were used for *ex vivo* analysis, and mice in cohort 4 (2 groups of 12 mice) for *in vivo* imaging.

In vivo imaging

Animals were transferred from the animal facility to the Cermep imaging platform (Lyon/Bron, France). Mice were placed into a chamber connected to an isoflurane anesthesia unit. Anesthesia was induced

1
2 using an airflow rate of 0.8 L/min and 4% isoflurane, airflow rate was then maintained to 0.6 L/min
3 with 2% isoflurane during the scans. After induction, mice were injected with 0.36 MBq/g of ^{18}F -NaF in
4 0.1mL saline via tail vein (19 scans) or in retro-orbital venous sinus (16 scans) when the tail veins were
5 not available. After injection, animals were placed in the prone position on the scanning bed. PET-CT
6 images were obtained using a micro PET-CT scanner (Inveon PET-CT, Siemens, Germany). Mice were
7 positioned into the CT system and imaged using the low magnification acquisition settings
8 (acquisition parameters: attenuation mode; projection: 120 ; rotation: 200° ; estimated scan time:
9 492s ; binning 4x4; effective voxel size: 0.111 x 0.111 x 0.111 mm³; voltage: 80 kV; current: 500 μA ;
10 filter thickness: 0.5 mm; exposure: 200 ms). After CT acquisition, mice were moved into the center of
11 the PET scanner (axial field of view: 127mm). PET acquisition started exactly one hour after ^{18}F -NaF
12 injection, for a total scan time of twenty minutes. Then, mice were allowed to recover into a lead
13 shielded cage. Static images of the 20-min PET acquisitions were reconstructed with attenuation and
14 scatter correction by 3D ordinary Poisson ordered subsets expectation maximization (OP-OSEM3D)
15 with 4 iterations and a zoom factor of 2. The reconstructed volume was constituted of 159 slices of
16 128 x 128 matrix voxels, with voxel size 0.388 x 0.388 x 0.796 mm³. CT data were reconstructed using
17 a Feldkamp algorithm with a down sample of 1 (Inveon Acquisition Workplace, Siemens). After
18 reconstruction, the PET and CT data were coregistered. Images were analyzed using Inveon Research
19 workplace (Siemens). The presence of atherosclerotic plaques was evaluated both in CT and PET
20 images. Due to the higher resolution of the CT scan, regions-of-interest (ROI) of the aortic arch were
21 drawn on CT images. Only voxels above the threshold of 390 Hounsfield Unit (calcified structure) were
22 considered. The ROIs were exported onto the coregistered PET images in order to measure ^{18}F -NaF
23 uptake. Standardized uptake value ratio (SUVR) were calculated using the whole body SUV as
24 reference.

1 After euthanasia, the heart and vasculature were perfused with sterile 0.9% NaCl. The aortic root and
2 the aortic arch, with the major arteries that stem from them (brachiocephalic, left common carotid
3 and left subclavian), were dissected under a microscope and frozen in optimal cutting temperature
4 medium (OCT, Thermo Scientific) and stored at -80 °C before serial cryo-sectioning. Abdominal aortas
5 were dissected, rinsed once with sterile phosphate-buffered saline (PBS) pH 7.4, and frozen until RNA
6 extraction. Cryostat sections (5- μ m thick) were cut at -21 °C using a Leica CM3050 S cryostat (Leica),
7 mounted on glass slides (SuperFrost Plus Gold glass slides, Thermo scientific) and stored at -80°C until
8 use. Four sections of 5- μ m thickness were harvested per slide, yielding 25 to 45 slides per mouse. Prior
9 to analysis, frozen tissue sections were air-dried for 10 min at room temperature and eight consecutive
10 sections were taken from each mouse at 15- μ m intervals. Calcification was imaged by near-infrared
11 fluorescence (NIRF) with the calcium tracer osteosense (OS) (PerkinElmer, ex/em 650/680 nm) as
12 previously described³⁶. Briefly, frozen sections were treated overnight with OS 680 (1:100) before NIRF
13 imaging. Quantification was performed by computer image analysis using Image J software (NIH,
14 Bethesda, MD) by averaging of measurements from 2 sections of 15 μ m apart. Alkaline phosphatase
15 activity was stained in serial sections using nitro blue tetrazolium/5-Bromo-4-chloro-3-indolyl
16 phosphate (NBT/BCIP) solution³⁷.

40 To perform CD68 immunohistochemical staining to detect macrophages, serial frozen sections of aortic
41 arch were fixed in acetone (-20 °C) for 10 min and were air-dried afterwards for 10 min. Endogenous
42 peroxidase activity was neutralized with 0.3% H₂O₂ for 10 min followed by 3 washing steps of 5 min
43 each using Tris buffered saline (TBS) pH 7.4 containing 0.025% Triton-X100. Sections were incubated
44 with TBS containing 5% normal goat serum (Abcam) and 1% bovine serum albumin (BSA) for 1 h to
45 reduce non-specific background staining. Sections were subsequently incubated overnight at 4 °C with
46 anti-CD68 antibody (Abcam ab125212) diluted in TBS containing 1% BSA. Horseradish peroxidase-
47 conjugated polyclonal anti-rabbit secondary antibody (Abcam) was applied for 1 h and then revealed
48 with a DAB staining kit (Abcam). Preparations were counterstained with hematoxylin-eosin staining

1 (Mayer's hematoxylin solution, Sigma). Negative control sections were analyzed using a similar
2 procedure excluding the primary antibody. Images of the sections were captured with an Eclipse TI-E
3
4 microscope fitted with a DSIQ2 digital camera combined with Nikon's NIS Elements imaging software
5
6 (Nikon Instruments Inc.). At least 2 sections per mouse were examined for CD68 immunostaining.
7
8
9

10 For oil Red O staining of neutral lipids, sections were rehydrated in PBS for 5 min, fixed with 10%
11 neutral buffered formalin for 5 min, extensively washed with water, and then treated with propylene
12 glycol for 2 min. The sections were then stained with oil red O solution (0.5% in propylene glycol) for
13
14 15 min at 60°C and extensively washed with water. After the oil red O staining procedure, the sections
15
16 were counterstained with hematoxylin-eosin staining (Mayer's hematoxylin solution, Sigma). Images
17
18 were captured with an Eclipse TI-E microscope and digital camera (Nikon), combined with Nikon's NIS
19
20 Elements imaging software. To visualize cartilage glycosaminoglycans, sections were stained with
21
22 Alcian blue 8GX (Sigma) at pH 2.5 (1% in 3% acetic acid).

31 **Blood biochemistry**

32
33 Blood was collected from mice by cardiac puncture under anesthesia with isoflurane. After blood
34
35 coagulation, serum was obtained through centrifugation of the blood for 15 min at 1,500 g at 4°C,
36
37 frozen in liquid nitrogen and stored at -80°C before analysis. Concentration of total cholesterol and
38
39 triglycerides were measured using a colorimetric (MAK043, Sigma) and a fluorimetric assay (MAK266,
40
41 Sigma), respectively. Total bile acids were assayed with a commercial enzyme-based colorimetric kit
42
43 (Abcam Ab239702). Serum IL-6 and haptoglobin levels were determined using the commercially
44
45 available ELISA kits (Fischer Scientific 10110623 and Abcam 157714, respectively). The alkaline
46
47 phosphatase activity assay was adapted from a previously published protocol and performed in a 96-
48
49 well plate³⁸. Briefly, sera were mixed with a concentrated buffer at a ratio of 2.85:1 (vol/vol) in order
50
51 to get final concentrations of 0.56 M 2-amino-2-methyl-1-propanol buffer pH 10.5, 1 mM MgCl₂ and
52
53 10 mM *p*-nitrophenylphosphate. Absorbance was acquired for 5 min at 405 nm (Tecan plate reader).

7
8
9 3D microarchitecture of the distal metaphyseal femur and cortical midshaft were carried out using a
10 Skyscan 1176 micro-CT scanner (Skyscan Inc.). The X-ray excitation voltage was set to 50 kV with a
11 current of 500 mA. A 0.5 mm aluminum filter was used to reduce beam-hardening artifacts. Samples
12 were scanned in 70% ethanol with a fixed voxel size of 9.08 μm . Section images were reconstructed
13 with NRecon software (version 1.6.1.8, Skyscan). The region of interest (ROI) to delineate trabecular
14 bone was drawn manually, away from the endocortical surface, starting at 0.5 mm underneath the
15 growth plate and ending at 1.5 mm. For cortical analysis, 0.5 mm on either side of the femur midshaft
16 were reconstructed. The global threshold was set at 0.394 g HA/cm³. Three-dimensional modeling and
17 analysis of bone volume to tissue volume ratio (BV/TV), trabecular number, trabecular separation,
18 cortical thickness, total porosity, were obtained with the CTA_n (version 1.9) and CTVol (version 2.0)
19 software.

Liver extraction and NMR measurement: The frozen tissues were weighed and then extracted according to Beckonert's procedure ³⁹ using the methanol-chloroform-water system [2:2:1.425 (v/v/v)], and including absorbance measurement using the Bradford reagent with BSA as standard. The upper methanol/water phase was collected, dried, lyophilized and stored at -80°C. Deuterated phosphate buffer at pH = 7.4 (200 mM) was added to the dried aqueous extract with TSP (sodium 2,2,3,3-tetradeutero-3- trimethylsilylpropionate) (Sigma-Aldrich) as internal chemical shift and quantification reference. ¹H NMR spectra were recorded at 298 K on a Bruker Avance spectrometer 500 equipped with a 5-mm TCI cryoprobe. The 1D pulse sequence (relaxation delay-pulse-acquisition) with pre-saturation for water (HOD) signal suppression was used. Acquisition parameters were as follows: relaxation delay 5.64 s, 30° pulse (4.5 μs) and acquisition time of 4.36 s. The spectral width of 15 ppm was used and 256 scans were collected. With this repetition time of 10 s, the ¹H resonances were fully relaxed. Data were processed using Bruker TopSpin software 3.2 with one level zero-filling and apodization (exponential, lb = 0.3 Hz) before Fourier transform, then phase correction, simple baseline correction and calibration ($\delta_{\text{TSP}} = 0$ ppm) were applied.

Chemometric analysis of NMR data: Data NMR matrices were obtained using facilities included in KnowItAll® (Wiley Science Solutions) and NMRProcFlow® (<https://nmrprocflow.org/>) ⁴⁰ software. First, the bucket list was obtained by the bin area method using the intelligent variable size bucketing tool included in the KnowItAll® package according to NMR signals assignment. Second, NMRProcFlow® pipeline was used for local baseline correction of spectra, alignment of NMR signals and integration of NMR area by that bucket list. Then integrated regions were normalized by dividing their areas by that of the internal standard TSP and by the weight of tissue. Statistical analysis, supervised Partial Least Squares-Discriminant Analysis (PLS-DA) and the nonparametric Wilcoxon test were carried out using the SIMCA-P+ 13.0.3 (Sartorius, Aubagne, France) and Matlab® (MathWorks, Natick, Massachusetts, USA) softwares.

¹H NMR absolute quantification of metabolites: Metabolites were assigned with an in-house metabolite database at pH = 7.4. A total of 34 metabolites were identified; 30 could be quantified.

1 Metabolite concentrations (ng/mg liver tissue) were given by $m_x = A_x/A_{TSP} \cdot 9/N_x \cdot 112 \cdot M_x/m_L$ with A_x
2 and A_{TSP} being the areas of the signals of metabolite X and TSP, 9 and N_x the number of protons of TSP
3 and metabolite X evoking the signals, 112 the number of nmol of TSP in the solution analyzed, M_x the
4 molecular weight of metabolite X and m the weight (mg) of tissue analyzed.

10 11 12 **Human samples**

13
14
15 Analysis in human samples has been performed on healthy and diseased carotid arteries. Carotid
16 plaques [n=101 calcified, and 14 non-calcified from the ECLAGEN biocollection ²⁵] were removed as a
17 single specimen by endarterectomy at the bifurcation from within the lumen. The ECLAGEN
18 biocollection was collected in accordance to the principles outlined in the Declaration of Helsinki. All
19 samples were 1-2 cm long. For histology, we analyzed sections of the lesion core present in each
20 arterial sample. Sample collection and handling were performed in accordance with our institutional
21 medical ethics committee (research protocol#PFS09-014, n°DC-2008-402), and all patients
22 participating in the study provided written informed consent. In the case of organ donors (healthy
23 arteries), the absence of patient opposition to organ donation and an informed and signed consent
24 was required from the patient's family. The arterial samples were fixed in 10% formalin for 48 h,
25 decalcified in 4.13% EDTA-0.2% paraformaldehyde pH 7.4 over 4 days in KOS sw10 (Milestone), and
26 embedded in paraffin. Following heat-induced epitope retrieval in EDTA pH 9, serial sections (4- μ m
27 thick) were stained with TNAP (Abcam), and Runx2 (Abcam) antibodies. Imaging of the sections was
28 obtained with the NanoZoomer device (Hamamatsu Photonics).

Results

Atherosclerotic plaque calcification is associated with TNAP activity in mouse and human lesions

Our first objective was to determine whether atherosclerotic plaque calcification is associated with TNAP activity in the serum, in the plaques, or in both compartments. To this purpose, we thoroughly characterized where and when calcification initiates in aortas from *ApoE*^{-/-} mice. Aorta calcification was first imaged *in vivo* at 19, 25, 31 and 34 weeks using μ CT to quantify calcium volume, and ¹⁸F-NaF μ PET to determine fluoride incorporation in nascent crystals, and therefore calcification activity (Suppl. Fig. 1A and Fig. 1A). μ CT data showed that calcium deposition in the aorta progressed in an almost exponential manner from 19 weeks to 34 weeks of age (Fig. 1B and Suppl. Fig. 1B). Calcification activity also increased from 25 to 31 weeks of age, then it slowed-down between 31 and 34 weeks (Fig. 1C and Suppl. Fig. 1C). Histologically, using the calcium fluorescent dye osteosense, microcalcification of about 10-20 μ m in size was detected in the aortic arch, in mice aged 19-21 weeks (Fig. 1D). These first calcified regions grew and fused in the arch until 31 weeks (Fig. 1D,E), to sometimes fill the whole aortic arch (Suppl. Fig. 1D). In parallel, new calcifications appeared in other arteries, such as the left common carotid (Fig. 1D). The total surface of calcifications determined *ex vivo* increased exponentially (Fig. 1F), and similarly to the total volume of calcium measured *in vivo* with μ CT (Fig. 1B). We then asked whether TNAP activation in the plaques and/or in the blood was associated with plaque calcification. Strikingly, calcification was consistently associated with TNAP activity in atherosclerotic plaques (Fig. 1G). Moreover, TNAP activity was commonly detected in aortic plaques from 17-19 week-old mice (Fig. 1H), suggesting that TNAP activation preceded microcalcification, and was responsible for its formation. On the other hand, serum TNAP activity remained unchanged from 17 to 31 weeks (Suppl. Fig. 1E). These results strongly suggested that local TNAP, but not liver or circulating TNAP, participated in plaque calcification in *ApoE*^{-/-} mice.

1 We next wondered which cells expressing TNAP might be involved in atherosclerotic plaque
2 calcification. In *ApoE*^{-/-} mice, calcification was shown to develop into cartilaginous metaplasia ²⁰.
3
4 However, there is still some uncertainty as to whether plaque calcification in these mice is induced by
5
6 hypertrophic chondrocytes, or whether like in humans, in association with calcifying macrophages ⁴²,
7
8 or with macrophage debris ⁴³. Like in Rattazzi's characterization of *ApoE*^{-/-} mice ²⁰, macrocalcification
9
10 unambiguously developed within cartilaginous metaplasia, as firstly demonstrated by the
11
12 colocalization of osteosense and alcian blue staining (Fig 2A). Moreover, the expression pattern of the
13
14 chondrocyte differentiation markers *Sox9*, *Acan*, *Runx2* and *Alpl* (Fig. 2B) was very similar to the
15
16 calcification activity measured with ¹⁸F-NaF μPET, with a rise from 25 weeks followed by a plateau (Fig.
17
18 1C). In these cartilaginous metaplasia, macrocalcification likely relied on TNAP expressed by
19
20 hypertrophic chondrocytes. Indeed, the evolution of *Alpl* transcripts encoding TNAP was very similar
21
22 to that of the chondrocyte marker *Acan*, and strongly associated with that of the transcription factor
23
24 *Runx2*, known to stimulate chondrocyte hypertrophy and *Alpl* expression (Fig. 2B,C). Finally, these
25
26 cartilaginous macrocalcifications were devoid of CD68-positive cells (Fig. 2A), suggesting that
27
28 macrophages did not directly participate in their growth. On the other hand, microcalcification was
29
30 often observed in locations enriched in macrophages, and not yet positive for alcian blue staining for
31
32 cartilage glycosaminoglycans (Fig. 2A). Therefore, it is possible that, before growing within
33
34 cartilaginous metaplasia, microcalcification formed in association with TNAP in macrophage-like cells

65

42. In conclusion, these first data collectively suggested that TNAP, expressed in plaques by hypertrophic chondrocytes and/or macrophages, was responsible for plaque calcification in *ApoE*^{-/-} mice.

We then sought to investigate whether TNAP is also locally associated with calcifications in human carotid plaques. This was more uncertain because cartilage metaplasia has never been reported in human plaques, and because bone metaplasia occurs less frequently, and predominantly in peripheral arteries ²⁵. We analyzed a biocollection of human carotid plaques in which the calcification morphology

1 has been characterized in details ²⁵. In these lesions and independently of the calcification size and
2 morphology, TNAP was consistently located at the proximal periphery of calcifications (Fig. 3).
3
4 Interestingly, TNAP was expressed in both RUNX2-positive and RUNX2-negative cells. Considered
5
6 together, these results in humans and mice strongly suggested that TNAP is involved in plaque
7
8 calcification. To validate this hypothesis in *ApoE*^{-/-} mice, we chose to inhibit TNAP in a preventive
9
10 manner, from 10 weeks of age, by administrating 30 mg/kg/day of SBI-425 admixed in the HFD ³⁵. This
11
12 treatment was stopped at 25 weeks to determine the involvement of TNAP in the initiation of plaque
13
14 calcification.

16
17
18
19
20

21 **TNAP inhibition in mice decreases cholesterolemia and reduces atherosclerotic plaque development**

22
23 As recently shown in other disease models ^{15, 44}, SBI-425 administration was well-tolerated, with no
24
25 effect on food intake, weight gain, or all-cause mortality (Suppl. Fig. 2A). Moreover, not only TNAP
26
27 inhibition did not deteriorate trabecular or cortical bone architecture, but also it tended to preserve
28
29 it, although not at a statistically significant level (Suppl. Fig. 2B). Even more unexpectedly, while TNAP
30
31 inhibition had no significant effect on serum glucose and non-esterified fatty acids (NEFAs), it strongly
32
33 decreased the levels of triglycerides (TGs) and cholesterol (Fig. 4). Since hypercholesterolemia is the
34
35 driving force for atherosclerosis in *ApoE*^{-/-} mice ⁴⁵, SBI-425 treatment also affected atherogenesis. If
36
37 the plaques of mice treated with SBI-425 presented similar levels of lipid content (%) (Fig. 5A,B), they
38
39 were significantly smaller (Figure 5A,C). Moreover, TNAP inhibition also decreased aortic
40
41 inflammation, as demonstrated by the significant reduction in the relative levels of the inflammatory
42
43 markers *Cd68*, *Rankl*, *Opn*, *Il8*, *Il1b*, *Il6* (Fig. 5D), and tended to reduce serum IL-6 concentration (Fig.
44
45 5E). Calcium accumulation and calcification activity were also impaired, as determined *in vivo* with μ CT
46
47 and ¹⁸F-NaF μ PET (Fig. 5F and 5G respectively). Histological analyses with osteosense, which in our
48
49 hands was the most sensitive method for this imaging, detected calcification in only 4 mice out of 12
50
51 treated with SBI-425 (33%), whereas all control mice presented with calcification (Fig. 5H). The
52
53 reduction of plaque calcification in mice treated with SBI-425 probably resulted from the beneficial
54
55
56
57
58
59
60
61
62
63
64
65

1 effect of SBI-425 on cholesterolemia and plaque development. Indeed, TNAP inhibition not only
2 prevented calcification, but it also prevented cartilage formation, as illustrated by the absence of alcian
3 blue-positive cartilaginous metaplasia in aortic plaques that were devoid of calcification (Fig. 5B).
4
5 Nevertheless, SBI-425 also likely prevented calcification by directly inhibiting TNAP activity in plaques.
6
7 We already reported that TNAP inhibition prevents calcification in cultured mouse VSMCs trans-
8 differentiated into chondrocytes ⁴⁶. We report here that TNAP was activated in human VSMCs
9 stimulated to trans-differentiate into osteochondrocyte-like cells, and that its inhibition also prevented
10 calcification (Suppl. Fig. 3). Collectively, these data suggested that SBI-425 administration impaired
11 atherosclerosis by reducing blood cholesterol levels, and locally inhibited plaque calcification. Since in
12 *ApoE*^{-/-} mice, blood cholesterol is predominantly transported by liver-derived very low density
13 lipoproteins (VLDLs) ⁴⁵, we next explored the effects of SBI-425 on the liver.

28 **Liver TNAP reduces hypercholesterolemia by dephosphorylating phosphocholine**

29
30 Transcript levels of *Alpl*, encoding TNAP, showed a broad peak between 19 and 27 weeks in the liver
31 of *ApoE*^{-/-} mice (Fig. 6A), which was concomitant with the accumulation of cholesterol (Fig. 6B) and TGs
32 (Fig. 6C) in the liver, and the release of TGs in the blood (Fig. 6D). Moreover, there was a positive
33 correlation between *Alpl* transcript levels and the TG content in the liver in 25-week-old mice (Fig. 6D).
34
35 Inhibition of TNAP from 10 to 25 weeks did not change the liver content of cholesterol (Fig. 6F) and
36 TGs (Fig. 6G). Since TNAP inhibition reduced the levels of TGs and cholesterol in the circulation but not
37 in the liver, these results suggested that liver TNAP participated in their release. We therefore
38 hypothesized that TNAP inhibition induced liver inflammation or fibrosis to exert these effects through
39 VLDL release. However, SBI-425 administration had no effect on liver inflammation, as revealed by the
40 levels of *Ly6g*, *Tnfa*, *Il1b* or *Hb* transcripts (Fig. 6H), and by the concentration of the liver acute phase
41 protein haptoglobin in the blood (Fig. 6I). Moreover, it did not impact liver fibrosis, as demonstrated
42 by the similar contents of hydroxyproline in treated and untreated mice (Fig. 6J).

Then, to further identify the mechanisms explaining how TNAP inhibition decreased serum lipid levels while unaffected lipid content in the liver, we used a metabolomics approach to determine hepatic metabolites whose levels were significantly impacted by SBI-425 administration. Multivariate statistical analysis on metabolomics data (PLS-DA) for the 30 detected metabolites, did not show any major impact of TNAP inhibition on liver metabolism (Suppl. Fig. 2C). Nevertheless, TNAP inhibition seemed to decrease phosphocholine levels in the liver (Fig. 6K, $p=0.07$), a phosphorylated compound and thus a putative TNAP substrate. Extracellular phosphocholine dephosphorylation in the liver is necessary to allow choline uptake in hepatocytes⁴⁷, intracellular synthesis of phosphocholine, and generation of phosphatidylcholine, which is required for VLDL production and TG and cholesterol release in the blood⁴⁸. This mechanism explains why choline-deficient diets or genetic deficiency in liver phosphatidylcholine production result in liver steatosis, reduced VLDL levels and impaired atherosclerosis in *ApoE*-deficient mice^{49, 50}. This possible decrease in liver phosphocholine was moreover intriguing considering the recent report that TNAP-deficient mice develop exacerbated liver steatosis when fed a HFD but not a choline-deficient diet⁵¹. We therefore believe that TNAP-dependent inhibition of phosphocholine dephosphorylation in the liver by SBI-425 administration, likely contributed to the beneficial effects of SBI-425 on serum lipids and atherosclerosis. Indeed, we observed a significant inverse relationship between the content of phosphocholine and the levels of cholesterol and TGs in the liver, indicating that when phosphocholine content was the most reduced by SBI-425 administration, the liver content of TGs and cholesterol was the highest (Fig. 6L). Moreover, we provide here evidence that phosphocholine is a TNAP substrate. The quantification of P_i release from phosphocholine in presence or absence of the parental inhibitor of SBI-425 (MLS-0038949), indicated that mouse and human recombinant TNAP were equally potent in dephosphorylating phosphocholine (Fig. 6M). Finally, the cholesterol that was not released in VLDLs in mice treated with SBI-425 was probably transformed into bile acids (BAs) since the liver content of BA was almost significantly increased by SBI-425 treatment (Fig. 6N). Unfortunately, we did not harvest the bile and

could not explore whether bile excretion was increased by TNAP inhibition in *ApoE*^{-/-} mice, as it is in rats⁵².

Discussion

1
2
3
4 The main finding of this study is that the systemic pharmacological inhibition of TNAP prevented
5
6 dyslipidemia and protected *ApoE*^{-/-} mice from atherosclerosis and plaque calcification. These beneficial
7
8 effects most likely relied on the inhibition of liver TNAP. Like in humans, whom liver TNAP production
9
10 and release in the blood are associated with the development of MetS²⁶⁻³², hepatic TNAP expression
11
12 in *ApoE*^{-/-} mice showed a similar trend as TG levels in liver and serum. We provide here evidence that
13
14 a function of this hepatic TNAP is to participate in the release of lipids from hepatocytes into circulating
15
16 VLDLs. Indeed, when TNAP was inhibited, the levels of lipids in the blood were significantly reduced.
17
18 TNAP may be the yet unknown phosphatase that dephosphorylates phosphocholine in the liver, to
19
20 allow the uptake of choline in hepatocytes⁴⁷. In the mouse liver, TNAP is mainly expressed in
21
22 endothelial cells⁵³, where probably reside ENPP6, the enzyme that generates phosphocholine from
23
24 glycerophosphocholine, and where is suspected to be the phosphatase hydrolyzing phosphocholine
25
26 into choline⁴⁷. Following its uptake in hepatocytes, intracellular choline is then rephosphorylated into
27
28 phosphocholine to generate phosphatidylcholine, which is the main phospholipid involved in VLDL
29
30 production⁴⁸. This hypothesis is appealing because choline deficiency or genetic deficiency in liver
31
32 phosphatidylcholine production reduces blood cholesterol levels and impairs atherosclerosis in *ApoE*-
33
34 deficient mice⁴⁸⁻⁵⁰. Phosphocholine levels in the liver showed a strong tendency to decrease in
35
36 response to SBI-425 administration *in vivo*. In addition, mouse and human TNAP were equally potent
37
38 in dephosphorylating phosphocholine *in vitro*. However, why TNAP inhibition did not exacerbate liver
39
40 steatosis in *ApoE*^{-/-} mice remains elusive, since choline-deficient diets induce liver steatosis⁴⁹. We
41
42 suspect that steatosis was prevented because of the previously described liver TNAP function in bile
43
44 excretion. In addition to being active in liver endothelial cells, hepatic TNAP is also localized in the
45
46 membrane of hepatocytes and cholangiocytes facing bile canaliculi and ducts⁵³⁻⁵⁶. At this location,
47
48 TNAP is thought to reduce the secretory processes of the intrahepatic biliary epithelium, as
49
50 demonstrated by the significant increase in bicarbonate secretion and basal bile flow induced by TNAP
51
52

64
65

1 inhibition in rats ⁵². Since in our experiments, TNAP inhibition tended to increase the content of bile
2 acids in the liver, we suspect that cholesterol catabolism into bile acids and bile acid excretion were
3
4 also enhanced, thereby preventing steatosis.
5
6
7

8
9 To summarize, TNAP inhibition limited atherosclerosis development, likely through impaired
10 phosphocholine dephosphorylation, decreased choline uptake and phosphatidylcholine production in
11 hepatocytes, and reduced TG and cholesterol release in VLDLs. This reduction in atherosclerotic
12 development was reflected in mice treated with SBI-425 by smaller plaques in aortas, with less
13 inflammation, and less calcification. While the decrease in plaque size and inflammation likely resulted
14 from the inhibition of liver TNAP, the strong reduction in the number of aortic calcifications in mice
15 treated with SBI-425 probably also relied on the inhibition of local TNAP blockade. Indeed, we observed
16 that in mouse and human plaques, TNAP expression preceded calcification, and colocalized with
17 calcium deposits once they had formed. Moreover, TNAP inhibition in human VSMCs stimulated to
18 calcify totally prevented calcium deposition. This result is consistent with previous report by Tani et al,
19 showing that SBI-425 treatment efficiently blocked vascular calcification in a mouse model of chronic
20 kidney disease (CKD) ⁴⁴.

34
35
36
37
38
39

40 In conclusion, TNAP inhibition might represent a promising therapeutic option, not only to prevent
41 vascular calcification in patients with CKD, but also to reduce hypercholesterolemia and
42 atherosclerosis development in individuals with MetS, in whom TNAP levels are associated with
43 mortality risk ²⁶⁻³². In our experiments in *ApoE*^{-/-} mice, SBI-425 administration for 15 weeks did not
44 induce negative effects in plaques, blood, liver or bones. While TNAP activation during liver disease in
45 mice fed a HFD was proposed to participate in the dephosphorylation and detoxification of
46 lipopolysaccharide (LPS) ⁵⁷, we observed no increase in serum LPS levels in animals treated with SBI-
47 425 as compared to controls (data not shown). Moreover, administration of SBI-425 tended to
48 decrease, and not increase, circulating IL-6 levels, and those of the acute phase protein haptoglobin,
49

65

1 indicating that systemic and liver inflammation were probably reduced, and not increased by SBI-425.

2 Finally, SBI-425 administration not only did not lead to bone architecture degradation, but instead also
3
4 tended to increase the bone volume as compared to untreated animals. Mice treated with SBI-425
5
6 seemed globally healthier than untreated mice; they were less dyslipidemic and less inflammatory,
7
8 explaining why their bones were preserved despite the important function of TNAP in bone
9
10 mineralization.

4 **Figure 1: TNAP activity is locally associated with plaque calcification in mice.** Representative *in vivo*
5 imaging of aortic calcification (red arrow) with μ CT (top) and ^{18}F -NaF μ PET/ μ CT (bottom) in a 34-week-
6 old mouse (A), and its quantification by μ CT (B) and ^{18}F -NaF μ PET (C). Histological analysis of
7 calcification after osteosense (OS) staining in *ApoE*-deficient mice at 21 weeks, 25 weeks and 31 weeks
8 (D). Quantification of calcification number (E) and surface (F) after OS staining at 17 (n=8), 19 (n=8), 21
9 (n=8), 23 (n=8), 25 (n=6), 27 (n=6), 29 (n=6) and 31 weeks (n=8). TNAP activity staining in the aortic
10 arch shown in D at 21 weeks (G). OS staining and TNAP activity staining in a 19-week-old mouse (H).
11 All quantitative results are shown as mean \pm standard deviation, and statistical analyses were
12 performed with one way ANOVA (F) and student's t-test (B, C, E, H). CT: computed tomography; NC:
13 necrotic core; OS: osteosense; PET: positron emission tomography; SUVR: standardized uptake value
14 ratio.
