ARTICLE HISTORY

Compiled November 18, 2022

ABSTRACT

The automatic extraction of materials and related properties from the scientific literature is gaining attention in data-driven materials science (Materials Informatics). In this paper, we discuss Grobid-superconductors, our solution for automatically extracting superconductor material names and respective properties from text. Built as a Grobid module, it combines machine learning and heuristic approaches in a multi-step architecture that supports input data as raw text or PDF documents. Using Grobid-superconductors, we built SuperCon², a database of 40324 materials and properties records from 37700 papers. The material (or sample) information is represented by name, chemical formula, and material class, and is characterized by shape, doping, substitution variables for components, and substrate as adjoined information. The properties include the T_c superconducting critical temperature and, when available, applied pressure with the T_c measurement method.

materials informatics, superconductors, machine learning, nlp, tdm

1. Introduction

In recent years, with the creation of computational databases, such as the Materials Project (MP) [1] and the Open Quantum Materials Database (OQMD) [2], and then experimental data repositories such as NIMS MDR (<http://mdr.nims.go.jp>) [3], focus has been steadily shifting towards a data-driven design of materials, which is often called Materials Informatics (MI). Such an approach is expected to accelerate the exploration of functional materials because it is not limited to the intuition or experience of very little genius researchers. In this new paradigm, the efficient use of data to guide experiments and material property prediction through the use of machine learning methods takes center stage. For example, data-driven methods have been used to search/design magneto-caloric materials [4–6], photo-catalysts for hydrogen splitting [7], thermoelectrics [8], and superconductors [9]. In such a data-driven search, one of the most important keys lies in the availability of the data, which should at least should consist of compositions of materials and their physical properties. In the

Corresponding authors: Luca Foppiano (luca@foppiano.org) and Masashi Ishii (ISHII.Masashi@nims.go.jp)

specific case of superconductivity, most of the data-driven works [9–11] rely on a single database: SuperCon (<http://supercon.nims.go.jp>).

SuperCon is a structured database of superconductor materials and properties; it was developed at the National Institute for Materials Science (NIMS) in Japan. At the time of writing this paper, SuperCon contained about 33000 inorganic and 600 organic materials and is the “de-facto” standard in data-driven research for superconductors materials (about 4400 articles contain the mention “*SuperCon database*” in Google Scholar). However, the SuperCon harvesting process is currently fully manual “from scratch”: humans have to read the human-readable printed matter such as PDF documents and enter the information into the system. The efficiency is directly proportional to the number of available human curators. Considering the cost of database construction, it is necessary to consider an assisted or alternative system that improves throughput while ensuring data quality equivalent to that of manual extraction.

As a solution, we are developing a hybrid data extraction method from scientific literature that combines automation using text data mining and manual curation. The automated system extracts and formats potential data and proposes them to the curator as “pre-cooked” structured data by (1) highlighting the relevant entities on the original document and (2) pre-filling the extracted information in a tabular format. In building the automated part of this hybrid system (training, evaluation) we used SuperMat, an annotated linked dataset from scholarly documents in superconductor research, which we recently constructed [12].

In this work, we present Grobid-superconductors: a system that automatically extracts structured information related to superconductor materials and properties from scientific literature. The tool is a specialised module of Grobid (Generation of Bibliographic Data) [13], a machine learning library designed to parse and structure scientific documents. Grobid provides an open-source platform for building specialised modules including astronomical entities recognition [14], dictionaries [15], software mentions [16], and physical measurements extraction [17]. Grobid provides several built-in features including access to PDF document layout information, citation resolution, bibliographic information consolidation through biblio-glutton [18] (a fast open-source reference matching service for CrossRef data), and a diverse set of machine learning (ML) architectures from a fast linear Conditional Random Field (CRF) to the latest state-of-the-art deep learning implementations.

Using Grobid-superconductors and other sub-tools, we established a pipeline to process a large number of documents and obtain an automated database of superconductor materials and properties. We processed 37770 papers from ArXiv (<https://arxiv.org>) and obtained a database of 40324 records. This new database, named SuperCon², can become an automated staging area for SuperCon, when bridged by a curation interface. During the project, there was also an opportunity to focus on properties that have recently become of greater interest and that are underrepresented in SuperCon. For example, the “pressure” applied to obtain superconductivity (about 20 records in SuperCon), has gained attention because it can radically change the physical structure of a material. In addition, the “method” used to measure the superconducting transition temperature T_c (about 600 records in SuperCon) can be used to semantically recognise multiple T_c ’s obtained from the same material or sample (e.g., distinguish calculated and experimental values of T_c).

2. Grobid-superconductors

We developed Grobid-superconductors as a Grobid module following principles (multi-step, sentence-based, full-text-based) discussed in a previous preliminary study [19]. Grobid has several advantages: 1) it can be integrated with pdfalto (<https://github.com/kermitt2/pdfalto>), a specialised tool for converting PDF to XML, which mitigates extraction issues such as the resolution of embedded fonts, invalid character encoding, and the reconstruction of the correct reading order, 2) it allows access to PDF document layout information for both machine learning and document decoration (e.g., coordinates in the PDF document); and, 3) it provides access to a set of high-quality, pre-trained machine learning models for structuring documents. Grobid-superconductors is structured as a three-steps process illustrated in Figure 1 and described in the Sections 2.1, 2.2, and 2.3.

Abstract versus full-text At the time of writing this paper, we are aware of related works that utilise text from abstracts as training data for machine learning. The main reason for using abstracts is that they are usually freely available as text [20], and contain condensed information [21,22]. Accurately parsing the full-text presents more challenges, however, but they are mitigated by Grobid and, the full-text contain a broader range of information, including the sample preparation process, negative results (e.g., absence of superconductivity for certain samples), and background information (e.g., reports on other materials from referenced works). Thus, grobid-superconductors is built to support full-text documents.

Paragraphs versus sentences Another question related to natural language processing (NLP) is whether to use sentence-based or paragraph-based text. While paragraphs can be extracted as part of the layout of PDF documents, obtaining sentences adds an additional step in which text is processed with a sentence segmenter. However, sentences are almost always shorter by definition, and in deep learning, this has advantages. In training and prediction, sentences will likely be shorter than the “max sequence length” limitation (e.g., 512 tokens for transformers). During training, sentences also use less memory and allow us to train models with a larger “batch size”, which has been shown to improve efficiency and obtain better results [23].

We chose to use sentence-based text in Grobid-superconductors after performing preliminary experiments on our tasks typologies, but on a smaller scale. For the Named Entities Recognition (NER) task we trained and evaluated a sequence labelling model for each version (paragraph-based and sentence-based) on four annotated documents (3/1 document partition for training/evaluation) from SuperMat [12]. As indicated in Table 1, the F1-score increased by 17.94 percentage points when the sentence-based text was used.

For the Entity Linking (EL) task, we want to maximise precision. In our previous work [24] we noticed that limiting linking entities within the same sentence (versus paragraph) would obtain higher precision (68.7% versus 57%) at the expense of lower recall (6.5% versus 10.7%), and F1-score (11.87% versus 18.01%). Therefore, in both our tasks we found evidence that a sentence-based dataset is more beneficial than paragraph-based dataset.

2.1. Document structuring and pre-processing

In the first step of our process, the PDF document is converted into an internal model based on a list of text statements, tokens, and features. The input document is processed using the Grobid original models, where we apply customised processes for document header and content. We select a subset of bibliographic information from the header: title, authors, DOI, publisher, journal, and year of publication, and we consolidate them via Grobid to match the publisher’s quality (even by processing the “preprint version” of the publication). The superconductors entities extraction is applied to the content, only on relevant text items: title, abstract, text content from body or annexes, text content from figure and table captions (Figure 2).

We use the collected reference markers (also called *reference callouts*) from the text as features for improving the paragraph segmentation in sentences: the segmentation is cancelled if the end of sentence falls within the boundaries of a reference marker. For example, a sentence containing a reference in the form “Foppiano et. al.” may be mistakenly segmented in the middle at the token “et.”.

2.2. Named Entity Recognition

In the second step, the Named Entity Recognition (NER) task is performed on the previously extracted text.

2.2.1. Overview

As illustrated in Figure 3 the “superconductor parser” extracts the main superconductor-related information by aggregating the resulting entities from two ML models. The Superconductors ML model was developed based on the SuperMat schema [12], and the Quantity ML model was developed in a separated Grobid module for measurement extraction [17] and the output is limited to only temperatures and pressures. Overlapping entities are merged, exacted duplicates are removed, and the largest entities (in terms of string length) are preserved. The resulting entities are summarised in Table 2.

Entities of type `<material>`, which may contain mixed heterogeneous information, are passed in the cascade to the “Material parser” which aggregates ML and other tools. First, the entity is passed through a Material ML model to segment and identify its content (Table 3). Then, different processes are applied, depending on which information is available. These processes include the following:

- Formulas are decomposed into a structured composition. We identify each element-stoichiometry pair (e.g., “O”: 7.0) using `mat2chem` [20] and `Pymatgen` [25]; if only the material name is available, we lookup its formula (e.g., hydrogen to H),
- Using heuristics, we classify the formula by assigning multiple classes as they are understood from superconductor researchers, for example cuprate, oxides, alloys, etc.
- Using the variables and values extracted, we substitute them into partial formulas. For example, in `La 4 Fe 2 A 1-x 0 7` ($A=Mg,Co$; $x=0.1,0.2$), we substitute A and x using their parsed values, and applying permutations, we obtain four *resolved formulas*: `La 4 Fe 2 Mg 0.9 0 7`, `La 4 Fe 2 Mg 0.8 0 7`, `La 4 Fe 2 Co 0.9 0 7`, and `La 4 Fe 2 Co 0.8 0 7`.

Finally, after all entities are extracted, the post-processing aggregates different mentions of the same materials using the parsed formulas at the document-level. For example, formula with partial substitutions such as $\text{La}_{2-x}\text{Fe}_x\text{O}_7$ ($x = 0.1, 0.2$) will be aggregated with materials like $\text{La}_{2-x}\text{Fe}_x\text{O}_7$ appearing in other sections of the same document.

2.2.2. Machine Learning study

In this section we discuss the novel ML models we have trained for extracting specialised entities: the Superconductor ML model and the Material ML model (Figure 3). SuperMat [12], our training dataset, contains 164 papers as of the time of writing and is composed of annotated full-text and layout features from PDF documents.

For both ML models we trained and evaluated the following four architecture/implementations: linear CRF (CRF), bidirectional LSTM with CRF [26] (BidLSTM-CRF), bidirectional LSTM with CRF with Features [26] (the same as (BidLSTM-CRF) with an additional input channel for features; BidLSTM-CRF_FEATURES), and SciBERT [27] using a CRF as the activation layer (Scibert).

The ML models are interfaced by Grobid, which uses the Wapiti[28] implementation for linear CRF, and DeLFT (Deep Learning For Text) [29] for deep learning models. The architectures CRF and BidLSTM-CRF_FEATURES make use of the orthogonal features we have summarised in Table A5.

Superconductor ML model

Holdout set The holdout set evaluation consists in using a fixed part of a dataset for validation. The selection must be performed to reproduce the same distribution of entities of the original dataset. We assembled the holdout set by manually selecting 32 documents (24%) from SuperMat, making sure they had a similar ratio of examples, entities and unique entities with the remaining 76% (132 documents) which was used as training set (Figure 4a). Maintaining the same rate for entity type distribution between the two sets was more challenging: on average, we obtained about 15-18% of labels of each type in the holdout set (Figure 4b), except for the `<material>` label (23%).

We defined the “out-of-domain” ratio as the number of unique entities from the holdout set that were not in the training set. The holdout set “out-of-domain” ratio was on average around 72%, which challenge the model generalisation (every 100 entities in the holdout set, 72 were never seen before during training). Most of the labels had an “out-of-domain” ratio above 50% (Figure 5); `<material>`, the most important label, had the highest ratio (82%) while `<me_method>` and `<pressure>` have the lowest (25% and 33%). The low ratio of `<me_method>` can be explained by their low entity variability (11.44%).

Positive sampling We trained the model with positive sampling by removing the examples without entities (negative examples, Figure 4a). This approach provided an improvement of 2% in both precision and recall as compared to the result without sampling when testing against the holdout set. Additional experiments with active and random sampling [16] with ratios of negative examples of 0.1, 0.25, 0.5 and 1.0 did not provide stable evidence suggesting scoring improvements when testing against

the holdout set.

Evaluation The best results were obtained by Scibert with an F1 of 77.03% and a recall of around 80.69% (Table 4). The features did not provide any improvements with RNN models: BidLSTM_CRF and BidLSTM_CRF_FEATURES resulted in the same F1 score. This result comes as a surprise because features such as superscript/subscript were expected to be determinants for recognising material sequences.

The <pressure> label had the lowest performance scores in all architectures. We believe that 274 training examples are not a sufficient large number considering that pressure expressions can be dependent on the context because they can refer to different types of pressures (e.g., annealing pressure). The label with the highest score was <material>, with F1 values of 80.77% and 78.06% for Scibert and BidLSTM_CRF, respectively. In addition, <material> had the highest “out-of-domain” ratio in the holdout set (greater than 75%, Figure 5) and the highest “label variability” (the ratio between unique entities and total entities, about 42%), which suggests that the model recognises correctly materials that has not been “seen” during the training. On the other hand, the <me_method> label, which has lower “label variability” (around 11%) and a low “out-of-domain” ratio, had an F1 score of 66.56% with Scibert and 65.92% with BidLSTM_CRF. For <tc>, the CRF outperformed the other architectures (F1 score of 83.96%), especially Scibert (78.35%). This outcome can be explained by the extremely low variability (12.69%) of entities labelled as <tc>.

Scibert shows good generalisation capacity for unseen examples or examples appearing in different contexts. For example, in Figure 6a, only Scibert correctly extracts “above 100K”, while CRF misses it completely and BidLSTM_CRF misses “above”. In the training data, “above 100K” is not present, but “below 100K” and “~100K” are present, and several other entities contain the token “above” and Scibert can understand that the token “above” is relevant to the temperature. In a second example (Figure 6b), only Scibert can correctly extract “W-C nanowire” which is not present in the SuperMat training data. Unfortunately, we cannot check whether “above 100K” or “W-C nanowire” are also present in the dataset used in the pre-train of SciBERT by their authors [27] because the data are not available.

Material ML model To train the Material ML model we created a special dataset with an additional layer of labels (Table 3), which included the material information represented by entities annotated as <material> in the SuperMat documents.

Holdout set In this model we created an independent holdout set because the manual annotation work is performed on smaller chunks of text and requires less effort than annotating sentences as when we developed SuperMat. We used material data extracted from a dataset of 500 documents (500-papers) from three publishers: *American Institute of Physics* (AIP), *American Physical Society* (APS) and *Institute of Physics* (IOP) [24]. The resulting holdout set has a average coverage greater than 25% (Figure 7) and an average “out-of-domain” ratio of 83.93% (Figure 8).

Evaluation Scibert obtained the best results, with F1 at 84.15% (Table 5). The inclusion of features in the BidLSTM_CRF architecture only improved results by less than 1% (from 83.13 to 83.76%). The label <fabrication> did not perform well with any architecture, most likely because it is too generic (Table 3), and the content is too heterogeneous. Another label, <substrate> has only one-third of the training exam-

ples of <fabrication> but obtained results that were three times higher with Scibert, suggesting that <fabrication> should be split into separate and more homogeneous labels.

2.3. Entity Linking

Entity linking (EL) links materials and their corresponding properties.

We use a rule-based algorithm, but there are other approaches such as the use of dependency parsing [30–33]. We did not use these because it was difficult to find a suitable dependency parser for scientific texts, and complementary methods based on complex rule sets were needed to compensate for the poor performance of the parser.

In our algorithm, pairs of entities are linked focusing on three types of link:

- **material-tcValue**: The link between a material and its corresponding T_c .
- **tcValue-pressure**: The link between T_c and its related critical pressure.
- **me_method-tcValue**: The link between T_c and its corresponding measurement method.

Entities of type <tcValue> are pre-processed through a classifier that establishes whether or not they temperatures related to the superconductivity. This is used to exclude other temperatures (e.g., annealing, transition, Curie) which might be incorrectly extracted by the previous step. This rule-based classifier combines the extracted entities of T_c expressions (label <tc>) with a set of predefined standard terms. If a temperature is not considered a T_c , it is excluded from the list of possible linking candidates.

Two scenarios are considered. First, if entities to be linked in the sentence are only two they are linked automatically, else further rules are applied. If the word “respectively” appears in the sentence, we apply “order-linking”. For example, consider the following sentence:

P-or Ba-122 and Co-doped Ba-122 have lower T_c 's of about 30 K and 24 K, respectively, which makes helium free operation questionable.

It contains the word “respectively”, and by applying “order-linking”, *P-or Ba122* is assigned to *30 K* and *Co-doped Ba-122* to *24 K*.

If the word “respectively” does not appears in the sentence, we apply “distance-linking” which works by defining the distance measurement d as a value calculated as the numbers of characters between the centroid of each entity. Entities surrounded by parenthesis are expanded to the whole parenthesis, and its centroid is updated. As an example, in the sentence

We tested two materials MgB2 ($T_c = 39$ K) and FeSe ($T_c = 16$ K).

39 K is closer to FeSe ($d=10$) than to MgB2 ($d=11$). In this example, however, both temperatures entities would be expanded to their containing parenthesis (e.g. “39 K” to “(Tc = 39 K)”). In this case the centre of the entity “39 K” is shifted toward the left, from the initial value of 38 to 35 and the distance from MgB2 is reduced from $d=11$ to $d=8$. As a result, the MgB2 entity is correctly linked to “39 K”.

The distance calculation is also adjusted with the addition of “penalties” by doubling the calculated distance when certain keywords or punctuations (“,”, “.”, “;”, “and”, “but”, “while”, “whereas”, “which”, “although”) appear between two entities because they represent a logical separation of predicates [34]. In the above example, the distance between 39 K and FeSe would be doubled ($d=20$) and the link would not

be made.

This rule-based linking was evaluated using the linked entities from Super-Mat [12] (Table 6) and is divided considering each link type. The F1 score for the `material-tcValue` was about 80% with a precision of 88.40%. `tcValue-pressure` F1 score was 3% lower than `material-tcValue` considering much less data available (support was 118 compared with 726).

2.4. End to end evaluation

End-to-end evaluation (E2EE) measures the capacity of the system from the PDF documents until the final linked results. We limited the scope of the E2EE to the triplet ‘material- T_c -pressure’ which, at the moment, is the backbone upon which the database is built. We performed the E2EE on the “500-papers” dataset where we manually examined the resulting database as follows: 1) we marked invalid records and 2) we identified the cause of failure from a predefined set of five *error types* (Figure 9):

- **From table:** the extracted text is wrongly extracted from a table. Although table content is ignored, the error rate from the Grobid library is still relevant due to the lack of training data.
- **Extraction:** entities are not recognised, wrongly recognised, or partially recognised.
- **Quantity extraction:** quantity entities (pressure, temperature) are not correctly extracted. We measured this error separately to identify the failure that could be shared with the Quantity ML model.
- **T_c classification:** the temperature is wrongly classified as superconducting T_c .
- **Linking:** given the initial steps were performed correctly, the resulting entities are not linked correctly.

The E2EE scores are summarised in Table 7. Recall is omitted because it is less relevant and difficult to calculate manually. The precision score (micro average) was 72.60% for all the subsections, although the error rates of figure captions (59.28%) and unknown subsections (57.14%) were clearly lower than those of the other subsections (> 70%). The ‘unknown’ subsections indicate that the extracted text’s structure was not well identified by Grobid but it was nevertheless aggregated. The overall score increases to 73% when excluding unknown subsections, 75.24% when excluding figure captions, and 79.14% when excluding both. Excluding these two subsections will not impact the amount of text, because both account for less than 20% of the total number of subsections.

The error types are summarised in Figure 10. The most common failures originate from T_c classification (40%), Linking (32%), and Extraction (20%). The most common T_c classification failures are as incorrect recognition of 1) relative values of T_c (e.g., 1 K higher than material X); 2) values indicating the transition temperature width (ΔT_c); 3) temperature values that are not T_c , for example, material synthesis temperatures (T), other critical transition temperatures that are not superconducting (e.g., T_{Curie}); and 4) values of temperature at which there is no superconductivity (e.g., “at 70 K there is no superconductivity”). “Linking errors” mainly occur when the text compare relative values of T_c using materials as the basis for comparison (e.g., “The $T_c = 38$ K is similar to the one of MgB_2 ”). Finally, “Extraction” issues mainly originate from: 1) implicit mention of the main material when experimented using different “substrates” combination, and 2) mismatches between `<material>` and `<class>` which,

by definition, overlap.

3. Supercon²

We created SuperCon² by processing 37770 research papers belonging to the category *cond-mat.supr-cond* in ArXiv. Currently SuperCon² contains 40324 records including 2052 triplets with applied pressure (*material-T_c-pressure*), and 3602 records with explicit measurement method (*material-T_c-measurement method*). The schema of SuperCon² is summarised with examples in Table 8.

The data is processed and ingested through the asynchronous Map-Reduce approach [35]. The “extraction task” (Map) processes the PDF documents by accessing Grobid-superconductors via REST API and stores their processed representation together with the original PDF document. Furthermore, the “aggregation task” (Reduce) reduces the document information into a synthesised tabular format. We store the processed document representation in JSON format. The processed documents are kept separately and used for displaying the enhanced PDF document (Figure 11). The pipeline uses a persistence layer for storage and reporting (logger).

We built a visualisation interface to exploit the extracted information. Users can search in the synthesised tabular data, access the PDF document enriched with the extracted information (Figure 11), and export locally in CSV, TSV and Microsoft Excel formats.

4. Conclusion

In this work, we present our solution for automatically building a database of materials and properties from scientific literature. Our contribution is composed of: 1) Grobid-superconductors, a specialised open-source system that processes PDF documents combining ML and rule-based methods to extract and link relevant information in superconductors research; 2) a pipeline allowing large-scale document processing; and 3) a visualisation interface for rapid data exploration, which includes PDF document information enrichment.

We made SuperCon², a database with 40324 records of superconductors materials and properties, including the applied pressure and the T_c measurement method. SuperCon² is available in text format at <https://github.com/lfoppiano/supercon>.

In the future, we plan to improve our tools by 1) extracting more properties, such as crystal structure type, space groups type, and lattice structure; 2) training supervised models for the “Linking step”; and 3) extending the interface to support data correction toward efficient curation. We confirmed the good generalisation ability of the Scibert architecture for the entity extraction task. Although we hope to obtain better results using materials science pre-trained BERT, such as MatSciBERT [36], the gain might be just minimal for relatively larger models [37].

Acknowledgement

Our warmest thanks to Sae Dieb, who contributed with fruitful discussion on this project, and to Patrice Lopez, the author of Grobid [13], DeLFT [29], and other several interesting TDM projects for his continuous support and help with ideas, suggestions,

and discussions.

Data and code availability

Grobid-superconductors is available on Github at <https://github.com/lfoppiano/grobid-superconductors> and the code is released under license Apache 2.0. SuperCon² is available in text format at <https://github.com/lfoppiano/supercon>.

Figures & Tables

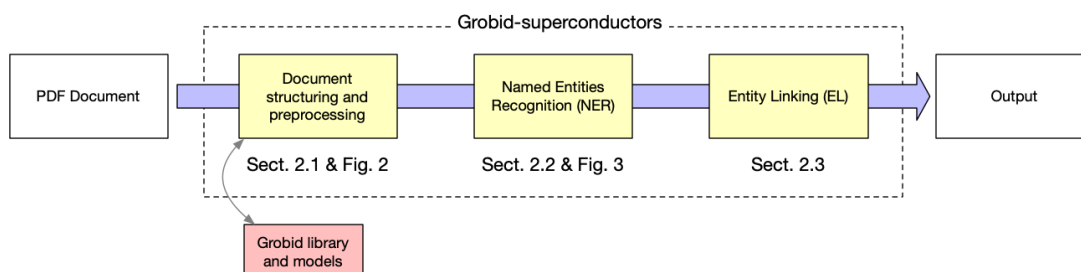

Figure 1. Processing pipeline for extracting superconductors materials and properties.

Table 1. Results from cross-validation for sentence-based and paragraphs-based text.

Label	Precision	Recall	F1
Paragraph-based micro avg.	44.44	27.21	33.76
Sentence-based micro avg.	48.41	50.00	51.70

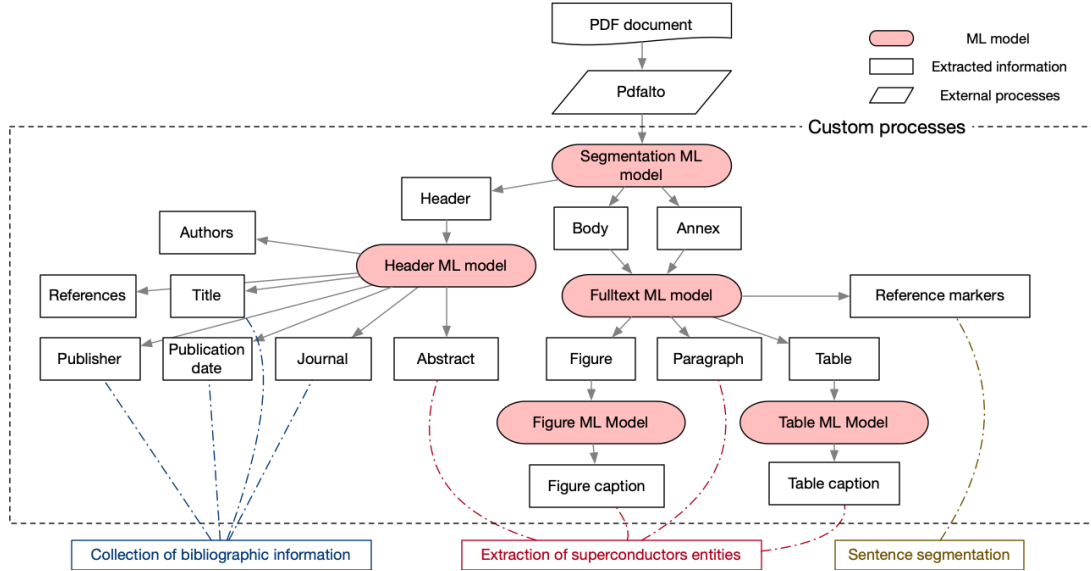

Figure 2. Grobid-superconductors extraction processes (bibliographic information, superconductor entity extraction and sentence segmentation) within the Grobid cascade data flow.

Table 2. Entities extracted by the superconductors parser.

Entity (tag)	Description
Material (<material>)	Materials and samples names, formulas (including stoichiometric formulas), substitution variables of values and elements, shape, doping, and substrate
Class (<class>)	Groups of materials having similar characteristics or common strategic compounds that define their nature
T _c value (<tcValue>)	The value of the superconductor critical temperature
T _c expressions (<tc>)	Expressions in the text that provide information about the phenomenon of superconductivity related to a value, interval or variation of the T _c
Measurement method (<me_method>)	Technique used to measure or calculate the presence of superconductivity
Applied pressure (<pressure>)	Applied pressure when superconductivity is recorded

Table 3. Entities extracted by the material parser.

Entity (tag)	Description
Name (<name>)	The canonical name of a material (e.g., hydrogen, PCCO, carbon)
Formula (<formula>)	Chemical formula of the material (e.g., Pr _{1.869} Ce _{0.131} Cu _{0.4-} MgB ₂ , La _{2-x} Sr _x CuO ₄)
Doping (<doping>)	Doping ratio and doping materials that are adjoined to the material name (e.g., Zn-doped, 2% Zn-doped)
Shape (<shape>)	shape of the material (e.g. single crystal, polycrystalline, thin film, powder, film)
Substitution variables (<variable>)	Variables that can be substituted in the formula.
Substitution values (<value>)	Values expressed in the doping.
Substrate (<substrate>)	Substrates as defined in the material name
Fabrication (<fabrication>)	Additional information that does not belong to any of the previous tags (e.g., intercalated, electron-doped)

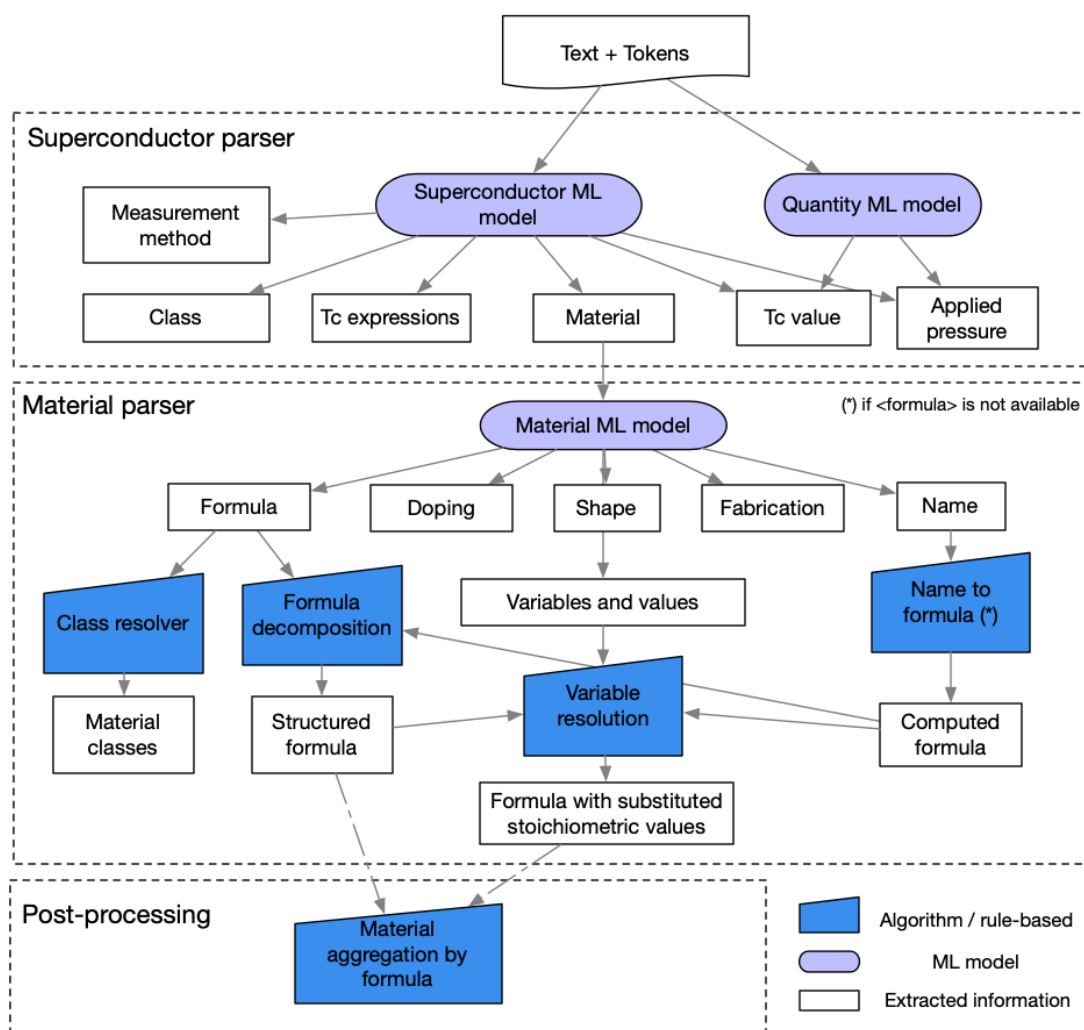

Figure 3. Cascade architecture in the NER step. The white rectangles indicate the extracted information (described in Tables 2 and 3).

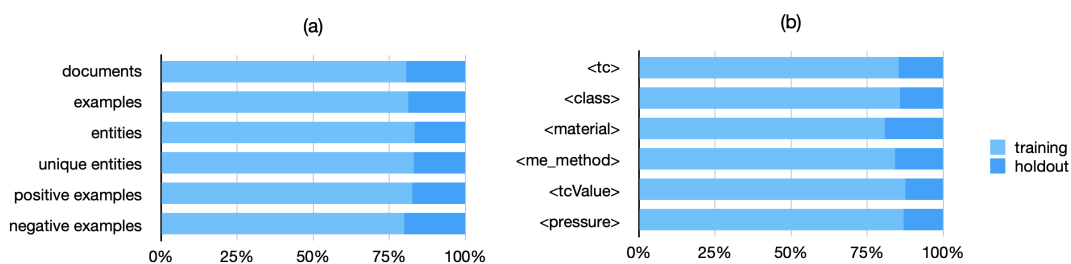

Figure 4. Holdout/training set distribution for (a) general metrics and (b) entity labels; entities and unique entities indicate the number of labelled entities with and without value duplicates, respectively, and positive examples (+) and negative examples (-) indicate the number of sentences with at least one entity and with no entities, respectively.

Figure 5. Holdout “out-of-domain” rates. The entities from the holdout set that are also in the training set are “in-domain” and the entities that are not in the training set are “out-of-domain”.

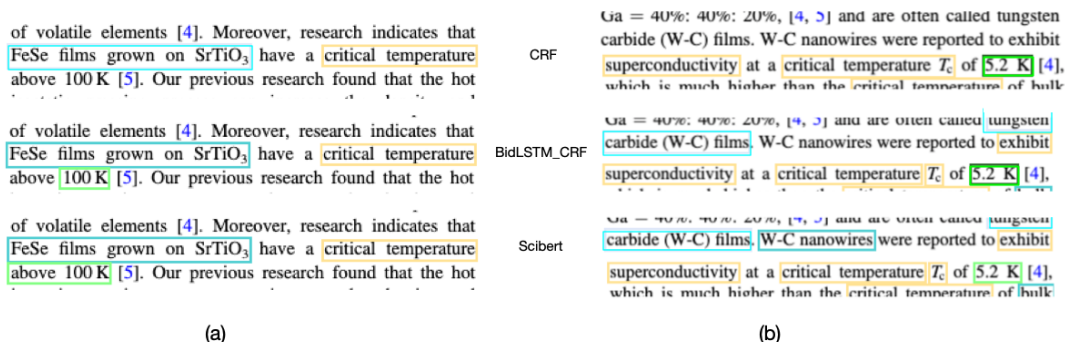

Figure 6. Examples taken from two sources [38,39] of results from three different architectures: CRF, BidLSTM_CRF and, Scibert. The boxes annotating the text represent the extracted entities (material are indicated in light blue, T_c in green, and T_c expressions in yellow).

Table 4. Evaluation scores (%) for the Superconductor ML model in the four architectures. For the DL architecture the results are averaged over 5 runs. Support (Supp) indicates the number of labels in the training data. Values in bold indicate the highest score. P: precision, R: recall.

Structural, electronic, vibrational, and superconducting properties of hydrogenated chlorine

Artur P. Durajski¹⁾ and Radosław Szczęśniak
*Institute of Physics, Czestochowa University of Technology, Ave. Armii Krajowej 19,
 42-200 Czestochowa, Poland*

(Received 29 March 2018; accepted 29 July 2018; published online 16 August 2018)

Recent measurements have set a new record for the superconducting transition temperature (T_c) at which a material loses electrical resistivity and exhibits ideal diamagnetism. Theory-oriented experiments show that the compressed hydride of Group VI (hydrogen sulfide, H_2S) exhibits a superconducting state at 203 K. Moreover, a Group V hydride (phosphorus hydride, PH_3) has also been studied and its T_c reached a maximum of 103 K. The experimental realisation of the superconductivity in H_2S and PH_3 inspired us to search for other hydride superconductors. Herein, we report theoretical studies of the electronic, vibrational, and superconducting properties of hydrogenated chlorine (H_3Cl , representative of the Group VII hydride). First-principles calculations performed for H_3Cl in the pressure range 150–250 GPa show that the investigated $Im\bar{3}m$ phase has a large electron-phonon coupling parameter and the resulting application of the Migdal-Eliashberg formalism yields a remarkably high superconducting temperature of 198 K at 150 GPa. Published by AIP Publishing. <https://doi.org/10.1063/1.5031202>

I. INTRODUCTION

Searching for the superconducting state at critical temperature as high as possible is currently one of the major activities in condensed matter physics.^{1–6} The great breakthrough in this area occurred in 2014 when the hydrogen sulfide (H_2S) was predicted theoretically by Li *et al.* to be a novel conventional high-temperature superconductor with an estimated maximal transition temperature of about 80 K at 160 GPa.⁷

Shortly after this theoretical report, compression in a diamond anvil cell of a sulfur hydride system leads to the confirmation of these predictions and direct experimental observation of two superconducting states: (i) $T_c = 50–150$ K for low-temperature prepared samples and (ii) $T_c = 170–203$ K for room-temperature prepared samples.⁸ The superconducting

measurements^{12,13,15,16} confirming that the stable $Im\bar{3}m$ phase is responsible for high- T_c superconductivity. Interestingly, Guigüe *et al.* conducted experiments which employed direct synthesis of pure H_2S from S and H elements.¹⁷ At high pressure, the obtained H_2S samples are identified to have the $Ccmm$ phase up to 160 GPa. On this basis, Guigüe *et al.* suggested that the body-centered cubic $Im\bar{3}m$ structure is rather more metastable than the thermodynamic ground state.^{4,17} Most recently, Goncharov *et al.* reported that $Ccmm$ is admittedly stable in a wide pressure range, but unlike the previous observations of Guigüe *et al.*, they found that $Im\bar{3}m$ H_2S is the most favorable crystalline phase above 140 GPa.¹⁸

The measured critical temperature exhibits a pronounced isotope shift consistent with BCS theory.^{19,20} This fact allows considered H_2S to be a conventional phonon-mediated super-

material

name: H₃Cl

class: Alloys, Hydrides
formula: H₃Cl

Figure 11. Example of a superconductors research PDF document [40] enriched with extracted annotations. Materials information (class, formula) and properties (T_c) are summarised in the information box when the users click on the highlighted annotated entity in the text.

Table 8. Summary and description of the SuperCon² schema. “Internal information” is technical information not accessible to the users.

Field name	Description	Examples
<i>Material information</i>		
Raw material	The material or sample as it appears in the text	
Name	Canonical name of a material	PCCO, PCO, Metal diboride, hydrogen, carbon
Formula	Material expressed as chemical formula. This includes also formulas with stoichiometric variables	$Pr_{1.869}Ce_{0.131}CuO_{4-\delta}$, MgB_2 , $La_{2-x}Sr_xCuO_4$
Doping	Doping ratio and doping materials that might be adjoined to the material	Overdoped, underdoped, optimally doped, bulk, pure, 1% Zn, Zn (from Zn-doped XYZ)
Shape	The shape of the material or the sample	Single crystal, polycrystal, wire, powder, film
Variables	Variables that can be substituted in the formula	$x = 0$, RE=Ln,St
Class	Material classification according to the domain-experts taxonomy	cuprates, oxides, and alloys
Fabrication	All the information that does not belong to any of the previous tags	Intercalated, synthesized by MBE method, electron-doped, hole-doped
Substrate	Substrate material described in the raw material	PCCO films onto $Pr_2CuO_4(PCO)/SrTiO_3$
<i>Properties</i>		
Critical Temperature	Superconducting critical temperature	
Applied Pressure	Pressure applied when measuring the superconducting critical temperature	
Measurement Method	Method for measurement of the superconducting critical temperature	Magnetic susceptibility, specific heat, calculation, prediction, resistivity
<i>Document bibliographic information</i>		
Section	The main body section of the paper	Header, body, annex
Subsection	The secondary segmentation area of the paper	Paragraph, table caption, figure caption, title, abstract
Authors, Title, DOI, Publisher, Journal, Year	Bibliographic information of the document	
<i>Internal information</i>		
Hash, Timestamp	Hash calculated on the binary content of the original PDF document and the timestamp when the document was processed.	

Appendix A. Additional information

Table A1. Holdout/Training set distribution (%) between training and holdout sets for the Superconductor ML model. Positive examples indicate the number of sentences with at least one entity, and negative examples the number of sentences with no entities.

	training	holdout	% holdout/training
documents	132	32	24.24%
