## Abstract

Normalizing Flows (NF) are powerful likelihood-based generative models that are able to trade off between expressivity and tractability to model complex densities. A now well established research avenue leverages optimal transport (OT) and looks for Monge maps, i.e. models with minimal effort between the source and target distributions. This paper introduces a method based on Brenier’s polar factorization theorem to transform any trained NF into a more OT-efficient version without changing the final density. We do so by learning a rearrangement of the source (Gaussian) distribution that minimizes the OT cost between the source and the final density. We further constrain the path leading to the estimated Monge map to lie on a geodesic in the space of volume-preserving diffeomorphisms thanks to Euler’s equations. The proposed method leads to smooth flows with reduced OT costs for several existing models without affecting the model performance.

## 1 Introduction

Modeling high dimensional data is a central question in data science as they are ubiquitous in applications. Various tasks such as probabilistic inference, density estimation or sampling of new data require accurate probabilistic models that need to be defined efficiently. There exists a large variety of generative models in the literature. Among other

<sup>1</sup> IMT Atlantique: {guillaume.morel, lucas.drumetz, simon.benaïchouche, francois.rousseau}@imt-atlantique.fr

<sup>2</sup> IRISA: nicolas.courty@irisa.fr

approaches, variational autoencoders (VAES) (Kingma and Welling, 2014; Rezende et al., 2014) and generative adversarial networks (GAN) (Goodfellow et al., 2014) are frequent choices, each with their strengths and weaknesses.

**Normalizing flows.** A third popular class of generative models is Normalizing flows (NF). NF models transform a known probability distribution (Gaussian in most cases) into a complex one allowing for efficient sampling and density estimation. To do so they use a smooth diffeomorphism  $\mathbf{f} : \mathbb{R}^d \rightarrow \mathbb{R}^d$  which maps a target probability distribution  $\mu$  to the known source distribution  $\nu = \mathbf{f}_\# \mu$  (Dinh et al., 2014; Rezende and Mohamed, 2015). In practice the flow must satisfy the change of variables formula:

$$\log p_\mu(\mathbf{x}) = \log p_\nu(\mathbf{f}(\mathbf{x})) + \log |\det \nabla \mathbf{f}(\mathbf{x})|. \quad (1)$$

There are many possible parameterizations of  $\mathbf{f}$ , usually relying on automatic differentiation to train their parameters via first order optimization algorithms. For density estimation applications, training is done by maximizing the likelihood of the observed data. The data are generally high dimensional and accessing  $p_\mu(\mathbf{x})$  for a given  $\mathbf{x}$  requires computing determinant of the Jacobian matrix of  $\mathbf{f}$ . This operation has a complexity of  $O(d^3)$  in general and thus a requirement for the flows architecture is to have a tractable determinant of the Jacobian while remaining expressive enough (Dinh et al., 2014; Kingma and Dhariwal, 2018; Rezende and Mohamed, 2015; Papamakarios et al., 2021).

**Optimal transport.** A diffeomorphism transforming any well-behaved distribution into another always exists in theory (Papamakarios et al., 2021). However, there can be many ways to transform one probability measure  $\mu$  into another probability measure  $\nu$ , and therefore the function  $\mathbf{f}$  is generally not unique. This has led to many proposed architectures in the literature (Kingma and Dhariwal, 2018; Grathwohl et al., 2018; Huang et al., 2018; De Cao et al., 2020; Papamakarios et al., 2017). The question of choosing the ”best” transformation among all existing ones is therefore crucial, independently from how accurately  $\mu$  models the target distribution. One way to make the architecture unique (under appropriate conditions on the two distributions) is to use optimal transport (Hamfeldt, 2019; Peyré et al., 2017; Santambrogio, 2015; Villani, 2008), that is to

**Figure 1:** A GP transformation applied on particles sampled from a two dimensional normal distribution. The mean and standard deviation stay the same; only the positions of the particles change.

choose the one giving the Wasserstein distance between  $\mu$  and  $\nu$ , with a squared  $\mathcal{L}_2$  ground cost:

$$W_2^2(\mu, \nu) = \min_{\mathbf{f}} \int_{\mathbb{R}^d} |\mathbf{f}(\mathbf{x}) - \mathbf{x}|^2 d\mu(\mathbf{x}), \quad \nu = \mathbf{f}_{\#}\mu. \quad (2)$$

An optimal model in the sense of (2) minimizes the total mass displacement which can be a desirable property even if it is often a difficult task. In particular Brenier’s theorem (Brenier, 1991) states that the optimal function  $\mathbf{f}$  is the gradient of a scalar convex function, which is widely used when solving (2).

One key property of OT mappings is that they should better preserve the structure of the distribution compared to non OT transformations. This makes them particularly appealing for machine learning applications, and may also help with generalization performance (Karkar et al., 2020).

**Optimal transport and NF models.** Including OT in NF models has recently received much attention with various approaches to obtain a map  $\mathbf{g}$  which satisfies the property (2). Among all these methods, many use either directly Brenier’s theorem (Brenier, 1991) or the dynamic OT formulation with the Benamou-Brenier approach (Benamou and Brenier, 2000). One important remark is that most of the approaches considered need dedicated architectures in order to satisfy the OT property. For example the transformation  $\mathbf{f}$  is often written as neural network modeling the gradient of a (possibly convex) scalar function (Finlay et al., 2020a; Huang et al., 2020; Onken et al., 2020; Zhang et al., 2018). This sometimes requires some particular training process (Finlay et al., 2020a; Huang et al., 2020; Onken et al., 2020) and/or the addition of some penalization terms in the loss function (Onken et al., 2020; Finlay et al., 2020b; Yang and Karniadakis, 2020). When considering the Benamou-Brenier formulation, the normalizing flow is interpreted as the discretization of a continuous ordinary differential equation (Chen et al., 2018b) and the optimal transport problem is then solved dynamically (Finlay et al., 2020b; Onken et al., 2020; Zhang et al., 2018).

## 1.1 Main contributions

**Polar factorization.** An overlooked implication of Brenier’s theorem is the so-called polar factorization theorem,

that states that the optimal transport map  $\nabla\psi$  solving (2) can be factorized into the composition of two functions  $\nabla\psi = \mathbf{s} \circ \mathbf{f}$ , the function  $\mathbf{f}$  being some arbitrary smooth map from  $\mu$  to  $\nu$  and  $\mathbf{s}$  an associated measure preserving function of  $\nu$  (Brenier, 1991). The idea we exploit is the possibility, from a given flow  $\mathbf{f}$  (and its corresponding inverse  $\mathbf{g} = \mathbf{f}^{-1}$ ), to rearrange the distribution  $\nu$  using  $\mathbf{s}$  to obtain a new map reducing the OT cost without changing the distribution given by the push-forward  $\mu := \mathbf{g}_{\#}\nu = (\mathbf{g} \circ \mathbf{s}^{-1})_{\#}\nu$ . The OT-improved map can then be obtained with the composition  $\mathbf{g} \circ \mathbf{s}^{-1}$ . Interestingly this property is not as popular as the previous one and to our knowledge is not used when dealing with OT and NF models. Yet normalizing flows can take advantage of this formulation mostly because the distribution  $\nu$  is known and simple (here and in the following  $\nu$  is a standard normal) which make it possible to construct architectures preserving  $\nu$ .

**Gaussian preserving flows.** Our work differs from the state of the art as we do not propose a new normalizing flow model. Instead we propose to use Brenier’s theorem to compute the Monge map for any pre-existing architecture. Indeed there exists a wide variety of architecture available in the literature (Kingma and Dhariwal, 2018; Grathwohl et al., 2018; Huang et al., 2018; De Cao et al., 2020; Papamakarios et al., 2017) each with their pros and cons which sometimes depend specifically on the test case considered. Our idea is to use Brenier’s polar factorization theorem to rearrange the points in the known distribution to obtain the optimal map associated with a given flow. We consider the most common case where the known distribution is a standard normal and call such rearranging maps Gaussian Preserving (GP) flows, see Figure 1. An important point is that by construction our GP map will only change the OT cost of the model. The target density and therefore the training loss given by the model will stay the same. This allows us to take any pre-trained model and compute the associated Monge map, thus improving the model in terms of OT displacement from the source to the target distribution, without changing the modeled density see Figure 2.

**Construction of divergence free functions in high dimensions.** We show that divergence free functions can be used to model GP flows. We therefore derive an effective construction of divergence free functions in high dimensions and apply it in the latent space of some popular VAE models.

**Euler’s equations.** Since several GP flow models can solve the same OT problem, we also look for a way to find the “best” GP flow. This is somehow similar to the approaches from (Finlay et al., 2020b; Onken et al., 2020) where the trajectories of a continuous normalizing flow are penalized to be straight lines. This is not strictly needed to find the Monge map but can be interpreted as some geodesic over all the flows which solve the associated OT problem. In this work, we show that the geodesics associated with the OT problem are actually given by solutions to the Euler

**Figure 2:** Eight gaussians test case with colored distributions. A GP flow is trained on a pre-trained BNAF model (De Cao et al., 2020) to reduce the OT cost.

equations, following a celebrated result by Arnold (Arnold, 1966). The penalization of Euler’s equations in high dimensions and its practical implementation is therefore also considered, which is to the best of our knowledge an original contribution.

### Disentanglement preservation with optimal transport.

Finally we show one potential interest of GP flows by studying the preservation of the data structure experimentally. More specifically we focus on the preservation of disentanglement on the dSprites (Matthey et al., 2017) and MNIST (Lecun et al., 1998) datasets in some variational auto-encoder (VAE) latent space. On this particular example we show that OT allows to improve the preservation of the structure of the latent data points which is otherwise destroyed when applying the NF model.

## 2 Polar factorization theorem

The main idea is to use the Brenier’s polar factorization theorem to construct the Monge map with a rearrangement of the known probability distribution  $\nu$ . To preserve the conventions from Brenier’s paper (Brenier, 1991), we study the OT problem defined from the known probability distribution  $\nu$  to  $\mu$  and therefore consider the function  $\mathbf{g} := \mathbf{f}^{-1}$ .

**Theorem 1** (Brenier’s polar factorization (Brenier, 1991)). *Let  $(\mathcal{X}, \nu)$  be a probability space,  $\mathcal{X} \subset \mathbb{R}^d$  open bounded. Then for each non-degenerate  $\mathbf{g} \in L^p(\mathcal{X}, \nu, \mathbb{R}^d)$ , there exists a unique convex function  $\psi : \mathcal{X} \rightarrow \mathbb{R}$  and a measure preserving function  $\mathbf{s} : \mathcal{X} \rightarrow \mathcal{X}$  such that*

$$\mathbf{g}(\mathbf{x}) = \nabla \psi(\mathbf{s}(\mathbf{x})),$$

and  $\mathbf{s}(\mathbf{x})$  minimizes the cost  $\int_{\mathcal{X}} |\mathbf{g}(\mathbf{x}) - \mathbf{s}(\mathbf{x})|^2 d\nu(\mathbf{x})$ .

Our goal is to leverage the polar factorization theorem in order to solve the OT problem between  $\nu$  and  $\mu := \mathbf{g}_{\#}\nu$  where  $\mathbf{g}$  is given and  $\nu = \mathcal{N}(\mathbf{0}, \text{Id})$ , by looking for the rearrangement  $\mathbf{s}$  via an optimization problem. To do so we need to construct a class of measure preserving maps.

**Remark 1.** *Since in practice we consider  $\nu$  to be a standard normal, the domain  $\mathcal{X}$  is not bounded and therefore does not strictly satisfy the hypothesis of Theorem 1. We do not*

*investigate this point further and simply quote a remark from Brenier’s work (Brenier, 1991): “we believe that the result is still true when  $\mathcal{X}$  is unbounded, provided that  $p > 1$  and  $\int_{\mathcal{X}} \|\mathbf{x}\|^q \beta(\mathbf{x}) d\mathbf{x} < +\infty$ , where  $1/q + 1/p = 1$ ”. The function  $\beta(\mathbf{x}) = e^{-\|\mathbf{x}\|^2/2}$  is the probability density of  $\nu$ , and the inequality is therefore satisfied.*

## 3 Gaussian preserving flows

In order to apply Brenier’s polar factorization theorem, it is therefore needed to construct a class of measure preserving maps. Since we consider the case where  $\nu$  is a standard normal, we call such maps Gaussian preserving (GP). All proofs of the propositions and lemmas are given in Appendix B.

Consider two probability measures  $\alpha$  and  $\beta$  with density  $h_\alpha$  and  $h_\beta$  respectively. A map  $\mathbf{s}$  is measure preserving between  $\alpha$  and  $\beta$  if it satisfies the change of variable equality (same as (1) without the log)  $h_\alpha(\mathbf{x}) = h_\beta(\mathbf{s}(\mathbf{x})) |\det(\nabla \mathbf{s}(\mathbf{x}))|$ . In our case, we want  $\mathbf{s}$  to be Gaussian preserving therefore  $h_\alpha = h_\beta = e^{-\|\mathbf{x}\|^2/2}$  and one gets

$$|\det \nabla \mathbf{s}(\mathbf{x})| = e^{(\|\mathbf{s}(\mathbf{x})\|^2 - \|\mathbf{x}\|^2)/2}. \quad (3)$$

It turns out that Lebesgue preserving functions (i.e. satisfying  $|\det \nabla \phi| = 1$ ) can be used to construct maps satisfying (3). In the following we will denote  $\text{erf} : \mathbb{R}^d \rightarrow \mathbb{R}^d$  the distribution function of a one dimensional Gaussian (that is  $\text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt$ ) applied component wise.

**Proposition 1.** *Let  $\mathbf{s}$  be a smooth Gaussian preserving function (i.e. satisfying (3)). Then there exists  $\phi : (-1, 1)^d \rightarrow (-1, 1)^d$  such that  $|\det \nabla \phi| = 1$  and*

$$\mathbf{s}(\mathbf{x}) = \sqrt{2} \text{erf}^{-1} \circ \phi \circ \text{erf}\left(\frac{\mathbf{x}}{\sqrt{2}}\right), \quad \mathbf{x} \in \mathbb{R}^d.$$

From now on we will focus on the construction of volume and orientation preserving maps (i.e. satisfying  $\det \nabla \phi = 1$ ) since functions satisfying  $\det \nabla \phi = -1$  can be constructed from them see Appendix B.1.2. Moreover, one has the following result regarding the regularity of GP flows.

**Lemma 1.** *Assume the Monge map and the NF architecture are  $C^1$  diffeomorphisms. Then the corresponding GP flow  $\mathbf{s}$  is  $C^1$ , the associated function  $\phi$  is also  $C^1$  and either satisfies  $\det \nabla \phi(\mathbf{x}) = 1$  everywhere or  $\det \nabla \phi(\mathbf{x}) = -1$  everywhere.*

### 3.1 Volume-orientation preserving maps

First we introduce the space  $\text{SDiff}(\Omega)$  we will working with from now on. Let  $\text{Diff}(\Omega)$  be the set of all diffeomorphisms in  $\Omega$  then  $\text{SDiff}(\Omega) := \{\psi \in \text{Diff}(\Omega), \det(\nabla \psi)(\mathbf{x}) = 1, \forall \mathbf{x} \in \Omega\}$ , where  $\Omega = (-1, 1)^d$ . That is we need a transformation which satisfies two properties: 1) the function must be volume and orientation preserving, 2) the solution must stay in the domain  $(-1, 1)^d$ . Consider the following ODE:

$$\begin{cases} \frac{d}{dt} \mathbf{X}(t, \mathbf{x}) = \mathbf{v}(t, \mathbf{X}(t, \mathbf{x})), & \mathbf{x} \in \Omega, \quad 0 \leq t \leq T, \\ \mathbf{X}(0, \mathbf{x}) = \mathbf{x}. \end{cases} \quad (4)$$

We impose two conditions on the velocity  $\mathbf{v}$ :

$$\begin{aligned} \nabla \cdot \mathbf{v} &= 0, & \text{in } \Omega, & (5) \\ \mathbf{v} \cdot \mathbf{n} &= 0, & \text{on } \partial\Omega, & (6) \end{aligned}$$

where  $\mathbf{n}$  is the outward normal at the boundary of  $\Omega$ . We define  $\phi$  to be the solution at the final time  $\phi(\mathbf{x}) := \mathbf{X}(T, \mathbf{x})$ . Property (5) implies that  $\det \nabla \phi = 1$ , and property (6) ensures that  $\phi$  does not escape  $\Omega$ . Any function in  $\text{SDiff}(\Omega)$  can be written as a solution to (4) for  $d \geq 3$  (Shnirelman, 1993), for  $d = 2$  some pathological cases can be constructed (Shnirelman, 1994).

**Divergence free vector fields.** First we focus on the vector fields satisfying (5) for arbitrary large dimensions. Property (6) can then be incorporated with very little additional work.

**Proposition 2.** *Consider an arbitrary vector field  $\mathbf{v} : \mathbb{R}^d \rightarrow \mathbb{R}^d$ . Then  $\nabla \cdot \mathbf{v} = 0$  if and only if there exists smooth scalar functions  $\psi_j^i : \mathbb{R}^d \rightarrow \mathbb{R}$ , with  $\psi_j^i = -\psi_i^j$  such that*

$$v_i(\mathbf{x}) = \sum_{j=1}^d \partial_{x_j} \psi_j^i(\mathbf{x}), \quad i = 1, \dots, d, \quad (7)$$

where  $\mathbf{v} = (v_1, \dots, v_d)$ .

To impose the boundary conditions (6) one can simply multiply each  $\psi_j^i$  by  $(x_i^2 - 1)(x_j^2 - 1)$ .

**Lemma 2.** *Let  $\Omega = [-1, 1]^d$  and consider the functions  $\psi_j^i(\mathbf{x}) = (x_i^2 - 1)(x_j^2 - 1)\tilde{\psi}_j^i(\mathbf{x})$  where  $\tilde{\psi}_j^i(\mathbf{x}) : \mathbb{R}^d \rightarrow \mathbb{R}$  are arbitrary scalar functions satisfying  $\tilde{\psi}_j^i = -\tilde{\psi}_i^j$ . Then the function  $\mathbf{v}$  defined in Proposition 2 satisfies  $\nabla \cdot \mathbf{v} = 0$  and  $\mathbf{v} \cdot \mathbf{n} = 0$  on  $\partial\Omega$ .*

The incompressible property (5) and the boundary conditions (6) can be exactly implemented in the network in any

dimension. Note however that in order to get all the incompressible vector fields (7), we need to construct at least  $d(d-1)/2$  arbitrary scalar functions. See Appendix A for the practical construction of these divergence free functions in high dimensions.

## 4 Euler's geodesics

GP flows give a way to compute the Monge map for any trained NF architecture. Many transformations can achieve this goal and the question of finding the best flow among all volume preserving transformations need to be considered.

### 4.1 Arnold's theorem

In 1966, Arnold (Arnold, 1966) showed that the flow described by Euler's equations coincides with the geodesic flow on the manifold of volume preserving diffeomorphisms. This theoretical result therefore gives the reason why regularizing our flows with Euler's equations is a desirable property. Mainly that Euler's equations take the path with the lowest energy to reach the final configuration. Consider the Euler equations:

$$\begin{cases} \partial_t \mathbf{v} + (\mathbf{v} \cdot \nabla) \mathbf{v} = -\nabla p, & t \in [0, T], \mathbf{x} \in \Omega, \\ \nabla \cdot \mathbf{v} = 0, & t \in [0, T], \mathbf{x} \in \Omega, \\ \mathbf{v} \cdot \mathbf{n} = 0, & t \in [0, T], \mathbf{x} \in \partial\Omega, \\ \mathbf{v}(0, \cdot) = \mathbf{v}_0, \end{cases} \quad (8)$$

where  $\mathbf{v} := \mathbf{v}(t, \mathbf{x})$  is the velocity field,  $p := p(t, \mathbf{x})$  the pressure and  $\mathbf{n} := \mathbf{n}(\mathbf{x})$  the outward normal at the boundary of  $\Omega$ . We introduce  $\mathcal{E}$  the energy of a smooth function  $\mathbf{X}(t, \cdot)$ :

$$\mathcal{E}(\mathbf{X}) = \int_0^T \int_{\Omega} \frac{1}{2} |\partial_t \mathbf{X}(t, \mathbf{x})|^2 d\mathbf{x} dt, \quad (9)$$

Now assume  $\phi \in \text{SDiff}(\Omega)$ . Arnold's problem's consists in finding the path  $\mathbf{X}(t, \cdot)_{t \in [0, T]}$  in  $\text{SDiff}(\Omega)$  joining the identity to  $\phi$  which minimizes  $\mathcal{E}$ :

$$\min_{\mathbf{X}(t, \cdot) \in \text{SDiff}(\Omega)} \mathcal{E}(\mathbf{X}), \quad \mathbf{X}(0, \cdot) = \text{Id}, \quad \mathbf{X}(T, \cdot) = \phi(\cdot). \quad (10)$$

In other words (10) is the geodesic in  $\text{SDiff}(\Omega)$  between  $\text{Id}$  and  $\phi$ .

**Theorem 2** (Arnold (1966)). *Assuming the existence of a solution to Arnold's problem,  $\mathbf{X}$  is solution to (10) if and only if  $\mathbf{v}(t, \mathbf{x}) := \partial_t \mathbf{X}(t, \mathbf{x})$  satisfies Euler's equations (8).*

### 4.2 Penalization of Euler's equations in high dimensions

Numerical schemes developed to efficiently solve the Euler equations (Canuto et al., 2007; Quarteroni, 2009) (mainly for fluid mechanics problems, i.e. for dimensions up to 3)

scale badly when the dimension increases. In this work, the solution to Euler’s equations is interpreted as the geodesic to reach the solution of the OT problem and the dimension can be arbitrary large. Therefore we approach the equation (8) through a penalization procedure which can be carried out in any dimension. As explained in the previous section we notice that the second and third equations in (8) are satisfied by construction in the network.

Our remaining goal is to constrain the network to be a smooth solution to  $\partial_t \mathbf{v} + (\mathbf{v} \cdot \nabla) \mathbf{v} = -\nabla p$ . The left hand side can therefore be written as the gradient of a scalar function and we note that if a vector  $\mathbf{w}_{t,\mathbf{x}} \in \mathbb{R}^d$  satisfies  $\mathbf{w}_{t,\mathbf{x}} = \nabla p(t, \mathbf{x})$ , then its Jacobian is symmetric  $\nabla \mathbf{w}_{t,\mathbf{x}} = (\nabla \mathbf{w}_{t,\mathbf{x}})^T$ . In order to solve the first equation in (8), we propose to penalize the non-symmetric part of the Jacobian for the total derivative of  $\mathbf{v}$ . Since a Jacobian-vector product can be efficiently evaluated in high dimensions (unlike the calculation of the full Jacobian which is computationally expensive), we do not calculate directly the Jacobian and use instead the following property of symmetric matrices: if  $M$  is symmetric then  $\mathbf{y}^T M \mathbf{z} - \mathbf{z}^T M \mathbf{y} = 0$ ,  $\forall \mathbf{y}, \mathbf{z} \in \mathbb{R}^d$ . The idea is to sample random vectors  $\mathbf{y}, \mathbf{z}$  during the training and to penalize this term for the total derivative, that is to minimize:

$$R(\mathbf{x}) := \mathbb{E}_{\mathbf{y}, \mathbf{z}} \left[ \int_0^T (\mathbf{y}^T (\nabla \mathbf{w}_{t,\mathbf{x}}) \mathbf{z} - \mathbf{z}^T (\nabla \mathbf{w}_{t,\mathbf{x}}) \mathbf{y})^2 dt \right], \quad (11)$$

with  $\mathbf{y}, \mathbf{z} \sim \mathcal{N}(\mathbf{0}, \text{Id})$  and  $\mathbf{w}_{t,\mathbf{x}} = \partial_t \mathbf{v} + (\mathbf{v} \cdot \nabla) \mathbf{v}$ . In practice, we do not compute the full time integral in (11) as it would be computationally too expensive but calculate the penalization only at our time steps discretization.

**Approximation of the total derivative.** To reduce the computational burden, we do not calculate exactly the total derivative  $\mathbf{w}_{t,\mathbf{x}}$  but use an approximation of its Lagrangian formulation instead. More precisely, consider the variable  $\mathbf{X}(t, \mathbf{x})$  from (4) that is the position of a particle at time  $t$  with initial position  $\mathbf{x}$ . We recall the equality (see Appendix B.3.1)  $\frac{D}{Dt} \mathbf{v}(t, \mathbf{X}(t, \mathbf{x})) = \partial_t \mathbf{v}(t, \mathbf{X}(t, \mathbf{x})) + (\mathbf{v}(t, \mathbf{X}(t, \mathbf{x})) \cdot \nabla) \mathbf{v}(t, \mathbf{X}(t, \mathbf{x}))$  and therefore choose to approximate the right hand side by using a first order Taylor expansion of  $D\mathbf{v}/Dt$ :

$$\frac{D}{Dt} \mathbf{v}(t, \mathbf{X}(t, \mathbf{x})) \approx \frac{\mathbf{v}(t^{n+1}, \mathbf{X}(t^{n+1}, \mathbf{x})) - \mathbf{v}(t^n, \mathbf{X}(t^n, \mathbf{x}))}{\Delta t}, \quad (12)$$

$\Delta t := t^{n+1} - t^n$ . In practice,  $\Delta t$  is set to  $2\sqrt{\varepsilon}$  where  $\varepsilon$  is the machine precision. This approximation can be easily computed since it requires only the evaluation of the velocity at two positions of a particle.

## 5 Procedure

In order to solve the optimal transport problem, we consider the inverse of the transformation given in Theorem 1 (that

is  $\mathbf{f} := \mathbf{g}^{-1}$ ) because the NF architectures are defined in practice from the unknown probability distribution  $\mu$  to a Gaussian distribution  $\nu$  and are not always easily invertible.

The GP flow is parametrized as a standard residual network (ResNet) with a Runge-Kutta 4 time discretization (Atkinson, 1989) (other discretizations are possible) and is estimated by minimizing  $\|\mathbf{x} - \mathbf{s} \circ \mathbf{f}(\mathbf{x})\|^2$  over the parameters of the velocity field. In practice when regularizing with Euler’s equations, we replace the term  $\nabla \mathbf{w}$  in (11) by (12) and calculate the Jacobian-vector product with the function `torch.autograd` from pytorch. A parameter  $\lambda > 0$  is also added in front of the penalization term:

$$\min_{\boldsymbol{\theta}} E_{\mu(\mathbf{x})} \left[ \|\mathbf{x} - \mathbf{s}_{\boldsymbol{\theta}} \circ \mathbf{f}(\mathbf{x})\|^2 + \lambda R_{\boldsymbol{\theta}} \circ \text{erf} \circ \frac{\mathbf{f}(\mathbf{x})}{\sqrt{2}} \right], \quad (13)$$

where the vector  $\boldsymbol{\theta}$  denotes the parameters of the velocity field  $\mathbf{v}$ ,  $\mathbf{f}$  is the NF architecture,  $\mathbf{s}$  the GP flow and  $R$  corresponds to the term penalized with Euler’s equations. The subscript  $\boldsymbol{\theta}$  has been added to emphasize the dependence of  $\mathbf{s}$  and  $R$  to the parameters. To minimize (13), a sampling strategy from the probability distribution  $\mu$  is required. Two possibilities can be considered:

- If we do not want to invert the NF model (for example if it is computationally expensive) we can simply minimize the first term in (13) over the training data. The probability distribution  $\mu$  in (13) is then the unknown distribution from which the data are taken. This assumes however that the training data are correctly mapped to the standard distribution  $\nu$  with  $\mathbf{f}$ .
- If the NF model is cheap to invert, we consider the points  $\mathbf{f}^{-1}(\mathbf{x}_G)$  where  $\mathbf{x}_G$  are samples from the standard normal distribution  $\nu$ . In this case, the probability distribution  $\mu$  in (13) is the transformation of  $\nu$  by the inverse of the NF model  $\mu = \mathbf{f}_{\#}^{-1} \nu$ .

If the NF model transforms perfectly the training data over the standard normal  $\nu$ , these two approaches are equivalent. If this is not the case, we notice that the second approach requires a cheap inverse of the NF model, but has the advantage of not using any training data to train the GP flow and may therefore better generalize.

## 6 Results

We apply GP flows on two popular NF models: BNAF, a discrete NF (De Cao et al., 2020) for two-dimensional test cases and FFJORD, a continuous NF (Grathwohl et al., 2018) for higher dimensional cases. Both of these models are solid references among NF and do not incorporate any OT knowledge in their architecture or training procedure. The codes are taken from the official repositories. The

[github.com/rtqichen/ffjord](https://github.com/rtqichen/ffjord), [github.com/nicola-decao/BNAF](https://github.com/nicola-decao/BNAF), [github.com/CW-Huang/CP-Flow](https://github.com/CW-Huang/CP-Flow)

FFJORD model has an inverse function directly available in the code, which is not the case for the BNAF model. For this reason we consider only the FFJORD model when interpolating in the latent space of the dSprites and MNIST datasets because interpolations require the NF architecture to have an inverse function available.

### 6.1 Density estimation on toy 2D data

We perform density estimation on several 2d standard toy distributions (Grathwohl et al., 2018; Wehenkel and Louppe, 2019). First we consider the eight gaussians test case and study the transformation of a uniform mesh by the NF model. We run the BNAF model and the GP transformation is then computed on the pre-trained BNAF model. To compare our results we consider the CP-Flow architecture (Huang et al., 2020). The CP-flow network is constrained to be the gradient of a scalar convex function and converges by construction towards the optimal map (provided the optimization problem reaches a global minimum), making it a good candidate for comparison. As shown in Figure 3, the mesh transformation when adding the GP flow is getting closer to the CP-Flow one, and the OT cost is roughly the same. Another illustration of the transformation of the source distribution is given at the bottom of Figure 3. We clearly see the added value of GP flow, as the points’ configuration gets much closer to an isotropic distribution indicating that we get closer to the Monge map. Note that adding the GP flow does not affect the estimated density nor the test loss.

**Euler’s penalization.** To highlight the value of using the Euler’s penalization we turn our attention to the two moons dataset. First, to evaluate the quality of the solution with the proposed approach, we compare our solution with a more standard method where the initial condition is optimized through a numerical scheme (implemented in Pytorch, so as to be differentiable) which directly solves the Euler equations, in the line of ”differentiable physics” approaches (de Avila Belbute-Peres et al., 2018). The baseline numerical scheme is a spectral method, a very efficient and popular numerical method (Canuto et al., 2007). We do not go into details on how to implement such methods since they are restricted in practice to low dimensions and we refer to (Canuto et al., 2007; Quarteroni, 2009) for a complete presentation. On Figure 4, we compare three different cases: GP alone, GP with Euler penalization and GP with Euler constrain through a spectral method. As indicated by the OT costs the final positions of particles are very similar for each model. Turning our attention to the trajectories, the initial incompressible velocities and the energy  $\bar{E} = \frac{1}{N} \sum_{i=1}^N \int_0^T \frac{1}{2} \|\mathbf{v}(t, \mathbf{x}_i)\|^2 dt$  are very close both for the penalization-based procedure and the spectral method which shows that we can correctly solve the Euler equations in 2D with our penalization approach (the additional benefit being the generalization to high dimensions). Without the addition of the Euler constraint however, the initial velocity

field looks very different resulting in a higher energy, and thus a transformation that does not correspond to a geodesic in  $\text{SDiff}(\Omega)$ .

### 6.2 An example of application: improving disentanglement preservation with optimal transport

Disentangled representations allow to encode the data in a latent space where change in one direction result in the change over one generative factor in the data. Recently the construction of variational auto-encoders (VAE) (Kingma and Welling, 2014) with disentangled latent space has received much attention (Higgins et al., 2016; Burgess et al., 2018; Chen et al., 2018a; Kim and Mnih, 2018). Applying a NF architecture to such latent space may be needed for various tasks such as density estimation, generative process or general interpolation. The latter requires however to preserve as much of the data structure as possible when transforming the probability distribution. We therefore propose to experimentally study disentanglement preservation of NF with and without OT. To do this we apply a NF architecture (FFJORD in our case) to the VAE’s latent distribution and consider the addition of a GP flow. For the disentangled interpolation in the NF target (gaussian) space we consider the same directions which are present in the VAE latent space and are aligned with the axes. This may be a little naive since these directions could be slightly modified depending on the source and target distributions, but it seems a good enough approximation here. Our experiments are run with the  $\beta$ -TCVAE architecture (Chen et al., 2018a) and the latent space dimension is 10.

**dSprites dataset.** The dSprites dataset (Matthey et al., 2017) is made of  $64 \times 64$  images of 2D shapes procedurally generated from 5 ground truth independent latent factors. These factors are shape, scale, rotation, x and y positions of a sprite. Since the factors are known, we can compute a quantitative evaluation of disentanglement and we choose here to consider the metric from (Eastwood and Williams, 2018) on the continuous factors (i.e. all the factors except the shape) for the three criteria: disentanglement, completeness and informativeness. Table 1 shows that FFJORD destroys the latent structure and gives the worst disentanglement, completeness and informativeness scores. Adding GP flows allow to recover the same disentanglement score as the initial latent space and get values closer both for completeness and informativeness. Note that the disentanglement score is slightly better with FFJORD+GP than the initial one but this is probably only due to some approximation in the metric used here. On Table 2 the OT costs are compared, and as expected GP flows allow to reduce the OT cost without changing the loss. Interestingly GP flows with no additional regularization do not converge completely to the Monge map because particles get out of the domain at some point, making it impossible to continue the training process

**Figure 3:** Eight gaussians test case. Top: density estimation. Middle: deformation of a uniform mesh by the NF model. Bottom: Colored source distribution. From left to right: CP-Flow (OT=2.62, loss=2.86), BNAF (OT=2.88, loss=2.85), BNAF+GP (OT=2.60, loss=2.85).

**Figure 4:** Two moons test case with the BNAF model (initial OT=1.35). Top: target density after the application of the GP flow. Bottom: representation of the initial incompressible velocity field  $\mathbf{v}_0$  of the GP flow. From left to right: GP only ( $\mathcal{E} = 0.28$ , OT=1.05), GP with Euler through the penalization procedure (11) ( $\mathcal{E} = 0.09$ , OT=1.04), GP with a spectral method solving directly the Euler equations ( $\mathcal{E} = 0.08$ , OT=1.06). For the last two mentioned the initial velocity fields are the same and the energy  $\mathcal{E}$  is lowered showing that the penalization procedure efficiently solve Euler's equations.

| Model              | Disent.     | Compl.      | Inform.     |
|--------------------|-------------|-------------|-------------|
| Init. latent space | 0.58        | <b>0.81</b> | <b>0.55</b> |
| FFJORD             | 0.39        | 0.26        | 0.62        |
| FFJORD+GP          | <b>0.59</b> | 0.68        | 0.61        |
| FFJORD+GP+EULER    | <b>0.59</b> | 0.67        | 0.59        |

**Table 1:** Quantitative evaluation from (Eastwood and Williams, 2018) of disentanglement (higher is better), completeness (higher is better) and informativeness (lower is better) on the dSprites dataset. Adding GP flows make the scores closer to the initial ones.

| Model           | dSprites    | MNIST       |
|-----------------|-------------|-------------|
| <b>OT cost</b>  |             |             |
| FFJORD          | 10.45       | 6.81        |
| FFJORD+GP       | 5.60        | <b>3.17</b> |
| FFJORD+GP+EULER | <b>5.26</b> | 3.20        |
| <b>Loss</b>     |             |             |
| FFJORD          | -17.52      | -0.45       |
| FFJORD+GP       | -17.52      | -0.45       |
| FFJORD+GP+EULER | -17.52      | -0.45       |

**Table 2:** Losses and mean OT costs. GP flows reduce the OT cost without changing the loss. Adding Euler regularization allows to further reduced the OT cost on the dSprites dataset.

(the training is stopped at  $\approx 200$  epochs). We conjecture that this may be due to non-smooth trajectories of our GP flows and a regularization is therefore needed. As shown on Table 2 adding Euler regularization fixed this issue and allows to further reduce the OT cost.

To illustrate the preservation of disentanglement, some interpolations are also presented in Figures 5 and 6 in Appendix D. The dimensions are sorted with respect to their KL divergence in the initial latent space and therefore only the first dimensions carry information: each of the first 5 lines correspond to a generative factor while the last dimensions leave the image unchanged. This structure is lost when mapping the latent space to a Gaussian distribution with the FFJORD architecture. The addition of a GP flow fixed this issue and the interpolation better match the initial latent one.

**MNIST dataset.** We also consider the MNIST dataset (Lecun et al., 1998). As opposed to the dSprites test case, GP flows do not seem to have trouble to converge here without Euler penalization and therefore we obtain comparable OT costs with and without Euler regularization see Table 2. Since the generative factors are not known in this case we cannot make a quantitative evaluation of disentanglement as we did for the dSprites dataset. We focus instead on the interpolations presented in Figures 7 and 8 in Appendix D. GP flows better preserve the data structure of the initial latent space compare when applying only the FFJORD

model. This can be seen in particular on the last two rows of each block which are not changing in the initial latent space. This structure is lost with the FFJORD model and recovered when training a GP flow.

## 7 Discussion

This article describes a method to reduce the OT cost of any pre-trained NF model without changing the estimated target density. The proposed method scales reasonably well and does not require to constrain the architecture of the original model. The procedure relies on building Gaussian preserving flows to rearrange the source distribution to satisfy the OT property. The proposed approach is based on incompressible vector fields which allow to use a nice interpretation of Euler’s equations as a geodesic in the group of volume-preserving diffeomorphisms between the identity and the transformation minimizing the OT cost. This original contribution allows to add a regularity condition to the estimated map in addition to simply enforcing the OT property.

**Perspectives.** The numerical experiments presented here pave the way to new research perspectives. First compared to other OT approaches in the NF literature, GP flows is to the best of our knowledge the first one which does not constrain the NF architecture to obtain the Monge map. This could be a great advantage when the NF architecture is already constrained for other reasons (for example to satisfy some symmetries or data-related properties). We believe that in this case GP flows may stand out as it could be difficult to further constrain the network to satisfy the OT property with other standard approaches. The proposed approach could also be a starting point to investigate other type of (potentially non OT) costs, and more specifically non-quadratic OT costs, such as the  $L_1$  norm which is much less considered in the literature due to the lack of theoretical foundations (the OT map is not the gradient of a convex function anymore). In a GP-based framework, such extension could be easily implemented since we do not rely explicitly on this property.

**Limitations.** The main limitation of the proposed method is probably related to the number of independent functions require to construct incompressible vector fields in high dimensions. Indeed, as explained in Proposition 2 one needs to construct at least  $d(d-1)/2$  scalar functions to get all the divergence free vector fields in dimension  $d$ . In practice our approach requires  $d-1$  vector valued functions in  $\mathbb{R}^d$  allowing to apply GP flows in the latent space of some popular VAE’s model. Still, a way to optimize GP flows over subfamilies of incompressible vector fields (while still converging to the Monge map) would be a nice extension to this work. Finally, let us mention that while Euler’s regularization adds nice properties to the flows considered,

The code will be made available after the review process.

---

it also increases the computational time required to train the model.

## A Practical construction of incompressible vector fields in high dimensions

The goal here is to have a GPU-friendly construction of the incompressible vector fields given in Proposition 2. In the following we consider stationary divergence free functions but the time variable can be added with no additional work simply by considering functions in  $\mathbb{R}^{d+1}$  instead of  $\mathbb{R}^d$  (the gradients are still taken only on the space variables though). All the proofs are given in Appendix B.

**Notations.** Regarding the notations we will use the operator  $\text{diag}$  for two distinct cases: 1) When  $\mathbf{w}$  is a vector  $\text{diag}(\mathbf{w})$  denotes the diagonal matrix obtained from the vector  $\mathbf{w}$ . 2) When  $W$  is a matrix  $\text{diag}(W)$  denotes the vector obtained from the diagonal of  $W$ . The operation  $\cdot$  denotes the scalar product between two vectors. Finally we have adopted the convention that when a scalar multiplies a vector it multiplies each of its component.

**Practical construction.** Let  $\mathbf{u}^n : \mathbb{R}^d \rightarrow \mathbb{R}^{d-n}$ . We construct a divergence free function with the functions  $\psi_j^i$  defined as

$$(\psi_j^i)^n = \begin{cases} u_{i-n}^n - u_{j-n}^n, & \text{if } i, j \geq n+1, \\ 0, & \text{otherwise.} \end{cases} \quad (14)$$

To construct this divergence free function we define the matrix  $(\nabla \mathbf{u}(\mathbf{x}))^n \in \mathbb{R}^{d \times d}$  and the vector  $\mathbf{1}^n \in \mathbb{R}^d$  as

$$(\nabla \mathbf{u}(\mathbf{x}))_{ij}^n = \begin{cases} \partial_{i-n} u_{j-n}^n, & \text{if } i, j \geq n+1, \\ 0, & \text{otherwise.} \end{cases}, \quad (15)$$

$$\mathbf{1}_i^n = \begin{cases} 1, & \text{if } i \geq n+1 \\ 0, & \text{otherwise.} \end{cases}.$$

**Lemma 3.** Let  $n \in \mathbb{N}$ ,  $n \leq d-2$  and consider the function  $\mathbf{u}^n : \mathbb{R}^d \rightarrow \mathbb{R}^{d-n}$ . Then the vector field  $\mathbf{v}^n : \mathbb{R}^d \rightarrow \mathbb{R}^d$  defined as

$$\mathbf{v}^n(\mathbf{x}) = (\nabla \mathbf{u})^n \mathbf{1}^n - [\text{diag}(\nabla \mathbf{u})^n \cdot \mathbf{1}^n] \mathbf{1}^n, \quad (16)$$

is divergence free.

To construct the functions (16) we need 1) to compute the product between the Jacobian of a vector valued function and a constant vector 2) sum the diagonal elements of the Jacobian matrix. Both of these operations can be done efficiently on GPU. Note that in order to satisfy the boundary conditions  $\mathbf{v}^n \cdot \mathbf{n} = 0$  one can modify the equation (16) as in Lemma 2 to obtain

$$\mathbf{v}^n(\mathbf{x}) = (\mathbf{x}^2 - 1) \odot [2M^n \mathbf{x} + (\nabla \mathbf{u})^n(\mathbf{x})(\mathbf{x}^2 - 1) - ((\mathbf{x}^2 - 1) \cdot \text{diag}(\nabla \mathbf{u}(\mathbf{x}))^n) \mathbf{1}^n], \quad (17)$$

where  $M_{ij}^n = u_i^n - u_j^n$ , if  $i, j \geq n+1$  and  $M_{ij}^n = 0$  otherwise.

It is possible to recover all the incompressible functions from Proposition 2 by adding the blocks  $\mathbf{v}^0 + \mathbf{v}^1 + \dots + \mathbf{v}^{d-2}$ .

**Proposition 3.** Let  $\mathbf{v}$  be a divergence free function in  $\mathbb{R}^d$ . Then there exists  $d - 1$  functions  $\mathbf{v}^0, \dots, \mathbf{v}^{d-2}$  constructed as in Lemma 3 such that

$$\mathbf{v}(\mathbf{x}) = \sum_{n=0}^{d-2} \mathbf{v}^n(\mathbf{x}).$$

The attentive reader would have noticed that with the vector functions  $\mathbf{u}^n$ ,  $n = 0, \dots, d - 2$  we have a total of  $(d + 2)(d - 1)/2$  independent scalar functions while Proposition 2 only requires the construction of  $d(d - 1)/2$  scalar functions leaving  $d - 1$  additional functions which are not strictly needed to obtain the divergence free vectors. This is due to the vectorized constructions (16)-(17) which allow a fast evaluation of the divergence free functions on GPU. Having  $d - 1$  additional scalar functions in return is not a big issue since the general order remains  $O(d^2)$ .

Also note that the practical implementation of the equations (14)-(15) requires to find a pythonic way to efficiently pad a group of matrices with different dimensions. We have not yet find such way and therefore have simply chosen in our applications to construct  $d - 1$  vector valued functions  $\mathbf{u}^n \in \mathbb{R}^d$ ,  $n = 0, \dots, d - 2$  and fill the appropriate dimensions in (14)-(15) with 0. Again even if not optimal this is not a big issue as it multiplies the number of independent scalar functions by a factor 2, but the general order remains  $O(d^2)$ .

In practice, we have written the functions  $\mathbf{u}^n$  as the output of a big function  $\mathbf{u} : \mathbb{R}^d \rightarrow \mathbb{R}^{(d-1) \times d}$  allowing to evaluate all the functions  $\mathbf{u}^n$  in a single pass. The vector  $\mathbf{u}$  is written as the composition of linear functions with some simple non linearity

$$\begin{aligned} \mathbf{u}(\mathbf{x}) &= M_n \mathbf{x}_n + \mathbf{b}_n, \\ \mathbf{x}_i &= \sigma(M_{i-1} \mathbf{x}_{i-1} + \mathbf{b}_{i-1}), \quad i = 1, \dots, n - 1, \quad (18) \\ \mathbf{x}_0 &= \mathbf{x}, \end{aligned}$$

where  $M_i$  are rectangular matrices,  $\mathbf{b}_i$  a vector field and typically we have taken  $\sigma = \tanh$ . One big advantage of the formulation (18) is that the Jacobian of  $\mathbf{u}$  (and therefore of all the functions  $\mathbf{u}^n$ ) can be computed analytically

$$\begin{aligned} \nabla \mathbf{u}(\mathbf{x}) &= M_n \nabla \mathbf{x}_n, \\ \nabla \mathbf{x}_i &= \text{diag}(\sigma'(M_{i-1} \nabla \mathbf{x}_{i-1} + \mathbf{b}_{i-1})) M_{i-1}, \end{aligned} \quad (19)$$

for  $i = 1, \dots, n - 1$ . The formulation (19) therefore allows a fast evaluation of the term (16) in particular when summing the diagonal elements of the Jacobian. In our experiments we have noticed that the analytical formulation of the Jacobian (19) was faster than using `torch.autograd`.

## B Technical material

### B.1 Gaussian preserving flows

#### B.1.1 Proof of Proposition 1

We recall that here  $\text{erf} : \mathbb{R}^d \rightarrow \mathbb{R}^d$  is the distribution function of a one dimensional Gaussian applied component wise.

**Proposition.** Let  $\mathbf{s}$  a smooth Gaussian preserving function satisfying (3). Then there exists  $\phi : (-1, 1)^d \rightarrow (-1, 1)^d$  such that  $|\det \nabla \phi| = 1$  and

$$\mathbf{s}(\mathbf{x}) = \sqrt{2} \text{erf}^{-1} \circ \phi \circ \text{erf}\left(\frac{\mathbf{x}}{\sqrt{2}}\right), \quad \mathbf{x} \in \mathbb{R}^d. \quad (20)$$

*Proof.* We recall some basic properties about the distribution function of a one dimensional Gaussian and its inverse. One has for  $x \in \mathbb{R}$

$$\begin{aligned} \text{erf}(x) &= \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt, \quad \frac{d}{dx} \text{erf}(x) = \frac{2}{\sqrt{\pi}} e^{-x^2}, \\ \frac{d}{dx} \text{erf}^{-1}(x) &= \frac{\sqrt{\pi}}{2} e^{(\text{erf}^{-1}(x))^2}. \end{aligned} \quad (21)$$

Consider the function  $\phi : (-1, 1)^d \rightarrow (-1, 1)^d$  defined as

$$\phi(\mathbf{x}) = \text{erf} \circ \frac{\mathbf{s}}{\sqrt{2}} \circ \sqrt{2} \text{erf}^{-1}(\mathbf{x}). \quad (22)$$

The goal here is to show that  $|\det \nabla \phi| = 1$  then equation (20) will follows from (22). By definition

$$|\det \nabla \phi(\mathbf{x})| := \left| \det \nabla \left( \text{erf} \circ \frac{\mathbf{s}}{\sqrt{2}} \circ \sqrt{2} \text{erf}^{-1}(\mathbf{x}) \right) \right|.$$

Applying the equalities (21) component wise and denoting  $\mathbf{x} = (x_1, \dots, x_d)$  one gets

$$\begin{aligned} |\det \nabla \phi(\mathbf{x})| &= \left| \prod_i \frac{2}{\sqrt{\pi}} e^{-\left(\frac{\mathbf{s}}{\sqrt{2}} \circ \sqrt{2} \text{erf}^{-1}(\mathbf{x})\right)_i^2} \right. \\ &\quad \times \frac{\det \nabla \mathbf{s}(\sqrt{2} \text{erf}^{-1}(\mathbf{x}))}{\sqrt{2}} \\ &\quad \left. \times \prod_i \sqrt{2} \frac{\sqrt{\pi}}{2} e^{(\text{erf}^{-1}(\mathbf{x}))_i^2} \right|, \end{aligned}$$

since the determinant of the composition is the product of the determinants. That is

$$\begin{aligned} |\det \nabla \phi(\mathbf{x})| &= \left| \prod_i e^{-\left(\frac{\mathbf{s}}{\sqrt{2}} \circ \sqrt{2} \text{erf}^{-1}(\mathbf{x})\right)_i^2} \times \det \nabla \mathbf{s}(\sqrt{2} \text{erf}^{-1}(\mathbf{x})) \right. \\ &\quad \left. \times \prod_i e^{(\text{erf}^{-1}(\mathbf{x}))_i^2} \right|, \end{aligned}$$

which can be written

$$\begin{aligned} |\det \nabla \phi(\mathbf{x})| &= e^{(-\|\mathbf{s}(\sqrt{2} \text{erf}^{-1}(\mathbf{x}))\|^2 + \|\sqrt{2} \text{erf}^{-1}(\mathbf{x})\|^2)/2} \\ &\quad \times |\det \nabla \mathbf{s}(\sqrt{2} \text{erf}^{-1}(\mathbf{x}))|. \end{aligned}$$

Finally using  $|\det \nabla \mathbf{s}(\mathbf{x})| = e^{(\|\mathbf{s}(\mathbf{x})\|^2 - \|\mathbf{x}\|^2)/2}$  one obtains  $|\det \nabla \phi(\mathbf{x})| = 1$ .  $\square$

### B.1.2 Orientation reversing functions

In the following Lemma we prove that very orientation reversing function satisfying  $\det \nabla \psi = -1$  can be written as the composition of a volume and orientation preserving function and the function  $\mathbf{h}(x_1, \dots, x_d) = (-x_1, x_2, x_3, \dots, x_d)$ .

**Lemma.** Assume  $\psi : \mathbb{R}^d \rightarrow \mathbb{R}^d$  is a function satisfying  $\det \nabla \psi = -1$  and let  $\mathbf{h}(x_1, \dots, x_d) = (-x_1, x_2, x_3, \dots, x_d)$ . Then there exists a volume and orientation preserving function  $\phi$  such that  $\psi = \phi \circ \mathbf{h}$ .

*Proof.* We define  $\phi$  as  $\phi = \psi \circ \mathbf{h}$ . This function is indeed volume and orientation preserving since it satisfies  $\det \nabla \phi = \det \nabla \psi \det \nabla \mathbf{h} = 1$ . By noticing  $\mathbf{h} \circ \mathbf{h} = \text{Id}$  one gets  $\psi = \phi \circ \mathbf{h}$ .  $\square$

### B.1.3 Proof of Lemma 1

**Lemma.** Assume the Monge map  $\mathbf{m}$  and the NF architecture  $\mathbf{g}$  are  $C^1$  diffeomorphisms. Then the corresponding GP flow  $\mathbf{s}$  is  $C^1$ , the associated function  $\phi$  is also  $C^1$  and either satisfies  $\det \nabla \phi(\mathbf{x}) = 1$  everywhere or  $\det \nabla \phi(\mathbf{x}) = -1$  everywhere.

*Proof.* The definition of  $\mathbf{s} := \mathbf{m} \circ \mathbf{g}^{-1}$  ensures that  $\mathbf{s}$  is indeed  $C^1$ . Moreover since  $\mathbf{g}$  is invertible either  $\det \nabla \mathbf{g} > 0$  everywhere or  $\det \nabla \mathbf{g} < 0$  everywhere (if  $\det \nabla \mathbf{g}(x) = 0$  this would mean that  $\mathbf{g}$  is not invertible at this point) and the same argument applies to  $\mathbf{g}^{-1}$  and to the Monge map  $\mathbf{m}$ . Therefore the equality  $\mathbf{s} = \mathbf{m} \circ \mathbf{g}^{-1}$  implies that either  $\det \nabla \mathbf{s} > 0$  everywhere or  $\det \nabla \mathbf{s} < 0$  everywhere. The equality  $\phi = \text{erf} \circ \frac{\mathbf{s}}{\sqrt{2}} \circ \sqrt{2} \text{erf}^{-1}$  shows that  $\phi$  is also  $C^1$  and that the sign of  $\det \nabla \phi$  does not change.  $\square$

## B.2 Divergence free functions

### B.2.1 Proof of Proposition 2

**Proposition.** Consider an arbitrary vector field  $\mathbf{v} : \mathbb{R}^d \rightarrow \mathbb{R}^d$ . Then  $\nabla \cdot \mathbf{v} = 0$  if and only if there exists smooth scalar functions  $\psi_j^i : \mathbb{R}^d \rightarrow \mathbb{R}$ , with  $\psi_j^i = -\psi_i^j$  such that

$$v_i(\mathbf{x}) = \sum_{j=1}^d \partial_{x_j} \psi_j^i(\mathbf{x}), \quad i = 1, \dots, d, \quad (23)$$

where  $\mathbf{v} = (v_1, \dots, v_d)$ .

*Proof.* 1) First we prove that  $\nabla \cdot \mathbf{v} = 0$ . The divergence of  $\mathbf{v}$  can be written

$$\nabla \cdot \mathbf{v} = \sum_i \partial_{x_i} \sum_j \partial_{x_j} \psi_j^i.$$

Using  $\psi_j^i = -\psi_i^j$  one has

$$\nabla \cdot \mathbf{v} = \sum_i \left( \sum_{\substack{j \\ j < i}} \partial_{x_i} \partial_{x_j} \psi_j^i - \sum_{\substack{j \\ j > i}} \partial_{x_i} \partial_{x_j} \psi_j^i \right), \quad (24)$$

For the term  $\sum_i \sum_{\substack{j \\ j < i}} \partial_{x_i} \partial_{x_j} \psi_j^i$  on the left hand side one can sum over the index  $j$  first instead of the index  $i$  that is

$$\sum_i \sum_{\substack{j \\ j < i}} \partial_{x_i} \partial_{x_j} \psi_j^i = \sum_j \sum_{\substack{i \\ i > j}} \partial_{x_i} \partial_{x_j} \psi_j^i.$$

Injecting this equality in (24) one gets

$$\nabla \cdot \mathbf{v} = \sum_j \sum_{\substack{i \\ i > j}} \partial_{x_i} \partial_{x_j} \psi_j^i - \sum_i \sum_{\substack{j \\ j > i}} \partial_{x_i} \partial_{x_j} \psi_j^i = 0.$$

2) Now we prove that every vector field satisfying  $\nabla \cdot \mathbf{v} = 0$  can be written under the form (23). The proof from Stephen Montgomery-Smith is available online for completeness we rewrite it here. The proof is made by induction with the following assumption.

**Assumption 1.** Let  $k \in \mathbb{N}$ ,  $k \leq d$ . Given a smooth vector field  $\mathbf{v}$  such that  $\text{div}_k \mathbf{v} := \sum_{i=1}^k v_i = 0$ , there exists scalar functions  $\psi_j^i : \mathbb{R}^d \rightarrow \mathbb{R}$ ,  $1 \leq i, j \leq k$  with  $\psi_j^i = -\psi_i^j$  such that  $v_i = \sum_j \partial_j \psi_j^i$ .

The Assumption 1 is trivial for  $k = 0$ . Suppose it is true for  $k - 1$  we prove it for  $k$ : assume  $\text{div}_k \mathbf{v} = 0$  and let

$$f_1(x_1, \dots, x_n) = \int_0^{x_1} \partial_k v_k(\xi, x_2, \dots, x_n) d\xi. \quad (25)$$

Since  $\partial_1 f_1 = \partial_x v_k$  one has

$$\partial_1(v_1 + f_1) + \partial_2 v_2 + \dots + \partial_{k-1} v_{k-1} = 0.$$

Thanks to Assumption 1 there exists functions  $\psi_j^i$  with  $\psi_j^i = -\psi_i^j$  such that

$$v_1 + f_1 = \sum_{j=1}^{k-1} \partial_j \psi_j^1, \quad v_i = \sum_{j=1}^{k-1} \partial_j \psi_j^i, \quad \text{for } 2 \leq i \leq k-1. \quad (26)$$

Now we define

$$f_2(x_1, \dots, x_d) = \int_0^{x_1} v_k(\xi, x_2, \dots, x_{k-1}, 0, x_{k+1}, \dots, x_d) d\xi - \int_0^{x_k} f_1(x_1, \dots, x_{k-1}, \xi, \dots, x_d) d\xi, \quad (27)$$

then

$$\partial_k f_2 = -f_1, \quad (28)$$

and using (25) in (27) one gets

$$\begin{aligned} \partial_1 f_2 &= v_k(x_1, \dots, x_{k-1}, 0, \dots, x_d) \\ - \int_0^{x_k} \partial_k v_k(x_1, \dots, x_{k-1}, \xi, \dots, x_d) d\xi &= -v_k. \end{aligned} \quad (29)$$

Now we extend the functions  $\psi_j^i$ ,  $1 \leq i, j \leq k-1$  by defining  $\psi_k^1 = -\psi_1^k = f_2$  and  $\psi_k^i = -\psi_i^k = 0$  for  $2 \leq i \leq k$ . Then extending the equations (26) with  $k$  one has

$$\sum_{j=1}^k \partial_j \psi_j^1 = v_1 + f_1 + \partial_k f_2 = v_1, \quad \sum_{j=1}^k \partial_j \psi_j^i = v_i,$$

for  $2 \leq i \leq k-1$  and where we used the equality (28) in the first equation. Moreover with the definition of the function  $\psi_j^k$  one has

$$\sum_{j=1}^k \partial_j \psi_j^k = -\partial_1 f_2 = v_k,$$

thanks to (29). This prove Assumption 1 for  $k$ .  $\square$

## B.2.2 Proof of Lemma 2

**Lemma.** Let  $\Omega = [-1, 1]^d$  and consider the functions

$$\psi_j^i(\mathbf{x}) = (x_i^2 - 1)(x_j^2 - 1)\widetilde{\psi}_j^i(\mathbf{x}),$$

where  $\widetilde{\psi}_j^i(\mathbf{x}) : \mathbb{R}^d \rightarrow \mathbb{R}$  are arbitrary scalar functions satisfying  $\widetilde{\psi}_j^i = -\widetilde{\psi}_i^j$ . Then the function  $\mathbf{v}$  defined in Proposition 2 satisfies  $\nabla \cdot \mathbf{v} = 0$  and  $\mathbf{v} \cdot \mathbf{n} = 0$  on  $\partial\Omega$ .

*Proof.* Indeed since  $\psi_i^i = 0$  there is no  $\partial_{x_i}$  term which appear in the sum of (7) for the component  $v_i$ . The term  $x_i^2 - 1$  can therefore be factored that is  $v_i = 0$  if  $x_i = \pm 1$ . Hence  $\mathbf{v} \cdot \mathbf{n} = 0$  on  $\partial\Omega$ .  $\square$

## B.2.3 Proof of Lemma 3

**Lemma.** Let  $n \in \mathbb{N}^*$ ,  $n \leq d-1$  and consider the function  $\mathbf{u}^n : \mathbb{R}^d \rightarrow \mathbb{R}^{d-n}$ . Then the vector field  $\mathbf{v}^n : \mathbb{R}^d \rightarrow \mathbb{R}^d$  defined as

$$\mathbf{v}^n(\mathbf{x}) = (\nabla \mathbf{u})^n \mathbf{1}^n - \text{diag}(\nabla \mathbf{u})^n \mathbf{1}^n, \quad (30)$$

is divergence free.

*Proof.* As explain in Appendix A the formulation (30) is equivalent to consider  $\mathbf{v}^n$  under the form (7) with  $\psi_j^i$  defined as in (14). From Proposition 2 the function  $\mathbf{v}^n$  is divergence free.  $\square$

## B.2.4 Proof of Proposition 3

**Proposition.** Let  $\mathbf{v}$  be a divergence free function in  $\mathbb{R}^d$ . Then there exists  $d-1$  functions  $\mathbf{v}^0, \dots, \mathbf{v}^{d-2}$  constructed as in Lemma 3 such that

$$\mathbf{v}(\mathbf{x}) = \sum_{n=0}^{d-2} \mathbf{v}^n(\mathbf{x}). \quad (31)$$

*Proof.* Let  $\mathbf{v}(\mathbf{x})$  be a divergence free function and denote  $(\psi_j^i)$  its coefficients from (7). We construct the associate vectors  $\mathbf{u}^n$  of the functions  $\mathbf{v}^n$  procedurally: for  $k=1, \dots, d-1$ , we iteratively chose  $u_1^{k-1}$  arbitrarily and define the other components of the vector  $\mathbf{u}^{k-1}$  as

$$u_{j-k+1}^{k-1} = u_1^{k-1} - \sum_{n=0}^{k-2} (u_{k-n}^n - u_{j-n}^n) + \psi_j^k, \quad j \geq k+1, \quad (32)$$

note that the sum is well-defined because the components  $u^k$  are constructed iteratively from  $k=1$  to  $k=d-1$  and we have adopted the convention  $\sum_{n=0}^{-1} = 0$ . We claim that with this construction we recover the equality (31). Indeed from (32) one has

$$\psi_j^k = u_{j-k+1}^{k-1} - u_1^{k-1} + \sum_{n=0}^{k-2} (u_{k-n}^n - u_{j-n}^n), \quad j \geq k+1.$$

Using (14) one gets

$$\psi_j^k = (\psi_j^k)^{k-1} + \sum_{n=0}^{k-2} (\psi_j^k)^n, \quad j \geq k+1.$$

Again using (14) one has  $(\psi_j^k)^n = 0$  for  $n \geq k$  and therefore

$$\psi_j^k = \sum_{n=0}^{d-2} (\psi_j^k)^n, \quad j \geq k+1.$$

Since the coefficients  $\psi_j^k$  and  $(\psi_j^k)^n$  are all antisymmetric this equality is also satisfied for  $j < k+1$ . We conclude with the decomposition (7) of the divergence free functions.  $\square$

## B.3 Additional material

### B.3.1 Total derivative expansion

In this subsection we recall the expansion of the Lagrangian derivative  $\frac{D}{Dt} \mathbf{v}(t, \mathbf{X}(t, \mathbf{x})) = \frac{d}{dt} \mathbf{v}(t, \mathbf{X}(t, \mathbf{x})) + (\mathbf{v}(t, \mathbf{x}) \cdot \nabla) \mathbf{v}(t, \mathbf{X}(t, \mathbf{x}))$ . Assume  $\mathbf{X}(t, \mathbf{x})$  follows the ODE (4)

$$\begin{cases} \frac{d}{dt} \mathbf{X}(t, \mathbf{x}) = \mathbf{v}(t, \mathbf{X}(t, \mathbf{x})), & \mathbf{x} \in \Omega, \quad 0 \leq t \leq T, \\ \mathbf{X}(0, \mathbf{x}) = \mathbf{x}, \end{cases}$$

We recall that the notation  $d/dt$  must be understood as deriving the first variable of  $\mathbf{v}(t, \mathbf{X}(t, \mathbf{x}))$  while  $D/Dt$  represents the derivative in time of the function  $f(t) := \mathbf{v}(t, \mathbf{X}(t, \mathbf{x}))$ .

---

By deriving the first and second variable with respect to  $t$  one has

$$\frac{D}{Dt}\mathbf{v}(t, \mathbf{X}(t, \mathbf{x})) = \frac{d}{dt}\mathbf{v}(t, \mathbf{X}(t, \mathbf{x})) + \left(\frac{d}{dt}\mathbf{X}(t, \mathbf{x}) \cdot \nabla\right)\mathbf{v}(t, \mathbf{X}(t, \mathbf{x})).$$

Using  $\frac{d}{dt}\mathbf{X}(t, \mathbf{x}) = \mathbf{v}(t, \mathbf{X}(t, \mathbf{x}))$  one finally obtains

$$\frac{D}{Dt}\mathbf{v}(t, \mathbf{X}(t, \mathbf{x})) = \frac{d}{dt}\mathbf{v}(t, \mathbf{X}(t, \mathbf{x})) + (\mathbf{v}(t, \mathbf{x}) \cdot \nabla)\mathbf{v}(t, \mathbf{X}(t, \mathbf{x})).$$

## C Experiment details

We run the experiments on two separate GPUs: a NVIDIA Quadro RTX 8000 and a NVIDIA TITAN X. Our loss is given by the negative log-likelihood (1). The FFJORD model has an inverse function directly available in the code, which is not the case for the BNAF model. Therefore, as explained in the Section 5, the GP flow is trained using  $\mathbf{f}^{-1}$  applied on a standard multi-dimensional normal distribution for FFJORD, whereas only the training data are used for BNAF.

**Toy datasets.** We give the parameters used for the 2D toy experiments in Table 3. We consider a training set of 80K samples and a testing set of 20K samples, 20 time steps with a Runge-Kutta 4 discretization and a GP flow with intermediate layers of size 15. For the Euler penalization we take the exact same parameters with  $\lambda = 5 \times 10^{-4}$  which is divided 5 times periodically by a factor 2.

**dSprites and MNIST datasets.** The VAE architecture used in the experiments is taken from the github repository of Yann Dubois. The parameters used for the GP flows are given in Table 4. For all test cases we consider a GP flow with 15 time steps, three intermediate layers of 50 parameters for the dSprites dataset and four intermediate layers of 50 parameters for MNIST. For the Euler penalization we take an initial parameter  $\lambda = 5 \times 10^{-5}$  which is then divided 5 times periodically by a factor 2 during the training.
