HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

The growing chaos of tuberculosis population genomics at the era of 'Big Data': sorting out the wheat from the chaff

Introduction

The publication of a couple of recent landmark papers (Freschi *et al.* 2021, Napier *et al.* 2021, Coscolla *et al.* 2021, Thawornwattana *et al.* 2021) claiming the discovery of new WGS-defined clades, prompted us to reevaluate both the SNP informativity and the hierarchical naming of some of the phylogenetical structures described in these articles. Thanks to a new proprietary informatical platform, **TB-ANNOTATOR**, we performed a benchmark analysis of these articles, and present results that allow to create new links between the pre-genomic and the post-genomic era for young researchers entering into the field, reassessing the SNP informativity, the link between polymorphic markers, and showing current discrepancies between studies, suggesting that even in large databases, the global population structure of MTBC remains strongly dependent on sample origin, WGS quality and bioinformatical tools. We also describe some recent improvements in phylogenetical analysis of MTBC.

Figure 2: RAxML-built-tree on 15901 public SRAs using the TB-ANNOTATOR informatic pipeline

In a former version with 6000 genomes, we show that L1, L5, L6, L7, L8 were sharing 3 SNPs and 288 variants with >95%, whereas L2,L3,L4,L7,L8 were sharing 0 SNPs and 0 variants, thus demonstrating the rooting of L7-L8 with L1,L5,L6,L9 branches and not with L2,L3,L4.

Material and Methods

15901 SRA were either downloaded from public databases (NCBI, EBI) or produced *in house*. The **TB-ANNOTATOR** pipeline is summarized in **Figure 1**. The Phylogenetic tree shown in **Figure 2** was produced using RaXML. **TB-ANNOTATOR** allows to deal not only with SNP but also with RDs, MGEs presence/absence and insertion sites.

Figure 1: general algorithm of TB-ANNOTATOR

Results

The definition of meaningfull phylogenetic branches in all lineages is improved by using **TB-ANNOTATOR**. As an example, **L5 and L6** are now better defined (see also Muhammed Rabi Sahal *et al.* poster). As another example, in **Figure 3**, **L1.1.2** is better defined by SNP position **20544** and now encompass two sublineages **L1.1.2.1** and **L1.1.2.2**, as shown below, these branches had been ignored by Freschi, Coll and Napier *et al.*

Figure 3: new definition of the L1.1.2 sublineage

In **L4, L4.5 and L4.7** structures had been ignored and **TB-ANNOTATOR** allows to gain a much deeper insight inot these families. In **L4** again, the last designated **L4.12** sublineage by Freschi was known since 2005 as « *East-Mediterranean 1* ».

Conclusion

we show by this benchmark study, that current WGS phylogenetical studies are very strongly subjected to **sampling bias** and that a stable global picture of MTBC population structure will only be achieved once a representative sample of MTBC genetic diversity will have been built. Current studies tend to preferably describe epi-linked clusters without assessing the global spatio-temporal historical picture
