HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destin ee au d ep ot et  a la diffusion de documents scientifiques de niveau recherche, publi es ou non,  emanant des  tablissements d'enseignement et de recherche fran ais ou  trangers, des laboratoires publics ou priv es.

Tn-seq → Transposon sequencing

Tn-seq is a genome-wide screening method that rapidly identifies, on a large panel of strains, genes related to a specific phenotype or growth condition in bacteria. It consists in random transposon mutagenesis in parallel coupled with high throughput sequencing.

Main steps

- creation of a pool of mutants by random insertion of a transposon
- growth (and selection)
- high-throughput sequencing of surviving cells

Essential genes

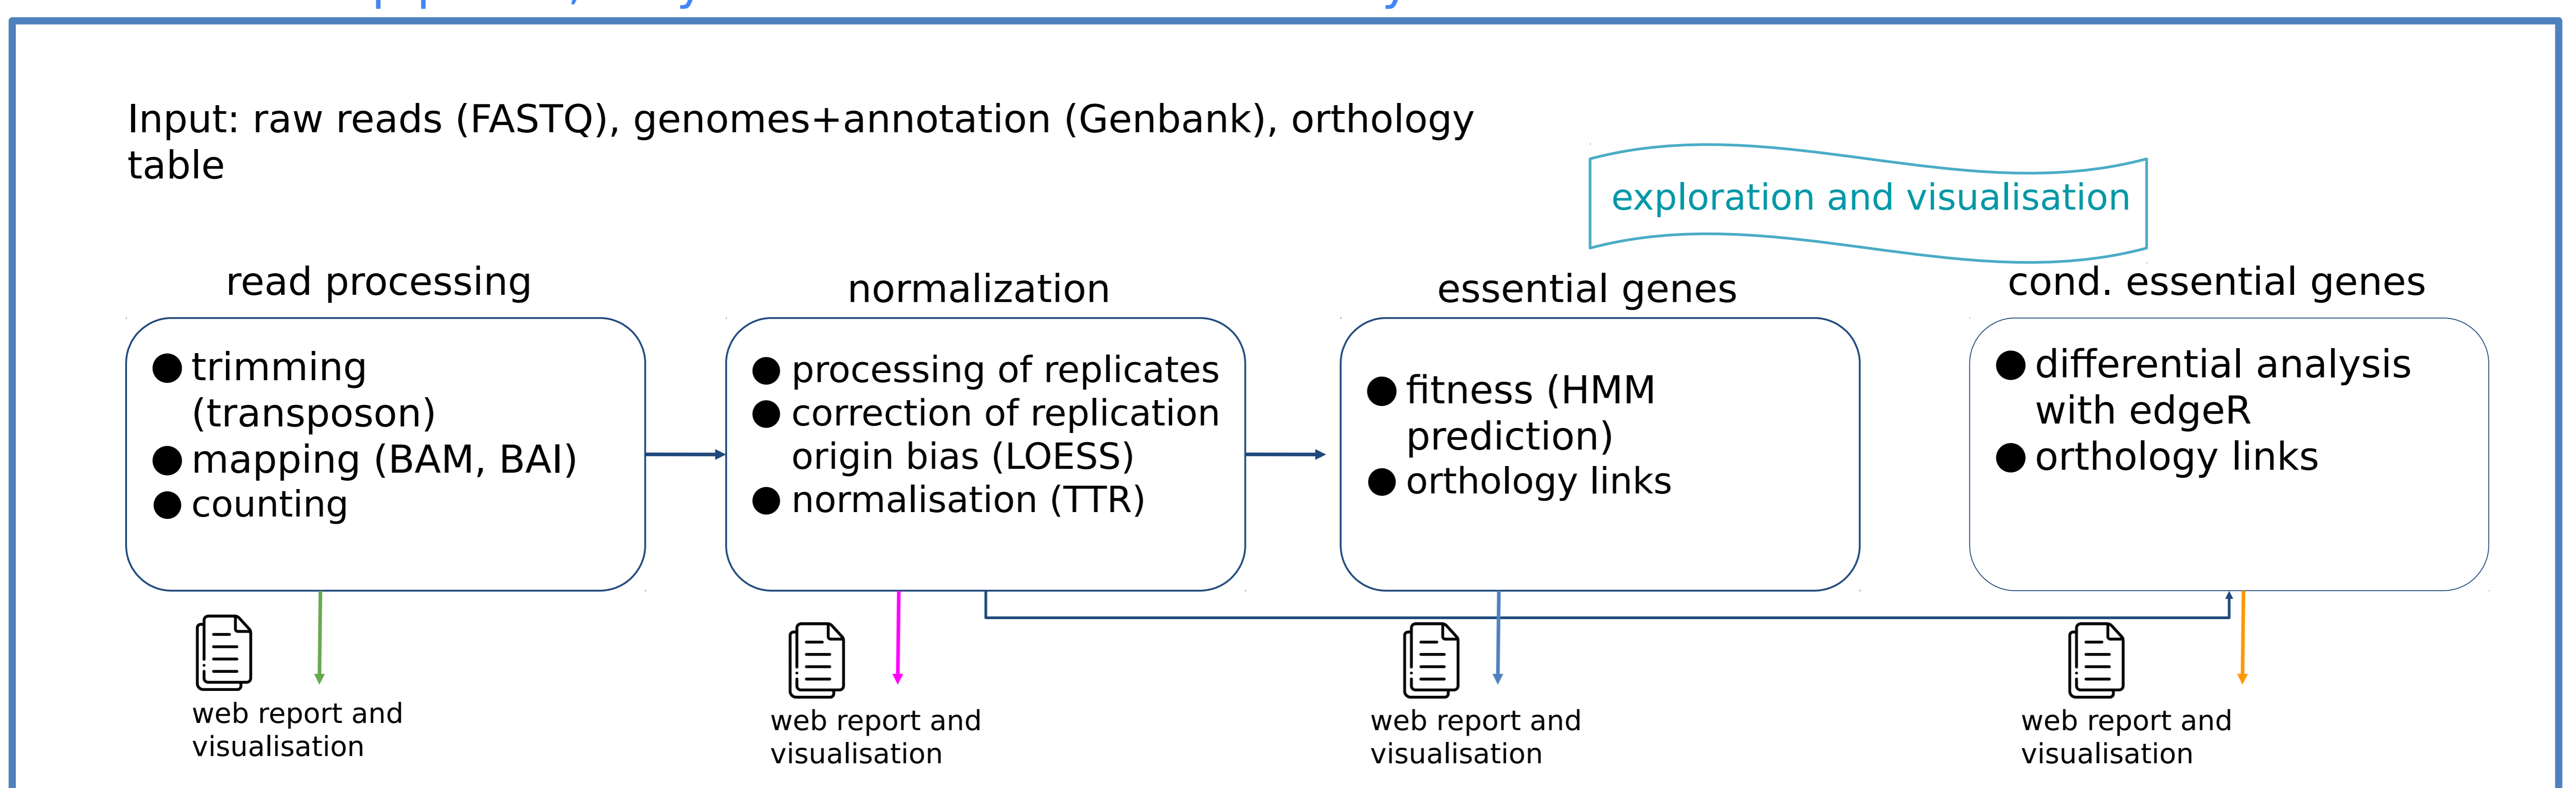

genes essential for growth under a given condition.

Conditionally essential genes

genes that are required for growth under one condition but not another

Example of applications: identification of virulence factors of pathogenic bacteria, identification of genes involved in antibioresistance, ...

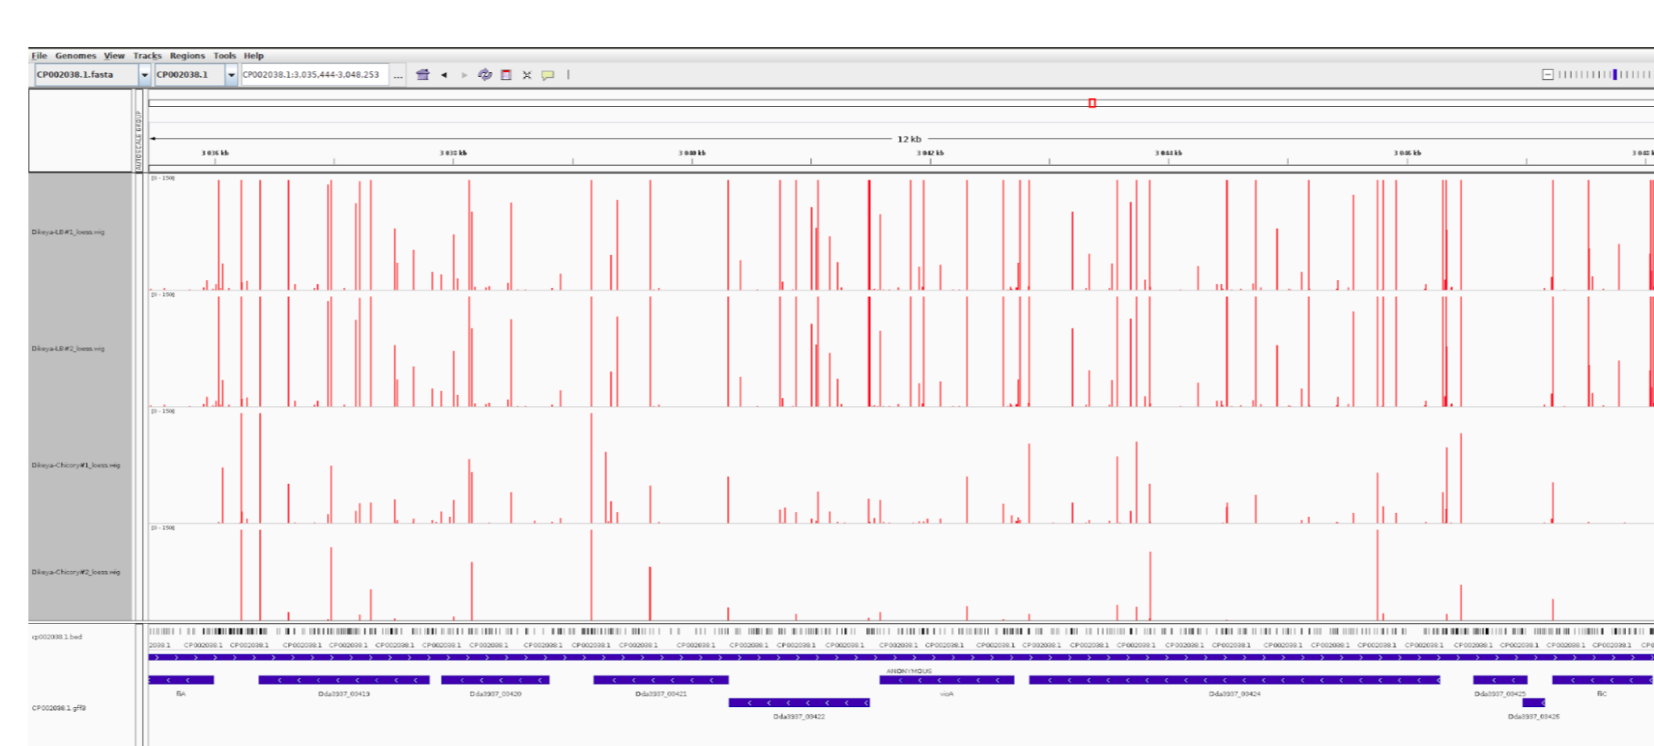

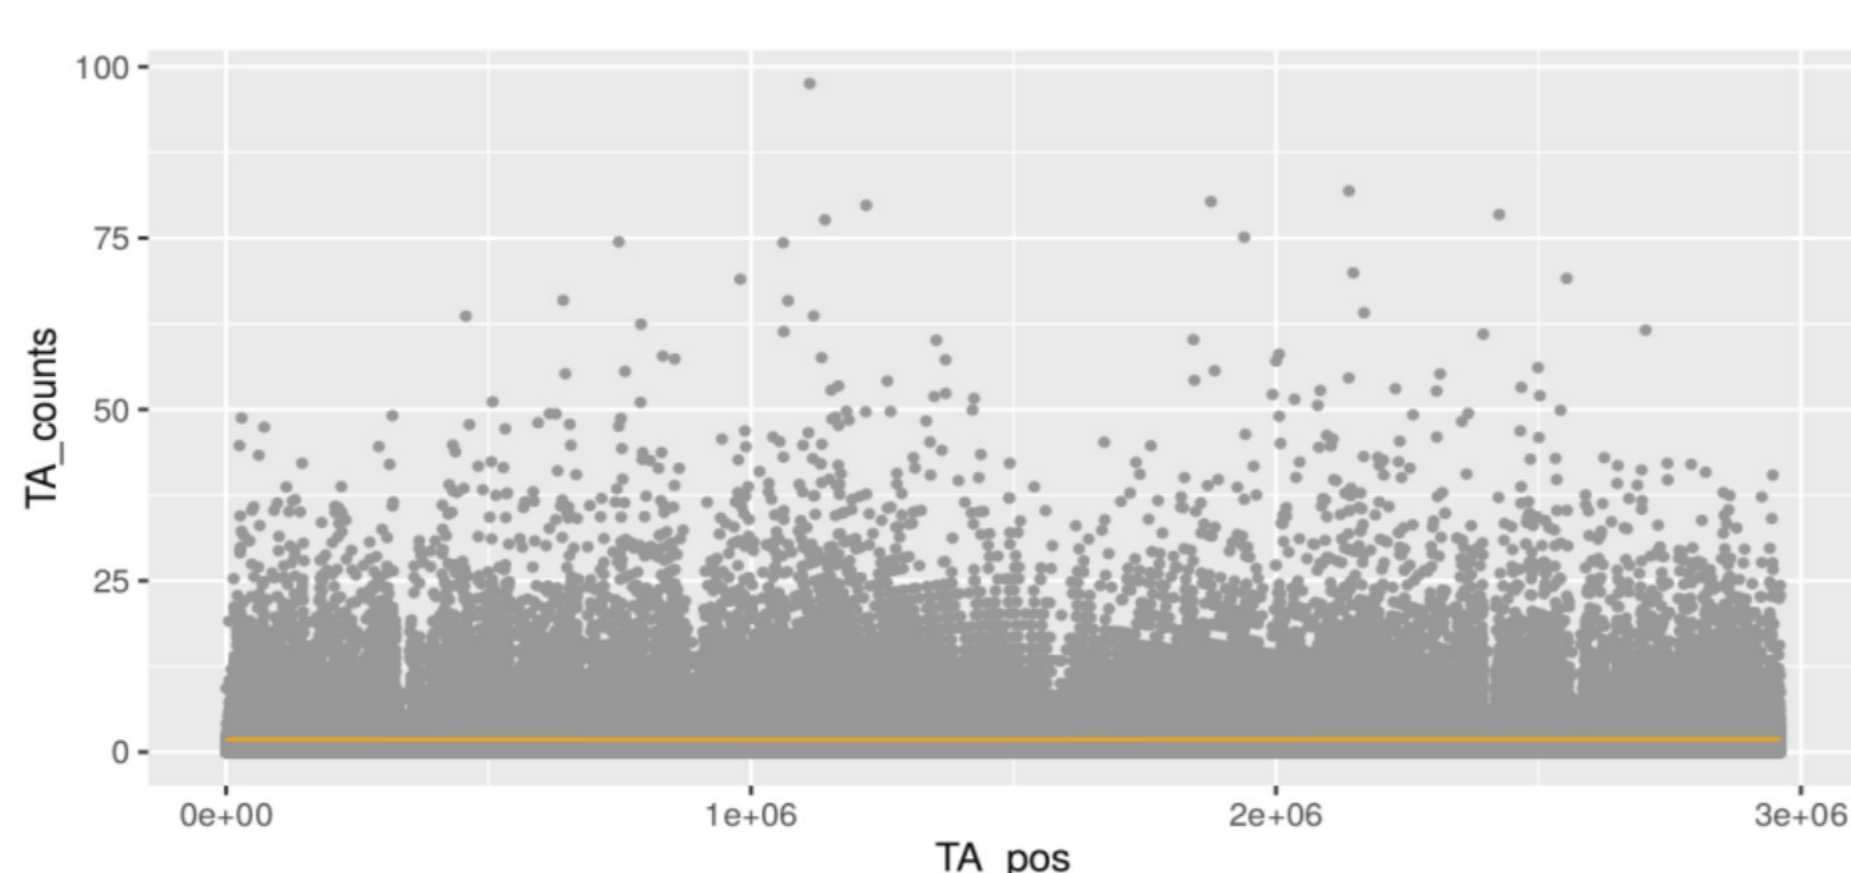

TnSeek → our pipeline, any number of conditions + any number of strains

TnSeek in practice → easy-to-install + easy-to-use

1. Download source at <https://gitlab.cristal.univ-lille.fr/bonsai/tNSEek>
2. Build the Docker image and run it
3. Connect to the Shiny server at <http://localhost:3838>

implemented in Python and R
installation with docker
reports in R markdown
web application for exploration and visualization: R Shiny & SQLite
