13 **Abstract:** Stable latexes containing unimolecular amphiphilic core-shell star-block polymers with a
14 triphenylphosphine(TPP)-functionalized hydrophobic core and an outer hydrophilic shell based on
15 anionic styrenesulfonate monomers have been synthesized in a convergent three-step strategy by
16 reversible addition-fragmentation chain-transfer (RAFT) polymerization, loaded with
17 [RhCl(COD)]₂ and applied to the aqueous biphasic hydrogenation of styrene. When the outer shell
18 contains sodium styrenesulfonate homopolymer blocks, treatment with a toluene solution of
19 [RhCl(COD)]₂ led to undesired polymer coagulation. Investigation of the interactions of
20 [RhCl(COD)]₂ and [RhCl(COD)(PPh₃)] with smaller structural models of the polymer shell func-
21 tions, namely sodium *p*-toluenesulfonate, sodium styrenesulfonate and a poly(sodium styrenesul-
22 fonate) homopolymer, in a biphasic toluene/water medium points to the presence of equilibrated
23 Rh-sulfonate interactions as the cause of coagulation by interparticle crosslinking. Modification of
24 the hydrophilic shell to a statistical copolymer of sodium styrenesulfonate and poly(ethylene oxide)
25 methyl ether methacrylate (PEOMA) in a 20:80 ratio allowed particle loading with generation of
26 core-anchored [RhCl(COD)TPP] complexes. These Rh-loaded latexes efficiently catalyze the aque-
ous biphasic hydrogenation of neat styrene as a benchmark reaction. The catalytic phase could be
recovered and recycled, although the performances in terms of catalyst leaching and activity evo-
lution during recycles are inferior to those of equivalent nanoreactors based on neutral or poly-
cationic outer shells.

1. Introduction

Aqueous biphasic catalysis is an elegant solution to facilitate catalyst recovery and recycling for processes that involve hydrophobic reactants and products [1], particularly when the catalyst is very expensive. To avoid catalyst leaching, the catalyst should have the lowest possible solubility in the reactant/product phase, while a rapid phase separation at the end of the reaction is critical for the process efficiency. In addition, the transformation should ideally not suffer from mass transport limitations. Since the catalyst must not go into the reactant/product phase, the catalytic act must occur in the aqueous phase, requiring non-zero water solubility for the reactants. The Rh/TPPTS-catalyzed hydroformylation of propene and butene (TPPTS = triphenylphosphine trisulfonate) is an

example of an industrially implemented large-scale aqueous biphasic process that obeys these principles [2]. This process, however, is inefficient for higher olefins, which do not have sufficient water solubility. Several approaches have been investigated to remove this bottleneck, including catalyst anchoring on thermomorphic polymers [3] or adding molecular transporters such as cyclodextrines [4, 5] or increasing the water/organic interface through the addition of surfactants [6, 7].

We have been interested in a different approach, based on the use of micellar nanoreactors that contain a hydrophobic core and a hydrophilic shell. The core serves to anchor the catalyst and constitutes a suitable medium for the reactants, while the shell stabilizes the nanoreactors in the aqueous phase dispersion (latex) [8-10]. The use of amphiphilic diblock copolymers is particularly attractive, because their self-assembly provides kinetically stable micelles in water. Additional advantages can be obtained by crosslinking the micellar arms, either at the shell or at the core level, thus generating unimolecular nanoreactors [11-14]. This modification removes the potential problems of extensive swelling and equilibria with free single chains, which are stabilized at the water-organic interface, and inverted micelles, which are stabilized in the organic phase, leading respectively to slow decantation and catalyst leaching.

Our approach is based on a one-pot synthesis of nanoreactors with a crosslinked core by a convergent reversible addition-fragmentation chain-transfer (RAFT) polymerization [15, 16], which produces an aqueous phase dispersion of the nanoreactors that can be directly used in catalysis. Two different polymer architectures, named core-crosslinked micelles (CCM) and nanogels (NG), see Figure 1, have been obtained by a small modification of the polymerization strategy. For the CCM synthesis, the water-soluble block resulting from the first step is chain-extended with only linear monomers, including the ligand-functionalized monomer, to yield a ligand-functionalized linear amphiphilic diblock copolymer. This step starts as a dispersion polymerization and entails “polymerization-induced self-assembly” (PISA) [17-20] to generate micelles, after which it continues as an emulsion polymerization. A crosslinker is then used to chain extend the amphiphilic diblock chains in the third and final step, yielding a unimolecular micelle with a small nanogel core. For the NG synthesis, on the other hand, all hydrophobic monomers (linear ones and crosslinker) are copolymerized together in the second and final step to chain-extend the water-soluble precursor. The main difference between the two architectures is that the ligands are anchored on flexible arms outside the crosslinked area in the CCM, whereas they are incorporated within the crosslinked area in the NG.

First generation CCM and NG polymers were built with a neutral hydrophilic shell based on linear chains of randomly copolymerized methacrylic acid (MAA) and poly(ethylene oxide) methyl ether methacrylate (PEOMA), where the PEO chains have an average degree of polymerization of 19, a functionalized polystyrene-based (PSt) core, and diethylene glycol dimethacrylate (DEGDMA) was used as a crosslinker [21-28]. The desired ligand was introduced by copolymerization of a suitably functionalized styrene in the second step, mostly 4-diphenylphosphinostyrene (DPPS) to yield PSt-anchored triphenylphosphine (TPP) functions [21, 25], but nanoreactors with other PSt-anchored ligands such as bis(*p*-methoxyphenyl)phenylphosphine [23], nixantphos [29], and a Rh-coordinated N-heterocyclic carbene [30], have also been developed. After coordination of suitable precatalysts, these polymers proved efficient and recyclable in aqueous biphasic 1-octene hydroformylation [21-23, 25] and in 1-octene and styrene hydrogenation [27]. However, the phase separation after catalysis turned out rather slow and led to non-negligible Rh leaching (ppm level) to the organic phase. The Rh leaching was shown to be associated to the transfer of the full nanoreactors to the organic phase, not to the loss of molecular Rh complexes from the nanoreactor core [22, 25], which is caused by the increased lipophilicity of the PEOMA grafts in the outer shell at the higher temperatures used in catalysis. Irreversible nanoreactor agglomeration, caused by interpenetration of the polymer particles and subsequent crosslinking through Rh-P binding, also limited the efficiency of these nanoreactors [26].

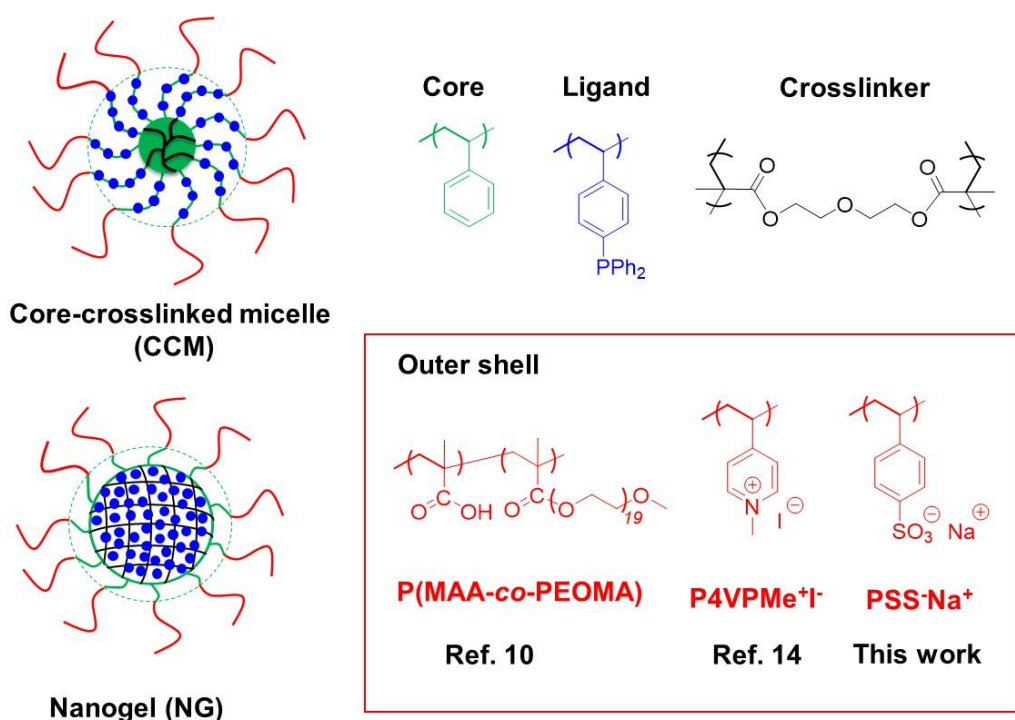

Figure 1. Architecture and composition of the core-crosslinked micelle (CCM) and nanogel (NG) particles.

In order to correct these problems, second-generation nanoreactors with an outer shell based on quaternized (methylated) 4-vinylpyridine (4VP) monomers, $-\text{[CH}_2\text{-CH(4-C}_5\text{H}_4\text{NMe}^+\text{I}^-)]_n-$, P(4VPMe⁺I⁻), were then developed Figure 1. After optimizing the polymer synthesis [31], CCM and NG particles with a TPP-functionalized PSt core were generated, charged with [RhCl(COD)]₂ to yield a core-anchored [RhCl(COD)(TPP)] precatalyst, and applied to the aqueous biphasic hydrogenation of styrene and 1-octene [32]. As anticipated, these catalytic nanoreactors exhibited improved properties: much faster decantation rates (minutes rather than hours) and lower catalyst leaching (< 100 ppb rather than > 1 ppm), while the turnover frequency (TOF) was similar to that of the first-generation nanoreactors, indicating equally efficient mass transport of the organic reactants and products through the neutral and polycationic shells.

We now wish to report the synthesis and catalytic application of third-generation nanoreactors, containing a permanently charged polyanionic outer shell built with poly(sodium styrenesulfonate) chains. This new type of outer shell is also able, thanks to the Coulombic repulsion, to block particle interpenetration and is not characterized by high-temperature hydrophobicity. The investigation of new types of shells was motivated by the quest of further performance improvements in terms of decantation speed and catalyst leaching. In addition, the successful strategy for the fabrication of the 2nd-generation nanoreactor was rather tedious [31, 32]. While these 3rd-generation polymers were more easily accessible than the 2nd generation ones, they presented an unexpected complication at the catalyst loading stage. Model studies with molecular compounds have allowed us to establish the reasons for these complications and to find a suitable solution through further shell modification, leading to the development of functional catalytic nanoreactors.

2. Materials and Methods

All manipulations were performed by Schlenk-line techniques under an inert atmosphere of dry argon. Solvents were dried by standard procedures and distilled under argon

128 prior to use. 4,4'-azobis(4-cyanopentanoic acid) (ACPA, >98%, Fluka), sodium 4-vinylben-
129 zenesulfonate (SS-Na⁺, >90%, Aldrich), poly(ethylene oxide) dimethyl ether (PEOMA, M_n
130 = 950 g mol⁻¹, Sigma-Aldrich), diethylene glycol dimethacrylate (DEGDMA, 95%, Aldrich),
131 and 1,3,5-trioxane (>99%, Aldrich), were used as received. Styrene (St, 99%, Acros) was
132 distilled under reduced pressure prior to use. The RAFT agent 4-cyano-4-thiothiopropyl-
133 sulfanyl pentanoic acid (CTPPA) or R₀-SC(S)SnPr (R₀ = -C(CH₃)-(CN)-CH₂CH₂COOH),
134 was prepared according to the literature [33]. The R₀-(SS-Na⁺)₁₄₀-SC(S)SnPr and R₀-(SS-
135 Na⁺)₁₄₀-b-St₅₀-SC(S)SnPr macroRAFT agents were synthesized as described in our recent
136 contribution [34]. The deionized water used for the syntheses and DLS analyses was ob-
137 tained from a Purelab Classic UV system (Elga Lab-Water).

138 Characterization Techniques.

139 *NMR spectroscopy.* All nuclear magnetic resonance spectra were recorded in 5 mm
140 diameter tubes at 297 K on a Bruker Avance 400 spectrometer. The ¹H and ³¹P chemical
141 shift were determined using the residual peak of the deuterated solvent (δ 2.50 for DMSO-
142 d₆, 4.79 for D₂O) as internal standard and are reported in ppm (δ) relative to tetrame-
143 thylsilane. The monomer conversions in the polymerizations were monitored by ¹H NMR
144 in DMSO-d₆ at room temperature by the relative integration of the protons of the internal
145 reference (1,3,5-trioxane) at 5.20 ppm and the vinylic monomer protons.

146 *Size exclusion chromatography (SEC).* The P(SS-Na⁺) chain growth was monitored by
147 SEC in water/acetonitrile (80/20 v/v) with 0.1 M NaNO₃ at 60 °C at a flow rate of 1.0 mL
148 min⁻¹ by using a Viscotek TDA305 apparatus (SEC-DMF) coupled with a multi-angle light
149 scattering (MALLS) detector (18 angles) from MALLS Wyatt Dawn Heleos. The measured
150 dn/dc values for the R₀-[(SS-Na⁺)<sub>0.2-co-PEOMA_{0.8}]₅₀-SC(S)SnPr in the eluent is 0.051 mL g⁻¹.
151 All polymers were analyzed at a concentration of 5 mg mL⁻¹ after filtration through a 0.45
152 μm pore size membrane. The separation was carried out on two columns from Agilent
153 Aquagel OH Mixed M. The software used for data collection and calculation was OmniSec
154 version 4.7 from Malvern Instruments.</sub>

155 *Dynamic light scattering (DLS).* The intensity-average diameters of the latex particles
156 (*D_z*) and the polydispersity index (PDI) were obtained on a Malvern Zetasizer NanoZS
157 equipped with a He-Ne laser (λ = 633 nm), operating at 25 °C. Samples were analyzed
158 after dilution (with deionized water) either unfiltered or after filtration through a 0.45 μm
159 pore-size membrane. The procedure without filtration allowed verification of the presence
160 of agglomerates. Zeta potential (ζ) determinations were also conducted on the same in-
161 strument by measuring the electrophoretic mobility.

162 *Transmission electron microscopy (TEM).* The morphological analyses of the copolymer
163 nano-objects were performed at the Centre de Microcaractérisation Raimond Castaing
164 (Toulouse France) with a JEOL JEM 1400 transmission electron microscope working at 120
165 kV. Diluted latex samples were dropped on a formvar/carbon-coated copper grid and
166 dried under vacuum for 24 hours.

167 Synthesis of phosphine-functionalized copolymer nanoreactors with an anionic 168 P(SS-Na⁺) shell.

169 *Preparation of latexes of the R₀-(SS-Na⁺)₁₄₀-b-St₅₀-b-(St<sub>1-y-co-DPPS_y)₃₀₀-SC(S)SnPr am-
170 phiphilic triblock copolymers.</sub>* The synthesis of all latexes of this type followed the same pro-
171 cedure, which is detailed here only for the product with y = 0.1. To the pale-yellow latex
172 of the R₀-(SS-Na⁺)₁₄₀-b-St₅₀-SC(S)SnPr macroRAFT agent (0.04 mmol of polymer, corre-
173 sponding to 0.56 mmol of SS-Na⁺ units, 3 mL of water) in a Schlenk tube under Ar were
174 added degassed styrene (1.24 mL, 1.12 g, 10.75 mmol; 270 equiv. per chain) and DPPS
175 (0.344 g, 1.20 mmol; 30 equiv. per chain) and trioxane (ca. 90 mg) as an internal standard.
176 A portion of a degassed ACPA/NaHCO₃ stock solution (0.11 mL, 2.2 mg ACPA, 7.96 μmol)
177 was then added and the resulting reaction mixture was stirred at 80 °C for 7 h, yielding a
178 white opalescent stable dispersion. The resulting polymer has a theoretical molar mass of
179 71099 g mol⁻¹. The weight percent polymer in the latex is 18.3 %. Using the same amounts
180 of R₀-(SS-Na⁺)₁₄₀-b-St₅₀-SC(S)SnPr, ACPA solution, water and trioxane but different
181 amounts of degassed styrene and DPPS led to latexes of the product with different molar

DPPS content (5% and 20%) in the hydrophobic block. For $y = 0.05$: $R_0-(SS-Na^+)_{140}-b-St_{50}-SC(S)SnPr$ (0.04 mmol of polymer, 3 mL of water), styrene (1.30 mL, 1.18 g, 11.34 mmol; 285 equiv. per chain), DPPS (0.17 g, 0.60 mmol; 15 equiv. per chain), $M_{n,th} = 68312 \text{ g mol}^{-1}$, polymer content = 17.7% (w/w). For $y = 0.2$: $R_0-(SS-Na^+)_{140}-b-St_{50}-SC(S)SnPr$ (0.04 mmol of polymer, 3 mL of water), styrene (1.10 mL, 1.00 g, 9.55 mmol; 240 equiv. per chain), DPPS (0.69 g, 2.39 mmol; 60 equiv. per chain), $M_{n,th} = 76582 \text{ g mol}^{-1}$, polymer content = 19.5% (w/w).

Preparation of latexes of the $R_0-(SS-Na^+)_{140}-b-(St_{1-y}-co-DPPS_y)_{300}-SC(S)SnPr$ amphiphilic diblock copolymers. The synthesis of all latexes of $R_0-(SS-Na^+)_{140}-b-(St_{1-y}-co-DPPS_y)_{300}-SC(S)SnPr$ ($y = 0.05, 0.1, 0.2, 0.25$) followed the same procedure as for the synthesis of $R_0-(SS-Na^+)_{140}-b-St_{50}-b-(St_{1-y}-co-DPPS_y)_{300}-SC(S)SnPr$ described in the previous section. For $y = 0.05$: $R_0-(SS-Na^+)_{140}-SC(S)SnPr$ (0.04 mmol of polymer, 3 mL of water), styrene (1.31 mL, 1.19 g, 11.4 mmol; 285 equiv. per chain), DPPS (0.17 g, 0.6 mmol; 15 equiv. per chain), $M_{n,th} = 63203 \text{ g mol}^{-1}$, polymer content = 16.7% (w/w). For $y = 0.1$: $R_0-(SS-Na^+)_{140}-SC(S)SnPr$ (0.04 mmol of polymer, 6 mL of water), styrene (1.24 mL, 1.12 g, 10.7 mmol; 270 equiv. per chain), DPPS (0.34 g, 1.20 mmol; 30 equiv. per chain), $M_{n,th} = 65834 \text{ g mol}^{-1}$, polymer content = 14.4% (w/w). For $y = 0.2$: $R_0-(SS-Na^+)_{140}-SC(S)SnPr$ (0.04 mmol of polymer, 6 mL of water), styrene (1.1 mL, 1.00 g, 9.6 mmol; 240 equiv. per chain), DPPS (0.69 g, 2.4 mmol; 60 equiv. per chain), $M_{n,th} = 71347 \text{ g mol}^{-1}$, polymer content = 15.5% (w/w). For $y = 0.25$: $R_0-(SS-Na^+)_{140}-SC(S)SnPr$ (0.04 mmol of polymer, 6 mL of water), styrene (1.03 mL, 0.94 g, 9.0 mmol; 225 equiv. per chain), DPPS (0.86 g, 3.0 mmol; 75 equiv. per chain), $M_{n,th} = 74104 \text{ g mol}^{-1}$, polymer content = 16.0% (w/w).

Preparation of CCMs with a 90:10 St/DEGDMA core: crosslinking of the $R_0-(SS-Na^+)_{140}-b-St_{50}-b-(St_{1-y}-co-DPPS_y)_{300}-SC(S)SnPr$ amphiphilic block copolymers. To the total volume of each of the $R_0-(SS-Na^+)_{140}-b-St_{50}-b-(St_{1-y}-co-DPPS_y)_{300}-SC(S)SnPr$ latexes obtained as described above (0.04 mmol of polymer) were successively added DEGDMA (0.133 mL, 144.3 mg, 0.6 mmol; 15 equiv. per chain), styrene (0.62 mL, 561.6 mg, 5.4 mmol; 135 equiv. per chain) and the degassed ACPA/ $NaHCO_3$ stock solution (0.11 mL, 2.2 mg ACPA, 7.96 μmol). The resulting reaction mixtures were stirred at 80 °C for 4 h resulting in complete comonomer consumption ($^1\text{H NMR}$ monitoring in $DMSO-d_6$) to yield the CCMs $R_0-(SS-Na^+)_{140}-b-(St_{1-y}-co-DPPS_y)_{300}-b-(DEGDMA_{0.1-co-St_{0.9}})_{150}-SC(S)SnPr$ ($y = 0.05, 0.1, 0.2$). Polymer content: 21.2% ($y = 0.05$), 21.7% ($y = 0.1$), 22.8% ($y = 0.2$); $[TPP] = 38.22 \mu\text{mol mL}^{-1}$ ($x = 0.05$), 76.90 $\mu\text{mol mL}^{-1}$ ($x = 0.1$), 154.92 $\mu\text{mol mL}^{-1}$ ($x = 0.2$).

Preparation of CCMs with a neat DEGDMA core: crosslinking of the $R_0-(SS-Na^+)_{140}-b-(St_{1-y}-co-DPPS_y)_{300}-SC(S)SnPr$ amphiphilic block copolymers. To the total volume of each of the $R_0-(SS-Na^+)_{140}-b-(St_{1-y}-co-DPPS_y)_{300}-SC(S)SnPr$ latexes obtained as described above (0.04 mmol of polymer) were successively added H_2O (1 mL), DEGDMA (0.134 mL, 144.4 mg, 0.6 mmol; 15 equiv. per chain) and the degassed ACPA/ $NaHCO_3$ stock solution (0.11 mL, 2.2 mg ACPA, 7.96 μmol). The resulting reaction mixtures were stirred at 80 °C for 3 h resulting in an essentially quantitative monomer consumption (< 1% of residual DEGDMA by $^1\text{H NMR}$ monitoring in $DMSO-d_6$) to yield the CCMs $R_0-(SS-Na^+)_{140}-b-(St_{1-y}-co-DPPS_y)_{300}-b-DEGDMA_{15}-SC(S)SnPr$ ($y = 0.05, 0.1, 0.2, 0.25$). Polymer content: 18.63% ($y = 0.05$), 14.26% ($y = 0.1$), 15.22% ($y = 0.2$), 15.61% ($y = 0.25$); $[TPP] = 43.71 \mu\text{mol mL}^{-1}$ ($x = 0.05$), 64.22 $\mu\text{mol mL}^{-1}$ ($x = 0.1$), 129.39 $\mu\text{mol mL}^{-1}$ ($x = 0.2$), 161.38 $\mu\text{mol mL}^{-1}$ ($x = 0.25$).

Preparation of NGs. To a Schlenk tube containing an aqueous solution of $R_0-(SS-Na^+)_{140}-SC(S)SnPr$ aqueous solution (10 mL, 0.04 mmol of polymer, corresponding to 5.55 mmol of $SS-Na^+$ units), were subsequently added H_2O (6 mL), 1,3,5-trioxane (ca. 42.1 mg), degassed styrene (1.31 mL, 1.18 g, 11.4 mmol), DPPS (0.173 g, 0.6 mmol) and DEGDMA (0.13 mL, 144.5 mg, 0.6 mmol) and a the degassed ACPA/ $NaHCO_3$ stock solution (0.11 mL, 2.2 mg ACPA, 7.96 μmol). The reaction mixture was stirred at 80 °C for 5 h to yield the NGs $R_0-(SS-Na^+)_{140}-b-(St_{285}-co-DPPS_{15}-co-DEGDMA_{15})-SC(S)SnPr$. The latex has a polymer content of 14.6% w/w ($[TPP] = 34.17 \mu\text{mol mL}^{-1}$).

Synthesis of phosphine-functionalized copolymer nanoreactors with an anionic $P(SS-Na^+-co-PEOMA)$ shell.

236 *Preparation the $R_0-[(SS-Na^+)_{0.2-co-PEOMA_{0.8}}]_x-SC(S)SnPr$ macroRAFT agent ($x = 50, 140$).*
237 A. $x = 50$. A portion of the ACPA stock solution (0.5 mL, 10 mg of ACPA, 0.36 mmol),
238 CTPPA (50 mg, 0.18 mmol), $SS-Na^+$ (372.2 mg, 1.8 mmol; $SS-Na^+/CTPPA = 10$), PEOMA
239 (6.86 g, 7.22 mmol; $PEOMA/CTPPA = 40$), ethanol (9 mL) and deionized water (21 mL)
240 were added to a 100 mL Schlenk tube with a magnetic stirrer bar. An internal reference
241 (1,3,5-trioxane, 40.2 mg, 0.47 mmol) was also added as for the determination of the mon-
242 omer conversion as a function of time by 1H NMR. The solution was purged for 45 min
243 with argon and then heated to 80 °C during 6 h in a thermostatic oil bath under stirring,
244 leading to quantitative conversion of both monomers. The experimental molar mass (from
245 SEC) for the final polymer is $M_n = 40780$ g mol $^{-1}$ with $D = 4.95$, versus a theoretical molar
246 mass of 40339 g mol $^{-1}$. The polymer content in the latex is 20.3% w/w.

247 B. $x = 140$. This polymerization was carried out under the same conditions as in part
248 A, except for using a lower CTPPA/monomer ratio [CTPPA (50 mg, 0.18 mmol), $SS-Na^+$
249 (1.042 g, 5.1 mmol; $SS-Na^+/CTPPA = 28$), PEOMA (19.21 g, 20.2 mmol; $PEOMA/CTPPA =$
250 112), ethanol (12 mL) and deionized water 42 mL). The theoretical molar mass is 112450 g
251 mol $^{-1}$. The polymer content in the latex is 26.33 % w/w.

252 *Preparation of latexes of the $R_0-[(SS-Na^+)_{0.2-co-PEOMA_{0.8}}]_x-b-St_{50}-SC(S)SnPr$ amphiphilic*
253 *diblock copolymers.* A. $x = 50$. To the 5 mL pale-yellow latex of the $R_0-[(SS-Na^+)_{0.2-co-}$
254 $PEOMA_{0.8}]_{50}-SC(S)SnPr$ macroRAFT agent (0.03 mmol of polymer, 7 mL of water) in a
255 Schlenk tube under Ar were added degassed styrene (0.17 mL, 0.15 g, 1.48 mmol; 50 equiv.
256 per chain) and ACPA stock solution (0.1 mL, 2 mg of ACPA, 7.13 μ mol). The solution was
257 purged for 45 min with argon and then heated to 80 °C during 5 h in a thermostatic oil
258 bath under stirring, leading to quantitative conversion of styrene. The theoretical molar
259 mass of 45544 g mol $^{-1}$. The polymer content in the latex is 10.3% w/w.

260 B. $x = 140$. This polymerization was carried out under the same conditions as in part
261 A. To the 5 mL pale-yellow latex of the $R_0-[(SS-Na^+)_{0.2-co-PEOMA_{0.8}}]_{140}-SC(S)SnPr$
262 macroRAFT agent (0.015 mmol of polymer, 5 mL of water) in a Schlenk tube under Ar
263 were added degassed styrene (0.09 mL, 0.078 g, 0.75 mmol; 50 equiv. per chain) and ACPA
264 stock solution (0.05 mL, 1 mg of ACPA, 3.57 μ mol). The theoretical molar mass of 117673
265 g mol $^{-1}$. The polymer content in the latex is 15.26% w/w.

266 *Preparation of latexes of the $R_0-[(SS-Na^+)_{0.2-co-PEOMA_{0.8}}]_x-b-(S_{0.9-co-DPPS_{0.1}})_{300}-$*
267 *SC(S)SnPr amphiphilic copolymers ($x = 50, 140$).* A. $x = 50$. To a Schlenk tube under Ar con-
268 taining the pale-yellow $R_0-[(SS-Na^+)_{0.2-co-PEOMA_{0.8}}]_{50}-SC(S)SnPr$ solution obtained as de-
269 scribed above (10 mL, 0.06 mmol of polymer) was added degassed water (16 mL), de-
270 gassed styrene (1.83 mL, 1.66 g, 15.9 mmol; 270 equiv. per chain) and DPPS (0.51 g, 1.8
271 mmol; 30 equiv. per chain). A portion of the degassed ACPA/ $NaHCO_3$ stock solution
272 (0.165 mL, 3.3 mg ACPA, 11.77 μ mol) was then added and the resulting reaction mixture
273 was stirred at 80 °C for 5 h, resulting in complete monomer consumption and yielding a
274 white opalescent stable dispersion. The resulting polymer has a theoretical molar mass of
275 77117 g mol $^{-1}$. The weight percent polymer in the latex is 15.2% and the phosphine con-
276 centration in the latex is 63.04 μ mol mL $^{-1}$.

277 B. $x = 140$. This polymerization was carried out under the same conditions as in part
278 A, except for using the $R_0-[(SS-Na^+)_{0.2-co-PEOMA_{0.8}}]_{140}-SC(S)SnPr$ solution (10 mL, 0.03
279 mmol of polymer), degassed styrene (0.93 mL, 0.84 g, 15.9 mmol; 270 equiv. per chain),
280 DPPS (0.26 g, 0.9 mmol; 30 equiv. per chain) and degassed ACPA/ $NaHCO_3$ stock solution
281 (0.1 mL, 2 mg ACPA, 7.14 μ mol). Complete monomer consumption led to a stable opales-
282 cent dispersion. The resulting polymer has a theoretical molar mass of 149210 g mol $^{-1}$. The
283 weight percent polymer in the latex is 18.6 % and the phosphine concentration in the latex
284 is 42.57 μ mol mL $^{-1}$.

285 *Crosslinking of the $P(SS-Na^+co-PEOMA)-b-P(St-co-DPPS)$ amphiphilic block copolymers*
286 *by a DEGDMA-styrene comonomer mixture. Preparation of $R_0-[(SS-Na^+)_{0.2-co-PEOMA_{0.8}}]_x-b-$*
287 *$(St_{0.9-co-DPPS_{0.1}})_{300}-b-(S_{0.9-co-DEGDMA_{0.1}})_{150}-SC(S)SnPr$ ($x = 50, 140$).* A. $x = 50$. To the total
288 volume of the $R_0-[(SS-Na^+)_{0.2-co-PEOMA_{0.8}}]_{50}-b-(St_{0.9-co-DPPS_{0.1}})_{300}-SC(S)SnPr$ latex (0.06
289 mmol of polymer chains) obtained as described above were successively added degassed

H₂O (34 mL), DEGDMA (0.198 mL, 0.214 g, 0.88 mmol; 15 equiv. per chain), styrene (0.91 mL, 0.83 g, 7.94 mmol; 135 equiv. per chain) and the degassed ACPA/NaHCO₃ stock solution (0.165 mL, 3.3 mg ACPA, 11.8 μmol). The resulting reaction mixture was stirred at 80 °C for 5 h resulting in complete consumption of both monomers (¹H NMR monitoring in DMSO-*d*₆). The weight percent polymer in the latex and the phosphine concentration in the latex are: 7.27 % and 27.89 μmol mL⁻¹.

B. x = 140. This polymerization was carried out under the same conditions as in part A, except for using the R₀-[(SS-Na⁺)_{0.2-co-PEOMA}_{0.8}]₁₄₀-SC(S)SnPr solution (0.03 mmol of polymer), DEGDMA (0.1 mL, 0.108 g; 0.04 mmol, 15 equiv. per chain), styrene (0.46 mL, 0.42 g, 4.03 mmol; 135 equiv. per chain) and the degassed ACPA/NaHCO₃ stock solution (0.08 mL, 1.7 mg ACPA, 5.97 μmol). The resulting polymer has a theoretical molar mass of 149210 g mol⁻¹. The weight percent polymer in the latex is 20.3 % and the phosphine concentration in the latex is 41.3 μmol mL⁻¹.

Crosslinking of the P(SS-Na⁺-co-PEOMA)-b-P(St-co-DPPS) amphiphilic block copolymers by neat DEGDMA. Preparation of R₀-[(SS-Na⁺)_{0.2-co-PEOMA}_{0.8}]₅₀-b-(St_{0.9-co-DPPS}_{0.1})₃₀₀-b-DEGDMA₉₀-SC(S)SnPr. To the total volume of the R₀-[(SS-Na⁺)_{0.2-co-PEOMA}_{0.8}]₅₀-b-(St_{0.9-co-DPPS}_{0.1})₃₀₀-SC(S)SnPr latex (0.06 mmol of polymer chains) obtained as described above were successively added degassed H₂O (34 mL), DEGDMA (1.184 mL, 1.281 g, 5.295 mmol; 90 equiv. per chain) and the degassed ACPA/NaHCO₃ stock solution (0.165 mL, 3.3 mg ACPA, 12.0 μmol). The resulting reaction mixture was stirred at 80 °C for 5 h resulting in complete monomer consumption (¹H NMR monitoring in DMSO-*d*₆). The weight percent polymer in the latex and the phosphine concentration in the latex are: 8.87 % and 27.862 μmol mL⁻¹.

Preparation of NGs. A. x = 50. To a Schlenk tube containing an aqueous solution of R₀-[(SS-Na⁺)_{0.2-co-PEOMA}_{0.8}]₅₀-b-St₅₀-SC(S)SnPr aqueous solution (0.03 mmol of polymer), were subsequently added H₂O (15 mL), degassed styrene (1.45 mL, 1.31 g, 12.6 mmol), DPPS (0.256 g, 0.89 mmol) and DEGDMA (0.1 mL, 108.2 mg, 0.45 mmol) and a the degassed ACPA/NaHCO₃ stock solution (0.083 mL, 1.7 mg ACPA, 5.92 μmol). The reaction mixture was stirred at 80 °C for 7 h to yield the NG R₀-[(SS-Na⁺)_{0.2-co-PEOMA}_{0.8}]₅₀-b-St₅₀-b-(St_{425-co-DPPS}_{30-co-DEGDMA}₁₅)-SC(S)SnPr. The latex has a polymer content of 10.1% w/w ([TPP] = 30.78 μmol mL⁻¹).

B. x = 140. This polymerization was carried out under the same conditions as in part A, except for using the R₀-[(SS-Na⁺)_{0.2-co-PEOMA}_{0.8}]₁₄₀-b-St₅₀-SC(S)SnPr solution (0.015 mmol of polymer), 5 mL H₂O, DPPS (0.128 g, 0.44 mmol; 30 equiv. per chain), DEGDMA (0.05 mL, 0.054 g, 0.22 mmol; 15 equiv. per chain), styrene (0.73 mL, 0.66 g, 6.34 mmol; 425 equiv. per chain) and the degassed ACPA/NaHCO₃ stock solution (0.0418 mL, 0.8 mg ACPA, 2.98 μmol). The weight percent polymer in the latex is 14.9 % and the phosphine concentration in the latex is 27.8 μmol mL⁻¹.

General procedure for Rh complexation to the phosphine ligand within CCM or NG core.

In a Schlenk tube was added 1 mL of the polymer latex and 3 mL of H₂O. Toluene (3 mL) was added and the mixture was stirred for 5 min, resulting in the CCM particle core swelling. Then a separately prepared solution of the desired amount of [RhCl(COD)]₂, depending on the target P/Rh ratio, in toluene (1 mL) was added to the latex and the mixture was vigorously stirred at room temperature, stopping the stirring at regular intervals (decantation was rapid, < 5 min) to assess the progress of the reaction.

General procedure for the catalyzed hydrogenation.

In a vial containing a magnetic stirrer was added 0.4 mL of the Rh-charged latex (CCM 10% or NG 10%), prepared as described in the previous sections. The desired amount of styrene was layered on top of the latex. For all experiments, irrespective of the substrate/Rh ratio, decane (internal standard) was then added to the organic layer (substrate/decane molar ratio ca. 4). The vial was then placed inside an autoclave, which was subsequently charged with dihydrogen (20 bar), placed in a thermostatic oil bath, and stirred at 1200 rpm. At the set reaction time, the stirring was stopped, the autoclave was

344 vented and the vial was taken out under argon. The latex decantation was rapid (<5 min).
345 After phase separation, the latex was extracted with toluene (3×0.3 mL). The combined
346 organic phases were used for the GC analysis. For the recycling experiments, a fresh sub-
347 strate solution (same amounts as in the initial run) was added to the same vial, followed
348 by reaction and product separation according to the same protocol.

3. Results

3.1. TPP-functionalized CCMs and NGs with hydrophilic P(SS-Na⁺) homopolymer blocks

351 The synthesis of the new polymers followed the same convergent strategy previously
352 used for the construction of CCMs and NGs with a neutral [21, 25] or polycationic [32]
353 outer shell, as already outlined in the Introduction, except for the nature of the hydrophilic
354 blocks assembled in the first step, as schematically shown in Figure 2. The final latexes
355 contain up to ca. 27% of polymer content in mass and have low viscosity, as expected for
356 stable suspensions of spherical micelles. The suspensions are stable, with no evidence of
357 coagulation over several months, but must be stored under an inert atmosphere to avoid
358 the slow aerial oxidation of the phosphine ligand to phosphine oxide. For convenience, all
359 new polymers described in this section, as well as references to their characterization data,
360 are summarized in the Supporting Information (Table S1). As additional help to the
361 reader, the polymer formulas in the manuscript text and Supporting Information are writ-
362 ten using the color coding of Figure 2. The α and ω chain ends of the macromolecule are
363 provided by the RAFT chain transfer agent 4-cyano-4-thiothiopropylsulfanyl pentanoic
364 acid (CTPPA) ($R_0 = -C(CH_3)(CN)CH_2CH_2COOH$). We have already optimized and re-
365 cently published [34] the synthesis of unimolecular CCMs that are fully equivalent to
366 those described here, except for the absence of ligand-functionalized monomer. As a short
367 summary, the aqueous dispersions of the micelles formed by the intermediate $R_0-(SS-Na^+)_{x-b}-St_y-SC(S)SnPr$ diblock copolymer were found unstable, featuring equilibria with
368 single chains and large agglomerates, especially for polymers with a short PSt block. How-
369 ever, the optimized polymer compositions ($x = 140$, $y > 300$) led to well-defined CCMs
370 with narrow size distributions after the final crosslinking step. For this reason, the synthe-
371 sis of the ligand-functionalized CCMs was pursued by fixing the degrees of polymeriza-
372 tion to 140 for the outer hydrophilic P(SS-Na⁺) shell and to 300 for the PSt core. The fraction
373 of DPPS (a solid monomer) in the St/DPPS mixture is limited by the DPPS solubility in
374 styrene (ca. 25% molar), because the suspension polymerization in the second step of the
375 CCM synthesis requires the presence of only two liquid phases in order to yield full mon-
376 omer conversion and produce well-defined micelles.

378 Given previously encountered difficulties (precipitation of DPPS as a result of the
379 faster incorporation of styrene, especially when using the higher DPPS fractions), a few
380 CCMs were also initially developed by first extending the $R_0-(SS-Na^+)_{140}-SC(S)SnPr$ mac-
381 romolecules with a short PSt block (50 monomer units), yielding an amphiphilic diblock
382 copolymer, which self-assembles. Further chain extension of the $R_0-(SS-Na^+)_{140}-b-St_{50}-$
383 $SC(S)SnPr$ macroRAFT agent with the St/DPPS mixture then starts off directly as an emul-
384 sion polymerization, removing any potential DPPS precipitation issues and ensuring full
385 incorporation of the DPPS monomer in the CCM core. Indeed, the ¹H NMR monitoring
386 indicates full consumption of all monomers (Figure S1). However, this precaution was
387 later found superfluous, as essentially complete DPPS incorporation (see Figure S2) with-
388 out precipitation also took place upon direct extension of the hydrosoluble $R_0-(SS-Na^+)_{140}-$
389 $SC(S)SnPr$ macroRAFT agent, even for a 25% molar DPPS fraction. The DLS and TEM
390 characterization of most of the resulting dispersions is collected in Figure S3. The DLS
391 measurements indicate the presence of micelles with average diameter in the 50-80 nm
392 range, although distributions of larger agglomerates are also observed for the unfiltered
393 dispersions. This behavior is quite similar to that observed for the equivalent diblock co-
394 polymers with a neat PSt block [34]. The NMR spectra of the self-assembled di/triblock

395 copolymers in DMSO-*d*₆ (Figures S1 and S2) only reveal the solvated P(SS-Na⁺) block res-
 396 onances, because DMSO is a bad solvent for polystyrene and the (St_{1-y}-co-DPPS_y)₃₀₀ or St₅₀-
 397 *b*-(St_{1-y}-co-DPPS_y)₃₀₀ cores do not have sufficient mobility. All resonances, however, became
 398 visible in D₂O after swelling the cores with CDCl₃ (see representative examples in Figure
 399 S4).

400
 401 **Figure 2.** Synthesis of the triphenylphosphine-functionalized CCM and NG particles with an outer
 402 P(SS-Na⁺) hydrophilic shell.

403 The final crosslinking step was carried out using either a 10:90 DEGDMA/St comon-
 404 er mixture or neat DEGDMA, using in all cases 15 DEGDMA units per macromolecular
 405 chain. As detailed in our recent contribution [34], using this amount of neat DEGDMA is
 406 sufficient to ensure quantitative crosslinking of all diblock copolymers without macro-
 407 gelation and generate single spherical CCMs with a narrow size distribution, as is also the
 408 case for the equivalent CCMs with a polycationic P(4VPM⁺) shell [31, 32]. Conversely,
 409 CCMs with a neutral P(MAA-co-PEOMA) shell could be crosslinked without macrogela-
 410 tion only when using a styrene-rich DEGDMA/St comonomer mixture [21]. All triblock
 411 copolymers (*i.e.* containing an intermediate St₅₀ homopolymer block) were crosslinked
 412 with the 10:90 DEGDMA/St comonomer mixture with quantitative incorporation of
 413 DEGDMA, only occasionally leaving a small residual amount of unreacted styrene (Fig-
 414 ure S5), to yield CCMs of composition R₀-(SS-Na⁺)₁₄₀-*b*-St₅₀-*b*-(St_{1-y}-co-DPPS_y)₃₀₀-*b*-(St_{0.9}-co-
 415 DEGDMA_{0.1})₁₅₀-SC(S)*n*Pr (*y* = 0.05, 0.10, 0.20). The DLS and TEM characterization of these
 416 polymers is summarized in Figure 3. The presence of a minor amount of aggregates is
 417 indicated by the DLS traces of the unfiltered dispersions (see Supporting Information,
 418 Figures S6 for *y* = 0.05, S7 for *y* = 0.1 and S8 for *y* = 0.2), but the filtered samples reveal only
 419 monomodal distributions with diameters close to 100 nm and the TEM images, confirm
 420 their spherical morphology. Interestingly, after swelling with toluene or chloroform, the
 421 average diameters of the particles do not significantly increase, contrary to what was ob-
 422 served in the similar TPP-free CCM particles [34]. However, swelling is clearly evidenced

by the ^{31}P NMR characterization: the TPP resonance at δ ca. -6.5 becomes visible only after swelling the cores with CDCl_3 (Figure S9). The probable reason for the D_z decrease upon addition of swelling solvents is a disaggregation action, reducing the impact of larger-size agglomerates and masking the size increase of the swollen cores.

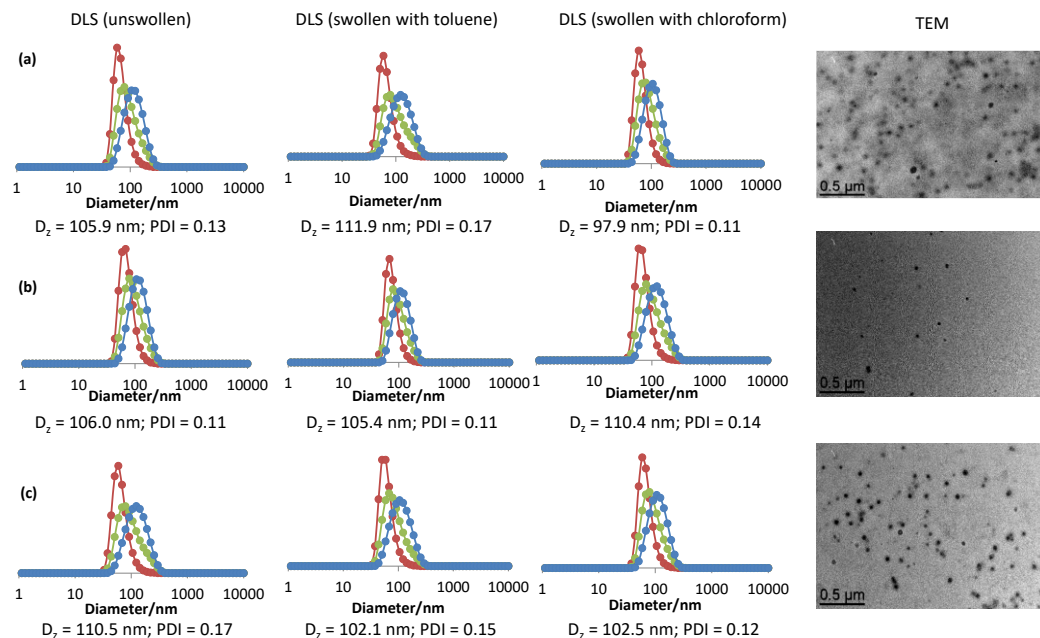

Figure 3. DLS (before and after swelling with toluene or chloroform) and TEM characterization of the CCMs $R_0\text{-}(\text{SS-Na}^+)_{140}\text{-}b\text{-St}_{50}\text{-}b\text{-}(\text{St}_{1-y}\text{-}co\text{-DPPS}_y)_{300}\text{-}b\text{-}(\text{St}_{0.90}\text{-}co\text{-DEGDMA}_{0.10})_{150}\text{-}SC(S)SnPr$. (a) $y = 0.05$; (b) $y = 0.10$; (c) $y = 0.20$. Color coding for the DLS size distributions: number (red), volume (green) and intensity (blue). The DLS traces are for dispersions filtered through a $0.45\ \mu\text{m}$ -pore filter.

All diblock copolymers (without an intermediate St_{50} homopolymer block), on the other hand, were only crosslinked with neat DEGDMA, once again with quantitative or nearly quantitative monomer incorporation (Figure S10) to yield CCMs of composition $R_0\text{-}(\text{SS-Na}^+)_{140}\text{-}b\text{-}(\text{St}_{1-y}\text{-}co\text{-DPPS}_y)_{300}\text{-}b\text{-}DEGDMA_{15}\text{-}SC(S)SnPr$ ($y = 0.05, 0.10, 0.20, 0.25$). The NMR characterization in $\text{D}_2\text{O}/\text{CDCl}_3$ is available in Figure S11. The DLS results (Figure 4) are very similar to those of the CCMs crosslinked with the St/DEGDMA comonomer mixture, at least for the particles with lower DPPS fraction ($y = 0.05, 0.10$). For those with higher DPPS fraction ($y = 0.20, 0.25$), the unswollen latexes show a greater contribution of larger size distributions, probably CCM agglomerates, which are particularly visible in the DLS of the unfiltered latexes (Supporting Information, Figures S12 for $y = 0.05$, S13 for $y = 0.10$, S14 for $y = 0.20$ and S15 for $y = 0.25$), but these are almost completely absent in the DLS of the swollen latexes, while the TEM images show the predominance of individual spherical particles (Figure 4). This is further evidence of the disaggregation action of the swelling solvent, which causes once again a reduction of the D_z values.

A compatibilizing solvent, able to solvate both the $\text{P}(\text{SS-Na}^+)$ shell and the $\text{P}(\text{St-co-DPPS})$ core and to break down the micelles of the diblock copolymer intermediate into single chains [35], was searched for the purpose of probing the crosslinking completeness (absence of residual uncrosslinked diblock arms in the CCM product by DLS analysis). For the very closely related TPP-free polymers, this analysis was successfully carried out in THF-water or DMF-water mixtures with $> 40\%$ water: the DLS of the $\text{P}(\text{SS-Na}^+)\text{-}b\text{-PSt}$ diblock chains revealed small objects ($d < 10\ \text{nm}$), while that of the corresponding $\text{P}(\text{SS-Na}^+)\text{-}b\text{-PSt}\text{-}b\text{-PDEGDMA}$ and $\text{P}(\text{SS-Na}^+)\text{-}b\text{-PSt}\text{-}b\text{-P}(\text{St-co-DEGDMA})$ crosslinked products proved the absence of a small diameter population, hence demonstrating the quantitative linking of all diblock arms [34]. The introduction of the DPPS comonomer in the hydrophobic block, on the other hand, did not allow finding suitable conditions for a complete

solvation of the uncrosslinked micelles in the form of single chains, probably because the incorporated DDPS renders the PSt block even more hydrophobic and perturbs the single chain – micelle equilibrium in favor of the latter. On the basis of the results presented in our previous investigation for the TPP-free CCM particles and the equivalence of the block composition (except for the DPPS incorporation) and polymerization conditions, we assume that the TPP-functionalized CCM are also characterized by quantitative crosslinking of all diblock arms.

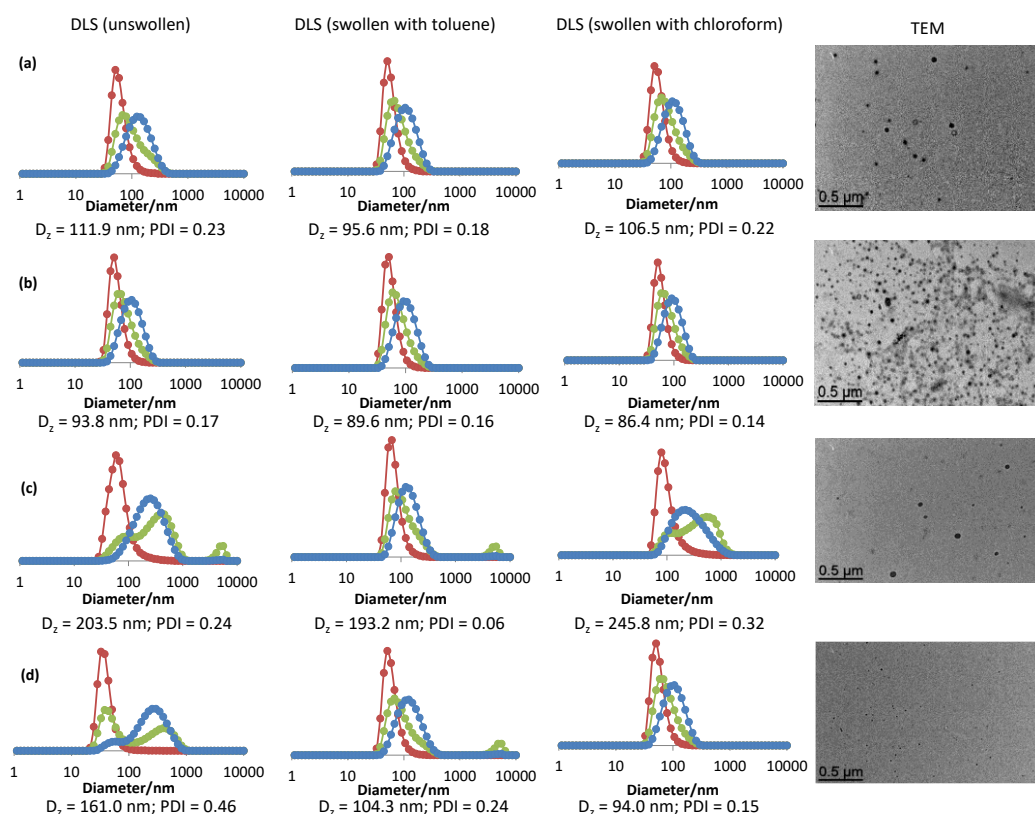

Figure 4. DLS (before and after swelling with toluene or chloroform) and TEM characterization of the CCMs $R_0\text{-}(\text{SSNa}^+)_{140}\text{-}b\text{-}(\text{St}_{1-y}\text{-co-DPPS}_y)_{300}\text{-}b\text{-DEGDMA}_{15}\text{-SC(S)SnPr}$. (a) $y = 0.05$; (b) $y = 0.10$; (c) $y = 0.20$; (d) $y = 0.25$. Color coding for the DLS size distributions: number (red), volume (green) and intensity (blue). The DLS traces are for dispersions filtered through a $0.45\ \mu\text{m}$ -pore filter.

Unimolecular amphiphilic copolymers with an NG architecture and an outer P(SSNa⁺) shell have not been previously described, to the best of our knowledge. The straightforward extension of the strategy that leads to NG nanoreactors with a neutral or polycationic hydrophilic shell to the P(SSNa⁺)-based macroRAFT agents (Figure 2) led to complete monomer conversion and stable latexes of well-defined NG particles with narrow size distributions. Particles with two different compositions were obtained, one starting from $R_0\text{-}(\text{SSNa}^+)_{140}\text{-SC(S)SnPr}$ and the second one starting from $R_0\text{-}(\text{SSNa}^+)_{140}\text{-}b\text{-St}_{50}\text{-SC(S)SnPr}$. The two products also differ by the amounts of St and DPPS comonomers. Characterization data available in the Supporting Information attest the quantitative conversion of all comonomers (by ¹H NMR, Figure S16), except for a small amount of residual styrene in one case, and the quality of the resulting CCM and NG particles (DLS of unswollen *vs.* toluene- and chloroform-swollen latexes, Figures S17 for $x,y,z = 0,285,15$ and S18 for $x,y,z = 50,425,30$). The DLS results of the filtered latexes are also shown in Figure 5, together with TEM images. In both cases, the size distribution in the number mode has an average diameter under 100 nm, though the presence of larger aggregates is shown by the volume and intensity distributions and by the high PDI values, particularly for the sample in Figure 5 (b). As already shown above for the CCM particles, treatment with

swelling solvents leads to lower D_z and PDI values, which is attributed to reduced aggregation.

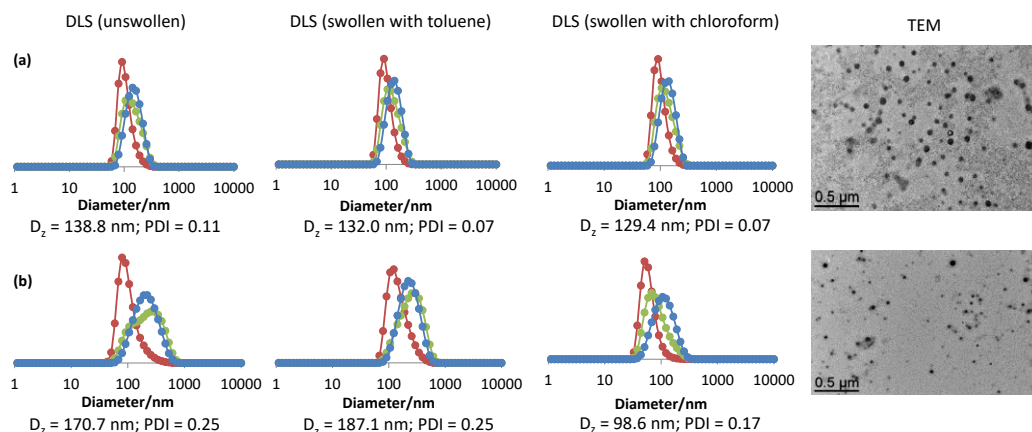

Figure 5. DLS (before and after swelling with toluene or chloroform) and TEM characterization of the NGs $R_0\text{-}(\text{SS}\text{-Na}^+)_{140}\text{-}b\text{-St}_x\text{-}b\text{-}(\text{St}_y\text{-co-DPPS}_z\text{-co-DEGDMA}_{15})\text{-SC(S)SnPr}$. (a) $x = 0$, $y = 285$, $z = 15$; (b) $x = 50$, $y = 425$, $z = 30$. Color coding for the DLS size distributions: number (red), volume (green) and intensity (blue). The DLS traces are for dispersions filtered through a $0.45\ \mu\text{m}$ -pore filter.

3.2. Treatment with $[\text{RhCl}(\text{COD})]_2$ and model studies

Following an identical protocol to that previously implemented to load the 1st and 2nd generation CCM/NG nanoreactors with the $[\text{RhCl}(\text{COD})]_2$ precatalyst [21, 25, 26, 32], the latexes of the anionic-shell polymers described above were first core-swollen by toluene. However, the subsequent addition of the $[\text{RhCl}(\text{COD})]_2$ toluene solution led to the immediate polymer coagulation, leaving a transparent and colorless supernatant liquid (see Figure S19). Since no such behavior was previously observed, neither for the neutral $\text{P}(\text{MAA-co-PEOMA})$ -based 1st generation nanoreactors nor for the cationic $\text{P}(4\text{VPMe}^+\text{I})$ -based 2nd generation ones, it seems likely that the rhodium complex interacts with the particle $\text{P}(\text{SS}\text{-Na}^+)$ shell, leading to particle aggregation and macrogelation. In order to find supporting evidence and to learn more about this phenomenon, a few tests were carried out with models of the CCM particle surface, starting with two molecular salts (sodium styrenesulfonate and *p*-tolylsulfonate, $\text{NaO}_3\text{SC}_6\text{H}_4\text{-4-R}$ with $\text{R} = \text{vinyl}$ and methyl , respectively), both in the absence and presence of PPh_3 . We have not been able to find previously published reports on the coordination chemistry of $[\text{RhCl}(\text{COD})]_2$ and $[\text{RhCl}(\text{COD})(\text{PPh}_3)]$ with sulfonate salts. These rhodium complexes are frequently used as precursors to generate cationic precatalysts with the $[\text{Rh}(\text{COD})\text{L}_2]^+\text{X}^-$ stoichiometry ($\text{L} = \text{monodentate}$ or $\text{L}_2 = \text{bidentate}$ ligand; $\text{X}^- = \text{non-coordinating anions}$, e.g. BF_4^- , PF_6^- , $\text{B}[3,5\text{-C}_6\text{H}_3(\text{CF}_3)_2]_4^-$, etc.), which also include several trifluoromethylsulfonate (triflate, OTf^-) salts, e.g. $[\text{Rh}(\text{COD})(\text{R-DuPHOS})]^+\text{OTf}^-$ ($\text{R} = \text{Me}$, Et , $i\text{Pr}$) [36, 37], but examples with other alkyl or arylsulfonates anions do not apparently exist. On the other hand, the coordinating properties of arylsulfonates are well established for phosphine-sulfonate chelating ligands in palladium polymerization catalysts [38].

The toluene solutions of complexes $[\text{RhCl}(\text{COD})]_2$ (yellow) and $[\text{RhCl}(\text{COD})(\text{PPh}_3)]$ (red, produced *in situ* from $[\text{RhCl}(\text{COD})]_2$ and PPh_3 in a 1:2 ratio) were layered on top of an aqueous solution containing an excess of the sulfonate salt, followed by vigorous stirring at room temperature for 3 h. The Rh/salt ratio (ca. 1:5) was adjusted to approximately reproduce the ratio used in the polymer loading experiments. When using the styrene sulfonate salt, the aqueous phase remained essentially colorless after decantation (Figure 6), while the aspect of the supernatant organic later was unchanged.

Figure 6. Photos of the final mixtures resulting from the vigorous room temperature stirring of a toluene solution of $[\text{RhCl}(\text{COD})]_2$ (with or without one equivalent of PPh_3 per Rh) and an aqueous solution of $\text{NaO}_3\text{SC}_6\text{H}_4\text{-4-R}$ ($\text{R} = \text{CH}=\text{CH}_2, \text{CH}_3$; $\text{Rh/sulfonate} = \text{ca. } 1:5$), followed by decantation.

When using the *p*-tolylsulfonate salt, on the other hand, the aqueous phase became pale yellow (more so in the absence of PPh_3 than in its presence). These results reveal a certain degree of interaction between the Rh center and ArSO_3^- (Scheme 1). In the absence of PPh_3 , the putative anionic chloro-sulfonate $[\text{RhCl}(\text{COD})(\text{O}_3\text{SAr})]^-$ complex or a bis-sulfonate $[\text{Rh}(\text{COD})(\text{O}_3\text{SAr})_2]^-$ product of ligand exchange (equation 1) is partially transferred to the aqueous phase. In the presence of PPh_3 , on the other hand, sulfonate addition to make a 5-coordinate $[\text{RhCl}(\text{COD})(\text{PPh}_3)(\text{O}_3\text{SAr})]^-$ is less favored, while a possible chloride/sulfonate exchange product, $[\text{Rh}(\text{COD})(\text{PPh}_3)(\text{O}_3\text{SAr})]$, being uncharged, might prefer to remain in the toluene phase. A weak interaction must nevertheless be present, because the aqueous solution is not completely colorless. The more extensive interaction of *p*-tolylsulfonate relative to SS-Na^+ may result from either a stronger coordinating ability or a greater hydrophilicity of the resulting rhodium complexes.

Scheme 1. Interaction of $[\text{RhCl}(\text{COD})]_2$ and $[\text{RhCl}(\text{COD})(\text{PPh}_3)]$ with arylsulfonate salts ($\text{Ar} = 4\text{-C}_6\text{H}_4\text{CH}_3, 4\text{-C}_6\text{H}_4\text{CH}=\text{CH}_2$).

Evidence in favor of a Rh-sulfonate interaction was also provided by a ^1H NMR investigation using $\text{DMSO-}d_6/\text{D}_2\text{O}$ as a compatibilizing solvent mixture. Upon mixing $[\text{RhCl}(\text{COD})]_2$ and $\text{NaO}_3\text{SC}_6\text{H}_4\text{-4-CH}_3$ ($\text{Rh/sulfonate} = \text{ca. } 1:5$), a slight upfield shift was observed for all three COD resonances (from 4.45, 2.42 and 1.99 ppm to 4.41, 2.36 and 1.93 ppm, respectively) and for one of the aromatic sulfonate resonances (7.55–7.52 ppm), while the other resonances of the sulfonate *p*-tolyl group (aromatic at 7.15 ppm and CH_3 at 2.27 ppm) remained essentially unshifted, see Figure S20. On the other hand, the $[\text{RhCl}(\text{COD})(\text{PPh}_3)]/\text{NaO}_3\text{SC}_6\text{H}_4\text{-4-CH}_3$ interaction ($\text{Rh/sulfonate} = \text{ca. } 1:5$) did not reveal any significant shift for the COD ^1H NMR resonances, but a slight upfield shift for the sulfonate aromatic resonances was again observed, see Figure S21.

Additional experiments were carried out by layering the toluene $[\text{RhCl}(\text{COD})]_2$ and $[\text{RhCl}(\text{COD})(\text{PPh}_3)]$ solutions on top of an aqueous solution of the $\text{P}(\text{SS}\cdot\text{Na}^+)$ macroRAFT

555 chains (degree of polymerization = 140), using again the same Rh/sulfonate ratio. In this
 556 case, the Rh species is nearly completely transferred to the aqueous phase in the absence
 557 of PPh_3 , to yield a transparent red solution, see Figure 7. The more extensive extraction of
 558 $[\text{RhCl}(\text{COD})]_2$ into the aqueous phase by the macroRAFT chain is probably favored by the
 559 formation of a bis-sulfonate complex through the action of the chelate effect, which is most
 560 likely (but perhaps not exclusively) implemented through the use of two adjacent mono-
 561 mer units in the chain. Therefore, a sulfonate function appears able to replace the chloride
 562 ligand (Scheme 2, equation 3). This result rationalizes the polymer coagulation observed
 563 when $[\text{RhCl}(\text{COD})]_2$ is added to the colloidal dispersion of the CCM or NG polymers:
 564 complexation to form a species with a coordination environment such as the product of
 565 equation 3 is also possible when the two sulfonate ligands are provided by two different
 566 polymer particle shells.

567 **Figure 7.** Photos of the final mixtures resulting from the vigorous room temperature stirring of a
 568 toluene solution of $[\text{RhCl}(\text{COD})]_2$ (with or without one equivalent of PPh_3 per Rh) and an aqueous
 569 solution of the $\text{R}_0\text{-(SS-Na}^+\text{)}_{140}\text{-SC(S)S}n\text{Pr}$ macroRAFT agent (Rh/sulfonate = ca. 1:5), followed by de-
 570 cantation.
 571

572 **Scheme 2.** Interaction of $[\text{RhCl}(\text{COD})]_2$ and $[\text{RhCl}(\text{COD})(\text{PPh}_3)]$ with the $\text{R}_0\text{-(SS-Na}^+\text{)}_{140}\text{-SC(S)S}n\text{Pr}$
 573 macroRAFT agent.
 574

575 Treatment of the aqueous macroRAFT solution with a toluene solution of
 576 $[\text{RhCl}(\text{COD})(\text{PPh}_3)]$, on the other, led to a turbid toluene phase, containing a large amount
 577 of orange coagulated polymer, and a transparent pale yellow aqueous phase, see Figure
 578 7. This confirms the ability of the sulfonate groups to bind the Rh center even in the pres-
 579 ence of PPh_3 . The greater interaction of the macroRAFT agent relative to the molecular
 580 salt suggests replacement of the chloride ligand and formation of a 5-coordinate anionic
 581 complex, once again favored by the action of the chelate effect (Scheme 2, equation 4). The
 582 presence of the tightly bonded hydrophobic phosphine ligand renders the product insol-
 583 soluble in water, while the presence of charged sulfonate functions and sodium counterions
 584 make it also insoluble in toluene, hence leading to precipitation.

¹H NMR investigations to probe the presence and the effect of the Rh-sulfonate interaction were again carried out in DMSO-*d*₆/D₂O, yielding similar results as the experiments with the molecular salts. In the absence of PPh₃ (Figure S22), the three COD resonances slightly shifted upfield (from 4.46, 2.42 and 1.99 ppm to 4.42, 2.36 and 1.93 ppm, respectively). In this case, the broader aryl and backbone aliphatic resonances of the macroRAFT chain did not show any significant shift. For the experiment with [RhCl(COD)(PPh₃)], Figure S23, which yielded a homogeneous solution, the change was less perceptible, with possibly a slight upfield shift of the broad resonances centered at ca. 2.33 and 1.95 ppm.

3.3. Synthesis of CCMs and NGs with a P(SS-Na⁺-co-PEOMA)-based shell

Given that the P(SS-Na⁺) homopolymer chains not only block the [RhCl(COD)]₂ migration through the shell, but even induce polymer coagulation, our shell engineering efforts continued with a decrease of the anionic monomer density, via dilution with a neutral monomer. The working hypothesis was that an increased average distance between the SS-Na⁺ monomers may weaken the Rh-shell interactions by removal of the chelate effect. Consequently, polymer coagulation may be disfavored and the Rh complexes may be able to migrate through the shell to eventually encounter the much stronger-binding TPP ligands in the core. As a diluting monomer, PEOMA was the natural choice on the basis of the previous incorporation of this monomer in the 1st-generation neutral-shell particles.[21-28] The SS-Na⁺ fraction in the [(SS-Na⁺)_x-co-PEOMA_{1-x}] shell blocks must be small enough to reduce the shell ability to capture the Rh complex, but sufficient to keep a significant shell-shell repulsion to avoid interpenetration and to maintain high-temperature hydrophilicity. All polymers developed in this contribution were made with the fixed molar fraction $x = 0.2$ (*i.e.* 20% of SS-Na⁺ monomers in the hydrophilic block). All these polymers are summarized in Table S2, which also serves as a reference for the characterization data.

The synthesis followed the same general procedure described above, except for the use of a 20:80 SS-Na⁺/PEOMA comonomer mixture in the first step (Figure 8), yielding R₀-[(SS-Na⁺)_{0.2-co-PEOMA_{0.8}}]_x-SC(S)SnPr. Two different degrees of polymerizations ($x = 50, 140$) were targeted to probe the effect of the hydrophilic shell thickness on the latex stability. Indeed, while the best charged-shell particles were formed with a high degrees of polymerization (140) for the P(SS-Na⁺) [34] and P(4VPMe⁺I) [31] homopolymer blocks, those with a P(MAA-co-PEOMA)-based neutral shell [21] only required a low degree of polymerization (30).

¹H NMR monitoring of the polymerization indicated essentially complete incorporation of both monomers (only traces of residual PEOMA were visible, see Figure 9 for $x = 50$ and Figure S24 for $x = 140$). Further analysis of the final latex ¹H NMR spectrum in DMSO-*d*₆ shows interesting features. Whereas the PEO resonances (OCH₂CH₂O at 3.48 ppm and OCH₃ at 3.21 ppm in the monomer) remain essentially unchanged in terms of their position and sharpness, the resonances of the methacrylate CH₃ protons at 1.84 ppm and of the SS-Na⁺ aryl protons at 7.4 and 6.9 ppm are extensively broadened after incorporation into the polymer chains. This demonstrates that the polymer backbone is much less solvated and thus less mobile in solution relative to the PEO side chains. These features will be of interest in comparison with those shown below for the CCM and NG polymers. Another point to note is that the water and ethanol OH protons give independent resonances in DMSO-*d*₆, indicating slow chemical exchange that can be attributed to the strong H-bonding with the proton-accepting solvent. The chemical shift of these two resonances changes from the initial to the final solution.

635

636

637

638

Figure 9. ¹H NMR monitoring of the SS-Na⁺/PEOMA copolymerization for the synthesis of the R₀-[(SS-Na⁺)_{0.2}-co-PEOMA_{0.8}]₅₀-SC(S)S*n*Pr macroRAFT agents. The NMR samples were prepared by adding a drop of the reaction mixture directly to the DMSO-*d*₆ solvent in the NMR tube.

639 A more detailed monitoring of the polymerization with $x = 50$ revealed a much faster
640 consumption of $SS\text{-}Na^+$. Indeed, when the charged monomer was completely consumed,
641 only ca. 60% of the PEOMA had been incorporated (Figure S25a). The SEC monitoring
642 (Figures S25b and c) showed that the polymer molar mass increased more or less linearly
643 with respect to the overall monomer conversion, although with quite high polymer dis-
644 persity (> 2). Therefore, the resulting water-soluble chains have a marked gradient topol-
645 ogy with a greater $SS\text{-}Na^+$ fraction at the α -end (R_0) and an essentially pure P(PEOMA)
646 homopolymer sequence at the ω -end (trithiocarbonate). The DLS analysis of the R_0 -[($SS\text{-}$
647 Na^+) $_{0.2-co-PEOMA_{0.8}}$] $_x$ -SC(S) $SnPr$ ($x = 50, 140$) solutions, after extensive dilution with wa-
648 ter, shows a dominant distribution of single chains (average diameter ca. 1 nm), plus a
649 minor population of larger aggregates ($d = 20\text{-}30$ nm) that is clearly visible only in the
650 intensity mode (Figure S26). The TEM images of these polymers, also shown in Figure
651 S26, show only ill-defined aggregates with no evidence of regular self-organization. The
652 analogous macroRAFT agents with the same degrees of polymerization made of $SS\text{-}Na^+$
653 homopolymer chains displayed very similar average size in solution and morphology as
654 a dry polymer [34]. In combination with the NMR evidence discussed above, the organi-
655 zation of these objects in the DMSO solution probably consist of a rather contracted back-
656 bone in the particle core, particularly for the $SS\text{-}Na^+$ -rich end of the gradient copolymer,
657 surrounded by the better solvated PEO chains. This statement seems further supported
658 by the 1H NMR spectrum of these two polymers in D_2O (Figure S27), in which the reso-
659 nances of the PEO chains (backbone methylene and chain-end methyl resonances at δ 3.63
660 and 3.31 ppm, respectively) are visible as narrow peaks ($w_{1/2} \sim 5$ Hz), as expected for well-
661 solvated protons with short correlation times, whereas those of the styrenesulfonate aro-
662 matic protons (at δ 7.56 and 7.11 ppm, $w_{1/2} \sim 60$ and 80 Hz) and main-chain aliphatic pro-
663 tons, including the methacrylate Me protons (in the δ 2-0.5 ppm region), are much
664 broader. The additional broad resonance observed at δ 4.1 ppm ($w_{1/2} \sim 60$ Hz), slightly
665 downfield-shifted from the strong PEO methylene resonance, is assigned to the first PEO
666 CH_2 group bonded to the methacrylate ester function; its greater linewidth results from
667 its proximity to the less mobile polymer chain.

668 These macroRAFT agents were chain-extended by either a short PSt homopolymer
669 block (50 monomer units per chain) or a longer P(St-co-DPPS) copolymer block (300 mon-
670 omers per chain, with the DPPS fraction fixed at 10%). Stable latexes were obtained in all
671 cases. For the R_0 -[($SS\text{-}Na^+$) $_{0.2-co-PEOMA_{0.8}}$] $_x$ -b-(St $_{0.9-co-DPPS_{0.1}}$) $_{300}$ -SC(S) $SnPr$ ($x = 50, 140$) diblock products,
672 the DLS and TEM characterization is shown in Figure S28. The $x = 50$ sample shows a
673 dominant population with ca. 5 nm average diameter and a second population around 50
674 nm (more evident in the intensity mode, Figure S28a), suggesting the formation of small
675 aggregates and micelles. The presence of spherical micelles is confirmed by TEM. For the
676 $x = 140$ sample (Figure S28b), the DLS shape is similar but the lower-size population has
677 a smaller average diameter (ca. 1 nm), more consistent with the presence of single chains,
678 while the TEM analysis reveals once again the presence of spherical micelles. Thus, single-
679 chain/micelle or smaller/larger micelle equilibria appear to be present in water. For the R_0 -
680 [($SS\text{-}Na^+$) $_{0.2-co-PEOMA_{0.8}}$] $_x$ -b-(St $_{0.9-co-DPPS_{0.1}}$) $_{300}$ -SC(S) $SnPr$ ($x = 50, 140$) products (1H NMR
681 monitoring shown in Figure S29), only the sample with $x = 50$ was investigated by DLS
682 and TEM prior to crosslinking (Figure S30). These analyses revealed a dominant popula-
683 tion of small spherical micelles (d ca. 8 nm from the DLS) and a minor population of larger
684 objects (d ca. 80 nm) that appeared to be vesicles from the TEM image.

685 The 1H NMR spectra of the diblock copolymers in $DMSO-d_6$ (Figure S29) reveal in-
686 teresting features: the $SS\text{-}Na^+$ resonances of the P($SS\text{-}Na^+$ -co-PEOMA) shell, which are
687 broad but visible in the spectrum of the water-soluble macroRAFT agent at δ 7.4 and 6.8
688 (Figure S24), are not only broad but also barely observable with much smaller than ex-
689 pected relative intensities when compared with the sharp and intense resonances of the
690 well-solvated PEO. The resonances of the P(St-co-DPPS) core are also not observed in
691 $DMSO-d_6$ but become visible after dispersion in a $D_2O/CDCl_3$ solvent mixture, while those
692 of the shell backbone and $SS\text{-}Na^+$ arene protons remain unobserved. This suggests that the

shell backbone remains unsolvated and is probably located at the interface between the CDCl_3 -swollen core and the outer aqueous solution. This behavior is identical to that previously described for the $\text{P}(\text{MAA-co-PEOMA})$ backbone of the 1st-generation neutral-shell CCM and NG polymers [26]. It can thus be concluded that the shell PEOMA monomers provide greater stabilization than the SS-Na^+ monomers to the water dispersions of the self-assembled diblock copolymers.

Like for the $\text{P}(\text{SS-Na}^+)$ -shell CCM particles described in part 3.1, the final crosslinking step was carried out with either a DEGDMA/styrene comonomer mixture or neat DEGDMA, both leading to stable latexes of spherical particles with a narrow size distribution. Crosslinking with the DEGDMA/styrene mixture gave polymers with average composition $\text{R}_0\text{-}[(\text{SS-Na}^+)_{0.2}\text{-co-PEOMA}_{0.8}]_x\text{-b-(St}_{0.9}\text{-co-DPPS}_{0.1})_{300}\text{-b-(St}_{0.9}\text{-co-DEGDMA}_{0.1})_{150}\text{-SC(S)SnPr}$ ($x = 50, 140$), whereas neat DEGDMA was used to obtain particles with average composition $\text{R}_0\text{-}[(\text{SS-Na}^+)_{0.2}\text{-co-PEOMA}_{0.8}]_{50}\text{-b-(St}_{0.9}\text{-co-DPPS}_{0.1})_{300}\text{-b-DEGDMA}_{90}\text{-SC(S)SnPr}$. The NMR monitoring and product characterization is available in Figures S31 and S32 and the DLS and TEM characterization is reported in Figure 10. The DLS of the two samples with the $[(\text{SS-Na}^+)_{0.2}\text{-co-PEOMA}_{0.8}]_{50}$ hydrophilic block, (a) and (c), reveal the presence of large aggregates in the unfiltered samples, but the size distributions become essentially monomodal after filtration, whereas the polymer with the $[(\text{SS-Na}^+)_{0.2}\text{-co-PEOMA}_{0.8}]_{140}$ hydrophilic block shows a monomodal distributions also in the unfiltered sample, (b). In all cases, the distribution is peaked around a 20-30 nm diameter in the number mode. The TEM images confirm the spherical morphology of the polymer particles.

Figure 10. DLS (left) and TEM (right) characterization of the $\text{R}_0\text{-}[(\text{SS-Na}^+)_{0.2}\text{-co-PEOMA}_{0.8}]_x\text{-b-(St}_{0.9}\text{-co-DPPS}_{0.1})_{300}\text{-b-(St}_{0.9}\text{-co-DEGDMA}_{0.1})_{150}\text{-SC(S)SnPr}$ [$x = 50$ (a); $x = 140$ (b)] and (c) $\text{R}_0\text{-}[(\text{SS-Na}^+)_{0.2}\text{-co-PEOMA}_{0.8}]_{50}\text{-b-(St}_{0.9}\text{-co-DPPS}_{0.1})_{300}\text{-b-DEGDMA}_{90}\text{-SC(S)SnPr}$ CCM. Color coding for the DLS size distributions: number (red), volume (green) and intensity (blue).

Simultaneous chain extension and crosslinking of the $\text{R}_0\text{-}[(\text{SS-Na}^+)_{0.2}\text{-co-PEOMA}_{0.8}]_x\text{-b-St}_{50}\text{-SC(S)SnPr}$ ($x = 50, 140$) macroRAFT agents with the St/DPPS/DEGDMA mixture (425:30:15 monomers per chain) led to NG polymers, the NMR and DLS/TEM characterization of which is reported in Figures S33 and S34, respectively. The resulting particles have once again spherical topology and the most probable diameter resulting from the

DLS distribution in the number mode is significantly smaller for the $x = 50$ sample (ca. 10 nm) than for the $x = 140$ sample (ca. 30 nm), but both are contaminated by larger size objects, clearly visible in the intensity mode.

A change of shell composition from P(SS-Na⁺) to P[(SS-Na⁺)_{0.2-co}-PEOMA_{0.8}] allowed the micelles of the diblock copolymer intermediate, P[(SS-Na⁺)_{0.2-co}-PEOMA_{0.8}]-*b*-P(St-co-DPPS), to be broken down into smaller objects by using a THF-water 60:40 mixture, although repeated measurements indicated a metastable situation with oscillation between very small objects (< 0.5 nm) and medium-size ones ($d \sim 1$ nm), together with a small number of larger aggregates (visible only in the intensity distribution), see the DLS of R₀[(SS-Na⁺)_{0.2-co}-PEOMA_{0.8}]_{50-b}-(St_{0.9-co}-DPPS_{0.1})₃₀₀-SC(S)SnPr in Figure S35a. The greater hydrophilicity of the P[(SS-Na⁺)_{0.2-co}-PEOMA_{0.8}] shell, as suggested by the ¹H NMR investigation, is probably responsible for a change of organization, tilting the self-organization equilibrium towards single chains in this mixed solvent. The DLS in the same solvent mixture of the corresponding R₀[(SS-Na⁺)_{0.2-co}-PEOMA_{0.8}]_{50-b}-(St_{0.9-co}-DPPS_{0.1})_{300-b}-(St_{0.9-co}-DEGDMA_{0.1})₁₅₀-SC(S)SnPr CCM, on the other hand, yielded a stable dispersion of micelles with narrow size distribution ($D_z = 119$ nm, PDI = 0.75) and no visible presence of smaller objects (Figure S35a), demonstrating the completeness of the crosslinking reaction.

3.4 [RhCl(COD)]₂ loading in the CCM and NG with the P(SS-Na⁺-co-PEOMA)-based shell

Treatment of the toluene-swollen CCMs and NGs with a P(SS-Na⁺-co-PEOMA) shell with a toluene solution of [RhCl(COD)]₂ resulted in transfer of the Rh complex to the latex phase without any polymer coagulation, as visually evident from the discoloration of the organic phase and the formation of a pale orange-colored and stable aqueous dispersion. Therefore, the SS-Na⁺ dilution strategy has successfully decreased the shell ability to interact with the Rh^I center. Coordination of the Rh complex to the core-anchored TPP ligands is demonstrated by the replacement of the uncoordinated TPP ³¹P NMR signal at δ ca. -6 ppm with the characteristic signal [21, 25, 26, 32] of the [RhCl(COD)(TPP@CCM)] complex at δ 29.4 ppm ($^2J_{\text{RhP}} = 150$ Hz), see Figure 11. As described previously, this signal is visible only when using a P/Rh ratio of 1:1 or smaller, because the presence of free TPP results in signal coalescence and broadening beyond detection at room temperature, because of a rapid degenerative exchange between free and coordinated TPP [21]. The catalytic runs (next section), however, were carried out under the previously optimized conditions, namely with a P/Rh ratio of 4.

Figure 11. ³¹P NMR spectrum of the R₀[(SS-Na⁺)_{0.2-co}-PEOMA_{0.8}]_{50-b}-(St_{0.9-co}-DPPS_{0.1})_{300-b}-DEGDMA₉₀-SC(S)SnPr CCM latex before (a) and after (b) loading with a toluene solution of [RhCl(COD)]₂ (P/Rh = 1:1).

3.5. Hydrogenation catalysis

The performance of the Rh-loaded CCM and NG nanoreactors with a P(SS-Na⁺-co-PEOMA) shell was evaluated in the aqueous biphasic hydrogenation of neat styrene. Previous work with neutral- and polycationic-shell nanoreactors have indicated the presence of an initial catalyst activation phase, a limited impact of mass transport kinetics (stirring

rate-dependent TOF) [22, 25], catalytic activities up to $> 300 \text{ h}^{-1}$ at 25°C and catalyst leaching down to ca. 0.1 ppm (for the polycationic-shell polymers). Under typical conditions, kinetic experiments carried out with two different nanoreactors confirmed the presence of an activation phase within the first couple of hours, followed by rapid substrate consumption and leading to complete conversion within ca. 10 h (average TOF = ca. 200 h^{-1}), see Figure 12. The two polymers used in these experiments differ in the thickness of the hydrophilic shell (DP of 140 or 50) and in the composition of the crosslinking monomers [(St_{0.9-co}-DEGDMA_{0.1})₁₅₀ vs. DEGDMA₉₀], but only the first variation is expected to potentially impact mass transport. The rough equivalence of the results indicates a minor impact of the shell thickness on the mass transport kinetics.

In terms of selectivity, all hydrogenations produced 100% ethylbenzene, without any ring hydrogenation to ethylcyclohexane, in accord with the previously reported performance of CCM/NG-embedded [RhCl(COD)(TPP)] precatalysts [27, 32]. This is consistent with the absence of metal reduction to generate metallic Rh nanoparticles (NPs), which is also attested by the absence of colour change for the recovered latex after catalysis, even after multiple recycles (*vide infra*). From previous work carried out in our laboratory, we know that Rh NPs can indeed be generated by H₂ reduction of core-anchored [RhCl(COD)(TPP)], but this only occurs in the absence of styrene, which acts as a π -acidic ligand to stabilize molecular Rh^I, and is accelerated by heating and by organosoluble bases (*e.g.* Et₃N) [39].

Figure 12. Conversion *vs.* reaction time for the hydrogenation of neat styrene with the R₀-[(SSNa⁺)_{0.2-co}-PEOMA_{0.8}]_{140-b}-(St_{0.9-co}-DPPS_{0.1})_{300-b}-(St_{0.9-co}-DEGDMA_{0.1})₁₅₀-SC(S)SnPr (a) and R₀-[(SSNa⁺)_{0.2-co}-PEOMA_{0.8}]_{50-b}-(St_{0.9-co}-DPPS_{0.1})_{300-b}-DEGDMA₉₀-SC(S)SnPr (b) CCMs. Reaction conditions: styrene/Rh = 2000, P/Rh = 4, T = 25°C , p(H₂) = 20 bar, stirring rate = 1200 rpm.

Recycling experiments carried out with both the CCM- and NG-embedded catalyst gave puzzling results (Figure 13 and detailed data in Table S3), when compared to those of the equivalent nanoreactors with the polycationic P(4VPMe⁺I) shell. First of all, the decantation process was not as rapid and clean [32], leaving evident opacity in the organic phase (see Figure S36). The previously investigated polycationic nanoreactors gave increased conversions after recycling, because of the pre-catalyst activation phase. Conversely, the present nanoreactors led to a significant activity decrease after the first run, followed by approximately constant activity in subsequent recycles. The activity drop was more substantial for the two nanoreactors with a thicker outer shell (DP = 140, Figure 13a and Figure 13c) and smaller for the shorter shell chain nanoreactor (DP = 50, Figure 13b). This phenomenon suggests the possible intervention of the shell sulfonate groups in the modification of the catalyst activity after pre-catalyst activation. During the activation phase, the COD ligand is presumably hydrogenated and removed to yield a less saturated Rh^I center, which may find a better stabilization by interacting with the sulfonate groups at the core-shell interface.

Figure 13. Conversion *vs.* recycle number for the hydrogenation of neat styrene with the polymer-embedded [RhCl(COD)(TPP)] precatalyst: (a) $R_0-[(SS-Na^+)_{0.2-co-PEOMA_{0.8}}]_{140-b-(St_{0.9-co-DPPS_{0.1}})_{300-b-(St_{0.9-co-DEGDMA_{0.1}})_{150-SC(S)SnPr}$; (b) $R_0-[(SS-Na^+)_{0.2-co-PEOMA_{0.8}}]_{50-b-(St_{0.9-co-DPPS_{0.1}})_{300-b-DEGDMA_{90-SC(S)SnPr}$; (c) $R_0-[(SS-Na^+)_{0.2-co-PEOMA_{0.8}}]_{140-b-St_{50-b-(St_{425-co-DPPS_{30-co-DEGDMA_{15}})-SC(S)SnPr}$. Reaction conditions: styrene/Rh = 2000, P/Rh = 4, T = 25 °C, p(H₂) = 20 bar, stirring rate = 1200 rpm, reaction time: 2.5 h.

In order to validate this hypothesis, control runs were carried out with a variety of model catalysts, see Table 1, using the same conditions and over a constant reaction time of 2.5 h. In comparison with the results given by the CCM (entries 1,2) and NG (entry 3) nanoreactors, all other runs provide higher TONs, a probable consequence of mass transport limitations for the catalytic nanoreactors. The molecular catalyst obtained from [RhCl(COD)]₂/PPh₃ is very active (entry 4), but intriguingly this activity dramatically drops when the reaction was carried out in the absence of a water phase (entry 5), even though all needed components are located in the organic phase. This phenomenon (improved reaction rates for reactions run “on water”) has also been highlighted in other cases [40, 41]. When using sulfonate-containing additives without phosphine (*p*-toluenesulfonate, entry 6, or the $R_0-[(SS-Na^+)_{0.2-co-PEOMA_{0.8}}]_{50-SC(S)SnPr$ macroRAFT agent, entry 7), very high activities were again obtained. However, these experiments led to the formation of metallic Rh NPs (see Figure S37), which are notoriously very active hydrogenation catalysts [42, 43]. Whenever phosphine ligands were present in the system, under the conditions of these catalytic runs, there was no evidence for the formation of Rh NPs. The combination of sulfonate groups and PPh₃ (entries 8-10) led to significantly reduced activities with respect to the experiment run with PPh₃ only (entry 4), although higher than for those with the nanoreactors. Therefore, these results validate the hypothesis that the shell sulfonate groups negatively interfere with the catalytic performance of the Rh^I active sites.

Table 1. Results of catalyzed styrene hydrogenations.^a

Entry	Additive	P/Rh	SS-Na ⁺ /Rh	Conv./%	TON (EB) ^c	TON (EC) ^c
1	$R_0-[(SS-Na^+)_{0.2-co-PEOMA_{0.8}}]_{140-b-(St_{0.9-co-DPPS_{0.1}})_{300-b-(St_{0.9-co-DEGDMA_{0.1}})_{150-SC(S)SnPr}$	4	3.73	29.4	588	0

^a Conditions (unless otherwise stated): [RhCl(COD)]₂ (0.60 mg, 2.43·10⁻³ mmol of Rh), V_{water} = 0.4 mL, V_{styrene} = 0.56 mL (0.508 g, 4.86 mmol, St/Rh = 2000), T = 25 °C, t = 2.5 h, p(H₂) = 20 bar, stirring

rate = 1200 rpm. ^b Average and standard deviation based on 5 parallel runs. ^c EB = ethylbenzene, EC = ethylcyclohexane. ^d Reaction carried out in the absence of water phase. ^e Reaction time = 20 h. ^f Extensive formation of metallic Rh NPs.

In addition to the unsatisfactory recycling performance, the ICP-MS analysis of the recovered organic phases revealed substantial catalyst leaching (up to 26.6 ppm of Rh, Table S3). The catalyst loss must be related to the transfer of the entire catalytic nanoreactors to the organic phase, not to the loss of molecular Rh species, also indicated by the above-mentioned opacity of the recovered organic phases. The DLS analysis of these phases confirmed the presence of the nanoreactors, with dimensions closely comparable to those measured in the initial latex (Figure S38), without any evidence for aggregation. Therefore, in terms of both long-term stability and leaching, these polymers are of lower interest than those with a neutral P(MAA-co-PEOMA) shell and especially than those with a polycationic P(4VPMe⁺I) shell.

4. Conclusions

Unimolecular amphiphilic core-shell star-block polymers with a tri-phenylphosphine-functionalized hydrophobic core and an anionic hydrophilic shell based on styrene sulfonate monomers have been synthesized, loaded with [RhCl(COD)]₂, and applied to the aqueous biphasic hydrogenation of styrene. The bottleneck related to the precatalyst loading, which results from Rh^I-sulfonate interactions, could be removed by “dilution” of the shell sulfonate functions with a neutral monomer, PEOMA. The resulting nanoreactors successfully catalyze the aqueous biphasic hydrogenation of styrene, but the performances are inferior to those of equivalent nanoreactors with neutral and polycationic shells. The lower activities observed during the recycles after the first run seem related to the catalyst alteration by migration towards the shell sulfonate functions. Hence, while the shell sulfonate dilution sufficiently suppresses the interaction with the “RhCl(COD)” fragment and allows shell crossing during the precatalyst loading phase, the interaction with the activated “RhCl(TPP)_x” functions during catalysis remains sufficiently strong to interfere with the operations of the active species. The higher catalyst leaching exhibited by these nanoreactors indicates their non-negligible transfer to the organic phase. This greater lipophilicity may result from the large fraction (80%) of PEO-containing monomers in the anionic shell. In all evidence, the presence of only 20% of charged sodium sulfonate groups does not impart sufficient lipophobicity to the nanoreactor shell. Further improvement of this catalytic tool requires the development of more lipophobic shells that are devoid of potentially coordinating functions, at least when mobile active species (*i.e.* anchored to the nanoreactor core *via* coordination bonds) are involved. In that respect, polycationic shells appear more promising than polyanionic ones. In addition, the synthetic protocol leading to the nanoreactor assembly should be as simple and as straightforward as possible. Efforts in this direction are continuing in our laboratory.

Supplementary Materials: Characterization data of all polymers (NMR spectra, DLS traces, TEM images), representative photos of the products and reaction mixtures, and details of the catalysis results (Figures S1-S38, Tables S1-S3) can be downloaded at: www.mdpi.com/xxx/s1.

Author Contributions: Conceptualization, R.P.; formal analysis, H.W., C.A.-F. and C.F.; investigation, H.W. and C.A.F.; resources, R.P.; data curation, E.M. and R.P.; writing—original draft preparation, R.P.; writing—review and editing, H.W., C.A.-F, E.M. and C.F.; visualization, H.W. and R.P.; supervision, E.M. and C.F.; project administration, E.M.; funding acquisition, R.P. All authors have read and agreed to the published version of the manuscript.

Funding: This research has received funding from the European Union’s Horizon 2020 research and innovation programme under the Marie Skłodowska-Curie grant agreement No 860322.

Data Availability Statement: Findable, Accessible, Interoperable and Reusable (FAIR) data related to this publication will be deposited in the HAL repository (<https://hal.archives-ouvertes.fr/>) under the DOI of the present publication.

Acknowledgments: We are grateful to the Centre National de la Recherche Scientifique (CNRS) for providing the research facilities and for additional financial support and to the China Scholarship Council for a Ph.D. fellowship to HW. We thank Lorenzo Vendrame and Dr. Florence Gayet for a few exploratory investigations.

Conflicts of Interest: The authors declare no conflict of interest. The funders had no role in the design of the study; in the collection, analyses, or interpretation of data; in the writing of the manuscript; or in the decision to publish the results.
