## Abstract

Causal links between inflammation and cancer are well-established, and research into the means of controlling the former is paramount. Netrin-1 is targeted in clinical trials as it displays pro-tumoral properties in inflammatory contexts in some organs, which led us to investigate its status with respect to inflammation in the liver. Here, based on a positive clinical correlation between netrin-1 levels and inflammation, experimentally confirmed in mice by inducing inflammation using poly(I:C) as a TLR3 agonist, we identify netrin-1 as a hepatic inflammation-inducible factor and decipher its underlying mechanism. Surprisingly, netrin-1 upregulation relied on a hitherto unknown mode of induction, namely its exclusive translational activation following the transfer of *NTN1* to the ER, ruling out any other traditional processes through exhaustive approaches. Our *in vitro* approaches unveiled a direct interaction between the Staufen-1 protein and netrin-1 mRNA, and were further validated in mice. Based on these findings, we finally explored the impact of a phase 2 clinical trial-validated humanized anti-netrin-1 antibody (NP137) on mice livers, and observed a clear anti-inflammatory activity. Hence, our results provide a better understanding of the interplay between inflammation and chronic liver disease and offer an innovative therapeutic perspective for interfering with their adverse evolution.

## 1 Introduction

2

3 Chronic liver diseases (CLDs) represent the main etiological conditions for the onset of liver  
4 injury, cirrhosis, and hepatocellular carcinoma (HCC) [1]. Though CLDs exhibit a high degree  
5 of diversity in terms of causal effects, ranging from infectious (hepatitis B and C viruses, HBV  
6 and HCV), to metabolic, to toxic and finally genetic, they all converge towards hepatic  
7 inflammation. This response in turn drives hepatocytic turnover, extracellular matrix  
8 accumulation, histological worsening and the long-term induction of carcinogenic mediators  
9 eventually leading to the development of HCC [2]. A clear understanding of the outcome of  
10 this inflammatory response and of its onset in the hepatic tissue is hampered by biologically  
11 opposite functions, as it favors viral and dead cell clearance, as well as histological wound  
12 healing, but exacerbates fibrogenesis, thus inducing cirrhosis and oncogenesis. Hence, the  
13 identification of factors involved in a harmful regulation of inflammation may lead to its clinical  
14 improvement.

15 We previously documented the pathogenic implication of netrin-1, a developmentally-regulated  
16 and secreted factor of neural origin [3], in liver diseases. Indeed, we showed that the  
17 expression of this factor is reactivated in several illnesses in adulthood, including several types  
18 of carcinomas [4-7] and also induced by HBV and HCV [8, 9]. Netrin-1 is well-known for  
19 preventing cellular apoptosis through its binding to 'dependence receptors' [5, 6, 10-15], and  
20 we demonstrated that it endowed hepatocytes with resistance to apoptosis during the unfolded  
21 protein response (UPR) [16], a hallmark of CLDs and cirrhosis [17-19]. Owing to the causal  
22 link between inflammation, cancer in general, and HCC, we hypothesized that hepatic  
23 inflammation and netrin-1 may be reciprocal influencers in the liver.

24 Owing to conflicting data on the implication of netrin-1 in inflammation, by either exacerbating  
25 [20-22] or dampening [23-25] the inflammatory response according to the chronic inflammation  
26 setting studied, we conducted extensive mechanistic experiments to document its implication  
27 in this organ, similarly to that described in inflammatory bowel disease and colorectal cancer  
28 [6, 26]. We first confirmed a clinical correlation between inflammation and netrin-1 upregulation  
29 in a cohort of HBV samples, which we then validated in mice using poly(I:C) to induce  
30 inflammation. Through a series of experiments on HepaRG cells and PHH, including polysomal  
31 isolation and fractionation, SILAC metabolic incorporation, and direct interaction assays, we  
32 dissected each step of netrin-1 biogenesis to comprehend its induction. We unveiled the  
33 implication of the Staufen-1 protein in netrin-1 mRNA localization at the ER, fostering its  
34 translation activation and identified distinct yet converging mechanisms in both hepatocytic  
35 environments. Finally, we confirmed these data in mice through netrin-1 capture experiments  
36 using a phase I and II clinical trial-validated (NCT02977195) humanized antibody [27] that  
37 reversed hepatic inflammation *in vivo*. Hence, we show that netrin-1 is a newly identified

38 hepatic inflammation-inducible factor endowed with pro-inflammatory properties, and that an  
39 antibody enabling netrin-1 capture may dampen hepatic inflammation, a dataset of general  
40 interest in CLD.

## 41 **Material and methods**

42

### 43 **Clinical samples**

44 Clinical liver samples were used under the French IRB 'CPP South-East IV' approval #A16/207  
45 (2016) related to the Inserm unit 1052 Hepatology biobank, France (#DC2008-235). Written  
46 informed consent was obtained from each patient and conformed to the ethics guidelines of  
47 the 1975 Declaration of Helsinki. Sample characteristics are shown in the **Suppl. Table 1**. All  
48 activity scores were determined by the pathology department of the Lyon University Hospital  
49 using standardized procedures.

50

### 51 **Animal housing, treatment and sample harvest**

52 All trials were performed under IRB agreement #CECCAP\_CLB\_2014\_015 as previously  
53 described (doi 10.15252/emmm.202012878). Eight-week-old C57BL/6J mice (Janvier  
54 Laboratories, Saint Berthevin, France) were injected intraperitoneally with poly(I:C) (Invivogen,  
55 Toulouse, France) at indicated doses or PBS for 16 h and sacrificed prior to liver harvest. Due  
56 to liver zonation considerations [28], all analyses were performed after selection on ice of the  
57 median hepatic lobe of all animals. Hepatic lobe samples were immediately snap frozen in  
58 liquid nitrogen and subsequently thawed on ice prior to homogenization using a Dounce  
59 apparatus previously refrigerated, followed by the addition of RIPA or polysome buffer (see  
60 below, protein or polysome-related studies) or Trizol (see below, total RNA-related studies,  
61 Invitrogen).

62

### 63 **Immunohistochemistry**

64 For histological examination, tissue samples were fixed in 10% buffered formalin and  
65 embedded in paraffin, and prepared according to conventional procedures.  
66 Immunohistochemistry was performed on an automated immunostainer (Ventana Discovery  
67 XT, Roche, Meylan, France) using the Discovery HRP Kit according to the manufacturer's  
68 instructions. Sections were incubated with an anti-netrin-1 antibody (1/500; see **Suppl. Table**  
69 **2**). Staining was visualized with DAB solution with 3,3'-diaminobenzidine as a chromogenic  
70 substrate. Finally, the sections were counterstained with Gill's hematoxylin.

71

### 72 **Flow cytometry analysis**

73 Pieces of liver were minced and digested in RPMI-1640 supplemented with mouse tumor  
74 dissociation enzymes (Miltenyi Biotec, Bergisch Gladbach, Germany) for 40 min at 37°C.  
75 Digested samples were filtered through a 70 µm nylon mesh to obtain uniform single-cell  
76 suspensions. Cells were washed with complete RPMI medium containing 10%  
77 decompemented FBS, 1% NEAA, 1% Sodium Pyruvate and 1% Penicillin-Streptomycin

78 (Gibco™) and resuspended in 500 µL of Flow Cytometry Staining Buffer (FCSB)  
79 (eBioscience™). 100 µL of cell suspension was used for staining in U-shaped 96-well plates.  
80 After PBS 1X washing, cells were stained with LIVE/DEAD™ Fixable Red Dead Cell Stain Kit  
81 for 30 min protected from light at room temperature. Fc receptors were blocked with anti-  
82 CD16/CD32 (TruStain FcX™; Biolegend) and cells were stained for cell surface antigens (see  
83 **Suppl. Table 2**). For intracellular staining, cells were fixed and permeabilized using the Fcγ3  
84 / Transcription Factor Staining Buffer Set (eBioscience™). Events were acquired on a BD-  
85 LSRII flow cytometer (BD Biosciences, Le Pont-De-Claix, France), collected with the BD  
86 FACSDiva 6.3.1 software and analyzed using Flowjo (or Flowlogic) software.

87

### 88 **Cell culture and siRNA/plasmids transfection**

89 Cells were grown in a 5% CO<sub>2</sub> humidified atmosphere at 37°C. All reagents pertaining to  
90 HepaRG cell culture were purchased from ThermoFischer Scientific (Les Ulis, France) unless  
91 otherwise indicated. HepaRG cells were seeded at a density of 4.10<sup>4</sup>/cm<sup>2</sup> in William's E  
92 medium containing insulin 5 mg/mL, penicillin 100 IU/mL, streptomycin 100 mg/mL, and 10%  
93 fetal bovine serum (Hyclone, Illkirch, France). The medium was supplemented with  
94 hydrocortisone hemisuccinate at a concentration of 5.10<sup>-5</sup> mol/L (Pharmacia Upjohn,  
95 Guyancourt, France). Medium was renewed twice a week. siRNAs (Flexitube, Qiagen, Les  
96 Ulis, France, **Suppl. Table 3**) and plasmids were transfected using RNAiMax (Thermo, Les  
97 Ulis, France) or Mirus LT1 reagents (Mirus-Bio, Euromedex, Souffelweyersheim, France),  
98 following the manufacturer's procedures at a final concentration of 10 nM and 1 µg/mL,  
99 respectively. All transfections were performed in suspension before distribution in wells and  
100 poly(I:C) treatment in order to prevent transfection yield variability. Primary human hepatocytes  
101 (PHHs) were isolated from surgical liver resections, after informed consent of patients (IRB  
102 agreements #DC-2008-99 and DC-2008-101) as previously described [29] and cultured in  
103 complete William's medium supplemented with 1.8% DMSO (Sigma, St Quentin, France). All  
104 PHH-related data were obtained from at least three distinct patients. For TLR3-specific or pan-  
105 TLR stimulation, cells were treated with Pam3-CSk4, LPS, FLA, FSL, Riboxol and LMW or  
106 HMW poly(I:C) (InvivoGen, Toulouse, France) three to four days after seeding (*i.e.* after having  
107 reached confluency) for the indicated time points and/or concentrations.

108

### 109 **Cell viability assays**

110 The Neutral Red (NR) assay was conducted as described by Repetto [30]. Briefly, the NR  
111 stock solution (40 mg NR dye in 10 mL PBS) was diluted in culture medium to a final  
112 concentration of 4 mg/mL and then centrifuged at 600g for 10 min to remove any precipitated  
113 dye crystals. Cells were then incubated with 100 µL of NR medium for 1 h. NR medium was  
114 removed and the cells washed with PBS. Plates were incubated for 10 min under shaking with

115 150 µL/well of NR destain solution (50% ethanol 96%, 49% deionized water, 1% glacial acetic  
116 acid). OD at 540 nm was measured.

117

### 118 **Western blotting**

119 Immunoblotting was performed using 40 µg of RIPA (50 mM Tris HCl (pH 8.0), 150 mM NaCl,  
120 1% NP-40, 0.5% sodium deoxycholate, 0.1% SDS, 10 mM sodium fluoride, 50 mM  
121 orthovanadate, 1x protease inhibitor cocktail (Roche))-processed cell lysates, then resolved  
122 on 8% or 10% SDS-PAGE, blotted onto nitrocellulose membranes (Amersham Biosciences),  
123 blocked using 5% low fat dried milk in TBS Tween 0.1% for 1 hour at RT and probed overnight  
124 at 4°C with corresponding antibodies listed in the **Suppl. Table 2**. After three washes in PBS-  
125 Tween 0.1%, membranes were incubated for 1 h at room temperature with secondary  
126 antibodies coupled to HRP (1/5,000, Sigma-Aldrich, St-Quentin, France) prior to  
127 chemiluminescence-based revelation using the Clarity Western ECL substrate (Bio-Rad,  
128 Versailles, France). The Western blot specificity of the netrin-1 antibody was extensively  
129 verified in-house prior to conducting experiments (**Suppl. Fig. 1**).

130

### 131 **Immunofluorescence**

132 Cells were fixed in -20°C methanol/acetone after one wash of ice-cold PBS, blocked in 5%  
133 goat serum (Eurobio, Les Ulis, France) at room temperature for 15 min, incubated overnight  
134 with corresponding antibodies listed in **Suppl. Table 2** in PBS/0.1% Triton X-100, washed prior  
135 to incubation with secondary antibodies listed in the **Suppl. Table 2**, mounted with DAPI. Cells  
136 were finally visualized under a confocal microscope (Leica SP5X, magnification 63X, Zoom =  
137 2).

138

### 139 **Netrin-1 immunoprecipitation**

140 For netrin-1 immunoprecipitation from tissue culture medium, serum-free medium  
141 complemented or not with heparin (2 µg/mL, Sigma-Aldrich, France), was applied to the cells  
142 overnight, 60 h after poly(I:C) treatment. 5x or 1x lysis buffer (20 mM Tris pH 7.5, 150 mM  
143 NaCl, 1 mM EDTA, 1 mM EGTA, 0.1% Triton X-100, Protease inhibitor cocktail 1x) were used  
144 for supernatant or total lysates immunoprecipitation, respectively. Two µg of anti-netrin-1  
145 NP137 antibody [27] / 5 mL of medium or 2 µg NP137 / mg of protein extracted from total  
146 lysates were incubated overnight on a rotating wheel at 4°C. Twenty µL of SureBeads™  
147 Protein A Magnetic Beads (Biorad) was added for 2µg of antibody, for 1 h on a rotating wheel  
148 at 4°C. Beads were then washed three times with lysis buffer 1x and eluted in 20 µL of 1x  
149 Laemmli buffer for 5 min at 95°C (Staufen-1, Netrin-1 IP) or extracted with acid phenol  
150 (Invitrogen) reagent followed by proteinase K extraction (Staufen-1 IP) as described earlier  
151 [31].

152

### 153 **Total RNA extraction and RT-qPCR**

154 Total RNA was extracted using Trizol (Invitrogen). One  $\mu\text{g}$  of RNA was DNase I-digested  
155 (Promega, Charbonnières, France) and then reverse transcribed using MMLV reverse  
156 transcriptase (ThermoFischer) according to the manufacturer's instructions. Pre-mRNA-  
157 targeting qPCR was tested for absence of DNA-based qPCR signal upon heat inactivation of  
158 MMLV. Quantitative real-time PCR was performed on 1/5<sup>th</sup> diluted samples on a LightCycler  
159 96 device (Roche, Meylan, France) using the low Rox qPCR mix (Bioline, Paris, France). PCR  
160 primer sequences (5'-3') and qPCR conditions are listed in the *ad hoc* section. Specificity of all  
161 primers (**Suppl. Table 4**) was assessed by melting curve analyses and agarose gel  
162 electrophoresis. Performance of all primers was quantified using serial 3-fold dilutions of target  
163 templates.

164

### 165 **Nascent RNA capture**

166 Cells were treated with 0.2 mM ethynyl uridine (EU) for 24 h in order to obtain nascent RNAs  
167 with an incorporated EU label. Total RNAs were isolated with Tizzol (Invitrogen). The EU-  
168 labeled RNAs were biotinylated and captured using the Click-it Nascent RNA Capture Kit (Life  
169 Technologies), in accordance with the manufacturer's instructions. One  $\mu\text{g}$  of total RNA was  
170 used for biotinylation with 0.25 mM biotin azide in the Click-iT reaction buffer. The RNAs were  
171 precipitated with ammonium acetate and ethanol and resuspended in UltraPure water. EU-  
172 labeled biotinylated RNAs were captured using Dynabeads MyOne Streptavidin T1 magnetic  
173 beads. 0.5  $\mu\text{g}$  of biotinylated RNAs was mixed with Click-iT RNA binding buffer and heated at  
174 68°C for 5 min, followed by the addition of the beads (25  $\mu\text{L}$  of suspension per reaction) and  
175 incubation at room temperature for 30 min while gently vortexing. The beads were immobilized  
176 using the DynaMag-2 magnet and were washed with Click-iT washing buffers 1 and 2. The  
177 washed beads were resuspended in Click-iT wash buffer 2 and used for cDNA synthesis.

178

### 179 **Sequential extraction**

180 This protocol followed Stephens et al. [32, 33] using the following buffer compositions.  
181 Permeabilization: 110mM KOAc, 25mM KHEPES pH7.2, 2.5mM Mg(OAc)<sub>2</sub>, 1 mM EGTA,  
182 0.015% digitonin, 1 mM DTT, 1 mM PMSF, 200 $\mu\text{M}$  VRC. Wash: 110 mM KOAc, 25 mM  
183 KHEPES pH 7.2, 2.5 mM Mg(OAc)<sub>2</sub>, 1 mM EGTA, 0.004% digitonin, 1 mM DTT, 1 mM PMSF,  
184 200 $\mu\text{M}$  VRC. Lysis: 400 mM KOAc, 25 mM KHEPES pH 7.2, 15 mM Mg(OAc)<sub>2</sub>, 1% (v/v) NP-  
185 40, 0.5% (w/v) DOC, 1 mM DTT, 1 mM PMSF, 200 $\mu\text{M}$  VRC. Briefly, aspiration of medium and  
186 washing of cells (100 mm Petri dishes) with 5-10 mL ice-cold PBS to remove any excess  
187 culture medium was first conducted. Flasks were then gently coated with digitonin-containing  
188 1 mL permeabilization buffer and shaken at 4°C on ice for 5 min. At this point, loss of plasma

189 membrane and soluble cytosolic contents could be observed using phase contrast microscopy  
190 (**Suppl. Fig. 2A**). The flasks were then straightened (vertical position) and the buffer allowed  
191 to drain for 1 min. The soluble material (cytosol) was transferred to a 1.5 mL microcentrifuge  
192 tube on ice, before gently washing the flasks with 5 mL of digitonin-free wash buffer, which  
193 was then discarded. The flasks were next coated with 1 mL of NP40-containing lysis buffer  
194 and shaken on ice for 5 min. At this point, only nuclei and insoluble cytoskeletal components  
195 remain attached to the culture flask, which once again could be visualized using routine phase  
196 contrast microscopy (**Suppl. Fig. 2B**). The flasks were subsequently straightened and the  
197 buffer allowed to drain for 1 min. The resulting soluble (membrane-bound) material was  
198 transferred to a 1.5 mL microcentrifuge tube. Finally, soluble lysates were clarified at 10,000g  
199 for 10 min at 4°C and the supernatants transferred to new tubes.

200

### 201 **Polysome isolation and profiling**

202 For polysome fractionation, cycloheximide (Sigma, 100µg/ml; Interchim, Montluçon, France)  
203 was added to the medium for 5 and/or 15 min, prior to harvesting. The medium was then  
204 removed and the cells washed with ice-cold PBS containing 100 µg/mL cycloheximide. The  
205 cells were then scraped, centrifuged at 800g for 5 min at 4°C and cytoplasmic RNA was  
206 obtained by lysis (20 strokes of a p1000 pipet) of the cell pellet in 1 mL of polysome buffer  
207 containing 10 mM Tris-HCl (pH 8.0), 140 mM NaCl, 1.5 mM MgCl<sub>2</sub>, 0.5% Nonidet P-40, and  
208 40 mM vanadyl ribonucleoside complexes (VRC), 100 µg/mL cycloheximide (CHX), 20 mM  
209 dithiothreitol (DTT), and 1 mM phenylmethanesulfonyl fluoride (PMSF), all reagents were  
210 supplied by Sigma. Mitochondria and membrane debris were removed by centrifugation  
211 (10,000g, 5 min, 4°C). The post-mitochondrial supernatants were overlaid onto a 15-40%  
212 sucrose gradient and spun at 38,000rpm for 2 h at 4°C in a SW41Ti rotor (Beckman Coulter,  
213 Fullerton, CA, USA). Fractions were collected from the top of each gradient using a 240 nm  
214 UV reader-coupled fraction collector (Brandel, Glasgow, UK). Free mRNPs, monosomes and  
215 polysomes were located through the interpretation of UV gradient traces. RNA extraction was  
216 done using the acid phenol approach detailed previously [8].

217

### 218 **Mass spectrometry-based proteomic analyses**

219

220 The gel bands containing immunocaptured netrin-1 from the three independent experiments  
221 were cut and digested in-gel using trypsin (modified, sequencing purity, Promega), as  
222 previously described [34]. The resulting peptides were analyzed by online nanoliquid  
223 chromatography coupled to MS/MS (Ultimate 3000 RSLCnano and Q-Exactive HF, Thermo  
224 Fisher Scientific) using a 60 min gradient. For this purpose, the peptides were sampled on a  
225 pre-column (300 µm x 5 mm PepMap C18, Thermo Scientific) and separated in a 75 µm x 250

226 mm C18 column (Reprosil-Pur 120 C18-AQ, 1.9  $\mu\text{m}$ , Dr. Maisch). The MS and MS/MS data  
227 were acquired by Xcalibur (Thermo Fisher Scientific).

228 Peptides and proteins were identified and quantified using MaxQuant (version 1.6.17.0) [35]  
229 using the Uniprot database (*Homo sapiens* taxonomy, May 2020 version) and the frequently  
230 observed contaminant database embedded in MaxQuant. Trypsin was chosen as the enzyme  
231 and two missed cleavages were allowed. Peptide modifications allowed during the search  
232 were: carbamidomethylation (C, fixed), acetylation (Protein N-ter, variable) and oxidation (M,  
233 variable). Minimum peptide length and minimum number of unique peptides were set at seven  
234 amino acids and one, respectively. Maximum false discovery rates - calculated by employing  
235 a reverse database strategy - were set at 0.01 of the peptide-spectrum match, peptide and  
236 protein levels. The netrin-1 ratio in heavy over medium forms (replicates 1 and 3) or medium  
237 over heavy forms (replicate 2) were calculated for each replicate based on the corresponding  
238 peptide ratios.

239

#### 240 **CLIP assay**

241 Poly(I:C) treated and mock cells were supplemented with 100  $\mu\text{g}/\text{mL}$  cycloheximide (5 min.  
242 37°C), then washed with ice-cold PBS, fixed under UV light (0.2  $\text{J}/\text{cm}^2$ ), scraped with ice-cold  
243 PBS, spun down at 1,000g for 5 min at 4°C and snap-frozen in liquid nitrogen. Cells were  
244 subsequently lysed in a buffer composed of 20 mM Tris pH 7.5, 150 mM NaCl, 1 mM EDTA,  
245 1 mM EGTA, 0,1% NP40, Protease inhibitor cocktail 1x, RNase Out 100 U/mL, and 400  $\mu\text{M}$   
246 VRC. The 35 strokes of Dounce homogenizer were applied to the sample before clarification  
247 at 5,000g for 5 min at 4°C. After preclearing using naked protein A-coated magnetic beads  
248 (Bio-Rad #161-4013), 2  $\mu\text{g}$  of IgG control or anti-Staufen antibody (**Suppl. Table 3**) was mixed  
249 to 0.5 mg of lysates overnight under rotating incubation at 4°C. Beads were then added to  
250 complexes and incubated on a rotating wheel at 4°C for 2 h, then washed twice with lysis  
251 buffer. Twenty  $\mu\text{g}$  of total lysates 1/6<sup>th</sup> of the IP fraction, as well as flow-through fractions were  
252 loaded onto SDS-PAGE gels for subsequent immunodetection of the proteins of interest.  
253 Staufen-1-bound RNA extraction was conducted using the acid phenol approach detailed  
254 previously [8]. Bound RNAs were retrotranscribed using the Superscript IV Vilo RT enzyme  
255 (Invitrogen) and corresponding cDNAs were amplified using the Bioline No-Rox qPCR kit.

256

#### 257 **Filter binding assay**

258 The *NTN1* 5'UTR was *in vitro* transcribed using the MEGAscript™ T7 Transcription Kit,  
259 (Ambion, #AMB13345) and then biotinylated (Pierce™ RNA 3' End Biotinylation Kit, Thermo  
260 #20160). HBV RNA epsilon loop was chemically synthesized and labeled (Genscript,  
261 Piscataway, USA). Sequences and genetic references are provided in **Suppl. Table 5**. RNA  
262 renaturation was performed by heating samples at 95°C for 5 min before slowly cooling to

263 room temperature. RNA constructs (0.1 nM) were then incubated with increasing  
264 concentrations of the purified recombinant Staufen-1 protein (Origen, #TP760787; 0-100 nM)  
265 in binding buffer (Tris-HCl, pH 7.4, 20 mM; K(AcO), 100 mM; KCl, 200 mM; Mg(AcO)<sub>2</sub>, 2.5 mM;  
266 DTT, 1 mM) for 30 min at 37 °C. The reactions were then loaded onto a filter sandwich  
267 composed of 0.45 µm nitrocellulose filters (GE Healthcare Life Science) located above nylon  
268 filters (GE Healthcare Life Science). Both membranes were pre-soaked in binding buffer and  
269 assembled in a dot-blot apparatus. Samples were directly added to the filters under vacuum  
270 and subsequently washed twice with 400 µL of ice-cold binding buffer while a vacuum was  
271 being applied. Both membranes were then UV crosslinked (0.12 J/cm<sup>2</sup>). Signal development  
272 was performed using the Chemiluminescent Nucleic Acid Detection Module Kit, thermo  
273 #89880. Quantification of the obtained signals was done using Image Lab. K<sub>d</sub> values were  
274 calculated using the Sigma Plot 8.02© software according to the equation  
275  $y = y_0 + (B_{max} \cdot x^n) / (K_d^n + x^n)$ , where y is the percentage of complexed RNA, B<sub>max</sub> is the binding  
276 yield, x is the concentration of the target RNA, K<sub>d</sub> is the dissociation constant and n is the Hill  
277 coefficient.

278

#### 279 **RUSH assay**

280 HepaRG cells transfected with a GFP-tagged A<sub>1</sub>AT RUSH reporter described previously [36]  
281 were treated or not with poly(I:C). After 72 h, cells were treated with 40 µM biotin and then  
282 fixed with 3% paraformaldehyde at different time points. After immunofluorescence staining,  
283 images were acquired on a Leica SP5 confocal laser scanning microscope using the 63× oil  
284 objective at two-fold magnification.

285

#### 286 **Netrin-1 Crispr cell lines**

287 A netrin KO Crispr cell line and its ad hoc control cell line were generated.

288 The Zhang lab protocol [37] was used. Briefly, guide sequences (**Suppl. Table 6**) were  
289 inserted into lentiCRISPR v2 (Addgene plasmid #52961) and lentiCRISPR v2-Blast (Addgene  
290 plasmid #83480). DNAs (Gag-Pol + Env + lentiCRISPRv2 or lentiCRISPRv2 Blast) were  
291 transfected into 2 × 10<sup>6</sup> HEK293T cells (ATCC CRL-1573) seeded the day before in 10-cm  
292 plates using calcium phosphate [38]. The medium (8 mL/plate) was replaced 16hrs after  
293 transfection. Virus-containing supernatants were harvested 24 h later, filtered through 0.45-  
294 µm pore-sized membranes, and stored at -80°C until further transduction. For selection of the  
295 resulting polyclonal cell lines, cells were plated at a density of 4.10<sup>4</sup>/cm<sup>2</sup> in a 35 mm Petri dish.  
296 The next day later, lentiviral transduction was done using 500 µL of medium to which were  
297 added 250 µL of each lentivirus supernatant, for two days. Cells were then put under selective  
298 pressure for the expression of both lentiviruses' cassettes using puromycin and blasticidin  
299 (Invivogen, gradually increasing concentrations from 4 and 8 µg/mL to 10 and 20 µg/mL within

300 two weeks, comprising two weekly trypsinization procedures). Cell lysates were then  
301 generated for netrin-1 KO monitoring by Western blot using the anti-netrin-1 reference  
302 Ab126729 (Abcam) prior to liquid nitrogen storage.

303

#### 304 **Netrin-1 release assay**

305 For netrin-1 release assays, Crispr control (HepaRG-Ctrl-KO) and netrin-1 KO (HepaRG-Net-  
306 KO#3) cell lines were seeded as depicted above, allowed to reach confluency for 4 days, and  
307 sequentially treated with recombinant soluble netrin-1 (125 ng/mL, R&D systems) followed by  
308 50 µg/mL poly(I:C) for the indicated times, before supernatant harvesting and its clarification  
309 (1,000g, 5 min, 4°C). Supernatants were washed with ice-cold PBS and processed for netrin-  
310 1 immunoprecipitation and Western blotting.

311

## 312 **Results**

313

### 314 Clinical and *in vivo* relevance of netrin-1 induction

315 In order to evaluate the clinical likelihood of an interplay between netrin-1 and inflammation in  
316 the liver, we first considered a potential association between netrin-1 and clinical activity  
317 scores, performing western blotting (after extensive anti-netrin-1 antibody validation, **see**  
318 **Suppl. Fig.1**) on a well characterized HBV-positive series of samples. Samples were selected  
319 based on several criteria in order to minimize confounding factors, namely gender (men only  
320 here due to availability), similar HBV sample-specific viral loads, fibrosis scores, platelet  
321 counts, prothrombin time, ALAT, albumin and bilirubin, leading to a cohort of 14 patients  
322 (**Suppl. Table 1**), the sample sizes of whom were compatible with multitarget immunoblotting.  
323 Samples were blotted for netrin-1 and  $\alpha$ -SMA, an inflammation-related marker in CLDs [39,  
324 40], and association between netrin-1 signals and activity were observed (**Fig.1A**), being  
325 however uncorrelated with corresponding netrin-1 mRNA signals (**Fig.1B and Suppl. Fig.3**).  
326 Based on activity scores, such data suggest that netrin-1 protein levels are correlated with liver  
327 inflammation in HBV patients.

328 In order to probe the robustness of these correlative clinical data, we first investigated the  
329 potential impact of experimentally-induced inflammation, using a panel of TLR ligands, namely  
330 Pam3-CSK4 as a TLR1/2 agonist, lipopolysaccharide (LPS) as a TLR4 agonist, FLA as a TLR5  
331 agonist, FSL as a TLR2/6 agonist, Riboxol (molecularly defined TLR3 agonist), and finally low  
332 or high molecular weight poly(I:C) as TLR3, RIG-I and MDA-5 agonists. Experiments were  
333 carried out on HepaRG cells as a source of essentially growth-arrested and untransformed  
334 cells representative of late-stage CLD [41, 42]. RIG-I was also probed as a control for the  
335 induction of inflammation. Pam3CSK4, LPS, FSL, Riboxol, and HMW poly(I:C) induced netrin-  
336 1, suggesting its broad spectrum of inflammation triggers, and therefore its relevance, in the  
337 hepatic environment (**Fig. 1C**). Chronic viral infections of the liver represent one of the major  
338 etiologies of CLDs. Both HBV and HCV viruses have been shown to be direct inducers of  
339 dsRNA-based responses [43, 44], which in turn unleash the subsequent inflammation in  
340 hepatocytes. HepaRG cells were previously shown to be broadly responsive to poly(I:C) [45].  
341 We hereafter focused on the dsRNA analog poly(I:C) of HMW, as a viral mimetic.

342 We then assayed inflammation-related netrin-1 induction in the liver *in vivo*. To achieve this,  
343 C57BL/6J mice of both sexes were challenged with HMW-poly(I:C), prior to harvesting their  
344 liver, and processing total RNA extracts for RT-qPCR on inflammation-related transcripts.  
345 Although poly(I:C) injection did not increase ALT levels (a well-known marker of liver  
346 inflammation) in mouse serum within the experimental timeframe (**Suppl Fig.4A**), several  
347 other markers of inflammation (*CXCL10*, *IL1B*, *IL6*, *KC*) were induced both in male and female  
348 mice. Interestingly, the overall inducibility of canonical inflammation markers was higher in

349 females. (**Suppl. Fig. 4B**). Intriguingly, though *NTN1* mRNA induction was not observed within  
350 total RNA populations, a western blot and IHC approach evidenced netrin-1 induction at the  
351 protein level, albeit to different extents with female mice being also more responsive (**Fig. 1D-**  
352 **E** and **Suppl. Fig. 5**). Such data suggest a causal link between inflammation, inflammation  
353 intensity, and netrin-1 induction, at least in the acute inflammatory context. In order to identify  
354 the cells implicated in netrin-1 induction, we performed intrahepatic IHC to detect netrin-1 in  
355 these murine samples. Netrin-1 staining yielded a homogenous and likely ubiquitous  
356 expression pattern, similar to previous data obtained in human liver [9]. Therefore, it is likely  
357 that netrin-1 staining was associated with the hepatocytic compartment, which makes up 80%  
358 of the liver mass and areas (**Fig. 1F**).

359

### 360 Translational induction of netrin-1

361 To gain further insight into the mechanisms of netrin-1 production, we conducted a set of *in*  
362 *vitro* experiments using HepaRG cells [41] and PHH that present two distinct phenotypes  
363 (preneoplastic and fully differentiated, respectively), and are deemed relevant for studying  
364 CLD-related mechanisms in untransformed hepatocytic cells. In HepaRG and PHH, poly(I:C)  
365 led to netrin-1 protein induction in a dose- and time-dependent manner. The RIG-I inducible  
366 marker was monitored to verify poly(I:C) activity. (**Fig. 2A**). As a laminin-related protein [46],  
367 netrin-1 is susceptible to be secreted and may also accumulate at the extracellular side of the  
368 plasma membrane. We thus tested netrin-1 signals by immunoprecipitation after heparin-  
369 based release of plasma membrane-bound netrin-1 in serum-free culture supernatants. Data  
370 indicate that the previously observed netrin-1 upregulation by Western blot affects its  
371 membrane-bound form along with its presence in the culture medium in both cell types (**Fig.**  
372 **2B**). We then ascertained that its upregulation was independent of its well-documented activity  
373 as a cell death inducer. We thus monitored cell viability upon poly(I:C) and heparin treatment,  
374 using the neutral red assay in wild-type HepaRG, PHH, and Crispr/Cas9 netrin-1 KO HepaRGs  
375 (**Suppl. Fig. 6A-C**). Previous data were confirmed, indicating that during inflammation, netrin-  
376 1 induction is not related to cell injury and is likely involved in cell death-unrelated processes.  
377 We next sought to unravel the molecular basis for netrin-1 induction. Similarly to mice, no  
378 significant increase in *NTN1* mRNA levels could be evidenced, either in HepaRG cells or in  
379 PHH (**Suppl. Fig. 7A**), upon analysis of total RNA pools. Total RNA levels for a given mature  
380 transcript depend on various processes that are active in real time, such as transcription,  
381 stability, and splicing. We initially focused on pre-mRNA levels, though no significant induction  
382 could be observed under poly(I:C) treatment in HepaRG or in PHH (**Suppl. Fig. 7B**). In order  
383 to rule out transcriptional induction in such contexts, we then performed a *Ntn1* promoter Luc  
384 reporter assay and a run-on assay aiming at quantifying *de novo NTN1* transcription under  
385 poly(I:C) treatment. No increase could be obtained following treatment of HepaRG cells with

386 poly(I:C), in either approach, indicating that netrin-1 was not regulated at the transcriptional  
387 level (**Suppl. Fig. 8A-B**).

388 To evaluate the possible implication of *NTN1* mRNA splicing in the final phenotype, we  
389 calculated the evolution of *NTN1* pre-mRNA over mRNA induction ratios upon poly(I:C)  
390 treatment. Again, no significant alteration of such ratios was observed (**Suppl. Fig. 9**),  
391 suggesting that regulation of splicing did not participate in netrin-1 protein increase. In order to  
392 safely orient subsequent studies towards post-transcriptional read-outs, we lastly quantified  
393 *NTN1* mRNA stability using the selective RNA polymerase II inhibitor triptolide [47]. In this  
394 assay, *NTN1* mRNA decay rate was unaltered (-1.3-fold) by poly(I:C) (**Suppl. Fig. 10**), arguing  
395 in favor of a post-transcriptional regulation.

396 Following the next step in the biogenetic processing of netrin-1, we then considered  
397 translational regulation as a potential contributor to netrin-1 protein induction. We first  
398 submitted HepaRGs, PHHs and mouse livers to total polysomal fractionation using sucrose  
399 gradient-based isopycnic ultracentrifugation followed by gradient trace monitoring, RNA  
400 extraction, and RT-qPCR on the *NTN1* transcript. Adequate fractionation could be evidenced  
401 using gradient UV traces. The presence of the peak of free messenger ribonucleoparticles  
402 (mRNPs), followed by the 40S, 60S and 80S ribosomal subunits, themselves finally followed  
403 by the typical oscillating profile of successive polyribosomes was delineated (**Fig. 3A**, black  
404 and red traces). As expected, translation was more active in early confluent HepaRG cells (as  
405 previously depicted [48]) than in resting, optimally differentiated, PHH, or mouse livers.  
406 Moreover, for HepaRG cells, the percentage of polysome-bound *NTN1* mRNA signals versus  
407 total *NTN1* signals remained unchanged upon poly(I:C) treatment (87.9% versus 86.0% in  
408 treated cells), whereas in PHH, a major shift of the *NTN1* signal could be observed towards  
409 the polysomal compartment of the gradient (46% versus 89%,  $p < 0.05$ ) (**Fig. 3B-C**). The  
410 absence of changes in mouse livers is concomitant to higher amounts of *NTN1* in heavy  
411 polysomes (fractions 13-17), that are associated with strong translational activity. In order to  
412 confirm this, an EDTA release control experiment was carried out. EDTA induces polysomal  
413 collapse through  $Mg^{2+}$  and  $Ca^{2+}$  chelation, enabling the evaluation of the genuine polysomal  
414 origin of the RT-qPCR signals, and reinforced these results (**Fig. 3A-C**).

415 Altogether, our data advocate for distinct modes of regulation of netrin-1 induction in HepaRG  
416 hepatocyte-like cells and fully differentiated environments such as PHH and mice livers. Mouse  
417 livers and PHH appear to activate total polysome-based translation of the *NTN1* transcript for  
418 the final induction of the protein. Yet, netrin-1 biogenesis mechanisms remain uncharted at  
419 this stage of the study in HepaRG cells, which are representative of late stage, preneoplastic,  
420 CLD.

421 In order to pursue the identification of the molecular basis of netrin-1 increase upon poly(I:C)  
422 treatment in HepaRG cells, the *de novo* incorporation of labeled amino acids into the netrin-1

423 sequence was quantified by MS after netrin-1 immunoprecipitation, using stable isotope  
424 labeling by amino acids in cell culture (SILAC) method. This SILAC approach indicated a 4.5-  
425 fold increase in *de novo* incorporation of amino acids in inflammatory conditions versus naïve  
426 cells (**Fig.3D-E**). These data suggest that if translation *per se* is not modulated in HepaRG  
427 cells, as found by polysomal fractionation, processes increasing the susceptibility of the *NTN1*  
428 transcript to translation are strong candidates.

429

430 Staufen-1 mediates netrin-1 induction through direct interactions with the *NTN1* transcript in  
431 preneoplastic cells

432 A majority of the transcriptome encoding secretory and membrane proteins is ER-bound [49].  
433 Netrin-1 is a secreted protein and its translation should naturally take place in association with  
434 the endoplasmic reticulum (ER) membranes so that co-translational translocation of the  
435 nascent peptide across the ER membrane may occur through the transient association of the  
436 peptide's signal sequence with the translocon [50]. Therefore, netrin-1 translation is  
437 conditioned by two distinct events: association with polyribosomes and accumulation of the  
438 transcript at the ER level for subsequent transfer of the native peptide to the secretory pathway.  
439 We took into consideration this process in order to determine divergences between HepaRG  
440 cells and PHH for netrin-1 induction. Based on the so-called 'sequential extraction' method  
441 [32, 33], which allows the investigation of mRNA partitioning between cytosol and microsomes,  
442 we verified netrin-1 enrichment following poly(I:C) treatment using three protein markers (RIG-  
443 I and caspase-3 as cytosolic proteins and the ER-associated PDI/P4HD protein, **Fig. 4A**).  
444 Whereas no significant alteration in cytosolic or membrane-bound levels of *NTN1* transcripts  
445 was evidenced upon poly(I:C) treatment in PHH, the level of *NTN1* transcript enrichment in  
446 membrane-bound versus cytosolic fractions increased by 7-fold in inflammatory HepaRG cells  
447 ( $p < 0.05$ ; **Fig. 4B**). These finding indicate that translational induction of netrin-1 occurs via the  
448 transfer of the *NTN1* transcript to the ER prior to its active translation in HepaRG cells.

449 We then focused on *NTN1* mRNA relocalization by conducting a bibliographic search for  
450 proteins participating in transport and translational regulation of highly structured, GC-rich,  
451 mRNAs in their 5' ends, which the *NTN1* transcript belongs to [16]. The double-stranded RNA  
452 binding domain-containing protein Staufen-1 (STAU1) shuttles between the cytosol and the  
453 ER thanks to its association with microtubules through its tubulin binding domain [51, 52].  
454 STAU1 is implicated in translational activation of GC-rich, structured, mRNAs 5'UTRs [53], and  
455 was shown to bind to the *NTN1* transcript in high throughput experiments [54, 55].

456 In resting cells, STAU1 displayed a granular staining also observed in other studies, where it  
457 associates with RNA granules before or after movement on microtubules [56-59]. Interestingly,  
458 poly(I:C) triggered the reconfiguration of STAU1 signals from a granular to a microtubule-like  
459 filamentous pattern, in accordance with other studies [51, 52, 56]. The number of STAU1-

460 positive granular foci per cell decreased 11-fold and the percentage of STAU1 filamentous  
461 staining-positive cells increased 9-fold with poly(I:C) (**Fig.5A-B**). STAU1 staining also  
462 displayed an increased overlap with PDI+ (ER) areas, quantified using the Li colocalization  
463 coefficient. (**Fig. 5C-D**)

464 In order to test direct interactions between Staufen-1 and the full length netrin-1 mRNA in our  
465 biological setting, we set-up a CLIP assay in UV cross-linked HepaRG cells using a variety of  
466 relevant negative and positive control transcripts [54, 55]. Immunoprecipitation conditions for  
467 STAU1 were first defined (**Fig. 6A**). Data depicted in this panel show significant increase in  
468 *NTN1* levels versus several other transcripts, in addition to a specific and positive impact of  
469 poly(I:C) *per se* on *NTN1* binding levels to STAU1. Percentages of transcript inputs are  
470 indicated in poly(I:C)-treated or untreated conditions in **Fig. 6B**.

471 To further probe such interactions, we carried out a filter binding assay, which provides  
472 information on the affinity of both partners and their class of interaction dynamics downstream  
473 of collected STAU1-bound, RNA-conjugated, biotin-avidin-HRP signals. Based on obtained  
474 profiles, filter binding data were fit to a sigmoidal equation to determine binding constants and  
475 to estimate the degree of binding cooperativity. Calculation of  $K_d$  led to a value of  $1.17 \pm 0.11$   
476 nM. Calculation of the Hill constant was done using the previously published formula:  $\text{Log}(81)$   
477  $/ \text{Log}(EC_{50}/EC_{10})$  [60] and led to a value of  $1.9 \pm 0.28$ , suggesting a moderately cooperative  
478 interaction. As a control, no interaction between an HBV epsilon loop RNA sequence and  
479 STAU1 was observed. In competition experiments, incubation of increasing concentrations of  
480 unlabeled *NTN1* 5'UTR led to displacement of the pre-bound labeled RNA as expected, while,  
481 again, no reversion of STAU1-*NTN1* 5'UTR complex-derived signals could be achieved using  
482 HBV control RNA **Fig.6C-D**. Altogether, such data suggest that the dsRNA binding protein  
483 STAU1 directly binds to the 5'UTR of the netrin-1 transcript, corroborating the accumulation of  
484 STAU1 at the ER level for enhanced susceptibility of this secreted protein's mRNA to  
485 translation upon poly(I:C) treatment.

486 In order to unequivocally test the functional implication of STAU1 in the accumulation of the  
487 *NTN1* transcript at ER sites for netrin-1 protein induction, we tested the effect of RNAi-  
488 mediated STAU1 depletion on poly(I:C)-induced *NTN1* accumulation at the ER and on netrin-  
489 1 induction. Both approaches showed reversion of poly(I:C)-induced netrin-1 signals (**Fig. 6E-**  
490 **G**). Moreover, these mechanistic data indicated that Staufen-1-dependent transcript transfer  
491 to the ER in non-differentiated cells (here represented by proliferative HepaRG cells),  
492 determined netrin-1 induction *in vitro*. They represent to our knowledge the first functional  
493 description of Staufen-1 in inflammation. A comparison of results obtained in HepaRG cells  
494 and PHH suggests that mRNA relocalization and translational activation seem to be mutually  
495 exclusive mechanisms across both cell environments, yet converging and enabling netrin-1  
496 induction.

497

498 Netrin-1 induction is unrelated to post-translational steps

499 In order to potentially define RNA relocalization as a unique contributor to netrin-1 upregulation  
500 during inflammation, the susceptibility of netrin-1 to enhanced secretion as well as its stability  
501 were considered downstream of this experiment. The hepatocyte is one of the major secretory  
502 cells of the human body. Since inflammation is also potentially regulated at the secretion level  
503 because of its important cytokinic component, we considered a potential impact of poly(I:C)  
504 treatment on cell secretion, which could itself regulate netrin-1 levels downstream of  
505 translation. Using the so-called RUSH (retention using selective hooks) assay [36] we treated  
506 or not HepaRG cells with poly(I:C) and, using immunofluorescence, we examined the ability of  
507 a fluorescent fusion form of alpha1-antitrypsin (AAT-GFP) to reach the Golgi apparatus  
508 (located using giantin staining) within the assay timeframe. As shown in **Suppl. Fig. 11A-B**,  
509 no noticeable difference was observed between colocalized signals derived from GFP or  
510 giantin in treated versus untreated cells. AAT being one of the most abundant and specific  
511 cargoes of the hepatocyte, such data suggest that the global secretory activity levels of  
512 HepaRG cells are not altered by poly(I:C), and that netrin-1 levels remain unaffected by this  
513 regulatory step.

514 To rule out the accumulation of netrin-1 through protein stability enhancement, we stopped  
515 translation by cycloheximide treatment prior to harvesting poly(I:C)-treated HepaRGs and PHH  
516 in a time-course assay and combined immunoprecipitation of cell-bound and secreted netrin-  
517 1. In these conditions, no alteration of netrin-1 protein decay rate could be evidenced (**Suppl.**  
518 **Fig. 12**). In association with previous data, these two last datasets provide final evidence that  
519 netrin-1 induction occurs through transcript localization regulation (undifferentiated HepaRGs)  
520 and translational activation (PHHs).

521

522 Induction mechanistics are constrained by the pathogenic status of origin of the cells

523 While HepaRG cells are capable of undergoing partial experimental hepatocytic re-  
524 differentiation under defined culture conditions, their pre-neoplastic status is established by  
525 their peritumoral origin in a cirrhotic liver [41]. In order to control netrin-1 induction mechanisms  
526 between HepaRG and PHH for the former's pathological origin, we submitted HepaRG cells  
527 to their usual hepatocytic differentiation protocol [42]. In polarized, quiescent and differentiated  
528 HepaRG, of note again, no *NTN1* induction occurred at the total RNA level in a context where  
529 netrin-1 protein is induced by poly(I:C). Yet, netrin-1 protein induction correlated with  
530 accumulation of *NTN1* mRNA in the membrane-bound compartment (**Suppl. Fig. 13**), as was  
531 the case with undifferentiated HepaRGs. This dataset indicates that the nature of post-  
532 transcriptional processes converging to netrin-1 induction is more constrained by the

533 pathological status of origin of the cells with respect to pre-neoplastic (HepaRG) or  
534 physiological (PHH) hepatic contexts than by their level of differentiation

535

536 A phase 2 trial-validated antibody enabling netrin-1 capture dampens inflammation in mice

537 As published in several studies, tissular inflammation may be altered by netrin-1 [20-22, 61]  
538 suggesting its mobilization in interstitial fluids. To test whether netrin-1 may act as an  
539 auto/paracrine factor with diffusible consequences, we monitored the behavior of exogenously  
540 added in-house validated recombinant netrin-1 [9], on netrin-1 KO Crispr cells upon poly(I:C)  
541 treatment. Using netrin-1 immunoprecipitation and Western blot, we observed that poly(I:C)  
542 mobilized netrin-1 within 2 hours from its cell-associated pool towards supernatants (**Suppl.**  
543 **Fig. 14**), hence arguing in favor of its regulatory role in hepatic inflammation at the  
544 microenvironmental level.

545 Considering that this diffusible status corroborated previously known tissular effects of netrin-  
546 1 [20-22, 61], we treated C57BL/6J mice with the clinically used and well tolerated anti-netrin-  
547 1 antibody NP137 (NCT02977195) [27] or its NP001 isotypic control 32h before challenging  
548 them with poly(I:C) for 16h and liver harvest. Treatment with the former did dampen poly(I:C)-  
549 induced netrin-1 induction (**Fig.7A**), that occurred, again, independently of *NTN1* RNA  
550 upregulation in all instances (**Fig.7B**). RT-qPCR conducted on a panel of inflammation-related  
551 cytokines (*CCL2*, *CXCL10*, *IL1B*, *IL6*, *KC* (ortholog of human IL8), *IL12B*, *IL15*, and *TGFB1*  
552 highlighted a causal relationship between netrin-1 inactivation and reversion of the induction  
553 of several of these cytokines (*CCL2*, *CXCL10*, *IL1B*, *KC*, and *TGFB1*, **Fig. 7B**). In order to  
554 further document this phenotype, we performed a flow cytometry analysis to monitor immune  
555 cell population regulation. Gating strategies are shown in **Suppl. Fig.15**, where the three left  
556 panels depict Ly6C<sup>+</sup> CD11<sup>low</sup> F4/80<sup>hi</sup> gating (from top to bottom: Poly(I:C)+ and NP001,  
557 Poly(I:C)+ and NP137, and finally Ly6C FMO on pooled cells from all mice). Monocyte-derived  
558 macrophages (CD45<sup>+</sup> CD11b<sup>+</sup> F4/80<sup>low</sup>) remained stable. Total Kupffer cells (CD45<sup>+</sup> CD11b<sup>low</sup>  
559 F4/80<sup>hi</sup>) counts were not regulated. However, the NP137 antibody reversed Ly6C<sup>+</sup> Kupffer cells  
560 counts. (**Fig.7C**). Hence, such data suggest that netrin-1 is an actionable target that further  
561 amplifies dsRNA-triggered liver inflammation, in accordance with its role in other organs 1 [20-  
562 22].

563

564 **Discussion**

565

566 Netrin-1 has been repeatedly identified as a cancer promoting agent [5, 6, 10-15]. Its  
567 expression is associated with inflammatory diseases that may themselves promote cancer  
568 onset [6, 26]. Given the causal link between inflammation, cirrhosis, and HCC [62-66], probing  
569 the direct impact of inflammation on netrin-1 expression in the liver was of interest.

570 Although transcriptional regulation has been considered a hallmark regulatory step in general  
571 cell biology and liver differentiation processes [67], increasing evidence suggests that  
572 processes that need swift temporal regulation in highly remodeled tissues, such as  
573 inflammation and, more generally, oncogenic processes and associated resistance, rely on  
574 translational modulation [68, 69].

575 Our experience in the liver field has been recurrently confronted with this type of regulation.  
576 Indeed, differentiation of HepaRG cells is strongly associated with important downregulation  
577 of a majority of transcripts at the total RNA level, together with a concomitant upregulation in  
578 polysomal fractions of a subset of hepatocytic differentiation-related mRNAs [70].  
579 Experimental activation of the mTOR/S6 kinase pathway, which is present in 45% of HCC  
580 cases [71], impairs hepatocytic differentiation, and impedes the translation of transcripts  
581 moderating lipid homeostasis and cell growth [31]. Upon the UPR, netrin-1 translation is  
582 selectively favored during global translational shut down, together with IRES-bearing  
583 transcripts implicated in cell survival and transformation [72]. Finally, the netrin-1 receptor  
584 UNC5-A is also translationally down-regulated upon HCV infection, including in patient livers  
585 [8]. Moreover, the liver is one, if not the most, active secretory and metabolic cell type in human  
586 physiology, in line with being exposed to real-time needs for metabolic and hence secretory  
587 regulation (acute phase, post-prandial phases). It is thus conceivable that the biogenesis of  
588 secreted factors such as netrin-1 are more often constrained by swift regulatory processes  
589 such as translational control in the liver than in other cell types. The present data, to be  
590 interpreted as a confirmation of the particular susceptibility of netrin-1 to post-transcriptional  
591 regulation, strengthens the need for more frequent molecular analyses of pathogenic  
592 processes using total RNA-unrelated enrichment methods, such as polysomal profiling, at least  
593 at the liver level.

594 In the present study, we have shown, depending on the cell system of interest, *i.e.*  
595 undifferentiated HepaRG or PHH, that netrin-1 biogenesis under inflammation was specifically  
596 regulated at the mRNA localization level in the former, while at the translational level *per se* in  
597 the latter case and that the pathogenic status of the cells conditioned these modes of induction.  
598 The presence of these mechanisms is of interest, since it appears that two distinct modes of  
599 post-transcriptional regulation actually converge towards a single phenotypic outcome, *i.e.*,  
600 netrin-1 increase. Pathophysiological needs for delivering this final phenotype therefore seems

601 to override cell type-specific functional singularities, suggesting that induced netrin-1 conveys  
602 important functions in the liver, either immunomodulatory [20-22, 61], or, on the long-term,  
603 hepatoprotective as an anti-apoptotic factor [5, 6, 10-15].

604 This phenotype relies on the RNA-binding protein Staufen-1, the implication of which is to date  
605 essentially undocumented in the regulation of inflammatory processes. However, Staufen-1  
606 has recently been shown to foster gastric cancer progression in a cyclin-dependent kinase-  
607 dependent manner [73] and also to take part in an EZH2-related, HCC promoting pathway  
608 [74], suggesting relevance of further studies aiming at characterizing its implication in end-  
609 stage liver disease through a possible netrin-1 involving axis.

610 From a more pathology- and therapy-oriented point of view, this study suggests a potential link  
611 between hepatic inflammation and liver disease progression through netrin-1. To date, in the  
612 liver, direct cross-talks between inflammation and HCC have been mainly defined through the  
613 IL-6/gp130/STAT3 axis [75]. We previously documented that progression towards HCC is  
614 associated with a sharp drop in *UNC5A* (netrin-1 receptors) expression levels [8], thereby  
615 functionally augmenting netrin-1 activity, following the dependence receptor theory [76]. Our  
616 study improves the understanding of the potential implication of inflammation in the evolution  
617 of CLDs, besides the well characterized IL-6/gp130/STAT3 cascade and identifies an  
618 actionable target for its modulation. Chronic inflammation of a given tissue is counterbalanced  
619 by a wound healing process leading to scar, acellular, tissue build up, made of ECM. As  
620 mentioned before, netrin-1 is a laminin-related protein that shares several structural features  
621 with ECM-constituting proteins. As a consequence, one may hypothesize that netrin-1 could  
622 participate in ECM build-up. The fact that netrin-1 promotes fibrosis in the inflammatory lung  
623 [77] strengthens the potential relevance of this hypothesis.

624 The humanized anti-netrin capture antibody NP137 developed by the authors [27] is currently  
625 under investigation in phase 2 clinical trials in general oncology (US Clinical Trials #02977195)  
626 and shows no clinical toxicity in a diversity of solid tumors contexts. The apparent anti-  
627 inflammatory activity of this antibody in the present setting argues in favor of its eventual  
628 transfer to the clinic for subsequent trials in histologically evolutive CLDs.

629

### 630 **Acknowledgements**

631 We thank B Bancel (pathologist, Lyon U. Hospital) for determining the activity scores, L Muller  
632 for technical assistance, A Paradisi for the netrin-1 promoter reporter plasmid, the CIQLE  
633 platform for assistance with confocal microscopy, and B. Manship for editing. RB and IC are  
634 recipients of a DevWeCan Labex (Laboratories of Excellence Network, ANR-LABX-061) and  
635 ANRS (ECTZ63958) predoctoral fellowships, respectively. Funding has been obtained through  
636 the same Labex consortium (ANR-LABX-061) and the French NCI (Inca PRT-K 19-033).  
637 Proteomic experiments were partially supported by the French NRA under projects ProFI

638 (Proteomics French Infrastructure, ANR-10-INBS-08) and GRAL, a program from the  
639 Chemistry Biology Health (CBH) Graduate School of University Grenoble Alpes (ANR-17-  
640 EURE-0003).

643 **Figure 1**

644 **Netrin-1 levels are correlated with activity scores in HBV-positive clinical liver**  
645 **specimens, induced in HepaRG cells by several TLR ligands and induced by poly(I:C)**  
646 **in mouse livers.**

647 **A.** HBV-infected liver tissues (clinico-biological features listed in supplementary table 1) were  
648 homogenized using a Dounce homogenizer in lysis buffer, centrifuged to remove debris,  
649 denatured, and visualized by SDS-PAGE. Netrin-1 and  $\alpha$ -SMA were probed using antibodies  
650 listed in **Suppl. Table 2**. Since actin staining is not correlated with the amount loaded, Ponceau  
651 staining is shown as well. **B.** Corresponding RNA data are plotted versus activity scores. **C.**  
652 Netrin-1 expression levels were evaluated by immunoblotting (n = 3 independent experiments).  
653 RIG-I was used as a poly(I:C) activity control. **D.** The levels of *NTN1* mRNA were quantified  
654 by RT-qPCR using *GUS* [78] as an internal reference. Mann-Whitney test (n.s.). **E.** Netrin-1  
655 expression levels were evaluated by immunoblotting using anti-RIG-I and anti-netrin-1  
656 antibodies. **F.** Liver slides were probed with the same anti-netrin-1 antibody prior to secondary  
657 antibody incubation and HRP-based visualization. Mouse samples were derived from the same  
658 hepatic lobe in all instances. Data are representative of a total of 40 mice (10 females, 10  
659 males, +/- poly(I:C); **see Suppl. Fig. 4** for comprehensive data).

671 **Inflammation activates translation of the *NTN1* transcript in HepaRG cells, PHH and**  
672 **mouse livers.**

673 HepaRGs, PHH and mouse livers samples were homogenized in polysome lysis buffer and  
674 loaded onto a linear sucrose gradient prior to isopycnic ultracentrifugation. **A.** Representative  
675 profile of UV gradient traces. **B.** *NTN1* distribution profile across the gradient. Total  
676 polyribosomes were fractionated, extracted and processed for *NTN1* by RT-qPCR (n = 3,  
677 HepaRG; n = 3 distinct PHH donors, n = 6 female mice). Mann-Whitney test, \* p < 0.05. **A-B.**

678 An EDTA release control assay was performed by adding EDTA to lysates immediately before  
679 ultracentrifugation (green values). **C.** Quantification of corresponding polysomal signals. **D.**  
680 Total lysates and supernatants derived from treated and control HepaRG cells previously  
681 adapted to dialyzed serum conditions for 14 days (and labeled with medium or heavy Lys or  
682 Arg isotopes supplemented in Lys/Arg-free William's E medium) were lysed with 5x lysis buffer  
683 and quantified for total protein amounts and mixed 1:1 prior to netrin-1 immunoprecipitation.  
684 **E.** Immunoprecipitated material was then run onto SDS-PAGE, submitted to tryptic digestion  
685 and subsequent isotope-specific mass spectrometry-based quantification (n = 3 independent  
686 experiments). The schematic diagram was drawn using the BioRender software. Mann-  
687 Whitney test, \*\*\* p < 0.001.

688

#### 689 **Figure 4**

690 ***NTN1* accumulates in membrane/ER-positive fractions upon poly(I:C) treatment in**  
691 **HepaRG cells.**

692 The Stephens et al. sequential extraction method was used as mentioned in the materials and  
693 methods section. **A.** Adequate partitioning was verified by Western blotting on PDI (internal  
694 membrane contents) and caspase-3 (cytosolic contents). RIG-I (cytosolic location) was also  
695 probed as a poly(I:C) activity control. Differential Ponceau Red staining profiles are shown. **B.**  
696 *NTN1* transcripts were monitored for their partitioning by RT-qPCR. Mann-Whitney test, \* p <  
697 0.05 (n = 3 (HepaRG), and n = 3 distinct PHH batches).

698

#### 699 **Figure 5**

700 **Poly(I:C) induces Staufen-1 relocalization and accumulation at endoplasmic reticulum,**  
701 **PDI-positive, sites.**

702 **A.** Representative immunofluorescence-based localization of PDI (red) and Staufen-1 (green).  
703 Nuclei were counterstained with Hoechst 33342. **B.** Number of Stau1-positive dots per cell and  
704 percentage of fibrillar Stau1-positive cells versus total cells are shown under resting or  
705 poly(I:C)-treated conditions. Mann-Whitney test after Shapiro-Wilk test (\* p < 0.05, n = 3  
706 independent experiments). **C.** Li diagrams and Li coefficient calculations for PDI and Staufen-  
707 1 colocalization quantification, respectively. Pixels present on the left and right sides of the y-  
708 axis, i.e., associated with negative and positive staining amplitude values, indicate exclusion  
709 and colocalization, respectively. Li coefficients were calculated using the JACop plugin from  
710 the ImageJ software (<http://rsb.info.nih.gov/ij/plugins/track/jacop.html>). Twenty random fields  
711 were acquired per biological sample, totaling 300-400 cells analyzed for each biological  
712 sample in a given single experiment (n = 3 independent experiments). **D.** Statistical  
713 assessment of the colocalization of PDI and Staufen-1. Red (PDI) and green (Stau1)  
714 fluorescence intensities were measured for each pixel along a 5µm line, using the Plot Profile

715 function of the ImageJ software. Spearman correlation coefficients for each couple of intensity  
716 values are indicated.

717

## 718 **Figure 6**

### 719 **Staufen-1 interacts with *NTN1* mRNA through its 5'UTR, and conditions *NTN1* transcript** 720 **relocalization and netrin-1 induction in proliferative HepaRG**

721 **A.** CLIP / Staufen-1 immunoprecipitation. HepaRG cell lysates derived from UV crosslinked  
722 monolayers were immunoprecipitated with naked, IgG control or anti-STAU1-coupled beads  
723 prior to elution and 1D SDS-PAGE. **B.** negative control (mitochondrial) transcripts, positive  
724 control [54] transcripts for STAU1 binding, and *NTN1* were quantified on immunoprecipitated  
725 materials relatively to inputs. Mann-Whitney test, \*\*\*  $p < 0.01$  ( $n = 5$  independent experiments).  
726 **C.** Filter binding assay. Biotin-labeled *NTN1* 5'UTR or HBV RNA epsilon loop at constant  
727 amounts were titrated for their ability to undergo trapping by the upper nitrocellulose membrane  
728 ('Nitro') or reach the lower nylon membrane ('N+') by increasing amounts of recombinant  
729 STAU1 protein. Corresponding quantification of HRP signals and obtained parameters are  
730 shown. **D.** Competition experiments using the filter assay approach. Pre-bound STAU1-*NTN1*  
731 5'UTR biotin(+) complexes were submitted to increased concentrations of unlabeled  
732 competitors (*NTN1* 5'UTR or HBV epsilon RNAs) and processed on both membranes.  
733 Corresponding quantification of HRP signals and obtained parameters derived from one  
734 representative experiment because of variability are shown ( $n = 5$  independent experiments).  
735 **E.** Impact of Staufen-1 depletion on netrin-1 induction was evaluated by immunoblotting. **F.**  
736 Adequate partitioning between cytosolic (C) and membrane (M) fractions was addressed by  
737 Western blotting on PDI (internal membrane contents) and caspase-3 (cytosolic contents).  
738 RIG-I (cytosolic location) was probed as a poly(I:C) activity and cytosolic control. **G.** *NTN1* was  
739 then quantified by RT-qPCR in both fractions. Mann-Whitney test, \*\* $p < 0.01$  ( $n = 3$   
740 independent experiments).

741

## 742 **Figure 7**

### 743 **Netrin-1 capture by a clinically used antibody dampens hepatic inflammation in mice.**

744 **A.** Hepatic netrin-1 levels were measured by western blotting. **B.** *NTN1* and indicated cytokines  
745 mRNAs levels were quantified by RT-qPCR using the *GUS* transcript as a reference. **C.**  
746 Percentage of positive live (DsRed) cells against CD45, CD11b, F4/80, Ly6C, CD3, CD8 and  
747 CD69 markers are indicated in the presence or absence of poly(I:C) and netrin-1 inactivation  
748 ( $n = 5-8$  mice per group).

749

## 750 **Figure 8**

751 **Netrin-1 is a pro-inflammatory factor up-regulated upon inflammation by exclusive**  
752 **translational activation or Staufen-1 dependent regulation processes in the liver.**

753 Poly(I:C) drives netrin-1 upregulation in hepatocytes through translational activation or  
754 Staufen-1-mediated accumulation to the ER membrane. Poly(I:C) alters netrin-1 binding to the  
755 extracellular side of the membrane and potentiates its activity as a secreted soluble factor.  
756 Blocking netrin-1 signaling with NP137 reverses Kupffer cells activation and pro-inflammatory  
757 cytokine transcripts amounts in total liver extracts.

758

759 **Supplementary Figure 1.**

760 **In-house assessment of anti-netrin-1 antibody staining reliability.**

761 **A-B.** A panel of hepatocyte-like cell lysates derived from *NTN1* mRNA negative or positive  
762 cells was probed by RT-qPCR and netrin-1 Western blotting, respectively, using the Abcam  
763 reference Ab126729. **C-D.** Crispr/Cas-9 engineered netrin-1 KO HepaRG cells and *NTN1*  
764 siRNA-treated HEK293T cells, respectively, were subjected to anti-netrin-1 immunoblotting  
765 using the same antibody.

766

767 **Supplementary Figure 2.**

768 **Sequential extraction method.**

769 Phase contrast microscopy of sequential extraction steps are shown for HepaRG cells. **A.** After  
770 stripping the intact cells of their cytoplasm (left panel) and then of their internal membrane  
771 contents (center), only nuclei remain visible as attached to the plastic dish (right panel, **B**).

772

773 **Supplementary Figure 3.**

774 **Netrin-1 protein levels and transcripts are not correlated in human liver tissues.**

775 HBV-infected liver tissues (clinico-biological features listed in supplementary table 1) RNA data  
776 are stratified in a sample specific manner.

777

778 **Supplementary Figure 4.**

779 **Poly(I:C) activity assessment in mice.**

780 **A.** ALT activity was monitored in the serum of the same mice challenged with poly(I:C). n = 10  
781 females and 10 males, +/- poly(I:C), corresponding to 40 animals. \* p < 0.05, \*\* p < 0.01, Mann-  
782 Whitney test after Shapiro-Wilk test. ULN, upper limit of normal values. **B.** C57BL/6J mice were  
783 challenged with poly(I:C), their liver harvested, and total RNA extraction processed for RT-  
784 qPCR on inflammation-related transcripts. Corresponding canonical markers of inflammation  
785 activation (*IL1B*, *IL6*, *CXCL10*, *KC* (ortholog of *hIL8*)) were monitored.

786

787 **Supplementary Figure 5.**

788 **Dot blot quantification of netrin-1 using in-house validated anti-netrin-1 antibody.**

789 **A.** Ponceau staining was used as a loading reference. N = 10 females and 10 males, +/-  
790 poly(I:C), corresponding to 40 animals.

791

792 **Supplementary Figure 6.**

793 **Poly(I:C) does not alter cell viability in HepaRG and PHH.**

794 Viability was quantified by the Neutral Red assay. **A.** n = 3 (HepaRG); n = 3 distinct PHH  
795 batches, **B.** n = 3 (Netrin-1-KO and control Crispr/Cas-9 HepaRG). Mann-Whitney test (n.s.).  
796 **C.** Cells were treated with heparin overnight prior to harvesting (HepaRG, n = 3, n.s).

797

798 **Supplementary Figure 7.**

799 ***NTN1* total RNA and pmRNA levels are unaffected by poly(I:C) either in a time- or dose-  
800 dependent manner in HepaRG cells and in PHH.**

801 **A.** The levels of *NTN1* mRNA were quantified by RT-qPCR using *GUS* as an internal reference.  
802 Statistical significance was determined using the Mann-Whitney test. (n.s.). **B.** The levels of  
803 *NTN1* pre-mRNAs (intron 1) were quantified likewise. No amplification occurred when using  
804 heat-inactivated RT (green square). Mann-Whitney test (n.s.). n = 3 independent experiments  
805 (HepaRG); n = 3 distinct PHH donors run in technical triplicates.

806

807 **Supplementary Figure 8.**

808 ***NTN1* transcription is not induced by poly(I:C) in HepaRG cells.**

809 **A.** The levels of *Ntn1* promoter-dependent Luciferase expression were evaluated using a *Ntn1*  
810 promoter (-1740; +1) Luc expressing plasmid. **B.** Quantification of *de novo* transcription of  
811 *NTN1* using a run-on assay. Mann-Whitney test (\* p < 0.05).

812

813 **Supplementary Figure 9**

814 ***NTN1* mRNA splicing remains unaffected by poly(I:C).**

815 **A.** *NTN1* mRNA over pmRNA ratios were calculated. Mann-Whitney test (n.s.). n = 3  
816 independent experiments (HepaRG), and n = 3 distinct PHH batches run in technical  
817 triplicates.

818

819 **Supplementary Figure 10**

820 ***NTN1* transcript stability is not regulated by poly(I:C).**

821 HepaRG cells were treated with poly(I:C) for 48hrs before adding the RNA polymerase II  
822 inhibitor triptolide to the medium and harvesting cells at different time points to quantify *NTN1*  
823 and *c-fos* (*FOS*) by RT-qPCR. **A.** Total mRNA integrity throughout the experimental time-  
824 course was monitored using the Bioanalyzer device. **B.** *c-fos* levels collapse was used as a

825 control for assessing triptolide activity. **C.** *NTN1* transcript decay rate in control and poly(I:C)-  
826 treated conditions was calculated. n = 3 independent experiments. Mann-Whitney test (n.s.).

827

### 828 **Supplementary Figure 11**

829 **Poly(I:C) does not alter the functionality of the hepatocytic secretory pathway using**  
830 **A<sub>1</sub>AT as a hepatocyte-specific major cargo.**

831 **A.** HepaRG cells were transfected with A<sub>1</sub>AT-GFP bearing plasmids in biotin-free medium and  
832 treated or not with poly(I:C). **B.** GFP and giantin colocalization were then estimated in a time  
833 course assay after the addition of biotin to the medium (means of n = 2 independent  
834 experiments are shown). Mann-Whitney test (n.s.).

835

### 836 **Supplementary Figure 12**

837 **Netrin-1 protein stability is not modified by poly(I:C)**

838 Cells were treated by poly(I:C) for 48 hours and with cycloheximide at 48 hours to stop  
839 translation. **A.** Cells and supernatants were then harvested and total netrin-1 pools  
840 immunoprecipitated before immunoblotting with netrin-1 antibody. **B.** Densitometry was  
841 performed to evaluate protein amounts (n = 6 independent experiments).

842

### 843 **Supplementary Figure 13**

844 **Netrin-1 induction in differentiated HepaRG cells relies on relocalization of the *NTN1***  
845 **transcript.**

846 **A.** Netrin-1 expression levels were evaluated by immunoblotting using an anti-netrin-1  
847 antibody. Inflammation induction was verified using anti-RIG-I antibody. **B.** *NTN1* expression  
848 levels were quantified by RT-qPCR. Mann-Whitney test (n.s.). **C.** Differentiated HepaRG were  
849 treated with cycloheximide, scraped, lysed and loaded atop of a linear sucrose gradient prior  
850 to isopycnic ultracentrifugation. Representative profile of UV gradient traces is shown. **D.** *NTN1*  
851 distribution profile across the gradient was identified by RT-qPCR. **C-D.** An EDTA release  
852 control assay was performed by adding EDTA to lysates immediately before ultracentrifugation  
853 (green values). **E.** Percentages of polysomal *NTN1* transcripts versus total are shown (n = 3).  
854 Mann-Whitney test (n.s.). **F.** Adequate partitioning was addressed by western blotting on PDI  
855 (internal membrane contents) and caspase-3 (cytosolic contents). RIG-I (cytosolic location)  
856 was probed as a poly(I:C) activity control. **G.** *NTN1* transcripts were monitored for their  
857 partitioning by RT-qPCR. Mann-Whitney test, \* p < 0.05. (All data shown derive from n = 3  
858 independent experiments).

859

### 860 **Supplementary Figure 14**

861 **Inflammation mobilizes netrin-1 from its cell-associated pool.**

862 Netrin-1 KO Crispr/Cas9 HepaRG cells were pretreated with recombinant netrin-1 (previously  
863 in-house validated for activity [9]) for 4 hours, and subsequently incubated with poly(I:C) for  
864 the indicated times. Cells were then submitted to total lysates- and IP-based immunoblotting  
865 for RIG-I as a poly(I:C) activity control and netrin-1. Tubulin and Ponceau staining were  
866 performed to ascertain purity of extracellular IP material. One experiment out of three is shown.  
867

868 **Supplementary Figure 15**

869 **Gating strategy for FACS experiment on mouse livers.**

870 Live cells singlets of interest were gated prior to CD45<sup>+</sup> sorting. Monocyte-derived  
871 macrophages are CD45<sup>+</sup> CD11b<sup>+</sup> Ly6G<sup>-</sup> F4/80<sup>lo</sup>. Kupffer cells are CD45<sup>+</sup> CD11b<sup>lo</sup> Ly6G<sup>-</sup>  
872 F4/80<sup>hi</sup>, and Ly6C<sup>+</sup> when pro-inflammatory.
