Abstract

A collision induced absorption (CIA) band has been measured near 6000 cm⁻¹ in a spectrum of 30 31 humidified CO_2 recorded by cavity ring down spectroscopy (CRDS) at low pressure (<1 atm). This 32 absorption adds a contribution to the H₂O+CO₂ continuum mostly originating from far wings of the CO₂ and H_2O resonance lines broadened by collisions with H_2O and with CO_2 , respectively. The observed 33 CIA corresponds to a simultaneous excitation of ${}^{12}CO_2$ and H_2O colliding molecules in the v_3 34 antisymmetric and v₁ symmetric stretching mode, respectively. CRDS spectra recorded near 5940 cm⁻ 35 36 ¹ with a highly enriched ¹³CO₂ sample provide a confirmation of the assignment since the measured CIA isotopic spectral shift (of about -68 cm⁻¹) coincides with that between the v_3 bands of ${}^{12}CO_2$ and 37 38 ¹³CO₂. The integrated binary coefficient of the two CIA is evaluated and found to be on the order of 2.3×10⁻³ cm⁻²amagat⁻². Classical molecular dynamics simulations (CMDS) of the considered CIA are also 39 40 presented, based on the dominant dipole induction mechanism associated with the vibrational matrix 41 elements of the dipole of CO₂ (v_3) and isotropic polarizability of H₂O (v_1). The results of the calculations are found in good agreement with the observations, thus further validating the attribution of the 42 43 observed CIA structure to the above mentioned double transitions.

44

45 I. Introduction

The absorption of light by pure water vapor involves two contributions. The first one is the 46 47 monomolecular absorption due to the rovibrational resonance lines which is proportional to the water 48 vapor pressure. The second one, varying smoothly with the frequency, is the so-called water vapor self-continuum, which is proportional to the squared molecular density as it is due to interactions 49 50 between pairs of water molecules. There are three potential contributions to this continuum, which 51 include the far wings of the resonance lines, collision-induced absorption (CIA) by interacting pairs of 52 free (unbound) molecules, and dimers (note that the latter may be considered as a part of the CIA 53 since they also involve the dipole of a pair of molecules, even though in many cases they negligibly 54 contribute to it). Similarly, the absorption spectrum of pure carbon dioxide involves resonance lines and a self-continuum contribution again resulting from the three contributions mentioned above 55 56 generating absorptions proportional to the squared gas density. Numerous experimental and 57 theoretical studies have been devoted to the self-continua of both H_2O and CO_2 (see [1] and chapters 58 V and VI of [2]) due to their importance for radiative transfer processes in the atmospheres of the Earth 59 and Venus, respectively.

60 However, the self-continua are not the only continua relevant for planetary applications. Since 61 planetary atmospheres are mixtures of various molecular species, there are additional "crossed" 62 absorption contributions, proportional to the product of the densities of the different colliding 63 molecules. This leads to non-additive absorption as for example in the Earth atmosphere in which the 64 H_2O - and CO_2 -air (or N_2) continua play, together with the H_2O self-continuum, a significant role which 65 has motivated a large number of studies (see [1] and chapters V and VI of [2]). Note that, until recently, it was generally considered that the associated atmospheric continua were essentially due to the far 66 67 wings of the air-broadened lines of H₂O and CO₂. The recent demonstration of the importance of an 68 N_2 absorption band induced by collisions with H_2O in the H_2O-N_2 continuum [3,4] pointed out the limits 69 of this assumption.

70 Due to its potential importance for the atmospheres of Early Mars and exoplanets, the 71 continuum in H₂O-CO₂ mixtures has recently received a renewed attention, nearly 30 years after 72 pioneer studies devoted to the CO₂-broadened line wings of H₂O for Venusian studies [5,6]. 73 Measurements and calculations have been made in order to characterize the influence of collisions 74 with H_2O on the wings of CO_2 lines [3,7,8] as well as that of collisions with CO_2 on the wings of H_2O 75 lines [7,9]. It is worth mentioning that the importance of non-additivity effects in absorption in 76 H_2O+CO_2 mixtures (in particular, those related to weak simultaneous transitions – see below) was first 77 discussed by Vigasin et al. in 1994, on the basis of infrared absorption spectra of moisture-containing 78 CO_2 in the liquid and gaseous phases [10].

79 Very recently, we have undertaken a series of measurements aiming to characterize the 80 absorption continuum of H₂O-CO₂ mixtures in the 1.6 μ m and 2.3 μ m windows and near 3.5 μ m, 81 corresponding to low opacity regions for both CO₂ and water vapor [11]. The "crossed" absorption 82 (proportional to the product of the H₂O and CO₂ densities) was observed to include an unexpected broad band, centered near 6000 cm⁻¹, in addition to the contributions of the far wings of the lines of 83 the monomers (note that pure CO_2 spectra do not exhibit any CIA band in this spectral region [12]). On 84 85 the basis of the spectral position of its center, this band was tentatively assigned to the simultaneous 86 collision-induced transitions involving a v_1 (Raman) excitation of H₂O and a v_3 (dipole absorption) 87 excitation of ${}^{12}CO_2$ [noted v₃(CO₂)+v₁(H₂O), hereafter] but no further analysis was made. Note that such 88 simultaneous transitions (sometimes also denoted as double transitions), resulting from the 89 polarization of one molecule (e.g. through a vibrational matrix element of the polarizability) by the 90 vibrating electric field of the collision partner (e.g. through a vibrational matrix element of the electric 91 dipole or quadrupole) have been observed (starting in the early 50's !) and analyzed for diverse molecular systems involving H₂ or N₂ (e.g. [13,14,15,16,17]), but also for pure CO₂ [18], CO₂-N₂ 92 93 [19,20,21,22,23] and CO₂-H₂ [24], to cite but a few. Also recall the pioneer work of Colpa and Ketelaar 94 [24] which set the theoretical bases for practical calculations of their integrated intensity.

95 In this paper, we revisit the $v_3(CO_2)+v_1(H_2O)$ CIA band both experimentally, by complementing 96 the natural CO_2 measurements reported in Ref. [11] by a new investigation using ${}^{13}CO_2$, and 97 theoretically, by using a simple induction model and molecular dynamics simulations. In the next 98 section, we summarize the conditions of the acquisition of the humidified CO₂ spectra by cavity ring down spectroscopy (CRDS). The different steps of the CIA retrieval by successive subtraction of the 99 100 different contributions from the measured spectra are also described in this section. In section 3, the 101 classical molecular dynamics simulations (CMDS) and the input data used for the prediction of the CIA 102 are described. The measured and calculated results are then presented and discussed in Sec. 4, before 103 concluding remarks (Sec. 5).

104

2. CRDS recordings and CIA retrieval

105 *2.1. Data acquisition*

The inherent sensitivity and baseline stability of cavity enhanced techniques make them particularly suitable to measure weak continua [25]. They, in particular, enable to use samples at subatmospheric pressure while traditional methods are generally combined with pressurized cells. This is crucial in the case of mixtures involving water vapor at room temperature, the limitation by the saturation pressure making accurate absorption measurements by FTS with long absorption pathlengths practically impossible in the atmospheric transparency windows. In contrast, measurements by CRDS and OFCEAS have recently led to accurate determinations of the self- and foreign (air)-continua of H₂O [26,27,28,29,30,31]. Another advantage of recordings at sub-atm pressures is that the contribution of local absorption transitions is easier to calculate and remove, since line-mixing effects may be disregarded and isolated line shapes can be used. For instance, CRDS was recently applied to the characterization of the O₂ CIA band at 1.27 µm both at NIST [32] and in our laboratory [33,34]. The use of low O₂ pressures enabled to minimize the impact of line mixing effects at no other control of the non-mixing effects.

120 The $v_3(CO_2)+v_1(H_2O)$ CIA band was observed in CRDS spectra of humidified CO₂ recorded in the 5725-6665 cm⁻¹ and 5856-5986 cm⁻¹ intervals, for natural CO₂ and ¹³CO₂ samples, respectively. 121 122 Distributed feedback (DFB) laser diodes were used as light sources, each of them covering a spectral range 20 to 30 cm⁻¹ wide by temperature variation. The cavity-ring down spectrometer used a 142 cm 123 124 long high finesse cavity fitted with two highly reflective dielectric mirrors. Ring down (RD) times were 125 of the order of 120 to 160 µs. Typically, ten RD times were averaged at each spectral step separated 126 by 0.005 cm⁻¹. A part of the laser light was sent into a wavelength meter (model 621-A IR from Bristol) 127 to monitor the laser frequency.

As detailed in Ref. [11], the spectra with natural CO₂ were recorded in flow regime using 128 129 H₂O+CO₂ mixtures with H₂O molar fractions between 3000 and 15000 ppmv. The gas flow of the 130 mixture (typically a few tens sccm inside the CRDS cavity) was produced using a commercial humidity 131 generator (from Omicron Technologies). The total pressure in the CRDS cavity was monitored by a 132 sensor from Edwards (1000 mbar full scale, accuracy 0.15 % of reading) and maintained at a fixed value 133 of 400 or 750 Torr with a solenoid valve and a software-based proportional integral loop acting on the 134 gas flow. The densities of CO₂ and H₂O (ρ_{CO_2} and ρ_{H_2O} , respectively) were obtained from the partial pressures and the cell temperature measured with a calibrated Pt100 sensor (2σ -uncertainty ±0.06°C) 135 136 fixed on the external wall of the cavity underneath the enveloping thermal insulation foam.

137 In the case of the recordings with humidified ${}^{13}CO_2$, the limitation of the gas consumption 138 (imposed by the cost of the ${}^{13}C$ enriched CO_2 tank) required to record the spectra in static regime. The 139 cell was thus first filled with about 6.5 Torr of water vapor and ${}^{13}CO_2$ (from Aldrich, 99 % ${}^{13}C$ 140 enrichment) was then added up to a total pressure of 400 Torr.

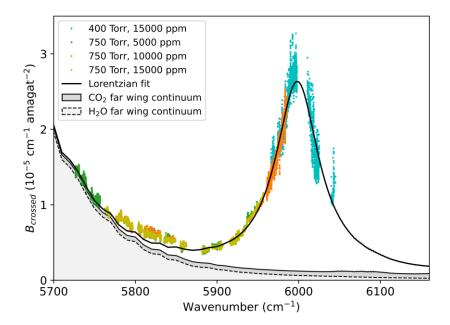

141 The baseline determination of the spectra relied on measurements performed with argon 142 before and after the recording with the (H₂O+CO₂) mixture, with the cavity pumped before each gas 143 filling (argon or mixture). The two argon spectra ensure that the cavity alignment (and thus the 144 baseline) is unchanged after pumping/filling cycles. By comparing the two argon spectra, the baseline 145 stability was found to be of the order of a few 10⁻¹⁰ cm⁻¹. In order to check the proportionality of the 146 retrieved "crossed" absorption to the $\rho_{CO_2}\rho_{H_2O}$ densities product, measurements were performed for 147 several values of the water molar fraction in natural CO₂. The study with ¹³CO₂ being mostly performed

- for validation of the assignment of the observed CIA structure, a single set of experimental conditions (~6.5 Torr of water vapor in 13 CO₂ at a total pressure of 400 Torr) was retained.
- 150 2.2. CIA retrieval
- 151 After baseline correction, the absorption coefficient, $\alpha(\nu)$, can be expressed as:

152
$$\alpha(\nu) = M_{CO_2}\rho_{CO_2} + M_{H_2O}\rho_{H_2O} + B_{CO_2}\rho_{CO_2}^2 + B_{H_2O}\rho_{H_2O}^2 + B_{crossed}\rho_{CO_2}\rho_{H_2O}$$
(1)

where $M_{CO_2}\rho_{CO_2}$ and $M_{H_2O}\rho_{H_2O}$ are the contributions due to the monomer local lines of CO₂ and H₂O (calculated within a ±25 cm⁻¹ range around the center wavenumber), respectively, and ρ represents the density (in amagat⁻¹). The B_{H_2O} and B_{CO_2} coefficients (in cm⁻¹amagat⁻²) correspond to the selfcontinuum coefficients of water and CO₂, respectively. $B_{crossed}$ is the crossed binary coefficient arising from the interaction of water and CO₂ molecules, thus involving both far line wings (of CO₂-broadened H₂O transitions as well as of H₂O-broadened CO₂ transitions) and CIA bands contributions.

159 In the case of natural CO₂, the HITRAN2016 database [35] was used to simulate the local CO₂ and H_2O monomer contributions with Voigt profiles truncated at ±25 cm⁻¹ excluding the pedestal of 160 the absorption lines (see details in Ref. [11]). The water self-continuum cross-sections B_{H_2O} were taken 161 from Ref. [30] while, for CO₂, the self-continuum cross-sections B_{CO_2} were taken from Ref. [12] or 162 measured in Ref. [11] below and above 5800 cm⁻¹, respectively. The $B_{crossed}$ binary coefficients 163 164 measured with the natural CO₂ sample for various water vapor molar fractions (from 3000 to 15000 ppm) and two total pressures (400 and 750 Torr) are presented in Fig. 1. While over the various 165 166 experimental conditions the $\rho_{CO_2}\rho_{H_2O}$ density product varied by a factor of 5, the set of retrieved $B_{crossed}$ values are found consistent within about 20 % in the CIA region near 6000 cm⁻¹. Fig. 1 also 167 168 includes a fit of the observed band, assuming a Lorentzian shape and fixing the far wing continuum 169 background to its value calculated by the χ -factor approach (see [11]). The parameters obtained from 170 this Lorentzian fit will be discussed in Sec. 4.

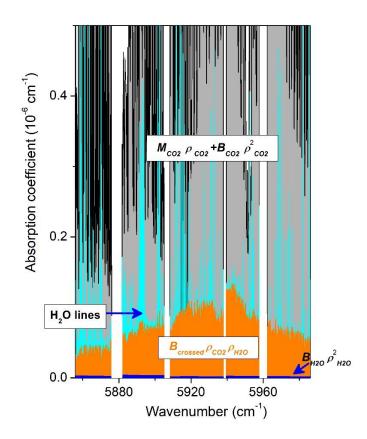

171

Fig.1: Overview of the binary coefficients measured in the 5725-6040 cm⁻¹ region including the $v_3({}^{12}CO_2)+v_1(H_2O)$ CIA band near 6000 cm⁻¹, for various total pressures and water vapor molar fractions. The best fit of the CIA using a Lorentzian function (black solid line) is superimposed to the far wing continuum background which was fixed to its value calculated by the χ -factor approach (see [11]).

176 In the case of humidified $^{13}CO_2$, the measurement of the CIA band is made more difficult because it falls in a region where CO₂ resonance lines are much stronger than with the natural sample. In order 177 to subtract the ¹³CO₂ contribution – $(M_{CO_2}\rho_{CO_2} + B_{CO_2}\rho_{CO_2}^2)$ in Eq. (1) – we did not try to simulate 178 179 separate contributions of the resonance lines and of the self-continuum of ¹³CO₂ and preferred to directly subtract a spectrum of dry ${}^{13}CO_2$ recorded at the same partial pressure of ${}^{13}CO_2$ as in the 180 humidified mixture used for the recordings (395 Torr). This, which disregards the effects of collisions 181 182 with H_2O on the central and wing regions of the ${}^{13}CO_2$ lines, is of likely small consequences considering 183 the relatively small (1.5%) amount of water vapor in the humidified sample. Fig. 2 shows the different contributions to the total absorption coefficient measured for a mixture of about 6 Torr of water in 184 ¹³CO₂ at a total pressure of 400 Torr. As adsorption on the walls of the CRDS affected the amount of 185 186 water in the cell, for the spectral interval corresponding to the tuning range of each DFB laser diode, 187 the water vapor partial pressure, p_{H_2O} , was determined from the integrated absorption coefficient of a few observed water lines. The obtained p_{H_2O} values were found to vary from 5.3 to 7.0 Torr for the 188 six DFB intervals covering the CIA region (5856-5986 cm⁻¹). These p_{H_2O} values were used to calculate 189 190 and subtract the water self-continuum [30] and the water resonance lines contribution (computed 191 using the HITRAN2016 line list [35]). As illustrated by Fig. 2, in our experimental conditions, the two water vapor contributions are much smaller than the ¹³CO₂ contribution. After subtraction of the 192 different contributions, the remaining absorption coefficient - $B_{crossed}\rho_{CO_2}\rho_{H_2O}$ - shows a clear bell 193 shape centered at about 5940 cm⁻¹ corresponding to the $v_3(^{13}CO_2)+v_1(H_2O)$ CIA band. Using the 194

determined p_{H_2O} values, the corresponding crossed binary coefficients, $B_{crossed}$, displayed in **Fig. 3** were derived. The obtained curve shows high frequency "noise" due to the imperfect removal of the strong ¹³CO₂ resonance lines. An improved description of the CIA band shape is obtained from a Lorentzian fit with a baseline (corresponding to the far wing continuum contribution) assumed to be constant with frequency. The parameters obtained from this fit will be discussed in Sec. 4.

200

201

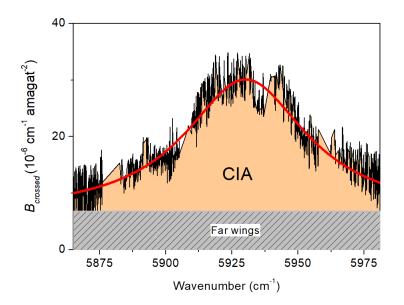

Fig. 2: Different contributions to the total absorption coefficient measured by CRDS with a mixture of water and
 CO₂ highly enriched in ¹³C. The total pressure was 402 Torr while the water vapor partial pressure varied between

204 5.3 and 7.0 Torr over the displayed region. The measured absorption coefficient is first reduced by the ${}^{13}CO_2$

205 contribution (lines and self-continuum - grey background) measured with a pure ${}^{13}CO_2$ sample. Then, the water

206 contribution (lines and self-continuum - cyan and blue background, respectively) is simulated and subtracted. The

207 absorption remaining after these subtractions (orange background) shows the bell shape profile of the $v_3({}^{13}CO_2)+v_1(H_2O)$ CIA band centered near 5930 cm⁻¹.

210Fig 3: Crossed binary coefficients in the region of the $v_3({}^{13}CO_2)+v_1(H_2O)$ CIA band. The best fit of the CIA Lorentzian211shape (red solid line) is superimposed to the continuum background due to the far wing continuum (dashed). The212background level was adjusted by the fit.

213

214 **3. Classical molecular dynamics simulations (CMDS)**

215 The CIA in the region of the $v_3(CO_2)+v_1(H_2O)$ simultaneous transitions was calculated using classical molecular dynamics simulations (CMDS), exactly as described in Ref. [3] for CO₂+H₂O, with the 216 217 only difference that the H₂O static isotropic polarizability matrix element $\langle v = 0 | \alpha_{iso}(H_2 0) | v = 0 \rangle$ 218 used in this previous study was here replaced by the vibrational matrix element $\langle v =$ 219 $0|\alpha_{iso}(H_20)|v_1=1\rangle$ (here, v=0 and $v_1=1$ stand for the (000) and (100) vibrational states of H₂O, 220 respectively). Since details on the CMDS can be found in Ref. [3] and references cited therein, only the 221 main elements are recalled here. The simulations start with the initialization, for each molecule, of its 222 center of mass position (inside a cubic box of dimensions defined by the gas density and total number 223 of molecules treated) and translational velocity vector, and of its angular orientation and rotational 224 angular momentum vector. These are set in order to verify the Boltzmann statistics for the considered 225 temperature. The propagation in time of these four molecular parameters is then computed using the 226 equations of classical mechanics fed by forces and torques due to intermolecular interactions 227 computed using the same input site-site CO₂-H₂O as in Ref. [3]. Periodic boundary conditions, nearest 228 neighbour spheres, the Verlet algorithm, and the quaternions approach [36] were used and about 5 229 million molecules were treated. After a temporization time of t_0 = 20 ps to let the system properly 230 thermalize, the dipole $\vec{\mu}_{ii}(t)$ induced in (*i*=CO₂, *j*=H₂O) colliding pairs was computed. As in Ref. [3], only 231 the component of the induced dipole due to the polarization of H_2O (through its isotropic polarizability $\langle v = 0 | \alpha_{iso}(H_2 0) | v_1 = 1 \rangle$) in the electric field of the CO₂ dipole (through $\langle v = 0 | \mu(CO_2) | v_3 = 1 \rangle$, 232 where v = 0 and $v_3 = 1$ stands for the $(v_1 v_2^{l_2} v_3) = (00^0 0)$ and $(00^0 1)$ vibrational states of CO₂, 233

234 respectively) was taken into account. This is convenient since the induced dipole – driven by the 235 $B_{1012}(R)$ term of Eq. (4.50) of [37] or the first term in Eq. (10) of Ref. [24] – then only depends on the 236 orientations of the CO₂ axis and of the vector between the centers of mass of the two molecules, and 237 is independent from the orientation of the H₂O molecule. Note that this disregards other induction 238 mechanisms, including the term originating from the anisotropic polarizability of the water molecule 239 (*i.e.* $\langle v = 0 | \Delta \alpha(H_2 0) | v_1 = 1 \rangle$). However note that, as discussed below, this contribution is likely 240 relatively small, while many other terms, such as those involving the product of the H₂O dipole element $\langle v = 0 | \mu(H_2 0) | v_1 = 1 \rangle$ and of the CO₂ polarizability $\langle v = 0 | \Delta \alpha(CO_2) \text{ or } \alpha_{iso}(CO_2) | v_3 = 1 \rangle$, vanish 241 due to symmetry considerations. As in Ref. [3], we used $\langle v = 0 | \mu(CO_2) | v_3 = 1 \rangle = 0.13$ a.u. [38, 39]. 242 243 For H₂O, $\langle v = 0 | \alpha_{iso}(H_2 O) | v_1 = 1 \rangle = 0.73$ a. u. was obtained, using the convention of Ref. [37], from the value of α_0^0 provided in Ref. [40] with $\alpha_{iso} = -\alpha_0^0/\sqrt{3}$. With the method and input data described 244 above, the induced dipole was computed from t_0 (= 20 ps) to $t_0 + \Delta t$ (= 5 ps) in the course of the CMDS. 245 246 Then its autocorrelation function was computed using t₀ as the time origin, averaged over all molecules 247 and Laplace-Fourier transformed to yield the absorption spectrum [41]. Note that our classical 248 calculations lead to a CIA structure that is automatically centered at the sum of the origins of the 249 v_3 (¹²CO₂) and v_1 (H₂O) bands, 2349+3657= 6006 cm⁻¹ for ¹²CO₂, because all the Q transitions of the H₂O 250 v_1 band, associated with the isotropic polarizability, then have the same imposed wavenumber of 3657 251 cm⁻¹. This, which leads to a difference of about +6 cm⁻¹ between the positions of the CIA peak in the 252 calculated and measured spectra, does not correspond to reality since the $(v = 0, J, K_a, K_c) \rightarrow$ 253 $(v_1 = 1, J, K_a, K_c)$ rovibrational transitions are all shifted to the red with respect to the band origin 254 of 3657 cm⁻¹ and spread over typically 10 cm⁻¹ [35]. In order to correct for this, the bar spectrum of the 255 true Q lines was convoluted by the raw CMDS-predicted CIA, which red-shifts the peak wavenumber by about -6 cm⁻¹ with respect to 6006 cm⁻¹, leading to a very good agreement with the experimental 256 findings as discussed below. In the case of ¹³CO₂, CMDS were computed as done for ¹²CO₂, using the 257 same value of $\langle v = 0 | \mu(CO_2) | v_3 = 1 \rangle$ [42,43], but a change of the v₃ band origin from 2349 to 2283 258 259 cm⁻¹.

260

261 4. Results and discussion

As said above, the ${}^{12}CO_2$ and ${}^{13}CO_2$ CIA bands as obtained from experiments were fitted assuming a Lorentzian band shape (see **Figs. 1** and **3**). In the case of the main isotopologue, the underlying far wing continuum was fixed to its value calculated by the χ -factor approach (see [11]). In the case of ${}^{13}CO_2$, the baseline was assumed to be constant with frequency and it was adjusted by the fit. The CMDS-computed spectra for ${}^{12}CO_2$ and ${}^{13}CO_2$ were fitted by a Gaussian function to determine the center position, their integration over wavenumber yielded the intensities, and the widths were 268 determined directly from the computed absorptions. The experimental and calculated centers, 269 integrated areas and half-widths at half-maximum (HWHM) are listed in Table 1, calling for several 270 remarks. The first is that the peak positions obtained for the measured spectra and from those computed using CMDS (corrected as explained in Sec. 3 to take the H₂O Q lines true quantum positions 271 272 into account) agree very well. The measured and calculated differences between the ¹²CO₂ and ¹³CO₂ values, of about 68 cm⁻¹, are in close agreement with the isotopic shift of the $v_3 = 1$ vibrational levels 273 of the two isotopologues (66 cm⁻¹) [44]. The second is that the measured and computed integrated 274 275 intensities also coincide, with differences well smaller than the experimental uncertainty (roughly estimated to 20 % and 30 % for ¹²CO₂ and ¹³CO₂, respectively). The integrated band intensities for the 276 277 two isotopologues are close, as could be expected from the fact that the CO₂ dipole matrix elements are practically identical [42,43]. Finally, the experimental and predicted HWHM are again consistent, 278 both showing a negligible isotope effect, as could be expected from the strong similarity between ¹²CO₂ 279 and ¹³CO₂. 280

284

A comparison between the measured and computed H₂O-¹²CO₂ density-normalized absorption 285 286 coefficients over the spectral range of the 1.6 µm window is displayed in Fig. 4. The calculated spectrum was obtained by adding the CIA predicted in the present study to the contributions of the 287 288 far wings of the H₂O-broadened transitions of CO₂ and of the CO₂-broadened lines of H₂O. The 289 associated values of the binary coefficients, $B_{CO_2-H_2O}$ and $B_{H_2O-CO_2}$, were calculated with the χ -factor 290 approaches developed in Refs. [8] and [9] respectively. As can be seen, the agreement is quite satisfactory which validates the prediction of all three contributions. However there is a noticeable 291 292 discrepancy between measured and computed values on the low frequency side of the CIA peak which 293 may be explained by the neglecting of the contribution of the anisotropic polarizability $\Delta \alpha$ of H₂O in 294 the CMDS computation of the collision-induced dipole. Indeed, first note that, since $\langle v =$ $0|\Delta\alpha(H_20)|v_1 = 1\rangle = 0.54$ a.u. (obtained from the value of α_0^2 provided in Ref. [40] and $\Delta\alpha =$ 295 $\sqrt{3/2} \alpha_0^2$) which is smaller than $\langle v = 0 | \alpha_{iso}(H_2 0) | v_1 = 1 \rangle = 0.73$ a. u. by a factor of about $\sqrt{2}$, the 296 297 integrated intensity due to this dipole induction mechanism should be about 2 times lower. In addition, the anisotropic polarizability selection rule allows not only Q but also O and S lines associated with J 298 299 \rightarrow J±2 transitions, the latter being spread over a broad spectral range of several 100 cm⁻¹ on both sides

of the central vibrational frequency. In summary, this contribution, which is weaker and spectrally
 much broader than that of the isotropic polarizability, may explain the above mentioned missing
 "background".

303

Fig 4: Crossed binary coefficients in the region of the $v_3({}^{12}CO_2)+v_1(H_2O)$ CIA band. The CIA predicted by CMDS calculations (blue) is added to the sum of the H_2O (light grey) and CO_2 (grey) far wing continua. Also shown are the smoothed experimental values from Ref. [11] (red, with a 1 σ error band).

308 It is worth mentioning that the $v_3(CO_2)+v_1(H_2O)$ CIA band presently measured in the gas phase 309 at sub-atmospheric pressure was pointed out nearly three decades ago in liquid CO₂+H₂O mixtures, 310 thus at considerably higher molecular densities [10]. Low resolution spectra were recorded with 311 grating spectrographs allowing for an estimation of the integrated absorption cross-section. A value of 8×10⁻⁴ cm⁻²amagat⁻² was estimated in the liquid phase, about three times smaller than our gas phase 312 value (2.6×10^{-3} cm⁻² amagat⁻²). Note that a similar tendency between liquid and gas phase CIA 313 314 intensities (normalized to squared density) was reported for the far-infrared CIA of pure CO₂ [45]. Let 315 us also mention that the simultaneous CO₂-H₂O transitions investigated in the present study have many 316 points in common with those of CO_2-H_2 observed and analyzed more than sixty years ago in [24]. 317 Indeed, both involve the $v_3 CO_2$ dipole and a vibrational change of the other molecule through the 318 polarizability.

In general, free collisions are believed to bring most of the contribution to CIA bands, except at (very) low temperature, while H₂O-CO₂ bound complexes, which are disregarded in the CMDS, are not expected to contribute significantly to the observed absorption feature. This seems reasonable at the room temperature of this study considering the expected very small portion of bound dimers. The agreement between the measured and CMDS integrated band intensities seems to confirm this 324 expectation. The H_2O-CO_2 bound complex which has been observed in matrices (e.g. [46]) and in 325 expansion jets (e.g. [47,48]) has a planar T-shaped structure with hydrogens pointing away from CO₂. The dissociation energy D_0 was estimated to be about 730 cm⁻¹ [49,50]. It is worth mentioning the 326 results of anharmonic vibrational calculations of the spectrum of this Van der Waals complex [51], 327 328 based on ab initio force field and electro-optical parameters. As expected, most of the predicted vibrational bands of the H₂O-CO₂ complex fall in coincidence with those of pure H₂O or CO₂ but, 329 330 interestingly, Pavlyuchko et al. concluded their article by noting that "...the combination transition $v_{OH}^{s} + v_{CO}^{as}$ [e.g. $v_{3}(CO_{2})+v_{1}(H_{2}O)$] in the vicinity of ~ 6000 cm⁻¹, falls occasionally in the 331 332 regions of relative transparency of both isolated monomers and can therefore be discriminated from 333 the monomer absorption" [51]. Although our observation cannot be interpreted as an absorption band of the H₂O-CO₂ bound complex, the above statement about the detection of simultaneous transitions 334 335 applies to the CIA in (H_2O+CO_2) gas mixtures.

5. Conclusion

337 The present study, thanks to measurements and classical molecular dynamics calculations made 338 for both ¹²CO₂-H₂O and ¹³CO₂-H₂O mixtures, has confirmed that the band observed around 6000 cm⁻¹ 339 in Ref. [11] is indeed due to the dipole induced in interacting (CO_2 , H_2O) pairs through the 340 $v_3(CO_2)+v_1(H_2O)$ simultaneous transitions, involving a $\Delta v_3 = 1$ change of CO₂ through the dipole and a 341 $\Delta v_1 = 1$ change of H₂O through the polarizability. It is worth emphasizing that this is the first demonstration of a purely collision-induced absorption contribution to the binary continuum in CO_2 + 342 343 H₂O gas mixtures, which was so far entirely attributed to the far line wings of the dipole transitions of 344 CO_2 broadened by H_2O and of H_2O broadened by CO_2 .

345 Note that other simultaneous transitions in H₂O+CO₂ gas mixtures exist which may be 346 detectable, since centered in some relatively transparent regions of the H₂O+CO₂ spectrum, and thus deserve investigation. The first $[v_3(CO_2)+v_3(H_2O)]$ is similar to the one studied in this paper, but in which 347 348 a H₂O v_3 Raman vibrational change is involved, which would lead to a CIA centered around 6105 cm⁻¹. 349 This CIA is expected to be small and broad, since $\langle v = 0 | \alpha_{iso}(H_2 0) | v_3 = 1 \rangle = 0$ [40] and thus only the $\langle v = 0 | \Delta \alpha(H_2 0) | v_3 = 1 \rangle$ matrix element contributes. Another contribution comes from the 350 $v_2(CO_2)+v_1(H_2O)$ transition, involving, among others, the contributions of the products $\langle v = v_1 \rangle = 0$ 351 $0|\Delta\alpha(H_20)$ and $\alpha_{iso}(H_20)|v_1=1\rangle\langle v=0|\mu(CO_2)|v_2=1\rangle$, which for ¹²CO₂ should peak near 4334 352 cm⁻¹. The associated CIA band is expected to be less intense than the one investigated in this study due 353 to the smaller central wavenumber and weaker CO₂ dipole matrix element ($\langle v = 0 | \mu(CO_2) | v_2 = 1 \rangle =$ 354 355 0.071 a.u. [38,39]). For completeness, note that two other simultaneous transitions should appear 356 around 2900 cm⁻¹, $v_1(CO_2)+v_2(H_2O)$ and $2v_2(CO_2)+v_2(H_2O)$, associated with the polarization of CO₂ by the dipole of H₂O, through the product $\langle v = 0 | \Delta \alpha(CO_2) \text{ and } \alpha_{iso}(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_2 = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_1 = 1 \text{ or } v_2 = 2 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_2 = 0 | \Delta \alpha(CO_2) | v_2 = 0 \rangle \langle v = 0 | \Delta \alpha(CO_2) | v_2 = 0 \rangle$ 357 358 $0|\mu(H_20)|v_2 = 1\rangle.$
