1 **Abstract**

2 The *Leptodactylus melanonotus* species group is an anuran clade widely distributed in the
3 Neotropics. This clade harbours many species that are difficult to identify because of
4 incomplete taxonomic knowledge, ambiguous species boundaries and distribution. Here,
5 we expand the understanding of species diversity of this *Leptodactylus* clade by analysing
6 mtDNA sequences for over 600 individuals, delimiting operational taxonomic units
7 (OTUs), and updating species identifications and distributions by linking sequences to
8 morphotypes and calls. Also, we review the morphological and acoustic traits traditionally
9 used as diagnostic characters of species within this group. The DNA-based species
10 delimitation analyses yielded 57 OTUs. Given that only 19 taxa are currently recognised as
11 valid species, our results suggest the existence of many unnamed species within the *L.*
12 *melanonotus* group. After reassessing morphological traits in the group, we concluded that
13 the combined use of dorsolateral fold, upper lip stripe, and belly colouration is sufficiently
14 informative for species identification in most cases, especially when associated with data
15 on geographic distribution and habitat use. Regarding advertisement calls, the patterns of
16 amplitude and frequency modulation, calling rate, dominant frequency, and frequency
17 modulation were also informative for species discrimination. Furthermore, we designate a
18 neotype for *L. wagneri*, for which we also describe the advertisement call, make
19 comparisons with congeners of the *L. melanonotus* group, especially with the partially
20 sympatric *L. leptodactyloides*. Lastly, we name and describe a new species endemic to the
21 Eastern Guiana Shield. Patterns of distribution and habitat use in the *L. melanonotus* group
22 revealed that sympatric occurrences are more commonly found among distantly related
23 species, whereas allopatric occurrences correspond to closely related ones. Speciation

1
2
3
4 24 between closely related species of the group seems to be related to ecological divergence
5
6 25 (open vs. forest habitats) in parallel with clear morphological and acoustic differentiation.

32 **Introduction**

33 With more than 8,400 currently recognised extant species (Frost, 2022), amphibians are a
34 species-rich group of terrestrial vertebrates, whose species discovery rate has increased
35 dramatically over the past decades (e.g., Köhler et al., 2005; Tapley et al., 2018; Streicher
36 et al., 2020) compared to other vertebrate groups (Miralles et al., 2020). This is particularly
37 true in South America, with no less than 1,410 species of amphibians described over the
38 past two decades (Rivera-Correa et al., 2021). Despite this acceleration in the number of
39 new species descriptions, there is a large number of amphibian species in the Neotropics
40 that remain undescribed, notably in Amazonia (Vacher et al., 2020). The rising rate of new
41 species descriptions has been leveraged mainly by the increased use of DNA-sequence data
42 in concert with morphology and, at least for anurans, bioacoustics (Rivera-Correa et al.,
43 2021). This practice has allowed species delimitations within groups that have been
44 taxonomically neglected for a long time, in many cases because of their overall
45 conservative morphology, which was traditionally considered too complex to analyse. This
46 was for example the case of the anuran genus *Adenomera*, containing 29 species of which
47 half of its species richness being described in the last decade. The taxonomy of *Adenomera*
48 frogs has benefited from the combined use of multiple sources of information (Fouquet et
49 al., 2014; Carvalho et al., 2021).

50 Another example of taxonomically neglected anuran clade with notoriously difficult
51 morphological identification is the *Leptodactylus melanonotus* species group. It contains 19
52 currently recognised species with considerable uncertainties in species boundaries and
53 distribution, and thus, in total species richness (Vacher et al., 2020; Gazoni et al., 2021).

1
2
3
4 54 Members of the *L. melanonotus* group are semi-aquatic frogs distributed from the Pacific
5
6 55 lowlands of Mexico [*L. melanonotus* (Hallowell, 1861)] to central north Argentina [*L.*
7
8 56 *podicipinus* (Cope, 1862)]; see Heyer (1994) for details on distribution and natural history.
9
10
11 57 The taxonomy of this *Leptodactylus* species group has been considered challenging due to
12
13 58 the high degree of intraspecific variation in morphological traits and the taxonomic
14
15 59 ambiguities of several nominal taxa. Since the phylogenetic study of *Leptodactylus*
16
17 60 published by de Sá et al. (2014), the phylogenetic relationships of species within the *L.*
18
19 61 *melanonotus* group and the taxonomic identity of the Amazonian *L. petersii* (Steindachner,
20
21 62 1864) were addressed, with the revalidation of its junior synonyms, *L. brevipes* Cope, 1887
22
23 63 and *L. intermedius* Lutz, 1930 (Gazoni et al., 2021). Nevertheless, many species of the *L.*
24
25 64 *melanonotus* group still lack an objective definition by linking morphological and acoustic
26
27 65 variation to molecular lineages.
28
29
30

31
32 66 Of particular taxonomic relevance are the species names assigned to populations of
33
34 67 the *L. melanonotus* group distributed in the Eastern Guiana Shield (EGS), north-eastern
35
36 68 Amazonia. There are four distinct morphotypes recognised in the EGS and associated with
37
38 69 species names: *L. intermedius*, *L. nesiotus* Heyer, 1994, *L. petersii*, and *L. validus* Garman,
39
40 70 1888 (Heyer, 1994; Jairam & Fouquet, 2018). In addition to these, a candidate new species
41
42 71 has been repeatedly reported from the EGS, referred to as several combinations: *L.*
43
44 72 *leptodactyloides* (Lescure & Marty, 2000; Ouboter & Jairam, 2012), *L. aff. leptodactyloides*
45
46 73 (*L. gr. podicipinus* C (Dewynter et al., 2008), *L. gr. podicipinus* C (Dewynter et al., 2020), *L. gr. wagneri* C
47
48 74 (Fouquet et al., 2012), *L. gr. wagneri* G-E-F (Fouquet et al., 2007), *L. gr. podicipinus* 2
49
50 75 (Fouquet et al., 2015), *L. sp. gr. podicipinus* (Fouquet et al., 2019), *Leptodactylus* sp.
51
52 76 Guiana (Vacher et al., 2020). Even though the names *L. leptodactyloides* (Andersson, 1945)
53
54
55
56
57
58
59
60

1
2
3
4 77 and *L. wagneri* (Peters, 1862) have also been applied to populations in the region (see
5
6
7 78 Lescure & Marty, 2000; Ouboter & Jairam, 2012), these two species were described from
8
9 79 Ecuador. The only type specimen linked to the name *L. wagneri* by Peters (1862) was
10
11 80 collected from the west side of the Andes of Ecuador, according to the original description.
12
13 81 Heyer (1970, 1994) reported this holotype as lost and changed, tentatively, the type locality
14
15 82 to ‘Pastassa’ (= Pastaza) in Amazonian Ecuador. In the original description of *L.*
16
17 83 *leptodactyloides*, its type locality was vaguely stated as ‘Río Pastaza’ in Ecuador
18
19 84 (Andersson, 1945). Because the Pastaza River stretches in Ecuador along 250 km, with an
20
21 85 elevation range from 1,900 m to 250 m, the exact location of the type locality of both *L.*
22
23 86 *wagneri* and *L. leptodactyloides* remain uncertain. *Leptodactylus leptodactyloides* was
24
25 87 synonymised with *L. wagneri* by Heyer (1970), but revalidated by Heyer (1994) when he
26
27 88 noted that these two names were originally associated with two distinct morphotypes in
28
29 89 western Amazonia.
30
31
32
33

34 90 In this review, we delimit Operational Taxonomic Units (OTUs) based on a
35
36 91 mitochondrial DNA dataset and re-evaluate species boundaries and distribution patterns of
37
38 92 the *L. melanonotus* species group based on congruence between the mtDNA-based species
39
40 93 delimitation and morphological and acoustic characters for 16 of 19 nominal species, plus
41
42 94 the putative new species from the EGS. Additionally, we reassess the taxonomic status and
43
44 95 geographic range of *L. wagneri* and *L. leptodactyloides* based on data from the type locality
45
46 96 region, the Pastaza Valley in Ecuador, and several other populations across Amazonia,
47
48 97 including the designation of a neotype for *L. wagneri*. In elucidating the taxonomic status
49
50 98 of nominal species in Amazonia, we confirm that populations from the EGS represent a
51
52 99 separate species, which is named and described herein as a new species.
53

2
3
4 1005
6
7 101 **Materials and methods**8
9 102 **Field data collection**

10
11 103 Extensive fieldwork focusing on the collection of specimens, tissue samples, and
12
13 104 advertisement calls of members of the *L. melanonotus* group has been conducted
14
15 105 throughout South America since the early 2000s by some of us and complementary
16
17 106 information was obtained from species housed in many herpetological collections and
18
19 107 sound archive repositories (see Fig. 1 and Tables S1–S2 for localities).
20
21
22

23 108

24
25 109 **Species delimitation, genetic diversity, and phylogenetic analysis**

26
27 110 We first delimited all major mtDNA lineages using a total of 624 partial sequences of the
28
29 111 16S rRNA gene, essentially comprising the entire geographic range of the *L. melanonotus*
30
31 112 group (see Table S1 for the molecular dataset and Appendix S1 for molecular data
32
33 113 acquisition). We obtained new 16S sequences for 181 specimens of the *L. melanonotus*
34
35 114 species group (Table S1), obtained through fieldwork and loans from collaborators. We
36
37 115 also retrieved homologous sequences from GenBank assigned to species of the *L.*
38
39 116 *melanonotus* group (441 accessions; Table S1). We added two terminals as outgroups: a
40
41 117 representative of the *L. latrans* group (*L. macrosternum* Miranda-Ribeiro, 1926), the sister
42
43 118 clade of the *L. melanonotus* group; and a representative of the *L. fuscus* group (*L.*
44
45 119 *notoaktites* Heyer, 1978), the sister clade of the other *Leptodactylus* species groups (de Sá
46
47 120 et al., 2014). All but five occurrence records were georeferenced (five NCBI sequences
48
49 121 lacked spatial information which could not be traced back) and used to create distribution
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4 122 maps with convex polygons using QGIS 2.14. DNA sequence alignment was conducted on
5
6 123 the MAFFT online server under the E-INS-i option with default parameters (Katoh &
7
8 124 Standley, 2013; Katoh et al., 2019). The final alignment was 1,727 bp long, but was
9
10 125 trimmed at both ends down to 613 bp for which more than 50% of the sequences were
11
12 126 complete (Appendix S2).

13
14
15 127 We applied three DNA-based single-locus species delimitation approaches: (a) a
16
17 128 distance-based method, the Automated Barcode Gap Discovery (ABGD; Puillandre et al.,
18
19 129 2012); (b) a single-threshold coalescent-based method, the Generalized Mixed Yule
20
21 130 Coalescent approach (single threshold GMYC; Monaghan et al., 2009; Pons et al., 2006);
22
23 131 and (c) a Poisson Tree Processes model approach (PTP; Zhang et al., 2013). The ABGD
24
25 132 delimitation was performed with a prior of intraspecific divergence P between 0.001 and
26
27 133 0.1, a proxy for minimum relative gap width, X , of 1, and a number of steps n equal to 30.
28
29 134 We kept the partition such that $P = 0.0129$, because it corresponded to the end of a plateau
30
31 135 for group number and it is close to the 1% threshold of intraspecific divergence proposed in
32
33 136 other vertebrates' delimitation studies using 16S barcodes (Puillandre et al., 2012).
34
35 137 Moreover, lower thresholds suggested an unreasonable number of OTUs and higher
36
37 138 thresholds clustered together well-diagnosable described species. For PTP delimitation we
38
39 139 first reconstructed a ML tree with RAxML v.8.2.4 (Stamatakis, 2014) using the GTR + Γ
40
41 140 model. The PTP delimitation was undertaken on the rooted tree, with 5 million Markov
42
43 141 chain Monte Carlo (MCMC) iterations, sampling every 1,000th iteration and discarding the
44
45 142 initial 20% iterations as burn-in. For the GMYC delimitation, we reconstructed a time-
46
47 143 calibrated phylogeny using BEAST 2.5.2 (Bouckaert et al., 2014). We used a birth and
48
49 144 death population model to account for extinction processes and incomplete sampling,
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4 145 including the same out-groups used in the RAXML reconstruction. We used a single
5
6 146 partition with a GTR + Γ + I substitution model, with an uncorrelated relaxed lognormal
7
8 147 clock model of rate variation among branches (Drummond et al., 2006). The root age,
9
10 148 corresponding to the common ancestor of *Leptodactylus*, was estimated based on the time-
11
12 149 calibrated phylogeny of Feng et al. (2017) and was consequently constrained with a normal
13
14 150 prior distribution (Mean = 25.7 mya, SD = 2). We consider it the best prior because Feng et
15
16 151 al. (2017) included an extensive dataset of nuclear loci for a large set of anurans and used
17
18 152 many reliable fossils as calibration points. For the MCMC parameters, we used four
19
20 153 independent chains of 100 million iterations, recording every 1,000th iteration and
21
22 154 discarding the first 10% iterations as burn-in.
23
24
25
26

27 155 We combined the log and the tree files of the independent runs using LogCombiner
28
29 156 2.5 discarding the first 20% iterations as burn-in (Bouckaert et al., 2014) and checked the
30
31 157 convergence of our parameters, confirmed by all ESS being above 100. Then, we extracted
32
33 158 the maximum clade credibility tree using Tree annotator 2.5 (Bouckaert et al., 2014)
34
35 159 reducing the number of trees ten times. We performed a GMYC delimitation on the
36
37 160 ultrametric tree using the GMYC function of the R package ‘splits’, version 1.0-11/r29
38
39 161 (Ezard et al., 2009), with a threshold interval between 0 and 10 mya and by using the single
40
41 162 threshold method. The OTUs were defined manually by a majority-rule consensus from the
42
43 163 results of the three methods, i.e., a lineage is considered as being an OTU if supported by at
44
45 164 least two of the three methods. The genetic divergences among OTUs and more
46
47 165 conservative definitions of species were estimated using uncorrected *p*-distances, calculated
48
49 166 in MEGA 10 using partial 16S (613 bp) mtDNA sequences (Table 1).
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4 167 The 16S sequences alone were not sufficiently informative to investigate deep
5
6 168 relationships within the *L. melanonotus* group. We completed the 1,727 bp 16S alignment
7
8
9 169 of 624 terminals with 143 partial sequences of the mitochondrially encoded cytochrome c
10
11 170 oxidase I gene (COI; 128 newly produced and 15 from GenBank; 648–658 bp). Sequences
12
13 171 were obtained as in Gazoni et al. (2021). The COI sequences were aligned using MAFFT,
14
15 172 and concatenated with the 16S alignment, leading to a 2,428 bp alignment (Appendix S3).
16
17
18 173 We reconstructed an ML tree with RAxML v.8.2.4 (Stamatakis, 2014) using the GTR + Γ
19
20 174 model and 1,000 pseudobootstrap replicates. We used *L. macrosternum* (*L. latrans* group)
21
22 175 and *L. notoaktites* (*L. fuscus* group) as out-groups.
23
24
25 176

27 177 **Morphology**

28
29 178 We examined specimens belonging to almost all currently recognised species of the *L.*
30
31 179 *melanonotus* group, including type specimens and/or topotypes, except for *L. wagneri* and
32
33 180 *L. leptodactyloides*, whose type localities are ambiguous (see Introduction), and an
34
35
36 181 additional species from the EGS unassigned to any currently valid taxon (see results;
37
38 182 Appendix S4). However, we examined specimens from the Pastaza River basin for both *L.*
39
40 183 *wagneri* and *L. leptodactyloides* (same region). We did not examine specimens of *L.*
41
42 184 *colombiensis* Heyer, 1994, *L. magistris* Mijares-Urrutia, 1997, and *L. pascoensis* Heyer,
43
44 185 1994, for which morphological traits were obtained from their original descriptions. In the
45
46 186 case of *L. sabanensis* Heyer, 1994, we had access to a single specimen (Appendix S4) not
47
48 187 linked to a DNA sequence but reported as a call voucher (see Taxonomic accounts).
49
50
51 188 Institutional acronyms of natural history collections follow Sabaj et al. (2020).
52
53
54
55
56
57
58
59
60

1
2
3
4 189 We determined the sex of examined specimens by the presence of vocal slits and
5
6 190 thumb spines in males, and through body size in females (usually larger than males) and
7
8 191 gonad examination. Small specimens were excluded from the morphological analyses. We
9
10 192 measured the following morphometric traits using digital callipers (± 0.1 mm): snout–vent
11
12 193 length (SVL), thigh length (THL), tibia length (TL), foot length (FL), hand length (HAL),
13
14 194 head length (HL), and head width (HW). Other morphometric traits were measured using
15
16 195 an ocular micrometre (± 0.1 mm) fitted to a stereomicroscope: eye diameter (ED),
17
18 196 tympanum diameter (TD), eye–nostril distance (EN), internarial distance (IND), length of
19
20 197 the internal metatarsal tubercle (IMT), length of the outer metatarsal tubercle (OMT),
21
22 198 Finger III disc (or unexpanded tip) width (Fin3DW), and Toe IV disc (or unexpanded tip)
23
24 199 width (Toe4DW). Some of these morphometric traits (IND, IMT, OMT, Fin3DW, and
25
26 200 Toe4DW) were not assessed for specimens of *L. wagneri*, because they were analysed a
27
28 201 few years before specimens of other species, and those five traits were not considered at
29
30 202 that time. We followed the definitions and terminology of Watters et al. (2016) for the
31
32 203 morphometric analysis.
33
34
35
36
37
38
39
40

41 205 **Acoustic data acquisition and analysis**

42
43 206 We recorded calls in the field and obtained additional calls from sound repositories of 16 of
44
45 207 17 species of the *L. melanonotus* group with described calls, of which ten species recorded
46
47 208 in the field had associated 16S and/or COI sequences (Tables S1–S2). The exception is *L.*
48
49 209 *colombiensis*, whose call was briefly described by de Sá et al. (2014), but the description
50
51 210 was not linked to a sound file or specific locality (presumably in Colombia). Besides,
52
53
54
55
56
57
58
59
60

1
2
3
4 211 digital copies of the original (analogue) sound recording are not available in the
5
6 212 Smithsonian Institution (A. Wynn pers. comm. to T.R.C.).
7

8
9 213 Calls were recorded in the field using digital recorders adjusted to sampling rates of
10
11 214 44.1 or 48.0 kHz and sample size of 16 bits, and unidirectional microphones. Recordings
12
13 215 were stored as uncompressed wave files. Sound files are housed in acoustic repositories
14
15 216 (see Table S2). In addition, some of the calls published in the most comprehensive review
16
17 217 of the *L. melanonotus* group (Heyer, 1994) were reanalysed. These were obtained either
18
19 218 from the Smithsonian Institution (USNM; Washington, DC, USA) or the Macaulay Library
20
21 219 collection (ML; Cornell Lab of Ornithology, Ithaca, NY, USA). Additional calls were
22
23 220 obtained from Fonoteca Tropical Jacques Vielliard (FNJV; Unicamp, Campinas, SP,
24
25 221 Brazil) and Fonoteca Zoologica de Madrid (FonoZoo; Madrid, Spain), or made available by
26
27 222 colleagues. The acoustic analysis was conducted in Soundruler 0.9.6.1 (Gridi-Papp, 2007),
28
29 223 built as a package interfacing with Matlab 6.5.2 scripts through automated procedures that
30
31 224 allow for unbiased quantification of acoustic traits among species. The main results of the
32
33 225 quantitative analysis are presented as minimum–maximum (mean \pm standard deviation).
34
35 226 Soundruler settings were: fast Fourier transform (FFT) size = 1024 samples, FFT overlap =
36
37 227 90%, window type = Hann, contrast = 70%. Note rate (per minute) was quantified manually
38
39 228 in Audacity 2.1.1 (Audacity Team, 2020). Descriptive statistics of acoustic traits are
40
41 229 presented as mean \pm standard deviation, and ranges include the span of values from the raw
42
43 230 dataset. Sound figures were produced using seewave 2.1.0 (Sueur et al., 2008) and tuneR
44
45 231 1.3.2 (Ligges et al., 2017) in R 3.5.0 (R Core Team, 2018). Settings for these were: window
46
47 232 = Hann, FFT size = 256 or 512 samples, FFT overlap = 90%; the intensity of frequency

11 236 **Results**

14 237 **Diversity of mtDNA lineages and species delimitation**

16 238 The phylogenetic tree obtained from the ML analysis of COI + 16S mtDNA dataset
17
18 239 recovered the *L. melanonotus* group as a single clade, even though *L. riveroi* Heyer &
19
20 240 Pyburn, 1983 is weakly supported (BT = 69%) as sister to the remaining species of the
21
22 241 group (Fig. 1). All other species of the *L. melanonotus* group form a strongly supported
23
24 242 clade (BT = 98%), with *L. pustulatus* (Peters, 1870) in the South American Dry Diagonal
25
26 243 and *L. diedrus* Heyer, 1994 in western Amazonia as early diverging lineages (not shown in
27
28 244 Fig. 1, but see de Sá et al., 2014 for distributions), and the remaining species forming a
29
30 245 nested clade (BT = 95%). We considered five main subclades within the latter group: (#1)
31
32 246 *L. colombiensis*, *L. melanonotus*, *L. validus*, *L. wagneri*, and a putative new species referred
33
34 247 to as *Leptodactylus* sp. from Colombia are distributed in lowland and highland forests in
35
36 248 the northern part of the distribution of the group; (#2) *L. brevipes*, *L. intermedius*, and *L.*
37
38 249 *podicipinus* occupy open habitats in the eastern part of the distribution of the group; (#3) *L.*
39
40 250 *discodactylus* Boulenger, 1884 and *L. griseigularis* (Henle, 1981) inhabit western
41
42 251 Amazonian forests; (#4) *L. leptodactyloides*, *L. natalensis* Lutz, 1930, *L. nesiotus*, and the
43
44 252 putative new species referred to as *Leptodactylus* sp. from the EGS, widely distributed in
45
46 253 forest and open habitats east of the Andes; (#5) and a subclade formed by no less than 18
47
48 254 major mtDNA lineages throughout Amazonia, which are assigned to *L. petersii*. Each of
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4 255 these lineages harbours spectacular diversity on mtDNA and corresponds to a separate
5
6 256 OTU.

7
8
9 257 Of the three species delimitation methods, ABGD was found to be the most
10
11 258 conservative, delimiting 49 OTUs. By contrast, PTP and GMYC delimited 70 and 59
12
13 259 OTUs, respectively (Fig. 1). The consensus of the results obtained from the three methods
14
15 260 resulted in the delimitation of 57 DNA-based OTUs, of which six (*L. diedrus*, *L.*
16
17 261 *intermedius*, *L. melanonotus*, *L. nesiotus*, *L. riveroi*, and *Leptodactylus* sp. from Colombia)
18
19 262 are represented by single OTUs. All other species are subdivided into several OTUs,
20
21 263 notably *L. petersii* which harbours an impressive diversity (maximum *p*-distance = 8.3% in
22
23 264 16S) and contains at least 18 OTUs. Mean interspecific *p*-distances among *L. petersii*
24
25 265 OTUs reach a minimum value of 3.0% in three instances (Table S3).

26
27
28
29 266 The OTU corresponding to *Leptodactylus* sp. from Andean Colombia (previously
30
31 267 identified as *L. colombiensis*) comprises a single terminal that is sister to a clade formed by
32
33 268 two OTUs of *L. colombiensis* (Andean Colombia) and *L. wagneri* (western Amazonia). In
34
35 269 principle, the two latter species have distinct morphotypes and do not occupy the same
36
37 270 habitat (Heyer, 1994), which is congruent with the distinct distributions of these OTUs
38
39 271 (Fig. 1). Regarding *Leptodactylus* sp., morphological and acoustic data remain unknown,
40
41 272 thus hampering a taxonomic evaluation.

42
43
44
45 273 One clade formed by EGS populations is highly divergent from *L. nesiotus* (also
46
47 274 from the Guiana Shield), altogether forming a moderately supported clade (BT = 74%).
48
49 275 Because these populations could not be linked to any known taxon and because
50
51 276 corresponding calling males exhibited a distinct vocalisation, we name and describe them
52
53 277 as a new species (see Taxonomic accounts). This clade from the EGS is formed by three
54
55
56
57
58
59
60

1
2
3
4 278 OTUs: one from the Brazilian state of Amapá and French Guiana, closely related to a
5
6 279 second OTU from eastern Suriname and northern Pará in Brazil (mean p -distance = 2.9% in
7
8 280 16S), and a third OTU from western and southern Suriname that is sister to the other two
9
10
11 281 OTUs (mean p -distance = 5.3% in 16S).
12

13 282

14 283 **Morphology**

15
16 284 The major taxonomic review of the *L. melanonotus* group (Heyer, 1994) and subsequent
17
18 285 studies have focused on several morphological characters of taxonomic relevance. Below,
19
20 286 we comment on their usefulness in species discrimination and their variation within and
21
22 287 among species of the group. It is important to highlight that distinct colour patterns can be
23
24 288 assessed more accurately either from live or preserved individuals, notably the upper lip
25
26 289 stripe and ventral colouration. In general, the upper lip stripe is easier to be observed
27
28 290 (outline and extension) from live frogs, whereas the belly colour patterns have better pale-
29
30 291 dark contrasts in preserved specimens. The exception is when specimens have been through
31
32 292 colour fading, making belly patterns unclear or completely immaculate.
33
34
35
36
37
38

39 293

40
41 294 **Snout-vent length (SVL).** Body size of adults is highly variable within and among species
42
43 295 and largely overlaps between sexes, but females are generally larger and more robust than
44
45 296 males. Although most species of the group can be classified into different categories of
46
47 297 body size (i.e., small, medium, and large species based on mean SVL; sensu Heyer, 1994),
48
49 298 the majority of species overlap in SVL ranges (see Species Accounts in Heyer, 1994). One
50
51 299 point to consider is the possibility that younger and older males can be reproductive (based
52
53 300 on thumb spines) synchronically. Therefore, SVL ranges may vary to a great extent in a
54
55
56
57
58
59
60

1
2
3
4 301 certain population throughout the breeding season. See below Taxonomic Accounts for
5
6 302 SVL variation among sympatric species of the *L. melanonotus* group.
7
8
9 303

10
11 304 **Dorsolateral fold.** A dorsolateral skin fold is present in most species of the *L. melanonotus*
12
13 305 group, but completely absent in *L. diedrus* (Fig. 2A) and *L. magistris*. The fold is also
14
15 306 absent in some specimens of *L. discodactylus*, *L. pascoensis*, and *L. pustulatus*. The
16
17 307 assessment of the dorsolateral fold can be biased in poorly preserved specimens, where it is
18
19 308 sometimes flattened. The dorsolateral fold can also be interrupted in one or more parts
20
21 309 along its length, forming a longitudinal glandular row. When present, this morphological
22
23 310 character usually generally varies within species from indistinct (i.e., the indication of a
24
25 311 glandular crest behind the upper eyelid, sometimes fragmented and barely visible; Fig. 2B),
26
27 312 and short (extending to the anterior third of the body; Fig. 2C) to moderate length
28
29 313 (extending to the anterior half of the body; Fig. 2D). The presence of long (extending to the
30
31 314 posterior third of the body, often interrupted; Fig. 2E) or complete (uninterrupted,
32
33 315 extending from behind the upper eyelid to the groin; Fig. 2F) folds is limited to a few
34
35 316 species. *Leptodactylus wagneri* has a distinctively long dorsolateral fold (Fig. 2E) and *L.*
36
37 317 *riveroi* is the only species of the group with a complete dorsolateral fold (Fig. 2F). Many
38
39 318 species generally have indistinct to short dorsolateral folds, especially *L. griseigularius*, *L.*
40
41 319 *leptodactyloides* (Fig. 2B), *L. nesiotus*, *L. sabanensis*, *L. validus*, and *Leptodactylus* sp.
42
43 320 from the EGS, whereas other species generally have short to moderate-length folds, notably
44
45 321 *L. brevipes*, *L. colombiensis*, *L. natalensis* (Fig. 2C), and *L. petersii*. However, the
46
47 322 extension of the dorsolateral fold is highly variable in some species. In addition to *L.*
48
49 323 *wagneri*, other species may exhibit intermediate- to long-length folds, notably *L.*

1
2
3
4 324 *intermedius*, *L. melanonotus*, and *L. podicipinus* (Fig. 2D). Overall, the extension of the
5
6 325 dorsolateral fold contributes to a certain extent to species discrimination in the *L.*
7
8 326 *melanonotus* group, but, given its high intraspecific variation, this character should
9
10 327 preferably be used in combination with other morphological and acoustic features, and
11
12 328 linked to locality data and habitat use (see below).
13
14
15

16 329

17
18 330 **Upper lip stripe.** Heyer (1994) described three states for this character (states A–C),
19
20 331 defined as (A) indistinct, as a lighter area below the eye, but the upper and lower limits of
21
22 332 the stripe are weakly defined (Fig. 3A); (B) extending from the posterior corner of the eye
23
24 333 towards the base of the arm (Fig. 3B); and (C) extending from under the mid-eye or
25
26 334 anterior to the eye towards the base of the arm (Fig. 3C). Colour contrasts of the upper lip
27
28 335 stripe may vary between sides of the body, sometimes making character states difficult to
29
30 336 determine, although it was possible in most cases to assign the specimen to one of the
31
32 337 character states based on one of the sides of the head. A few specimens among the species
33
34 338 scored for character states B or C may have an indistinct upper lip stripe (= A) or
35
36 339 completely lack the stripe on one side or both sides of the head. On the other hand, the
37
38 340 states B and C are mutually exclusive among species. Character state C is present in all
39
40 341 three species of the *L. podicipinus* clade (i.e., *L. brevipes*, *L. intermedius*, and *L.*
41
42 342 *podicipinus*; Gazoni et al., 2021), plus *L. melanonotus*, *L. nesiotus*, *L. pustulatus*, and *L.*
43
44 343 *riveroi* (Fig. 3C), even though two of them (*L. melanonotus* and *L. pustulatus*) often have a
45
46 344 fragmented or indistinct upper lip stripe. In the majority of examined specimens, state B is
47
48 345 present in *L. discodactylus*, *L. griseigularis*, *L. natalensis* (Fig. 3B), *L. petersii*, *L. validus*
49
50 346 (classified mostly as state A by Heyer, 1994), *L. wagneri*, and *Leptodactylus* sp. from the
51
52
53
54
55
56
57
58
59
60

1
2
3
4 347 EGS. Most specimens of *L. colombiensis*, *L. diedrus*, *L. leptodactyloides* (Fig. 3A), and *L.*
5
6 348 *sabanensis* are assigned to state A. *Leptodactylus pascoensis* is unique in lacking an upper
7
8 349 lip stripe. Based on the colour of the holotype of *L. magistris*, the species is classified as
9
10 350 state B. The upper lip stripe is a useful character for species discrimination in the *L.*
11
12 351 *melanonotus* group and can be assessed from both live and preserved specimens. However,
13
14 352 it is best used in combination with other morphological and acoustic traits, and also locality
15
16 353 data and habitat use, given the high levels of intraspecific variation, especially in cases of
17
18 354 sympatric occurrence among species of the group (Fig. 1).
19
20
21
22
23
24

25 355
26 356 **Toe tip morphology.** Almost all species of the group have toe tips unexpanded (Fig. 3D)
27
28 357 or slightly expanded (knob-shaped swollen; Fig. 3E). These character states (unexpanded or
29
30 358 slightly expanded) are variable within species. However, two species (*L. diedrus* and *L.*
31
32 359 *discodactylus*) have toe tips expanded into small discs compressed dorsolaterally with
33
34 360 grooves on the dorsal surface of the toe disc. There is one central longitudinal groove in *L.*
35
36 361 *diedrus* (Fig. 3F) and three to five longitudinal grooves (curved in the distal portion) in *L.*
37
38 362 *discodactylus* (Fig. 3G). The presence of toe discs is diagnostic for these two species in
39
40 363 comparison with congeners of the group, and the number of longitudinal grooves on toes
41
42 364 distinguishes the two species.
43
44
45
46
47

48 365
49 366 **Ventral colouration.** In adult males, the throat can be darkened or not, and such
50
51 367 colouration may extend posteriorly to the chest (Fig. 4). Also, the lower jaw is sometimes
52
53 368 covered with white spots (Fig. 4B). Within-species variation associated with these colour
54
55 369 patterns of the throat is extensive and, as such, did not contribute to species discrimination.
56
57
58
59
60

1
2
3
4 370 Major patterns of belly colouration of the *L. melanonotus* group were classified into
5
6 371 different types by Heyer (1994). Although intraspecific variation exists among the character
7
8 372 states proposed, most specimens fell mainly within one of them, which are: immaculate;
9
10 373 mottling (fine, moderate, or heavy)—the latter can form a peculiar anastomotic or
11
12 374 labyrinthine pattern; spotting (pale spots on a dark background). Also, colour patterns can
13
14 375 extend throughout the belly or fade away towards the hind limbs, so that the posterior belly
15
16 376 tends to be almost or completely immaculate. Three species (*L. petersii*, *L. riveroi*, and *L.*
17
18 377 *wagneri*) have a distinctive anastomotic pattern throughout the belly (Fig. 4C). Light to
19
20 378 heavy mottling throughout the belly, but generally not forming an anastomotic pattern (Fig.
21
22 379 4B), is present in *L. brevipes*, *L. discodactylus*, *L. melanonotus*, *L. natalensis*, and *L.*
23
24 380 *nesiotus*. A distinct pattern of mottling concentrated on the anterior portion of the belly and
25
26 381 chest, fading progressively towards the hind limbs (making the posterior belly almost or
27
28 382 completely immaculate; Fig. 4A), is present in *L. colombiensis*, *L. griseigularis*, *L.*
29
30 383 *leptodactyloides*, *L. pascoensis*, *L. sabanensis*, *L. validus*, *Leptodactylus* sp. from EGS, and
31
32 384 possibly *L. magistris* based on the colour characterisation of the holotype. Three species (*L.*
33
34 385 *intermedius*, *L. podicipinus*, and *L. pustulatus*) have a distinctive pale-spotted belly (Fig.
35
36 386 4D) and *L. diedrus* is unique in having an immaculate belly. Species of the *L. melanonotus*
37
38 387 group also may have the groin, posterior belly, and/or the ventral surface of hind limbs
39
40 388 bright yellow in life, such as *L. diedrus*, *L. griseigularis*, *L. leptodactyloides*, *L. nesiotus*, *L.*
41
42 389 *validus*, and *Leptodactylus* sp. from the EGS (see supplemental figures for life colours).
43
44 390 Bright yellow colouration in live frogs is likely present in additional species of the group
45
46 391 and, as such, we did not include it as a diagnostic character among species of the *L.*
47
48 392 *melanonotus* group.

1
2
3
4 393

5
6 394 **Thumb spine.** Adult males of almost all species of the *L. melanonotus* group have a pair of
7
8 395 black (keratinised) thumb spines at the base of the thumb (Fig. 4A, B, D), which is absent
9
10 396 in adult females (Fig. 4C). Keratinised spines can come off easily while examining
11
12 397 preserved specimens (and come off naturally in nature after the breeding season), but the
13
14 398 dermal base can still be observed. However, males of two species (*L. discodactylus* and *L.*
15
16 399 *pustulatus*) lack thumb spines. Such absence serves as a diagnostic trait of both species in
17
18 400 comparison with the other 17 species of the group.
19
20
21

22 401

23
24 402 **Posterior surface of the thigh.** Heyer (1994) described two character states: (i) a pale-
25
26 403 coloured stripe running along the posterior thigh length on a dark brown or black
27
28 404 background or (ii) a mottling pattern of pale spots and blotches intervening with a dark
29
30 405 brown or black background. Besides being highly variable within species, there are at least
31
32 406 a few intermediate states for the thigh stripe, which can be irregular and/or interrupted,
33
34 407 straight or sinuous, well-marked or weakly outlined in some portions. As an example, *L.*
35
36 408 *leptodactyloides* has been distinguished from other members of the *L. melanonotus* group
37
38 409 by the presence of a longitudinal stripe on the posterior surface of the thigh (Heyer, 1994;
39
40 410 de Sá et al., 2014), but most specimens of *L. leptodactyloides* morphologically examined by
41
42 411 us lack such stripes (see supplemental figures for life colours).
43
44
45
46
47

48 412

49
50 413 **Advertisement calls**

51
52 414 Members of the *L. melanonotus* group are well-known for their extended vocal repertoires
53
54 415 when compared to the other three *Leptodactylus* groups. Field observations made by us and
55
56
57
58
59
60

1
2
3
4 416 available data in the literature (e.g., Heyer, 1994; Prado et al., 2007) confirmed that some
5
6 417 species have complex intraspecific vocal interactions (male-male and male-female), which
7
8 418 might explain the multiple note types in their repertoires. However, the most frequent call
9
10 419 types produced, assumedly functioning as advertisement calls, tend to be relatively
11
12 420 stereotyped in structure and composed of a single note type (but see Gazoni et al., 2021 for
13
14 421 *L. petersii*). Major patterns in the temporal and spectral dimensions of advertisement calls
15
16 422 are presented in this section.
17
18
19

20 423

21
22 424 **Amplitude modulation (AM).** Most species of the group do not have regular AM patterns
23
24 425 (i.e., pulsing) in their calls (Figs. 5A, 6A–F). Five species of the *L. melanonotus* group have
25
26 426 amplitude-modulated calls (Figs. 5B–D, 6G–I), of which *L. riveroi* is unique in producing
27
28 427 calls with complete pulses (i.e., AM cycles separated by silent intervals; Fig. 5C). The call
29
30 428 of *L. riveroi* is composed of a series of two-pulse notes (Fig. 5C). Three species produce
31
32 429 calls with incomplete pulses (i.e., AM cycles not separated by silent intervals; Fig. 5B): *L.*
33
34 430 *petersii* call type 1 (sensu Gazoni et al., 2021; Fig. 6G), *L. wagneri* (Fig. 6I), and
35
36 431 *Leptodactylus* sp. from the EGS (Figs. 5B, 6H). The fifth species, *L. pustulatus*, also has a
37
38 432 unique call consisting of a complex combination of complete and incomplete AM patterns
39
40 433 (Fig. 5D, H).
41
42
43
44

45 434

46
47 435 **Calling rate.** Species that produce the shortest calls (note duration < 30 ms on average)
48
49 436 generally call at the fastest repetition rates (highest repetition rate > 200 notes/min), such as
50
51 437 *L. brevipes*, *L. leptodactyloides*, *L. natalensis*, and *L. nesiotus* (Table 2). Exceptions are *L.*
52
53 438 *griseigularis* and *L. melanonotus*, both having short notes and lower repetition rates (Table
54
55
56
57
58
59
60

1
2
3
4 439 2), and *Leptodactylus* sp. from the EGS which produces a long note (86 ms on average) at a
5
6 440 high repetition rate (highest repetition rate = 211 notes/min). We observed that species of
7
8 441 the group producing rapidly repetitive calls can call at a much slower rate depending on
9
10 442 motivation (intraspecific interactions), but species typically producing calls at slower rates
11
12 443 never call at such high rates (i.e., highest repetition rate > 200 notes/min). Therefore, the
13
14 444 repetition rate of calls was found to be a useful diagnostic trait among species of the *L.*
15
16 445 *melanonotus* group (Table 3).
17
18
19
20
21
22

23 447 **Frequency modulation (FM).** FM is prevalent in the calls of most species. The FM is
24
25 448 always upward and varies in the extent of modulation throughout the call. The dominant
26
27 449 frequency always coincides with the fundamental harmonic in *Leptodactylus* calls, from
28
29 450 which the FM was quantified. Species having the highest levels of FM can be visually
30
31 451 described in the spectrogram as an S-shaped spectral structure (Fig. 5G). The dominant
32
33 452 frequency is usually associated with the highest frequencies in the final portion of upsweep,
34
35 453 but can also coincide with lower frequencies in the first third/half in some calls. Calls with
36
37 454 pronounced upward modulation (FM > 1 kHz on average; Fig. 5G) are present in *L.*
38
39 455 *brevipes*, *L. discodactylus*, *L. griseigularis*, *L. intermedius*, *L. melanonotus*, *L. petersii* call
40
41 456 type 2 (sensu Gazoni et al., 2021), *L. podicipinus*, *L. sabanensis*, *L. validus*, and *L.*
42
43 457 *wagneri*, whereas *L. diedrus*, *L. leptodactyloides*, *L. natalensis*, *L. nesiotus*, *L. pustulatus*,
44
45 458 *L. riveroi*, and *Leptodactylus* sp. from the EGS have weak (FM < 100 Hz on average; Fig.
46
47 459 5E) or modest (FM < 600 Hz on average; Fig. 5F) upward modulation in their calls (Tables
48
49 460 2–3).
50
51
52
53
54
55 461

462 **Summary of phenotypic characters with taxonomic relevance**

463 After assessing the morphological and acoustic characters (previous two sections), next we
464 present the combination of those that are especially useful in species discrimination in the
465 *L. melanonotus* group (summarised in Table 3). The combined use of dorsolateral fold,
466 upper lip stripe, and belly colouration are the most reliable suite of characters for species
467 discrimination in the group and can be straightforwardly assessed because of their presence
468 among adult and juvenile specimens. Moreover, the association of morphological and
469 colour traits with locality data and habitat use is of great help in identifying species of the
470 group. To facilitate species discrimination among the species of the *L. melanonotus* group
471 based on advertisement call patterns, we classified them into three major ‘acoustic groups’,
472 as follows: (1) the ‘water drop’ pattern (Fig. 6A–C) is defined as a non-pulsed note with a
473 pronounced FM. This pattern occurs in six species: *L. intermedius*, *L. melanonotus* (Fig.
474 6A), *L. petersii* call type 2 (Fig. 6B), *L. podicipinus*, *L. sabanensis*, and *L. validus* (Fig.
475 6C); (2) the ‘bubbling’ pattern (Fig. 6D–F) is defined as a non-pulsed note with the shortest
476 durations (note duration < 30 ms on average) and the fastest repetition rates (highest
477 repetition rate > 200 notes/min, except *L. griseigularis*; Table 2). This pattern occurs in five
478 other species of the group: *L. brevipes*, *L. griseigularis* (Fig. 6D), *L. leptodactyloides* (Fig.
479 6E), *L. natalensis* (Fig. 6F), and *L. nesiotus*; (3) the ‘grunt’ pattern (Fig. 6G, H) is defined
480 as a note formed by incomplete pulses and with negligible to modest FM. This pattern
481 occurs in two species: *L. petersii* call type 1 (Fig. 6G) and *Leptodactylus* sp. from the EGS
482 (Fig. 6H). In addition to these three major patterns, the following species have unique calls
483 in the *L. melanonotus* group: *L. diedrus*, whose call consists of a non-pulsed note with long
484 duration and weak FM (Fig. 5E; Table 2); *L. discodactylus*, whose call consists of a non-

1
2
3
4 485 pulsed note with long duration and pronounced FM, which makes it sound like a whistle
5
6 486 (Fig. 5G; Table 2); *L. pustulatus*, whose call consists of a note with a complex amplitude-
7
8 487 modulated structure formed by both incomplete and complete AM (Fig. 5D, H; see also
9
10 488 Brandão & Heyer, 2005); *L. riveroi*, whose call is formed by a series of two-pulse notes
11
12 489 (Fig. 5C; see also Heyer & Pyburn, 1983); and *L. wagneri*, whose call consists of a single
13
14 490 note formed by incomplete pulses and with modest to pronounced FM (Fig. 6I).
15
16
17

18 491 We present next the taxonomic results derived from the review of phenotypic
19
20 492 characters used in the taxonomy of the *L. melanonotus* group linked to the DNA-based
21
22 493 phylogeny and species delimitation analysis. In summary, we (1) designate a neotype for *L.*
23
24 494 *wagneri* and provide the first quantitative analysis of its advertisement call; (2) update the
25
26 495 diagnosis and distribution of the sympatric *L. leptodactyloides* and allopatric *L.*
27
28 496 *griseigularis*; (3) reanalyse the advertisement calls of these two species and other ten
29
30 497 species of the group; and (4) name and describe *Leptodactylus* sp. from the EGS as a new
31
32 498 species. Along the taxonomic sections, we also highlight sympatric and allopatric species of
33
34 499 the group without a clear phenotypic diagnosis.
35
36
37
38

39 500

40 501 **Taxonomic accounts**

41 502

42 503 *Leptodactylus wagneri* (Peters, 1862)

43 504 (Tables 1, 2, 4; Figs. 1, 2E, 6I, 7)

44 505

45 506 **Type series.** A single specimen (the holotype), by original designation (Peters, 1862),
46
47 507 housed at the Zoologische Staatssammlung München (ZSM), the Bavarian State Collection
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4 508 of Zoology in Munich: ZSM 1080/0. This specimen was destroyed in World War II (see
5
6 509 Heyer, 1970; Glaw & Frazen, 2006). Heyer (1970) tentatively corrected the type locality
7
8 510 from ‘west of the Andes’ in Peters (1862) to the ‘Pastassa’ (= Pastaza) in Ecuador (ZSM
9
10 511 catalogue information), which most likely corresponds to a wide swath of territory
11
12 512 associated with the Pastaza River drainage. The Pastaza River in Ecuador extends along
13
14 513 ~250 km from the eastern Andean slopes (1,900 m elevation) to the border with Peru (250
15
16 514 m elevation). Peters (1862) describes that type specimen as an adult male (presence of
17
18 515 thumb spines) with 68 mm SVL. We agree with Heyer’s (1970) change because the only
19
20 516 species of *Leptodactylus* bearing thumb spines in western Ecuador are *L. melanonotus*, *L.*
21
22 517 *peritoaktites*, and *L. rhodomerus*. These three species are discriminated from *L. wagneri* in
23
24 518 the size range of adult males. Males of the two species of the *L. pentadactylus* group (*L.*
25
26 519 *peritoaktites*: SVL = 124–146 mm; *L. rhodomerus*: SVL = 112–144 mm; Heyer, 2005) are
27
28 520 much larger than those of *L. wagneri* (SVL = 46–60 mm), whereas males of *L.*
29
30 521 *melanonotus* are much smaller than the other species (SVL = 32–43 mm; de Sá et al.,
31
32 522 2014). In our sample, adult males of *L. wagneri* (SVL = 46–60 mm) do not reach the size of
33
34 523 the holotype (SVL = 68 mm), but it falls within the SVL range of the species, with females
35
36 524 larger than 80 mm. The other three species have SVL ranges far above or below the SVL of
37
38 525 the *L. wagneri* holotype.

39
40
41 526 Heyer (1970) designated the holotype of the sympatric *L. leptodactyloides* as the
42
43 527 neotype for *L. wagneri* because he regarded *L. leptodactyloides* as a junior synonym of *L.*
44
45 528 *wagneri*. The neotype designation was later invalidated by Heyer (1994), who considered
46
47 529 that *L. leptodactyloides* was a separate species from *L. wagneri*. The type locality of *L.*
48
49 530 *leptodactyloides* is ‘Río Pastaza’, Ecuador (Andersson, 1945). Our results indicate that
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4 531 specimens from the Pastaza River and surroundings, in Ecuador, belong to two separate
5
6 532 species, characterised by distinct phylogenetic positions within the *L. melanonotus* group,
7
8 533 as well as substantial differences in morphology and calls. In addition to these, two other
9
10 534 species of the group are known to occur in Ecuador: *L. discodactylus*, inhabiting western
11
12 535 Amazonia, and *L. melanonotus*, distributed across the Pacific lowlands from Ecuador to
13
14 536 Mexico. *Leptodactylus petersii* was also reported in Ecuador (Ron, 2002), but, based on
15
16 537 their morphology (long dorsolateral fold) and DNA sequences (genetic distance between
17
18 538 QCAZ-A 20244, GenBank accession #ON564909, and *L. wagneri* from Pastaza, e.g.,
19
20 539 USNM 320988, ($\leq 1\%$ in 16S), we concluded that those specimens (QCAZ-A 20242–7) are
21
22 540 instead conspecific with *L. wagneri*. To our knowledge, there are three distinct
23
24 541 morphotypes in Ecuador's province of Pastaza: (1) a large species (specimens from
25
26 542 Pastaza: male SVL 46–60 mm, mean = 53.3, $n = 19$; female SVL 62–70 mm, mean = 66.4,
27
28 543 $n = 5$; Table 4) with the upper lip stripe extending from the posterior corner of the eye and
29
30 544 anastomotic belly pattern, corresponding to *L. wagneri*; (2) a medium species (specimens
31
32 545 from Ecuador and Brazil: male SVL 35–45 mm, mean = 39.7, $n = 23$; female SVL 41–52
33
34 546 mm, mean = 45.5, $n = 9$) with the upper lip stripe usually indistinct and belly pattern
35
36 547 consisting of lightly mottling concentrated anteriorly (tending to immaculate posteriorly),
37
38 548 corresponding to *L. leptodactyloides*; and (3) a small species (specimens from Ecuador:
39
40 549 male SVL 27–29 mm, mean = 28.1, $n = 4$; female SVL 28–35 mm, mean = 32.7, $n = 3$)
41
42 550 with toe discs and with adult males lacking thumb spines, corresponding to *L.*
43
44 551 *discodactylus*. The latter two species are distinguished acoustically from each other (Figs.
45
46 552 5–6)—the call of *L. wagneri* from Ecuador is described in the present study and also differs
47
48 553 from those of the other two species (see Fig. 6I, and Diagnosis and Comparisons below).
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4 554 Although Peters' description of *L. wagneri* is brief, it is possible to associate the holotype
5
6 555 with the first morphotype presented earlier in this paragraph based on body size, as
7
8
9 556 previously stated by Heyer (1994). Given that the neotype designated for *L. wagneri* by
10
11 557 Heyer (1970) was later invalidated by the same author (Heyer, 1994), the name *L. wagneri*
12
13 558 is yet to be linked to a new name-bearing type specimen. Next, we update the diagnosis of
14
15
16 559 *L. wagneri*, designate and describe a neotype for the species, and provide the first
17
18 560 quantitative description of its advertisement call. The rationale for the *L. wagneri* neotype
19
20
21 561 designation is threefold: (i) define the nominal taxon objectively, (ii) clarify its taxonomic
22
23 562 status relative to congeners distributed in western Amazonia and Andean slopes, including
24
25 563 putatively new species, and (iii) circumscribe its type locality within the wide swath of
26
27 564 territory stretching across the Pastaza River drainage in Ecuador and adjacent Peru.
28

29
30 565

31
32 566 **Diagnosis.** The species is recognised in the *L. melanonotus* group by the following
33
34 567 combination of character states: (1) large size (male SVL 46–60 mm); (2) long dorsolateral
35
36 568 fold; (3) toe tips unexpanded; (4) upper lip stripe extending from the posterior corner of the
37
38 569 eye; (5) belly heavily mottled, forming an anastomotic pattern; (6) two keratinised spines
39
40
41 570 on the base of the thumb in adult males; (7) single-note advertisement call; (8) call formed
42
43 571 by incomplete pulses; (9) call with modest to pronounced FM.
44

45
46 572

47
48 573 **Comparisons with congeners of the *L. melanonotus* group.** *Leptodactylus wagneri* is
49
50 574 distinguished from all other species by the combination of large SVL (male SVL 46–60
51
52 575 mm; Table 4) and long dorsolateral fold (Figs. 2E, 7A). The species is also distinguished
53
54
55 576 from *L. diedrus* and *L. discodactylus* by having toe tips unexpanded (toe discs in the other
56
57
58
59
60

577 two species; Fig. 3F, G). *Leptodactylus wagneri* is distinguished by an upper lip stripe
578 extending from the posterior corner of the eye (Fig. 7A); extending from under the mid-eye
579 or over the snout in *L. brevipes*, *L. intermedius*, *L. melanonotus*, *L. nesiotus*, *L. podicipinus*,
580 *L. pustulatus*, and *L. riveroi*; absent in *L. pascoensis*. *Leptodactylus wagneri* has an
581 anastomotic belly pattern (Fig. 7B, D), differing from the ventral colouration of almost all
582 species of the group, except *L. petersii* and *L. riveroi*. *Leptodactylus wagneri* is also
583 distinguished by the presence of keratinised thumb spines in adult males (Fig. 7B, D);
584 absent in *L. discodactylus* and *L. pustulatus*. The advertisement call of *L. wagneri* is
585 frequency modulated and formed by incomplete pulses (Fig. 6I; Table 2). When combined,
586 these two acoustic traits distinguish *L. wagneri* from all other species of the *L. melanonotus*
587 group (Figs. 5–6; Tables 2–3).

588
589 **Neotype of *Leptodactylus wagneri*.** QCAZ-A 26219 (field number SC 14012; Fig. 7), an
590 adult male from the outskirts of Puyo (1.443070°S, 77.996660°W; 954 m elevation), in the
591 Province of Pastaza, central Ecuador, collected on 9 January 2004 by S. R. Ron. This
592 specimen is linked to a COI sequence (GenBank accession #MW284682).

593
594 **Description of neotype.** Adult male, SVL 57.2 mm, THL 28.8 mm, TL 29.4 mm, FL 27.5
595 mm, HAL 13.1 mm, HL 20.8 mm, HW 19.5 mm, ED 5.4 mm, TD 4.3 mm, EN 5.3 mm.
596 Snout sub-oval in dorsal view, rounded to acuminate in lateral view. Canthus rostralis
597 rounded; loreal region slightly concave; tympanic annulus well-defined, mostly circular
598 (TD = 80% ED), and partially covered by supratympanic fold; tympanic membrane
599 partially translucent; supratympanic fold from the posterior corner of the eye, over the

1
2
3
4 600 dorsal edge of the tympanic annulus, to the base of the arm; vocal sac subgular with a fold
5
6 601 from jaw extending to arm; vocal slits present; vomerine teeth in two nearly straight rows
7
8 602 medial and posterior to choanae and almost parallel to sagittal plane. Tongue elongated,
9
10 603 free from the posterior third. Two keratinised spines at the base of Finger I. Relative finger
11
12 604 lengths $IV = II < I < III$; fingers fringed laterally, especially in outer side of Finger I, and
13
14 605 inner side of Fingers II–III; finger tips rounded, slightly swollen in Fingers I and IV; inner
15
16 606 metacarpal tubercle mostly ovoid; outer metacarpal tubercle elongated. Subarticular
17
18 607 tubercles rounded; supernumerary tubercles absent. Dorsal surfaces of body and limbs
19
20 608 covered with brown-tipped (keratinised) tubercles, especially in the posterior half of body
21
22 609 length and hind limbs. Dorsolateral fold extending from behind the upper eyelid to $2/3$ of
23
24 610 body length, interrupted. Flank shagreened and glandular. Ventral surface of body and
25
26 611 limbs smooth, underside of thigh glandular. Relative toe lengths $I < II < V < III < IV$; toes
27
28 612 extensively fringed; toe tips rounded, unexpanded. Inner metatarsal tubercle elongated;
29
30 613 outer metatarsal tubercle nearly rounded. Tarsal fold extending $2/3$ of tarsus length, from
31
32 614 the inner metatarsal tubercle towards the heel. Subarticular tubercles nearly rounded to
33
34 615 oval; supernumerary tubercles absent. Sole of foot and tarsus covered with brown-tipped
35
36 616 tubercles.

37
38
39 617 In preservative, dorsal surfaces brown with darker brown blotches. Interorbital bar
40
41 618 light brown and grey; another bar of same colour extending obliquely from behind the
42
43 619 upper eyelid towards scapula. Upper lip stripe light brown; upper and lower lips with a few
44
45 620 scattered white spots. Flank light grey. Posterior surface of thigh pale and dark mottled
46
47 621 (contrast of brown shades). Throat faded brown, darker brown surrounding the lower jaw,
48
49 622 with white spots and blotches. Chest and especially belly heavily mottled, forming an

1
2
3
4 623 anastomotic pattern. Ventral surface of arms with an almost solid brown colour extending
5
6 624 from the elbow to the hand; hind limbs mottled. Ventral surface of hand, foot, and tarsus
7
8
9 625 dark brown and grey, except tubercles, and finger and toe tips, which vary from cream to a
10
11 626 light grey. Thumb spines solid black. Life colours are consistent with colour description in
12
13 627 preservative, but exhibiting well-defined colour contrasts, with reddish contrasts along the
14
15 628 dorsolateral fold and flank. Iris golden on the upper side, silvery white on the lower side.
16
17
18 629 Life colours of the neotype are available at BioWeb Ecuador (access through this link:
19
20 630 <<https://bit.ly/2ViPn1V>>).

21
22
23 631

24
25 632 **Variation.** Variation in life colours (photographs of the neotype and additional adult and
26
27 633 juvenile specimens) is available at Bioweb Ecuador (link: <<https://bit.ly/2ViPn1V>>).
28
29 634 Intraspecific variation was also characterised previously by Heyer (1994). The largest adult
30
31 635 specimen examined of *L. wagneri* is a female (QCAZ-A 56554: SVL = 84.3 mm),
32
33 636 rendering *L. wagneri* the largest species of the *L. melanonotus* group. Among the
34
35 637 specimens examined by us, dorsolateral fold was found to be shorter in specimens from the
36
37 638 eastern range of the known distribution of *L. wagneri* (e.g., INPA-H 15789; see Appendix
38
39 639 S4 for locality data). Specimens from the upper Amazon Basin in Brazilian Amazonia can
40
41 640 be assigned to *L. wagneri* by having a large SVL and an anastomotic belly pattern, but
42
43 641 some specimens have a shorter dorsolateral fold than the typically long fold present among
44
45 642 Ecuadorian specimens. Despite the morphological variation, we tentatively assign those
46
47 643 specimens to *L. wagneri*, but the acquisition of additional morphological and acoustic data
48
49 644 would help elucidate the patterns of geographical variation among *L. wagneri* populations
50
51 645 occurring in the eastern limit of its distribution range.
52
53
54
55
56
57
58
59
60

646

647 **Advertisement call.** The description is based on 12 calls of one male from the province of
648 Napo in Ecuador, and additional nine calls of a second male from the Eastern Andean
649 slopes in Peru (see Table S2 for details). The call (Fig. 6I) consists of a single, partly pulsed
650 note given at a rate of 50 to 55 (52.7 ± 3.8) per minute. Notes last 64 to 136 (103.2 ± 20.1)
651 ms, the rise time varies from 31 to 61 (46.4 ± 0.8) % of note duration. Notes are formed by
652 6 to 11 (7.9 ± 1.5) incomplete pulses with duration varying from 9 to 18 (13.1 ± 0.6) ms,
653 emitted at a rate of 63 to 118 (86.4 ± 1.9) per second. The dominant frequency varies from
654 1,572 to 1,898 ($1,722.1 \pm 22.9$) Hz and coincides with the fundamental harmonic. Notes
655 have a modest to pronounced frequency upsweep, ranging from 656 to 1,172 (962.0 ± 20.6)
656 Hz.

657

658 **Geographic distribution.** Based on the genotyped individuals plus specimens
659 morphologically assigned to the species, *L. wagneri* is circumscribed to western Amazonia,
660 distributed in Andean foothills (up to ~1,500 m elevation) and lowland Amazonian forests
661 of north-western Brazil, northern Peru, Ecuador, and Colombia, extending westward to the
662 Eastern Cordillera of Ecuador and Peru (Fig. 1).

663

664 **Notes on natural history.** Ecological and reproductive aspects were described in several
665 studies for a large-sized species of the *L. melanonotus* group from western Amazonia,
666 which we consider to represent *L. wagneri*. Main publications include Heyer and Peters
667 (1971), Heyer and Bellin (1973), Crump (1974), Duellman (1978), Heyer (1994), and
668 Rodríguez and Duellman (1994). According to these publications and field observations by

1
2
3
4 669 some of us, *L. wagneri* occurs in a wide variety of habitats, including river edges, forests,
5
6 670 forest clearings, and shallow swamps.
7
8

9 671

10
11 672 **Remarks.** A quantitative acoustic analysis of nominal *L. wagneri* was provided for the first
12
13 673 time in our study, but anecdotal descriptions had already been provided from Ecuadorian
14
15 674 and Peruvian Amazonia (Duellman, 1978; Rodríguez & Duellman, 1994). It is possible,
16
17 675 however, that morphological and acoustic characterisations might have contained both *L.*
18
19 676 *wagneri* and *L. leptodactyloides*, sympatric in western Amazonia. Other call descriptions
20
21 677 assigned to *L. wagneri* correspond to other species of the *L. melanonotus* group. The call of
22
23 678 *L. wagneri* described in the present study consists of a pulsed and frequency-modulated
24
25 679 note (Fig. 6I), whereas those described as consisting of a non-pulsed, frequency-modulated
26
27 680 note or a pulsed note without frequency modulation (Schlüter, 1980) should probably
28
29 681 correspond to the two call types of *L. petersii* or the call of *L. intermedius* (see Gazoni et
30
31 682 al., 2021 for further discussion). A quantitative analysis of calls of *L. wagneri* from four
32
33 683 different localities was provided by Straughan and Heyer (1976), but none of them could be
34
35 684 assigned to *L. wagneri* when compared to our data. The correct association between call
36
37 685 patterns and species is often not possible without complementary information on calling
38
39 686 habitat and morphological and/or colour patterns of the recorded males, but we tentatively
40
41 687 reassigned those calls to species, based on the currently available data on calls and
42
43 688 distribution of the *L. melanonotus* group. Calls described by Straughan and Heyer (1976)
44
45 689 from Belém, Pará (Eastern Brazilian Amazonia) and Aragua, Venezuela, are beyond the
46
47 690 known distribution range of *L. wagneri*. By combining dominant frequency and locality,
48
49 691 those calls could correspond to *L. intermedius* and *L. validus*, respectively (Table 2). Calls
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4 692 described by the same authors of other two populations assigned to *L. wagneri* are from the
5
6 693 Province of Sucumbíos in Ecuador. Based on the illustrated spectrogram for the calls from
7
8 694 Limoncocha (Straughan & Heyer, 1976: fig. 8) and quantified call traits (note duration and
9
10 695 dominant frequency), those calls most likely correspond to *L. leptodactyloides*. In contrast,
11
12 696 calls from Santa Cecilia do not match well the acoustic traits quantified for any of the three
13
14 697 species of the *L. melanonotus* group recorded in Amazonian Ecuador (i.e., *L. discodactylus*,
15
16 698 *L. leptodactyloides*, and *L. wagneri*), but they are closest in note duration, calling rate, and
17
18 699 dominant frequency to those of *L. discodactylus*.
19
20
21

22 700 We did not have access to original sound recordings of *L. colombiensis* to allow us
23
24 701 to reanalyse calls under the same analytical procedures and make direct comparisons with
25
26 702 the calls of *L. wagneri* described in our study. According to personal communication of
27
28 703 Addison Wynn (Smithsonian Institution) to one of us (TRC), the original (analogue) tape
29
30 704 recordings of *L. colombiensis* might have been lost due to sticky tape syndrome and a
31
32 705 digital copy of them is no longer accessible. It is possible that these closely related species
33
34 706 diverged phenotypically in morphology, but share a peculiar call pattern for the *L.*
35
36 707 *melanonotus* group consisting of a frequency-modulated note formed by incomplete pulses
37
38 708 (Fig. 6I; de Sá et al., 2014: fig. 104). The two species are geographically and ecologically
39
40 709 separated, being allopatric in lowland forests of western Amazonia (*L. wagneri*) and in
41
42 710 Andean Colombia (*L. colombiensis*), although the existence of a contact zone in
43
44 711 Colombia's Putumayo and Caquetá provinces is possible.
45
46
47
48
49

50 712

51
52 713 *Leptodactylus leptodactyloides* (Andersson, 1945)

53
54 714 (Tables 1, 2; Figs. 1, 2B, 3A, 6E, Fig. S1)

1
2
3
4 715

5
6 716 **Type series.** An unnumbered specimen housed at the Naturhistoriska riksmuseet (NRM),
7
8
9 717 the Swedish Museum of Natural History—Heyer (1970, 1994) adopted the obsolete
10
11 718 acronym NHRM; see Sabaj (2020) for details—by original designation (Andersson, 1945).
12
13 719 Heyer (1970) linked the type specimen to NRM 1945. NRM catalogue information links
14
15 720 the holotype to the Río Pastaza, specifically between the Río Puyo and Río Copotaza (Fig.
16
17 721 S1). In the same study, Heyer synonymised *L. leptodactyloides* with *L. wagneri*, two
18
19 722 sympatric species at the Pastaza Valley, their type locality. Later, Heyer (1994) revalidated
20
21 723 the species based on morphological data. Species of the *L. melanonotus* group recorded at
22
23 724 the Pastaza Valley are *L. discodactylus*, *L. leptodactyloides*, and *L. wagneri*. These three
24
25 725 species are easily distinguished from each other based on morphological and acoustic data
26
27 726 (Table 3) and are also distantly related to each other (Fig. 1). *Leptodactylus*
28
29 727 *leptodactyloides* (see Fig. S1 for the holotype) is a medium species distinguished by
30
31 728 lacking toe discs (present in *L. discodactylus*), and an indistinct or short dorsolateral fold
32
33 729 (long fold in *L. wagneri*), two keratinised thumb spines in adult males (absent in *L.*
34
35 730 *discodactylus*), anterior belly mottled, posterior belly tending to immaculate (mottling
36
37 731 throughout the belly in *L. discodactylus*; anastomotic pattern in *L. wagneri*). The
38
39 732 morphotype of *L. leptodactyloides* has been linked to a bubbling call pattern (Fig. 6E) with
40
41 733 occurrence in lowland Amazonian forests (but see Geographic distribution below; Fig. 1).

42
43 734 Three allopatric OTUs (mean *p*-distance = 2.9–3.2% in 16S; Table S3) have been
44
45 735 delimited and considered herein as *L. leptodactyloides* in the broad sense. One of them
46
47 736 (OTU #3, Fig. 1) is widespread throughout Amazonia and encompasses the type locality in
48
49 737 Ecuador. One of the two other OTUs (#50; Fig. 1) occupies south-western Amazonia,
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4 738 whereas the other OTU (#49; Fig. 1) occupies an Amazonian region south of the Amazon
5
6 739 River and extends southward outside Amazonia. Additional data are required to investigate
7
8
9 740 the variation among those groups of populations. Nevertheless, our preliminary analysis of
10
11 741 the morphology and calls associated with all three OTUs could not reveal consistent
12
13 742 differences. We thus consider the populations of all three OTUs as conspecific. In the
14
15 743 following sections, we update the diagnosis and distribution of *L. leptodactyloides*. Also,
16
17 744 we redescribe its advertisement call and those of two morphologically similar species of
18
19 745 the group (*L. griseigularius* and *L. sabanensis*) to allow direct interspecific comparisons.
20
21
22
23 746

24
25 747 **Diagnosis.** The species is recognised in the *L. melanonotus* group by the following
26
27 748 combination of character states: (1) moderate size (male SVL 35–45 mm); (2) indistinct to
28
29 749 short dorsolateral fold; (3) toe tips unexpanded; (4) upper lip stripe generally indistinct; (5)
30
31 750 anterior belly mottled, fading progressively towards hind limbs, posterior belly tending to
32
33 751 immaculate; (6) two keratinised spines on the base of the thumb in adult males; (7) single-
34
35 752 note advertisement call; (8) call non-pulsed; (9) short note duration (10–26 ms); (10) fast
36
37 753 repetition rate (highest repetition rate = 236 notes/min); (11) call frequency modulated; (12)
38
39 754 low dominant frequency (904–1,593 Hz).
40
41
42
43 755

44
45 756 **Comparisons with congeners of the *L. melanonotus* group.** *Leptodactylus*
46
47 757 *leptodactyloides* (male SVL 35–45 mm) is distinguished from the partially sympatric *L.*
48
49 758 *discodactylus* (male SVL 27–29 mm) and *L. petersii* (male SVL 26–32 mm; Gazoni et al.,
50
51 759 2021: table 3) by a larger body size, and from the partially sympatric *L. wagneri* (male SVL
52
53 760 46–60 mm) by a smaller body size. *Leptodactylus leptodactyloides* is also distinguished by
54
55
56
57
58
59
60

1
2
3
4 761 the combination of indistinct or short dorsolateral fold (Fig. 2B, Fig. S1), long in *L.*
5
6 762 *wagneri* (Fig. 2E), complete in *L. riveroi* (Fig. 2F), and absent in *L. diedrus* (Fig. 2A) and
7
8
9 763 *L. magistris*; absence of toe discs (present in *L. diedrus* and *L. discodactylus*; Fig. 3F, G);
10
11 764 anterior belly mottled, fading progressively towards hind limbs, posterior belly tending to
12
13 765 immaculate (Fig. S1), mottling throughout the belly in *L. brevipes* (Fig. 4B), *L.*
14
15 766 *discodactylus*, *L. melanonotus*, *L. natalensis*, *L. nesiotus*, *L. petersii* (Fig. 4C), *L. riveroi*,
16
17 767 and *L. wagneri* (Fig. 7B, D); spotted pattern in *L. intermedius* (Fig. 4D), *L. podicipinus*, and
18
19 768 *L. pustulatus*, immaculate in *L. diedrus*; upper lip stripe generally indistinct (Fig. 3A, Fig.
20
21 769 S1), upper lip stripe from under the mid-eye or over the snout in *L. brevipes*, *L.*
22
23 770 *intermedius*, *L. melanonotus*, *L. nesiotus*, *L. podicipinus*, *L. pustulatus*, and *L. riveroi* (Fig.
24
25 771 3C), and absent in *L. pascoensis*; presence of keratinised thumb spines in adult males (Fig.
26
27 772 S1), absent in *L. discodactylus* and *L. pustulatus*. All six adult specimens of *L. griseigularis*
28
29 773 examined by us have the upper lip stripe from the posterior corner of the eye, whereas it is
30
31 774 generally indistinct in *L. leptodactyloides*. Still, *L. leptodactyloides* is not easily
32
33 775 distinguished morphologically from *L. griseigularis* and *L. sabanensis*. Acoustic data
34
35 776 effectively distinguish the three species (see below for call redescrptions of the three
36
37 777 species). Despite being morphologically similar to each other, *L. leptodactyloides* and *L.*
38
39 778 *griseigularis* are distantly related to each other (Fig. 1); the phylogenetic position of *L.*
40
41 779 *sabanensis* has not been assessed.

42
43 780 The advertisement call of *L. leptodactyloides* (Fig. 5E) is formed by a non-pulsed
44
45 781 note with short duration (10–26 ms) emitted at a fast rate (highest repetition rate = 236
46
47 782 notes/min), a low dominant frequency (904–1,593 Hz), and a modest FM (345–689 Hz).
48
49 783 When combined, these acoustic characteristics distinguish *L. leptodactyloides* from all
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4 784 members of the *L. melanonotus* group occurring in Amazonia (Tables 2–3). From the two
5
6 785 morphologically most similar species, *L. leptodactyloides* is distinguished from *L.*
7
8 786 *griseigularis* by a lower dominant frequency (*L. leptodactyloides*: 904–1,593 Hz vs. *L.*
9
10 787 *griseigularis*: 1,938–2,864 Hz), a weaker FM (*L. leptodactyloides*: 345–689 Hz vs. *L.*
11
12 788 *griseigularis*: 1,120–1,723 Hz), and a faster repetition rate (*L. leptodactyloides*: 110–236
13
14 789 notes per minute vs. *L. griseigularis*: 90–104 notes per minute); from *L. sabanensis*, *L.*
15
16 790 *leptodactyloides* is mainly distinguished by a shorter note duration (*L. leptodactyloides*:
17
18 791 10–26 ms vs. *L. sabanensis*: 29–44 ms) and a faster repetition rate (*L. leptodactyloides*:
19
20 792 110–236 notes/min vs. *L. sabanensis*: 76 notes/min).
21
22
23
24
25
26

27 794 **Advertisement call of *L. leptodactyloides*.** The description is based on 681 calls of seven
28
29 795 males, obtained from multiple localities in Amazonia of Ecuador, Peru, and Brazil (see
30
31 796 Table S2 for details). The call (Fig. 5E) consists of a single, non-pulsed note given at a fast
32
33 797 rate of 110 to 236 (163.1 ± 42.7) per minute. Notes last 10 to 26 (18.9 ± 2.3) ms, the rise
34
35 798 time varies from 17 to 64 (31.0 ± 7.4) % of note duration. The dominant frequency varies
36
37 799 from 904 to 1,593 ($1,273.0 \pm 162.1$) Hz and coincides with the fundamental harmonic.
38
39 800 Notes have a modest frequency upsweep, ranging from 345 to 689 (496.2 ± 80.7) Hz.
40
41
42
43
44

45 802 **Advertisement call of *L. griseigularis*.** The description is based on 60 calls of three males
46
47 803 from the eastern Andean slopes in central and northern Peru (see Table S2 for details),
48
49 804 including the reanalysis of the recording analysed for the first acoustic description of the
50
51 805 species from Tingo María (type locality) by Heyer and Morales (1995). Because of the low
52
53 806 sound input, we could not accurately quantify the frequency modulation in the toptypical
54
55
56
57
58
59
60

1
2
3
4 807 calls. The call (Fig. 5D) consists of a single, non-pulsed note given at a rate of 90 to 104
5
6 808 (96.1 ± 7.5) per minute. Notes last 10 to 30 (18.5 ± 3.5) ms, the rise time varies from 18 to
7
8 809 69 (42.7 ± 10.9) % of note duration. The dominant frequency varies from 1,938 to 2,864
9
10 810 $(2,525.5 \pm 296.1)$ Hz and coincides with the fundamental harmonic. Notes have a well-
11
12 811 marked frequency upsweep, ranging from 1,120 to 1,723 $(1,479.4 \pm 100.4)$ Hz.
13
14
15

16 812

17
18 813 **Advertisement call of *L. sabanensis*.** The description is based on the reanalysis of 95 calls
19
20 814 from one male previously described from the Gran Sabana, in the Venezuelan state of
21
22 815 Bolívar (Heyer, 1994). The call (Fig. S2) consists of a single, non-pulsed note given at a
23
24 816 rate of 76 per minute. Notes last 29 to 45 (35.3 ± 3.4) ms, the rise time varies from 49 to 73
25
26 817 (62.0 ± 4.1) % of note duration. The dominant frequency varies from 1,529 to 1,873
27
28 818 $(1,678.5 \pm 54.7)$ Hz and coincides with the fundamental harmonic. Notes usually have a
29
30 819 modest or well-marked frequency upsweep, ranging from 474 to 1,163 (927.1 ± 116.5) Hz.
31
32
33

34 820

35
36 821 **Geographic distribution.** Based on the genotyped individuals plus specimens
37
38 822 morphologically assigned to the species, *L. leptodactyloides* is widely distributed in
39
40 823 lowland Amazonian forests from Ecuador to eastern Brazilian Amazonia. The species also
41
42 824 occurs in the savannah area close to the mouth of the Amazon River in the Brazilian state
43
44 825 of Amapá and in the Pantanal floodplains in the Brazilian state of Mato Grosso, as well as
45
46 826 other humid habitats in the open formations in adjacent Bolivia (distinct OTUs; see Fig. 1).
47
48
49

50 827

51
52 828 **Notes on natural history.** In south-western Amazonia of the Brazilian state of Acre, we
53
54 829 observed males calling from temporary rain pools in a human-altered area covered with
55
56
57
58
59
60

1
2
3
4 830 exotic grasses, located ~100 m from the closest forest fragment. Individuals recorded and
5
6 831 collected by us in San Martin, Peru (Pongo-Barranquita and Pucallpa; see Tables S1–S2)
7
8
9 832 were found in shallow flooded areas near slow-flowing streams in lowland Amazonian
10
11 833 forest. There were nearby clearings and the forest had some degree of human disturbance in
12
13 834 both cases. In the Pongo-Barranquita area, *L. discodactylus* was sympatric with *L.*
14
15 835 *leptodactyloides*, whereas *L. griseigularis*, also recorded and collected in the area, was not
16
17 836 collected in sympatry with *L. leptodactyloides*. In Ecuador, the species occurs in artificial
18
19 837 open areas, and secondary and primary forests. Vegetation types include *Terra Firme* forest
20
21 838 (forests with well-drained soil), *Várzea* forest (seasonally flooded forests), and swamps.
22
23
24
25 839 They are commonly found next to lakes and rivers.
26

27 840

29 841 **Remarks.** We examined a male specimen (ZUEC-AMP 9407) collected from the same
30
31 842 locality (Bolívar, Venezuela's Gran Sabana) where the calls (recording FNJV 31079;
32
33 843 deposited also in the Smithsonian under the accession USNM 225 and field code AJC 346)
34
35 844 assigned to *L. sabanensis* by W. R. Heyer were recorded by Adão J. Cardoso (AJC).
36
37 845 However, there is a mismatch between the dates of the recording and specimen collection.
38
39 846 It is relevant to mention that AJC himself did not link this specimen as a call voucher of
40
41 847 that recording. The collection date of this specimen is registered in the ZUEC catalogue as
42
43 848 19 June 1990, whereas the corresponding recording was made on 18 or 19 January in the
44
45 849 same year (registered by voice in the original recording by AJC). We cannot trace back if
46
47 850 the divergence between months, but the coincidence on the day of collection and recording,
48
49 851 might have been a typographical error, which would indicate that ZUEC-AMP 9407 could
50
51 852 be the call voucher of the recording FNJV 31079. During his narration at the end of the
52
53
54
55
56
57
58
59
60

1
2
3
4 853 recording, AJC mentioned that he was recording a *Leptodactylus* species with a horizontal
5
6 854 stripe under the eye. This favours the idea that ZUEC-AMP 9407 is not a call voucher
7
8
9 855 because this specimen has an upper lip stripe extending from the posterior corner of the eye
10
11 856 (i.e., character state B); such character state is also present in the adult female of *L.*
12
13 857 *sabanensis* in Figure 11 of Duellman (1997). We would expect that, by linking the recorded
14
15
16 858 call pattern from the Gran Sabana to a morphotype with a horizontal upper lip stripe, AJC
17
18 859 could have referred to (1) a species of the *L. fuscus* group (commonly known as white-
19
20 860 lipped frogs; see fig. 5 of Silva et al., 2020 for examples), (2) a species of the *L. bolivianus*
21
22 861 complex (also known as white-lipped frogs; Heyer & de Sá, 2011), or (3) another species of
23
24 862 the *L. melanonotus* group having the character state C of upper lip stripe (see Fig. 3C).
25
26
27 863 After reanalysing the recording FNJV 31079, we could discount all *Leptodactylus* species
28
29 864 with confirmed or potential occurrence in the Gran Sabana (Fig. 1; Heyer, 1994; Duellman,
30
31 865 1997; de Sá et al., 2014; Barrio-Amorós et al., 2019), except *L. longirostris* Boulenger,
32
33 866 1882, a terrestrial species (*L. fuscus* group) with a similar call, sympatric distribution, but
34
35 867 morphologically distinct from all species of the *L. melanonotus* group (see an adult male of
36
37 868 *L. longirostris* from the Gran Sabana in Fig. 208 of Barrio-Amorós et al. 2019; referred
38
39 869 therein as *L. sabanensis*). Then, we conducted an acoustic analysis ($n = 12$ males; 389
40
41 870 quantified notes) of *L. longirostris* (Fig. S2, Table 2; see Table S2 for locality data) and
42
43 871 found that the calls recorded from the Gran Sabana, originally assigned to *L. sabanensis*,
44
45 872 and those of *L. longirostris* overlap in all analysed traits. *Leptodactylus longirostris* is
46
47 873 reported as an abundant species throughout the Gran Sabana (Duellman, 1997). We
48
49 874 conclude that the calls recorded in the Gran Sabana could be conspecific with those of *L.*
50
51 875 *longirostris*, but assigned to *L. sabanensis* by Heyer (1994) in error. Perhaps Heyer
52
53
54
55
56
57
58
59
60

1
2
3
4 876 implicitly assumed that the male ZUEC-AMP 9407 should correspond to a call voucher
5
6 877 because of locality data. In this case, the advertisement call of *L. sabanensis* remains
7
8 878 unknown. We would require the collection of males linked to calls and DNA sequences to
9
10 879 confirm either possibility, focusing on both the morphotypes of the *L. melanonotus* group
11
12 880 (i.e., *L. sabanensis*) and *L. fuscus* group (i.e., *L. longirostris*) occurring in Venezuela's
13
14 881 Gran Sabana.

10
11 901 **Paratypes.** Six adult males (CFBH 45576–80 and 45583; field numbers CECC 3277–8,
12
13 902 3281–2, 3316, and 3697, respectively) and two adult females (CFBH 45581–2; field
14
15 903 numbers CECC 3276 and 3317, respectively) from Reserva Extrativista Beija-Flor Brilho
16
17 904 de Fogo (0.826528°N, 52.189333°W), in Pedra Branca do Amapari, state of Amapá, Brazil,
18
19 905 collected in 2019 and 2021 by C. E. Costa-Campos. Twenty-five adult specimens (18 males
20
21 906 and 7 females) from French Guiana, collected from 2009 to 2015: one male (MNHN-RA-
22
23 907 2021.0063; field number AF 0520) from Cisame camp, left margin of the Approuagues
24
25 908 (4.195265°N, 52.372028°W), collected by A. Fouquet; one male (MNHN-RA-2021.0064;
26
27 909 field number CAAM 40) from Montagne Cacao (2.349128°N, 53.215985°W) by O.
28
29 910 Chaline and M. Dewynter; one female (MNHN-RA-2021.0065; field number PG 784), by
30
31 911 A. Fouquet and E. Courtois, and one male (MNHN-RA-2021.0069; field number AF 0735),
32
33 912 by A. Fouquet, from St. Georges (3.811159–3.967639°N, 51.872250–51.889644°W); one
34
35 913 female (MNHN-RA-2021.0066; field number AF 0570) from Le Galion (4.766144°N,
36
37 914 52.432684°W) by M. Dewynter and K. Pineau; two males (MNHN-RA-2021-0067 and
38
39 915 MNHN-RA-2021-0068; field numbers AF 0702 and AF 0724, respectively) from Paracou
40
41 916 (5.275400°N, 52.923600°W) by A. Fouquet and P. Gaucher; one male (MNHN-RA-
42
43 917 2021.0070; field number AF 0810) from Savane Virgine (4.195900°N, 52.149000°W) by
44
45 918 A. Fouquet, E. Courtois, and M. Dewynter; one female (MNHN-RA-2021.0071; field
46
47 919 number AF 0885), by A. Fouquet, and one male (MNHN-RA-2021.0078; field number AF
48
49 920 1550), by A. Fouquet, A. Baglan, and M. Dewynter, from Matoury (4.857080–4.863239°N,

1
2
3
4 943 from Nassau (4.802620–4.804120°N, 54.555500–54.615020°W), eastern Suriname,
5
6 944 collected on 16–18 Dec 2014 by A. Fouquet and R. Jairam.
7
8

9 945

10
11 946 **Additional specimens.** Six adult specimens (four males and two females) from western
12
13 947 and southern Suriname, collected from 2014 to 2015: four males (MNHN-RA-2021.0090,
14
15 948 MNHN-RA-2021.0091, MNHN-RA-2021.0093, and MNHN-RA-2021.0094; field
16
17 949 numbers AF 1966, AF 1967, AF 2069, and AF2224, respectively) and one female (MNHN-
18
19 950 RA-2021.0092; field number AF 2058) from Sipaliwini (2.024390–2.179650°N,
20
21 951 56.085210–56.125080°W), collected by A. Fouquet and J. P. Vacher; one female (MNHN-
22
23 952 RA-2021.0095; field number AF 3369) from Bakhuis (4.762840°N, 56.779110°W) by A.
24
25 953 Fouquet, R. Jairam, and S. Cally. These six specimens, which form a distinct OTU
26
27 954 distributed in western and southern Suriname, were not included in the type series, given
28
29 955 the high genetic divergence displayed in comparison with the two other two OTUs assigned
30
31 956 to *L. fremitus* sp. nov. (mean *p*-distance = 5.3% in 16S). The low number of specimens and
32
33 957 recorded calls available for the divergent OTU from Suriname prevents us from evaluating
34
35 958 phenotypic variation and its taxonomic significance.
36
37
38
39
40

41 959

42
43 960 **Etymology.** The Latin word ‘fremitus’ can refer to a vibration transmitted through the body
44
45 961 (medical usage of the term), or a dull humming or roaring sound, among other kinds of
46
47 962 sounds. The epithet is related to the peculiar grunt sound produced by the new species.
48
49

50 963

51
52 964 **Diagnosis.** *Leptodactylus fremitus* is recognised in the *L. melanonotus* group by the
53
54 965 following combination of character states: (1) moderate size (male SVL = 34.1–47.5 mm);
55
56
57
58
59
60

1
2
3
4 966 (2) dorsolateral fold indistinct or short; (3) toe tips unexpanded; (4) upper lip stripe
5
6 967 extending from the posterior corner of the eye; (4) anterior belly mottled, fading
7
8 968 progressively towards hind limbs, posterior belly tending to immaculate; (5) two
9
10 969 keratinised spines at the base of the thumb in adult males; (6) single-note advertisement
11
12 970 call; (7) call formed by incomplete pulses; (8) fast repetition rate (highest repetition rate =
13
14 971 211 notes/min); (9) low dominant frequency (1078–1,443 Hz).
15
16
17
18 972

19
20 973 **Comparisons with congeners of the *L. melanonotus* group.** *Leptodactylus fremitus* (male
21
22 974 SVL = 34.1–47.5 mm; Table 4) can be distinguished from four of five sympatric species in
23
24 975 the EGS by a larger body size: *L. intermedius* (male SVL = 27.9–36.2 mm; Gazoni et al.,
25
26 976 2021), *L. nesiotus* (male SVL = 32.0–33.0 mm; Heyer, 1994), *L. petersii* (male SVL 26.4–
27
28 977 31.8 mm; Gazoni et al., 2021), and *L. validus* (male SVL = 30.6–35.6 mm; Appendix S4)—
29
30 978 the new species is mainly distinguished from the fifth sympatric (but not syntopic) species
31
32 979 in the EGS, *L. leptodactyloides*, in acoustic characteristics (see next paragraph; Table 2).
33
34 980 *Leptodactylus fremitus* is mainly distinguished from the other 19 species of the *L.*
35
36 981 *melanonotus* group by an indistinct or short dorsolateral fold (Figs. 8A–B, S3); long in *L.*
37
38 982 *wagneri* (Fig. 2E), complete in *L. riveroi* (Fig. 2F), and absent in *L. diedrus* (Fig. 2A) and
39
40 983 *L. magistris*. The new species is distinguished by an upper lip stripe extending from the
41
42 984 posterior corner of the eye (Figs. 8A–B, S3); extending from under the mid-eye or over the
43
44 985 snout in *L. brevipes*, *L. intermedius*, *L. melanonotus*, *L. nesiotus*, *L. podicipinus*, *L.*
45
46 986 *pustulatus*, and *L. riveroi* (Fig. 3C), generally indistinct in *L. leptodactyloides* (Fig. 3A),
47
48 987 and absent in *L. pascoensis*. *Leptodactylus fremitus* has the anterior belly mottled, fading
49
50 988 progressively towards hind limbs, and posterior belly tending to immaculate (Fig. 8F);
51
52
53
54
55
56
57
58
59
60

1
2
3
4 989 mottling throughout the belly in *L. brevipes* (Fig. 4B), *L. discodactylus*, *L. melanonotus*, *L.*
5
6 990 *natalensis*, *L. nesiotus*, *L. petersii* (Fig. 4C), *L. riveroi*, and *L. wagneri* (Fig. 7D); spotted
7
8 991 pattern in *L. intermedius* (Fig. 4D), *L. podicipinus*, and *L. pustulatus*, immaculate in *L.*
9
10 992 *diedrus*. The new species is distinguished from *L. diedrus* (Fig. 3F) and *L. discodactylus*
11
12 993 (Fig. 3G) by lacking toe tips developed into discs (Fig. 8E–F). *Leptodactylus fremitus* is
13
14 994 distinguished from *L. discodactylus* and *L. pustulatus* by the presence of two keratinised
15
16 995 thumb spines at the base of the thumb in adult males (Fig. 8D–F), absent in the other two
17
18 996 species.

19
20
21
22 997 *Leptodactylus fremitus* (endemic to the EGS) is more similar morphologically to the
23
24 998 allopatric *L. colombiensis* (Andean Colombia), *L. griseigularius* (endemic to Eastern
25
26 999 Andean slopes of Peru and Bolivia), and *L. sabanensis* (endemic to Venezuela's Gran
27
28 1000 Sabana), and the partially sympatric *L. leptodactyloides* (Fig. 1). In contrast, these species
29
30 1001 have distinct advertisement calls. *Leptodactylus fremitus* has a single-note call formed by
31
32 1002 incomplete pulses (Figs. 5B, 6H), differing from the non-pulsed calls of *L. griseigularis*
33
34 1003 (Fig. 6D), *L. leptodactyloides* (Fig. 6E), and *L. sabanensis* (Fig. S2). We did not conduct a
35
36 1004 quantitative acoustic analysis of *L. colombiensis*, yet it is possible to observe a noticeable
37
38 1005 frequency upsweep in the spectrogram provided in the original call description (de Sá et al.,
39
40 1006 2014: fig. 104), whereas the call of *L. fremitus* has a negligible or modest FM at the end of
41
42 1007 the call (Fig. 6H; Table 2). The irregular AM pattern in the call of *L. colombiensis* (de Sá et
43
44 1008 al., 2014: fig. 104) also differs from the regular AM pattern (incomplete pulses) in the call
45
46 1009 of *L. fremitus* (Figs. 5B, 6H). The call of *L. wagneri* (Fig. 6I) and the call type 1 of *L.*
47
48 1010 *petersii* (Fig. 6G) are also formed by incomplete pulses. From *L. wagneri*, the new species
49
50 1011 is distinguished by a weaker FM or no modulation at all (*L. wagneri*: 656–1172 Hz vs. *L.*
51
52
53
54
55
56
57
58
59
60

1
2
3
4 1012 *fremitus*: 0–431 Hz). From *L. petersii*, the new species is distinguished by a greater number
5
6 1013 of pulses per note (*L. petersii*: 3–5 vs. *L. fremitus*: 5–10) and longer note duration (*L.*
7
8 1014 *petersii*: 31–50 ms vs. *L. fremitus*: 59–105 ms). The call of *L. fremitus* is composed of a
9
10 1015 single note, whereas that of *L. riveroi* is formed by series of two-pulse notes (Fig. 5C). The
11
12 1016 temporal envelope of *L. pustulatus* calls consists of a series of both complete and
13
14 1017 incomplete AM (Fig. 5D), whereas that of *L. fremitus* consists of incomplete pulses
15
16 1018 regularly distributed throughout the calls (Fig. 5B). Along with the call description of *L.*
17
18 1019 *fremitus*, we redescribe the advertisement calls of the partially sympatric *L. nesiotus* and *L.*
19
20 1020 *validus* to allow direct interspecific comparisons.
21
22
23
24

25 1021

26
27 1022 **Description of holotype (Fig. 8).** Adult male, SVL 40.4 mm, THL 20.3 mm, TL 20.4 mm,
28
29 1023 FL 21.6 mm, HAL 10.0 mm, HL 15.6 mm, HW 15.4 mm, ED 3.9 mm, TD 3.3 mm, EN 4.5
30
31 1024 mm, IND 3.6 mm, IMT 1.9 mm, OMT 0.9 mm, Fin3DW 0.9 mm, Toe4DW 1.0 mm. Snout
32
33 1025 sub-oval in dorsal view, rounded to acuminate in lateral view. Canthus rostralis rounded;
34
35 1026 loreal region slightly concave; tympanic annulus well-defined, mostly circular (TD/ED =
36
37 1027 85%), covered by supratympanic fold above and posteriorly; tympanic membrane partially
38
39 1028 translucent; supratympanic fold from the posterior corner of the eye, over the dorsal edge of
40
41 1029 the tympanic annulus, to the base of the arm; vocal sac subgular; vocal slits present;
42
43 1030 vomerine teeth in two nearly straight rows medial and posterior to choanae and almost
44
45 1031 parallel to sagittal plane. Tongue elongated, free from the posterior third. Two keratinised
46
47 1032 spines at the base of Finger I, and a small keratinised area more distally. Relative finger
48
49 1033 lengths IV < II < I < III; fingers fringed laterally, especially in outer side of Finger I, and
50
51 1034 inner side of Fingers II–III; finger tips rounded, tip of Finger I slightly swollen; inner

2
3
4 1035 metacarpal tubercle cordiform; outer metacarpal tubercle ovoid (Fig. 3D). Subarticular
5
6 1036 tubercles rounded; supernumerary tubercles absent. Dorsal surfaces of body and limbs
7
8 1037 covered with white-tipped tubercles (some keratinised), especially on the posterior half of
9
10 1038 the body and hind limbs. Flank shagreened and glandular. Dorsolateral fold indistinct, with
11
12 1039 an indication behind the eyelids as a row of tubercles. Ventral surface of body and limbs
13
14 1040 smooth, underside of thigh glandular. Relative toe lengths $I < II < V < III < IV$; toes
15
16 1041 extensively fringed; toe tips rounded; tip of Toe II slightly swollen. Inner metatarsal
17
18 1042 tubercle elongated; outer metatarsal tubercle conical. Inner tarsal fold extending 2/3 of
19
20 1043 tarsus length, from the base of the inner metatarsal tubercle towards the heel. Fringe along
21
22 1044 the outer side of Toe V extending to outer metatarsal tubercle. Subarticular tubercles nearly
23
24 1045 rounded to oval; supernumerary tubercles absent. Sole of foot and tarsus covered with
25
26 1046 brown-tipped tubercles (keratinised).

27
28
29
30
31
32 1047 In preservative, dorsal surfaces (body and limbs) brown with lighter and darker
33
34 1048 brown blotches in the background. Interorbital blotch poorly delimited posteriorly,
35
36 1049 anteriorly bordered by a silvery horizontal bar. Upper lip stripe light grey; upper and lower
37
38 1050 lips white spotted. Flank light grey. Throat darkened (brown) with pale spots and dots.
39
40 1051 Chest and anterior belly brown mottled on a pale background; posterior belly immaculate.
41
42 1052 Underside of thigh finely mottled on a partially translucent, yellow background. Posterior
43
44 1053 surface of thigh black with a light grey mottling and an irregular, longitudinal stripe (on the
45
46 1054 right side). Palm of hand and sole of foot dark brown, except tubercles and finger and toe
47
48 1055 tips, which vary from cream to grey. Thumb spines solid black. In life, dorsal surfaces with
49
50 1056 different shades of brown. Upper side of the iris reddish brown, the lower side grey and
51
52 1057 dark brown. Upper lip stripe light brown; upper and lower lips with white spots and
53
54
55
56
57
58
59
60

1
2
3
4 1058 blotches. Flank with a gradient of light brown, red, and yellow towards the belly. Dorsal
5
6 1059 surface of thigh with dark brown transverse bars. Posterior surface of thigh black with a
7
8
9 1060 yellow mottling and an irregular, longitudinal stripe (on the right side). Throat light grey
10
11 1061 and light cream, belly and underside of thigh with a yellow mottling. Ventral surfaces of
12
13 1062 hand and foot dark brown, tarsus dark mottled on a light grey and yellow background.

14
15 1063 Thumb spines solid black.

16
17
18 1064

19
20 1065 **Variation in the type series.** Dorsolateral fold is mostly indistinct, but can be short,
21
22 1066 interrupted. Upper lip stripe is poorly outlined in CFBH 45580. This specimen also has its
23
24 1067 ventral colouration partially faded. Five specimens from Amapá (CFBH 45577–8, 45581–
25
26 1068 3) do not have any indication of longitudinal stripe on the posterior surface of the thigh.
27
28 1069 Dorsal colouration (especially in life) varies from light grey/brown to dark brown. Dark
29
30 1070 brown and black blotches can be present. In life, some specimens have a reddish
31
32 1071 colouration on the scapular region (MNHN-RA-2021.0072; Fig. S3). Mottling in life is
33
34 1072 usually formed by contrasts of black and bright yellow. Populations assigned to *L. fremitus*
35
36 1073 form two distinct OTUs (mean *p*-distance = 2.9% in 16S), one of them (OTU #6; Fig. 1)
37
38 1074 occupying French Guiana and Amapá (Brazil), the other (OTU #41; Fig. 1) occupying
39
40 1075 eastern Suriname and northern Pará (Brazil). Morphological and acoustic variation of these
41
42 1076 two groups of populations overlaps to each other, thus suggesting that the genetic
43
44 1077 divergence can be considered intraspecific variation.

45
46
47
48
49 1078

50
51
52 1079 **Advertisement call of *L. fremitus*.** The description is based on 312 calls of seven males,
53
54 1080 including the holotype and one paratype, from the Eastern Guiana Shield (Brazil, French

1
2
3
4 1081 Guiana, and Suriname; see Table S2 for details). The call (Figs. 5B, 6H) consists of a single
5
6 1082 note formed by incomplete pulses. Notes are given at a rate of 63 to 211 (124.2 ± 62.2) per
7
8 1083 minute. Notes last 59 to 105 (85.6 ± 7.6) ms, the rise time varies from 41 to 71 (56.7 ± 3.3)
9
10 1084 % of note duration. Notes are formed by 5 to 10 (7.6 ± 0.9) incomplete pulses with duration
11
12 1085 varying from 8 to 16 (11.3 ± 1.2) ms, emitted at a rate of 92 to 140 (117.9 ± 8.6) per
13
14 1086 second. The dominant frequency varies from 1,078 to 1,443 ($1,232.0 \pm 72.5$) Hz and
15
16 1087 coincides with the fundamental harmonic. Notes have a modest frequency upsweep or no
17
18 1088 modulation, ranging from 0 to 431 (173.1 ± 60.6) Hz.
19
20
21
22

23 1089

24
25 1090 **Advertisement call of *L. nesiotus*.** The description is based on the reanalysis of 30 calls of
26
27 1091 one male from the Trinidad Island (type locality), recorded by J. R. Downie and described
28
29 1092 by Heyer (1994), plus 48 calls of one male from French Guiana (see Table S2 for details).
30
31 1093 The call (Fig. S4) consists of a single, non-pulsed note given at a fast rate of 264 to 288
32
33 1094 (276.1 ± 17.3) per minute. Notes last 25 to 38 (29.4 ± 0.2) ms, the rise time varies from 16
34
35 1095 to 69 (47.9 ± 13.6) % of note duration. The dominant frequency varies from 1,421 to 1,938
36
37 1096 ($1,877.9 \pm 44.4$) Hz and coincides with the fundamental harmonic. Notes usually have a
38
39 1097 weak to modest frequency upsweep, ranging from 86 to 603 (539.2 ± 31.7) Hz.
40
41
42

43 1098

44
45 1099 **Advertisement call of *L. validus*.** The description is based on 456 calls of 11 males from
46
47 1100 Brazil, including lowland Amazonian forests (Amazonas State) and the savannah
48
49 1101 ecosystem in Roraima State, as well as Trinidad Island (see Table S2 for details). The call
50
51 1102 (Fig. 6C) consists of a single, non-pulsed note given at a rate of 62 to 161 (124.8 ± 31.1)
52
53 1103 per minute. Notes last 26 to 63 (45.9 ± 7.0) ms, the rise time varies from 16 to 66 ($38.8 \pm$
54
55
56
57
58
59
60

1
2
3
4 1104 10.5) % of note duration. The dominant frequency varies from 2,541 to 3,230 ($2,972.9 \pm$
5
6 1105 141.8) Hz and coincides with the fundamental harmonic. Notes usually have a pronounced
7
8
9 1106 frequency upsweep, ranging from 861 to 1,938 ($1,360.3 \pm 180.3$) Hz.
10

11 1107

12
13 1108 **Geographic distribution.** *Leptodactylus fremitus* is endemic to the EGS in north-western
14
15 1109 Pará (Brazil), French Guiana, and eastern Suriname. In French Guiana, *L. fremitus* is
16
17 1110 distributed across the entire territory, including the coastal forests. However, the species
18
19 1111 has not been recorded from Guyana, or the Brazilian states of Roraima and Amazonas,
20
21 1112 which indicates either a western range boundary in Suriname and the Brazilian state of Pará
22
23 1113 north of the Amazon River (Fig. 1) or sampling gaps, but in any case, the species is
24
25 1114 unambiguously circumscribed to the EGS. It is noteworthy that the westernmost
26
27 1115 populations in Suriname (Bakhuis and Sipaliwini) harbour a distinct mtDNA lineage,
28
29 1116 indicating the possible existence of an additional species. This distribution pattern (i.e.,
30
31 1117 endemic to the EGS) is shared many species in the region (Vacher et al., 2020) and the
32
33 1118 genetic break along the Maroni River strikingly mirrors those observed in other anuran
34
35 1119 species (Fouquet et al., 2012), such as *Allobates granti* (Kok et al., 2006), *Anomaloglossus*
36
37 1120 *surinamensis* Ouboter & Jairam, 2012, and *Pristimantis chiastonotus* (Lynch & Hoogmoed,
38
39 1121 1977).
40
41
42
43
44
45

46 1122

47
48 1123 **Habitat and natural history.** The species occupies marshy areas between 0 and 400 m
49
50 1124 elevation of primary and secondary forests, but is sometimes found also at sites under a
51
52 1125 certain degree of human disturbance near urbanised areas, notably flooded areas, such as
53
54 1126 ponds forming on the bed of streams and rivers. *Leptodactylus fremitus* occurs syntopically
55
56
57
58
59
60

1
2
3
4 1127 throughout its distribution range with *L. petersii* and syntopically in Suriname with *L.*
5
6 1128 *validus*. Groups of several juveniles of *L. fremitus* can sometimes be observed on the
7
8 1129 muddy banks. Breeding occurs throughout the rainy season. According to our field
9
10 1130 observations, males generally call at night from a cavity excavated at the water level on the
11
12 1131 wetland bank or beneath the leaves nearby. They are generally isolated, calling at a long
13
14 1132 distance from one another, but can sometimes form small choruses of 2–4 males. The foam
15
16 1133 nest protecting the egg clutch is produced in a previously excavated chamber, where it
17
18 1134 floats on the accumulated water (reproductive mode 13 of Haddad & Prado, 2005). When a
19
20 1135 female joins a male inside the chamber, the male emits a courtship vocalisation and
21
22 1136 performs particular courtship movements that have not yet been observed in detail. Another
23
24 1137 type of vocalisation is emitted during interactions between males. Once freely swimming,
25
26 1138 the tadpoles remain grouped (schooling behaviour) and at short distances from the female.
27
28 1139 Adult individuals, when manipulated, secrete a toxic substance from their skin that causes
29
30 1140 irritation to human skin and mainly when the secretion comes into contact with the mucosa.
31
32
33
34
35

36 1141 At the type locality (Serra do Navio, Amapá, Brazil), the holotype of *L. fremitus*
37
38 1142 was heard calling from inside a previously excavated underground chamber (partially filled
39
40 1143 with water) half a metre from the water course of a rocky-bottom rivulet. The chamber was
41
42 1144 excavated from underneath a thin layer of leaf litter so that one broad leaf protected it as the
43
44 1145 chamber's roof. As the leaf was pulled off the ground, the male was observed with only his
45
46 1146 head above the water, which he quickly submerged into the accumulated water inside the
47
48 1147 chamber. *Leptodactylus petersii* is the only sympatric species of the group at the type
49
50 1148 locality of *L. fremitus*.
51
52
53
54

55 1149
56
57
58
59
60

1
2
3
4 1150 **Remarks.** The advertisement and aggressive calls of *L. nesiotus* were recently
5
6 1151 characterised by Borzée et al. (2020). Those authors analysed advertisement calls of one
7
8 1152 male recorded in the field and two other males recorded in the laboratory. This call type
9
10 1153 was described as composed of two note types (named as pulses A and B). Our sample of *L.*
11
12 1154 *nesiotus* calls from Trinidad Island and French Guiana consisted of a single type of non-
13
14 1155 pulsed note emitted at a fast repetition rate as a typical bubbling call pattern, which is
15
16 1156 consistent with the original description (see Heyer, 1994: fig. 30). We reinterpret the
17
18 1157 second type of note (= pulse B) described in Borzée et al. (2020) as background calls of an
19
20 1158 antiphonal calling male, which is commonly observed among species of the *L. melanonotus*
21
22 1159 group with bubbling calls (see Fig. S4).
23
24
25
26
27
28

29 1160

30 1161 **Final comments on *Leptodactylus* taxa.** Information on two species (*L. magistris* and *L.*
31
32 1162 *pascoensis*) is limited to their original descriptions (Heyer, 1994; Mijares-Urrutia et al.,
33
34 1163 1997). Until now, their calls remain unknown and DNA sequences have not been linked to
35
36 1164 their morphotypes either. Besides these two species, *L. sabanensis* does not have any
37
38 1165 available DNA sequence and the calls originally assigned to the species might have been
39
40 1166 erroneously confused with calls of another *Leptodactylus* species, as stated earlier in our
41
42 1167 study. Therefore, future efforts in data collection should concentrate on these three species.
43
44 1168 Moreover, a better characterisation of intraspecific variation of populations currently
45
46 1169 assigned to *L. colombiensis* and *L. melanonotus* could shed light on potential cryptic
47
48 1170 diversity in the *L. melanonotus* group.

58
59
60

1172 **Discussion**

1173 The high diversity of mtDNA lineages within the *L. melanonotus* group indicates that
1174 species richness in the group might still be underestimated. Our DNA-based species
1175 delimitation resulted in 57 OTUs and included 16 nominal species out of 19 (84%). This
1176 figure matches the numerous studies focusing on other groups of Neotropical anurans,
1177 suggesting vast underestimations of species diversity (e.g., *Allobates* Réjaud et al., 2020;
1178 *Synapturanus* Fouquet et al., 2021; *Amazophrynella* Moraes et al., 2022). It is interesting to
1179 note, however, that some species of the group comprise several geographically structured
1180 lineages that could indicate population genetic structure rather than species boundaries
1181 (false positives). For example, *L. natalensis* displays genetic structure among populations
1182 distributed in the Atlantic Forest and Cerrado but without phenotypic disparity (i.e.,
1183 conservative morphology and calls). On the other hand, *L. petersii* displays a remarkable
1184 geographic structure and genetic divergence among populations throughout Amazonia and
1185 also exhibits pronounced phenotypic variation, which could indicate that multiple species
1186 are subsumed under *L. petersii*. In the case of *L. colombiensis*, there is one lineage in
1187 Andean Colombia (referred to herein as *Leptodactylus* sp. from Colombia) that was
1188 recovered as a putative new species. This is a region with limited phenotypic data (i.e.,
1189 morphological and acoustic data of taxonomic relevance) that can actually be linked to
1190 DNA sequences, which hampers an appropriate evaluation of its taxonomic status. Another
1191 limitation is the geographically restricted molecular sampling of *L. melanonotus*,
1192 particularly for Central American populations. Based on our results and sampling gaps,

1
2
3
4 1193 additional candidate new lineages within the *L. melanonotus* group are expected to be
5
6 1194 present in the Andes, Amazonia, and Central America.

7
8
9 1195 The currently available molecular data of *Leptodactylus* is essentially represented
10
11 1196 by fragments of mitochondrial DNA genes (16S, 12S, and COI), and the only nuclear DNA
12
13 1197 gene comprehensively sampled across the genus (rhodopsin) is not informative enough to
14
15 1198 investigate species relationships within the genus (e.g., Carvalho et al., 2021; Gazoni et al.,
16
17 1199 2021). The reduced number of sampled genes for *Leptodactylus* taxa may compromise our
18
19 1200 understanding of the phylogenetic relationships within the genus and the acquisition of
20
21 1201 additional molecular markers for more than 80 species distributed across the Neotropics
22
23 1202 remains necessary but a challenging task. However, our phylogenetic tree of the *L.*
24
25 1203 *melanonotus* group represents the most geographically and taxonomically complete until
26
27 1204 now. We acknowledge that the limited genetic data supporting our phylogenetic hypothesis
28
29 1205 might bias a broader understanding of the evolutionary history of this *Leptodactylus* group,
30
31 1206 and, as such, prevent us from conducting formal biogeographic analyses (e.g., ancestral
32
33 1207 area reconstruction). Nevertheless, in the next paragraph we offer a speculative
34
35 1208 interpretation of the diversification of the *L. melanonotus* group. We understand that such a
36
37 1209 discussion would serve as ground for future research on the historical biogeography of the
38
39 1210 *L. melanonotus* group and, more broadly, the entire genus *Leptodactylus*.

40
41 1211 Our phylogenetic hypothesis suggests that the *L. melanonotus* group might have
42
43 1212 originated in lowland Amazonian forests, where most diversification within this
44
45 1213 *Leptodactylus* group took place, a scenario shared by other co-distributed anuran groups
46
47 1214 (e.g., *Adenomera*: Fouquet et al., 2014; *Allobates*: Réjaud et al., 2020; *Pipa*: Fouquet et al.,
48
49 1215 2022). Assuming an Amazonian origin for the clade, subsequent diversification within the
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4 1216 *L. melanonotus* group would involve at least five dispersal events. *Leptodactylus pustulatus*
5
6
7 1217 may represent the first dispersal event outside Amazonia by occupying a vast area in the
8
9 1218 South American Dry Diagonal (not shown in Fig. 1, but can be visualised in fig. 126 of de
10
11 1219 Sá et al., 2014). Another possible dispersal event is related to a clade that occupied Andean
12
13 1220 Colombia (*L. colombiensis* and a second lineage reported herein as *Leptodactylus* sp. from
14
15 1221 Colombia, possibly endemic to that region; see Fig. 1), the Guiana Shield (*L. validus*,
16
17 1222 widely distributed across the region; Fig. 1), and the Pacific lowlands (Ecuadorian
18
19 1223 population of *L. melanonotus*; Fig. 1). In the case of *L. melanonotus*, assuming that this
20
21 1224 name represents a single taxonomic unit across its geographic range (but see a discussion
22
23 1225 on sequences assigned to the species in Gazoni et al., 2021), the species could have
24
25 1226 expanded northward into the Caribbean drainage of Colombia and Venezuela, and across
26
27 1227 Central America, and Mexico. This clade also contains the Amazonian endemic *L. wagneri*,
28
29 1228 which could have occupied lowland Amazonian forests secondarily. A possible third
30
31 1229 dispersal event is associated with the *L. podicipinus* clade, in which one species (*L.*
32
33 1230 *intermedius*) is widespread in Amazonia, whereas *L. brevipes* and *L. podicipinus* occupied
34
35 1231 open formations in central South America (Fig. 1). In the clade formed by *L. nesiotus* and
36
37 1232 *L. fremitus*, the geographic range of both species coincides with Amazonia. *Leptodactylus*
38
39 1233 *nesiotus* could have expanded towards coastal areas in northern South America and
40
41 1234 Trinidad Island, reaching an eastern limit in French Guiana (not occurring in the
42
43 1235 easternmost coastal area in French Guiana and also absent in adjacent Amapá, Brazil; Fig.
44
45 1236 1). In contrast, *L. fremitus* is a forest-dwelling species mostly associated with Amazonia but
46
47 1237 also occurs in coastal French Guiana. The latter species is endemic to the EGS (Fig. 1).
48
49 1238 Lastly, in the clade formed by *L. leptodactyloides* and *L. natalensis*, the first species has a
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4 1239 discontinuous distribution within Amazonia, possibly biased by misidentifications and
5
6 1240 insufficient sampling efforts, and is also distributed in the Chiquitano dry forests (Bolivia
7
8 1241 and Brazil), reaching Pantanal floodplains and Cerrado ecotone in Brazil (Fig. 1).
9
10
11 1242 *Leptodactylus natalensis* occupied a vast region of coastal Atlantic Forest and humid areas
12
13 1243 in the Cerrado and Caatinga (Fig. 1).

14
15 1244 Species of the *L. melanonotus* group use a wide variety of aquatic habitats as calling
16
17 1245 and breeding sites, such as rain water accumulated in puddles, areas seasonally flooded by
18
19 1246 rivers caused by water regimes, or flowing water systems (e.g., Heyer & Bellin, 1973;
20
21 1247 Heyer, 1994; Rodrigues et al., 2011). These environments are generated and maintained by
22
23 1248 hydrological dynamics (e.g., river seepages) or human activity in completely altered areas
24
25 1249 (e.g., uncovered sewage systems in urban perimeter). Calling and breeding habitats often
26
27 1250 indicate the occurrence of certain species in a region, but do not reflect phylogenetic
28
29 1251 relatedness. Pairs of closely related species of the *L. melanonotus* groups are generally
30
31 1252 allopatric and also diverge in phenotypic traits, such as *L. colombiensis* and *L. wagneri*, and
32
33 1253 *L. leptodactyloides* and *L. natalensis* (see Fig. 1). Most species of the group are forest
34
35 1254 dwellers widely distributed in lowland Amazonian forests, which use temporary pools and
36
37 1255 rivulets inside the forest, or seasonally flooded forests (Heyer, 1994). These include *L.*
38
39 1256 *diedrus*, *L. discodactylus*, *L. fremitus*, *L. petersii*, and *L. riveroi*—*L. petersii* being
40
41 1257 sympatric with all other five species in different parts of Amazonia. In contrast, *L.*
42
43 1258 *intermedius* is an Amazonian endemic species that occupies open habitats, including
44
45 1259 temporary rain pools in human-altered areas and floating meadows. *Leptodactylus*
46
47 1260 *leptodactyloides*, *L. validus*, and *L. wagneri* are species that have been reported to use both
48
49 1261 open and forest habitats. Populations of *L. leptodactyloides* and *L. validus* sampled by us in
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4 1262 the field generally prefer open habitats over forests as calling sites, whereas *L. wagneri* is
5
6 1263 more commonly found in forest habitats, being the distantly related *L. leptodactyloides* and
7
8 1264 *L. wagneri* sympatric in western Amazonia. *Leptodactylus nesiotus*, *L. podicipinus*, and *L.*
9
10 1265 *pustulatus* typically use open habitats. An intermediate pattern is observed across the
11
12 1266 geographic range of *L. brevipes* and *L. natalensis*. These two species exhibit plasticity in
13
14 1267 the range of preferred habitats, occurring predominantly in open formations or forests
15
16 1268 depending on the occurrence area. In some localities, shadowy habitats are usually
17
18 1269 preferred, such as forest borders, dense groves of Buriti palm (*Mauritia flexuosa*), and
19
20 1270 swampy areas inside the forest, often in forest clearings. In other localities, calling males
21
22 1271 are more often found in temporary rain pools in pastures, marshes, and artificial ponds.
23
24 1272 Interestingly, *L. podicipinus* does not occur syntopically either with *L. brevipes* or *L.*
25
26 1273 *natalensis*, even though *L. podicipinus* has a distinct call pattern (water drop call) in
27
28 1274 comparison with the bubbling calls of the other two, partially sympatric, species.
29
30
31
32
33

34 1275 The combination of geographical, ecological, and phylogenetic data of the *L.*
35
36 1276 *melanonotus* group suggests phylogenetic overdispersion, i.e., the most closely related
37
38 1277 species are often ecologically distinct and spatially distant from each other. Together, the
39
40 1278 reassessments provided in the present study highlight this widely distributed anuran clade
41
42 1279 as a future opportunity of understanding the evolution of ecological niche partitioning, as
43
44 1280 well as major morphological and acoustic patterns in the context of sympatric and allopatric
45
46 1281 species co-occurrence in open formations and forests across the Neotropics.

Table 2. Summary of the quantitative acoustic analysis of the *Leptodactylus melanonotus* group: advertisement call (= note) duration (ND) in milliseconds (except *L. riveroi* with a multi-note call), note repetition rate (NR) per minute, pulses per note (PP; N = non-pulsed), and dominant frequency (DF) and frequency modulation (FM) in Hertz. The same acoustic traits are presented for *L. longirostris* (*L. fuscus* group), sympatric with *L. sabanensis* (see text for details). Sample sizes: numbers of recorded males / analysed notes. * Data extracted from Gazoni et al. (2021), except for the note repetition rate (this study). Locality data of recorded males are provided in Table S2.

Species	ND (ms)	NR (min)	PP	DF (Hz)	FM (Hz)	Sample sizes
<i>L. brevipes</i> *	6–20	150–330	N	1,078–1,172 and 2,016–2,953	938–1,969	7 / 258

Table 3. Summary of morphological and acoustic characters of taxonomic relevance in the *Leptodactylus melanonotus* group. In characters that display high intraspecific variation (e.g., dorsolateral fold), the most frequent state was considered. Codes for character states: dorsolateral fold (abs: absent; i-s: indistinct to short; s-m: short to moderate; m-l: moderate to long; lon: long; com: complete); upper lip stripe (A: indistinct; B: from posterior eye corner; C: under the eye); belly pattern (ima: immaculate; mot1: mottling concentrated anteriorly; mot2: mottling throughout; ana: anastomotic; spot: spotted); toe tip (u-s: unexpanded to slightly swollen; disc1: developed into discs with a central longitudinal groove; disc3: developed into discs with at least three grooves); thumb spines (abs: absent; pre: present); amplitude modulation (abs: absent; inc: incomplete; com: complete); frequency modulation (wea: weak; mod: modest; pro: pronounced); calling rate (low; high). The definition of character states is detailed in the text. Character states of *L. petersii*'s call type 1 and 2 are presented in this order, separated by a slash.

Figure captions

Fig. 1. Maximum Likelihood tree obtained from the analysis of 2,428 bp (16S + COI) with branches collapsed according to the consensus of the results of the three species delimitation methods (based on 613 bp of 16S). Posterior probabilities are indicated at the internal branches. An asterisk indicates a posterior probability of 1.0. OTU numbers resulting from the consensus of the delimitation methods are shown along the vertical axis.

Fig. 2. Variation of the dorsolateral fold (A–E) in the *Leptodactylus melanonotus* group. (A) absent, *L. diedrus* (field number AF 4064); (B), indistinct or fragmented, *L. leptodactyloides* (AAG-UFU 5868); (C) short, *L. natalensis* (AAG-UFU 4984); (D) moderate to long (fragmented posteriorly), *L. podicipinus* (AAG-UFU 0098); (E) long, *L. wagneri* (QCAZ-A 38775); and (F) complete, *L. riveroi* (INPA-H 37253; photo by Leandro J. C. L. Moraes).

Fig. 3. Character states of the upper lip stripe (A–C) and toe tips (D–G) in the *Leptodactylus melanonotus* group. (A) Indistinct, *L. leptodactyloides* (AAG-UFU 5868); (B) from posterior eye corner, *L. natalensis* (AAG-UFU 4984); and (C) under the eye, *L. riveroi* (INPA-H 37253; photo by Leandro J. C. L. Moraes). (D) Unexpanded, *L. petersii* (AAG-UFU 6605); (E) slightly swollen, *L. validus* (AAG-UFU 3887); (F) toe discs with one central longitudinal groove, *L. diedrus* (AAG-UFU 3890); and (G) toe discs with four longitudinal grooves, *L. discodactylus* (ZUEC-AMP 11109).

Table S2. Sound recordings of species the *Leptodactylus melanonotus* group and *L. longirostris* (*L. fuscus* group) analysed in this study. ‘##’ corresponds to occasions when the recorded male was observed but not collected. Sound repositories: AAG-UFU, Universidade Federal de Uberlândia (Ituiutaba, Brazil); FNVJ, Universidade Estadual de Campinas (Brazil); FonoZoo, Fonoteca Zoológica de Madrid (Madrid, Spain); LH, Universidade Federal de Mato Grosso (Cuiabá, Brazil); Macaulay Library (ML), The Cornell Lab of Ornithology (Ithaca, United States); MNHN, Muséum National d'Histoire Naturelle (Paris, France); QCAZA, Pontifica Universidad Catolica del Ecuador (Quito, Ecuador); USNM, Smithsonian Institution (Washington DC, United States).

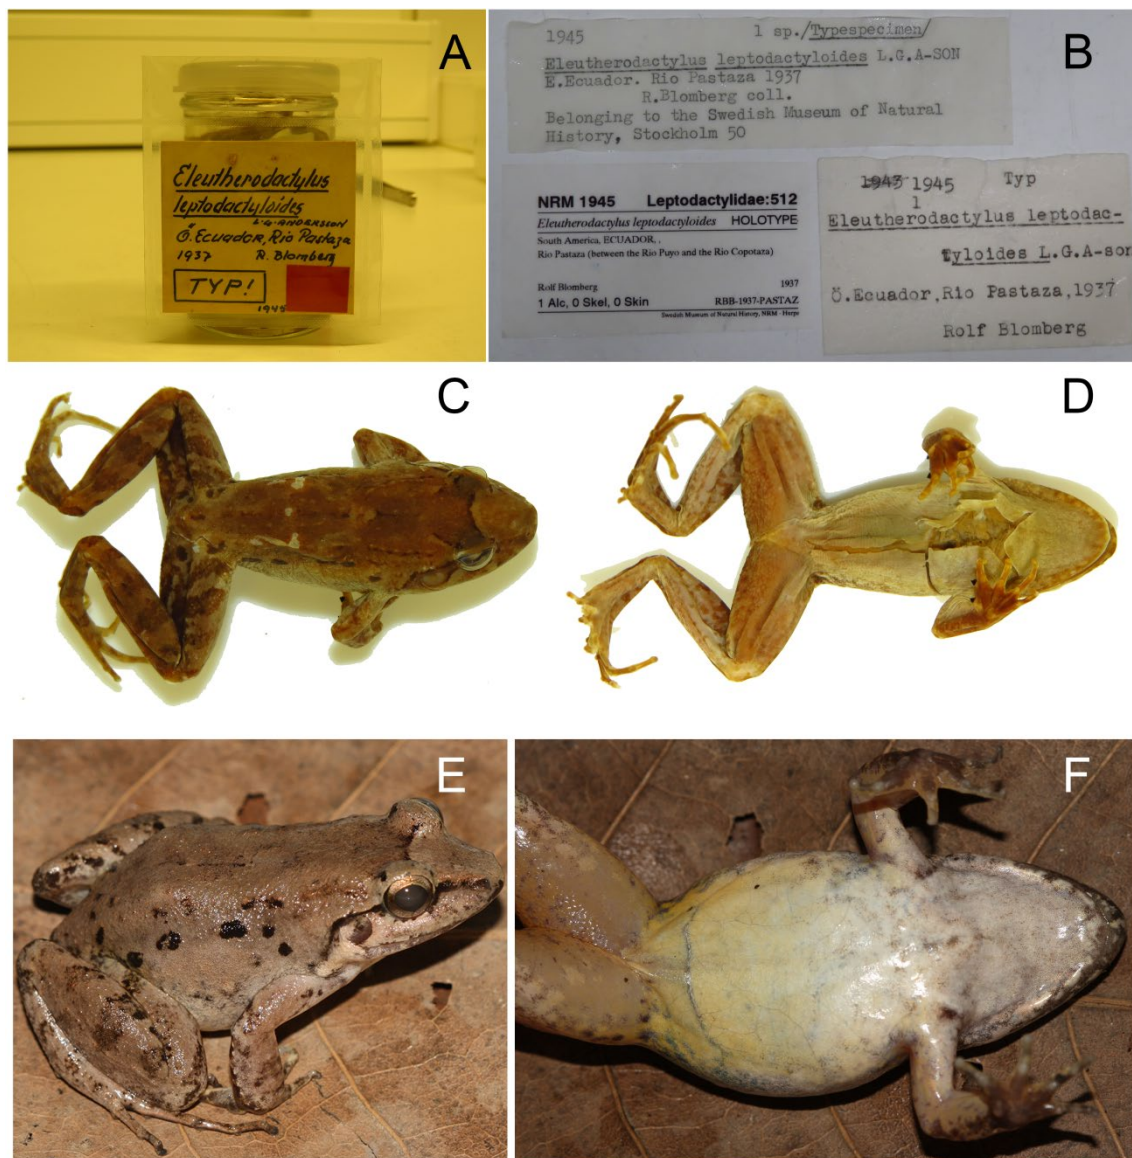

Fig. S1. Holotype of *Leptodactylus leptodactyloides* (NRM 945, adult male: SVL = 44 mm), housed at the Swedish Museum of Natural History. NRM catalogue information (A–B) associated with the holotype, and dorsal (C) and ventral (D) views of the entire specimen. Comparative specimen (E–F) of *L. leptodactyloides* (CFBH 43256, adult female: 43.8 mm). Note the similarity in the dorsolateral fold, spots and glands in the dorsum and flank, and ventral colouration without bold mottling or spotted pattern throughout the belly.

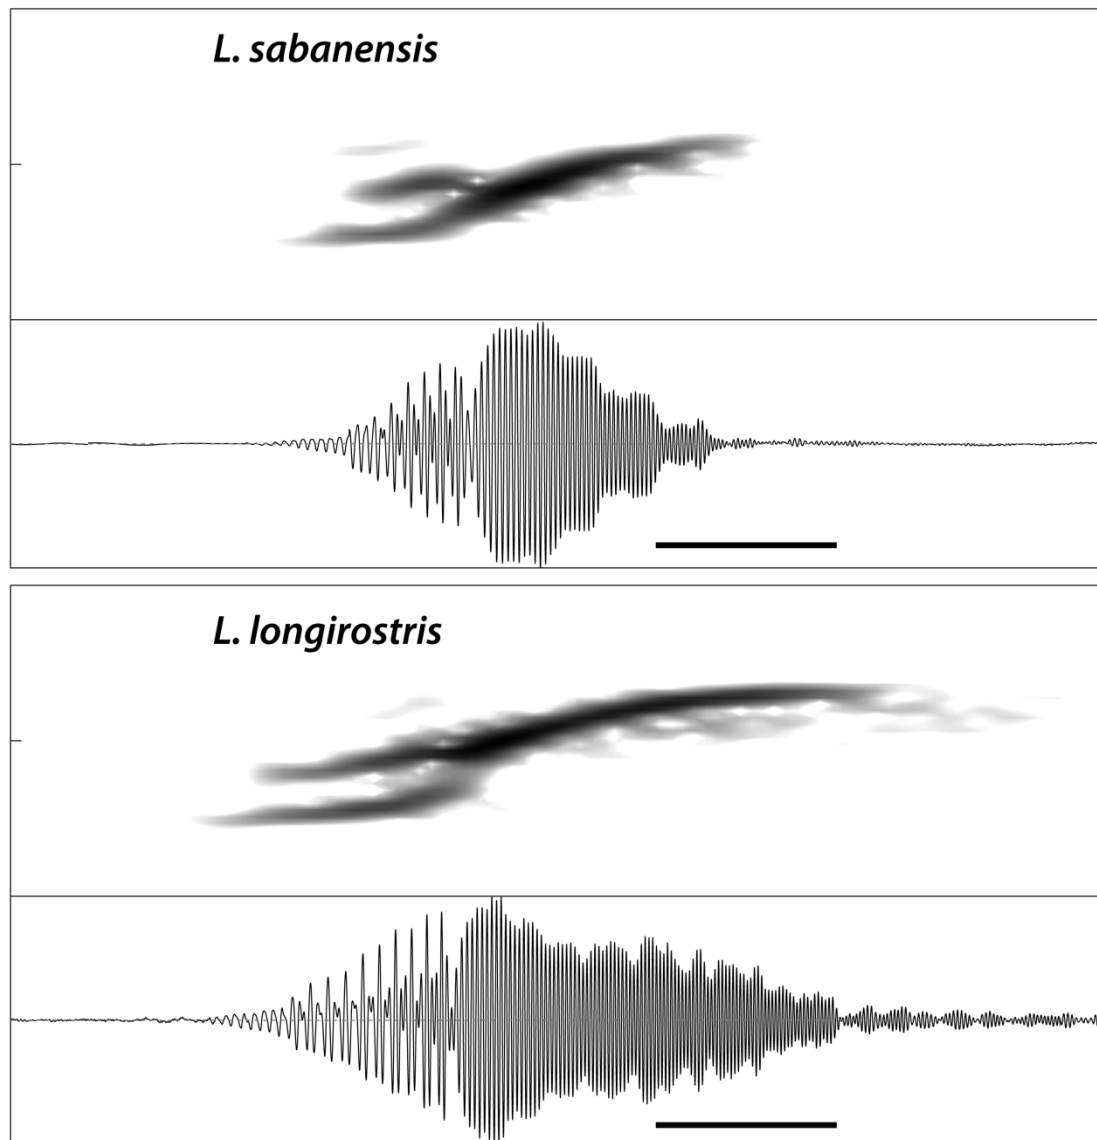

Fig. S2. Advertisement calls of *Leptodactylus sabanensis* from the Gran Sabana in Venezuela and the sympatric *L. longirostris*, a species of the *L. fuscus* group, from adjacent Brazil (Roraima). Spectrograms produced at a 4-kHz scale. For oscillograms, scale bars = 20 ms. See Supplemental Appendix 2 for detailed information.

Fig. S3. Variation in life colours of *Leptodactylus fremitus* sp. nov. (A–B) Paratype from French Guiana (MNHN-RA-2021.0072, adult male: SVL = 39.1 mm). (C–D) Non-type specimen from western Suriname (field number AF 2058, adult female: SVL = 42.4 mm).

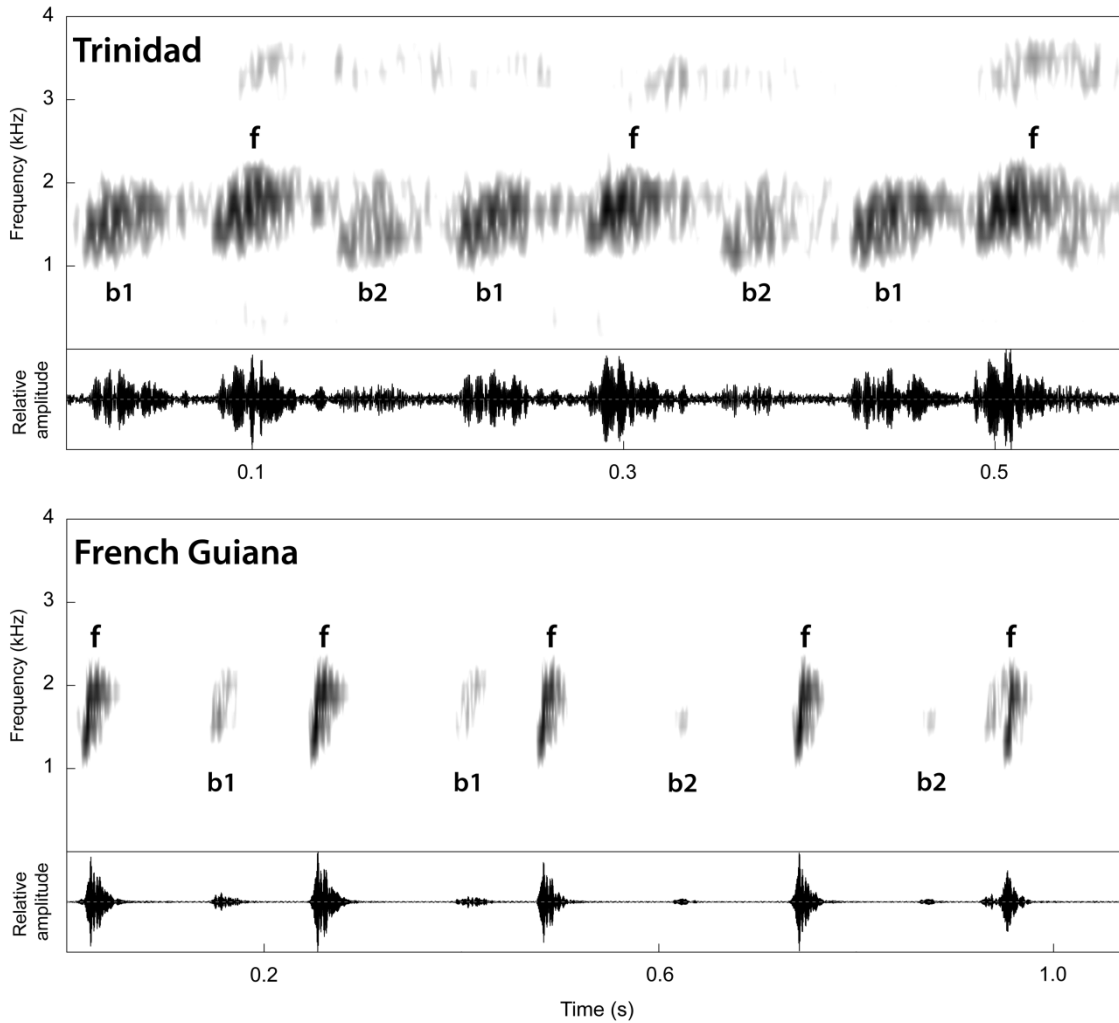

Fig. S4. Antiphonal calling in *Leptodactylus nesiotus* recorded from Trinidad Island and French Guiana. On both occasions, advertisement calls of the focal male (f) and antiphonal calling of two conspecific males in the background (b1 and b2).

31 **Supplementary text**

32 33 34 35 36 **Appendix S1.** Molecular data acquisition. 37

38
39
40
41 We extracted DNA from liver or muscle tissue samples (thigh or toe-clip) using the Wizard
42
43 Genomic extraction protocol (Promega; Madison, WI, USA) or ammonium acetate
44
45 precipitation method. We sequenced partial sequences of the 16S ribosomal RNA gene
46
47 (16S) using two approaches: (i) we amplified a 16S fragment using primers 16Sar-L and
48
49 16Sbr-H (Palumbi et al., 1991) and sanger sequenced these fragments as in Gazoni et al.
50
51 (2021); and (ii) we amplified a 16S fragment with primers N16R and N16F (Salducci et al.,
52
53 2005), and sequenced fragments in a Miseq Illumina sequencer. For that, primers N16R and
54
55
56
57
58
59
60

1
2
3
4 N16F were brcoded by adding NNN + 8-nucleotide labels (hereafter designated as “tags”)
5
6 for sample identification as all resulting PCR products were mixed into single libraries: 32
7
8 tags for forward primer (N16R) and 36 tags for reverse primer (N16F).
9

10
11 The final volume of PCRs was 20 μ l and contained 2 μ l of DNA extract diluted 10
12
13 fold, 10 μ l of Amplitaq Gold® 360 Master Mix (Life Technologies, Carlsbad, CA, USA),
14
15 5.84 μ l of Nuclease Free Water Ambion (Thermo Fisher Scientific, Massachusetts, USA),
16
17 0.25 μ M of each primer and 3.2 μ g of Bovine Serum Albumin (Roche Diagnostic, Basel,
18
19 Switzerland). We ran the PCR in duplicate for each sample, and we included blank PCR
20
21 controls in the analysis using nuclease-free water as template. First, the mixture was
22
23 denatured at 95°C for 10 minutes, followed by 40 cycles of 30 seconds at 95°C, 30 seconds
24
25 at 55°C, and 1 minute at 72°C, followed by a final step of 7 minutes at 72°C. Libraries of
26
27 mixed PCR products were sequenced using 2 x 250 paired-end reads sequencing
28
29 technology through MiSeq high throughput sequencing (Illumina) at the Génopole
30
31 (Toulouse, France). The resulting outputs were analysed with the OBITOOLS software
32
33 suite. Paired-end reads were assembled and merged, and we used the tag attached to the
34
35 primer to assign each read to its label. Then we removed low-quality reads (alignment
36
37 scores < 50, containing Ns or shorter than 50 bp). The resulting batch of reads was
38
39 dereplicated while keeping the coverage information (number of reads merged). All
40
41 sequences <300 bp were discarded. Eventually, every sequence that we included in our
42
43 dataset was all >380 bp long.
