12 **Highlights**

- 13 • An NMR instrumentation is developed to measure 3D velocity fields in microdevices
- 14 • MRI measurements in an arrow-type micromixer are compared to CFD simulations
- 15 • Small manufacturing defects strongly affect the flow and the mixing performance
- 16 • Good agreement is obtained between numerical data and experimental measurements

17 **Abstract**

18 3D velocity field measurements in an arrow-type micromixer are performed using nuclear
19 magnetic resonance (NMR) imaging methods. A specific device has been set up including a home-
20 made radiofrequency milli-coil matching the geometry of the manufactured micromixer, allowing
21 an improvement of the signal-to-noise ratio by a factor 7 comparing to a standard commercial
22 hardware. The NMR images obtained are compared to computational fluid dynamics (CFD)
23 simulations. The very good agreement obtained between numerical data and experimental
24 measurements revealed, on the one hand, the capacity of the developed method to perform a
25 detailed and accurate study of phenomena occurring in a microstructured system and on the other
26 hand, the great impact of small manufacturing defects on the hydrodynamics in a micromixer and
27 thus on the mixing performances.

28 Keywords: computational fluid dynamics, magnetic resonance imaging, micromixers, magnetic
29 resonance velocimetry, NMR instrumentation

30

31

32 **1. Introduction**

33 Microstructured reactors are attracting a lot of interest due to their intense heat and mass transfer
34 capabilities. Their potential has been demonstrated through many applications in chemistry and
35 process engineering, for example for flexible and decentralized synthesis processes (Hessel et al.,
36 2005; Lee & Fu, 2018). They allow fine control of selectivity in complex competitive syntheses,
37 and thus a reduction in purification costs and energetic impacts. The growing interest in these
38 microstructured systems has led to more and more innovative designs and a variety of different
39 geometries are presented in the literature from simple to complex (Bayareh et al., 2020). In the case
40 of micromixers, a simple design (T or Y shape) can be as efficient as a more complex one (Dreher
41 et al., 2009), the mixing performance being essentially related to the amount of mechanical energy
42 injected and whether it is injected at the precise location where it is needed (Falk & Commenge,
43 2010). The studies carried out on micromixers with the T and Y geometries showed that in a range
44 of Reynolds numbers between $Re = 5$ and $Re = 600$, several hydrodynamic regimes govern the
45 flow in the mixing channel and impact the mixing quality (Engler et al., 2004; Galletti et al., 2019;
46 Hsieh, 2013; Lobasov et al., 2018; Peng et al., 2022). With a high sensitivity to the local geometry
47 (channel angle and cross section), with increasing Reynolds number values, the so-called stratified
48 flow first evolves to a steady symmetric vortex flow, which becomes asymmetric, then periodic
49 and finally unsteady, before reaching the laminar-turbulent transition around $Re = 600$. These
50 flow regimes drastically improve the mixing quality and thus manage to reconcile performance and
51 manufacturing simplicity. Experimental quantification of the mixing efficiency of micro-mixers is
52 mainly performed via chemical characterizations using selective test reactions, such as the
53 Villermaux-Dushman protocol, in which information on the mixing performance is given by the
54 spectrophotometric analysis of the reaction products (Commenge & Falk, 2011). Other

55 experimental methods use optical detection, which is generally the method of choice to study
56 microfluidic devices. Optical methods are however limited to transparent media and might be either
57 invasive as they usually require the use of tracers that can alter the properties of the fluid system,
58 or inconclusive as soon as vortical multilamination effects alter the contrast in the field of view.
59 Additional information on the evolution of the flow regime in micromixers can be obtained by
60 means of analytical methods or numerical simulations, but the latter are generally performed in
61 ideal geometries i.e. without considering potential imperfections such as geometric defects that
62 may result from the fabrication of these microscale systems.

63 Experimental methods based on the nuclear magnetic resonance (NMR) phenomenon allow
64 non-invasive analysis of flows in microdevices. In literature NMR is conventionally used as a
65 powerful analytical method in chemistry (Ionin & Ershov, 1995), biology (Wüthrich, 1990),
66 rheology (Milec et al., 2022), porous media (Ferrari et al., 2018; Perrin et al., 2022), materials
67 (Blümich Bernhard, 2000; Robert et al. 2018), in the biomedical field (Pettegrew, 2012) or in
68 medicine through magnetic resonance imaging (MRI). Although existent, the literature on the
69 application of MRI tool for the characterization of hydrodynamics (Gladden & Alexander, 1996;
70 Stapf & Han, 2006) and compared to CFD simulations in engineering is sparser (Mendez et al.,
71 2017; Chung et al. 1993). Indeed, NMR gives access to quantitative 3D measurements of the flow
72 field, including in opaque devices that are inaccessible to optical velocimetry techniques.
73 Moreover, its time-resolution is sufficient for characterizing transient flow phenomena (Callaghan
74 & Xia, 1991; Oliveira et al., 2020; Seymour & Callaghan, 1997).

75 In practice, limitations related to measurement sensitivity may preclude the use of NMR on
76 small scale devices handling a very low fluid volume when using standard methods and commercial
77 hardware. Significant progress has been made over the last years in the NMR characterization of

78 such small systems (down to the nanoliter) (Lacey et al., 1999; Webb, 2012) by increasing the
79 strength of the static magnetic field (Fu et al., 2005) or by using cryoprobes (Kovacs et al., 2005).
80 Another efficient approach to improve the signal-to-noise ratio and allow direct access to the
81 internal parts of the microstructured device is to reduce the dimensions of the radio frequency (RF)
82 coil in order to cover the region of interest as closely as possible and thus maximize the so-called
83 filling factor, *i.e.* the fraction between the sample volume and the coil volume (Hoult & Richards,
84 2011; Webb, 2008, 2013). Specific three-dimensional or planar (two-dimensional) coils have been
85 designed for small volume samples (Eroglu et al., 2003; Massin et al., 2002; Olson et al., 1995;
86 Peck et al., 1995; Trumbull et al., 2000) using specific microfabrication techniques such as laser
87 processing or etching and copper printing (Klein et al., 2013a) or deposition on supports such as
88 polyimide films (Dechow et al., 2000; Meier et al., 2014; Murphree et al., 2007; Woytasik et al.,
89 2006). These types of coils are incorporated into microstructured devices for microscale studies
90 such as quantitative reaction monitoring of processes (Ciobanu et al., 2003; Wensink et al., 2005),
91 dynamic studies in devices handling small volumes (Harel & Pines, 2008; Klein et al., 2013b; J.
92 Zhang & Balcom, 2010; X. Zhang & Webb, 2005) or performing velocity field mapping and
93 distributions inside micromixers (Ahola et al., 2006, 2012; Akpa et al., 2007).

94 In this study, an NMR instrumentation is specifically developed for 3D velocity field
95 measurements in a micromixer of millimeter dimensions. The MRI results obtained are compared
96 to computational fluid dynamics (CFD) simulations to study the hydrodynamics in the device
97 highlighting the sensitivity of the flow and mixing performances to the presence of small
98 manufacturing defects.

99 **2. Materials and Methods**

100 **2.1. *Conception, fabrication and characterization of the micromixer***

101 The micromixer investigated in this study has been machined in a block of polymethyl methacrylate
102 (PMMA) using a digital milling machine. It consists of three cylindrical channels, with an internal
103 diameter of 1 mm, arranged in an arrow configuration (Figure 1). The mixing angle, $\theta = 30^\circ$,
104 defines the angle between the axes of the outlet and one inlet. The zone of confluence of the three
105 channels will be referred throughout this paper as “mixing zone”, and the point where their axes
106 are supposed to meet will be referred as "mixing point".

113

114

As discussed later in this paper, large differences were observed between the experimental

115

velocity measurements and the first CFD simulations, which raised doubts about the presence of

116

manufacturing defects in the prototype. In order to check this possibility, 3D images of the

117 micromixer were recorded by MRI and X-ray Computed Tomography (μ CT) for characterizing its
118 true geometry. The MRI was performed on a Bruker Avance III 600 WB spectrometer. The
119 superconducting magnet is oriented vertically and generates a static magnetic field B_0 with an
120 intensity of 14.1 T which corresponds to a proton ^1H Larmor frequency of 600 MHz. The
121 spectrometer is equipped with a commercial Bruker MicWB40 microimaging coil. The micromixer
122 was filled with a CuSO_4 solution 0.01 M in order to shorten the NMR relaxation time. The acquired
123 image, consisting of voxels of $100 \times 100 \times 54 \mu\text{m}^3$, provided a 3D mapping of the micromixer (see
124 Fig.S1 of the Supporting information). The analysis of the obtained data revealed a slight
125 misalignment of the three microchannels. Indeed, the two inlet axes and the outlet axis do not
126 perfectly converge toward the supposed mixing point (Fig. S2). Moreover, the images analysis
127 revealed the presence of two relatively large machining chips nearby the mixing zone, the first at
128 the end of one inlet, and the second one at the entrance of the outlet channel (Figure 2 and Fig.S3).

129 A X-ray μ CT scan was also performed in order to characterize the micromixer with a higher
130 spatial resolution. The dataset was recorded using a Phoenix Nanotom 180 *kV* GE X-ray system
131 with a source-sample distance of 30 *mm*, an accelerating voltage of 80 *kV* and a current of 80 μA .
132 The spatial resolution was set to 6.81 $\mu\text{m}/\text{voxel}$. 2 000 projections were made (as averages of 3
133 projections of 1 000 *ms* each), resulting in a scan time of 134 *min*. Data processing was done
134 using Avizo® 2022 and VGSstudio 3.5.

135

136

137

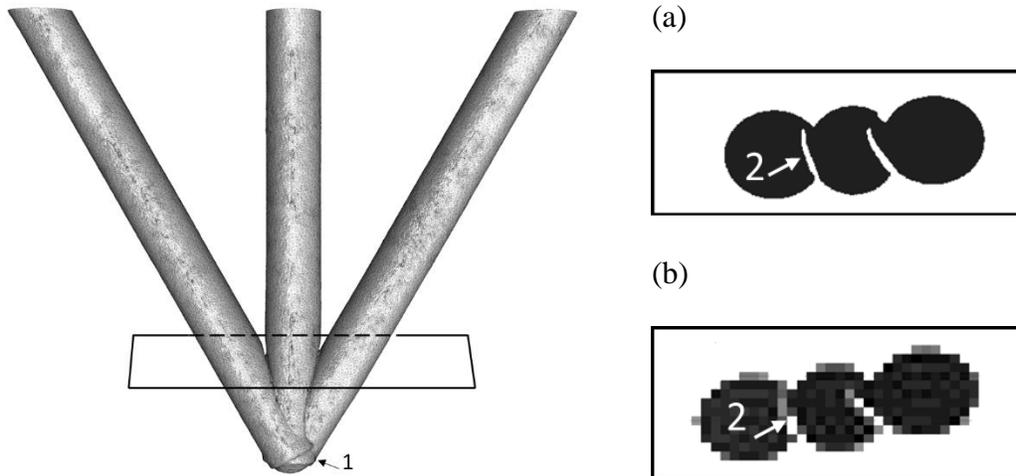

Figure 2: 3D image of the micromixer, obtained by X-ray μ CT, showing manufacturing defects. (1): The black arrow shows a misalignment of the 3 channels. (2): Ortho-slice recorded near the mixing point: the white arrows show the presence of solid parts as observed by X-ray μ CT (a) and MRI (b)

138 The raw images were segmented in order to isolate the three channels. The ortho-slice in the
 139 vicinity of the mixing point (Figure 2) confirmed the presence of the solid PMMA residues (white
 140 color, showed with the white arrows) that were not removed during the milling process.
 141 As discussed later in the results section, compared to the “ideal geometry” case, the presence of
 142 these defects leads to significant perturbations of the hydrodynamics in the micromixer.

143 2.2. MRI instrumentation and experiments

144 2.2.1. MR velocimetry measurements

145 MRI allows the localization of the ^1H NMR signal in order to reconstruct a 1D, 2D or 3D image.
 146 The principle relies on the application of consecutive magnetic field gradient pulses that make the
 147 main magnetic field B_0 vary along the three spatial directions and modifies the precession
 148 frequency of the proton ^1H nuclear magnetic moments according to Larmor's law (frequency
 149 encoding) as well as their phase (phase encoding). Details about the formation of MRI images are
 150 found in textbooks (Callaghan, 1991). The schematic of the 2D velocimetry gradient-echo sequence
 151 used in this study is shown on Figure 3. In order to measure velocity components, a specific

152 encoding of the positions of the magnetic moments is produced by two gradient pulses of amplitude
 153 G_v , duration δ and separated by a time Δ (Caprihan & Fukushima, 1990; Callaghan, 1991; Blümich,
 154 2000). The relationship linking the phase Φ of the measured NMR signal and velocity is given by
 155 the relation :

156
$$\Phi = \gamma \delta \Delta \vec{G}_v \cdot \vec{v}$$

157 where γ is the proton gyromagnetic ratio.

158 In practice, a phase difference image is recorded, taking as reference the image measured when
 159 $G_v = 0$. Since the direction in which the flow is measured is determined by the direction of the
 160 encoding gradient, the velocity vector is determined at each position in a 2D section by applying
 161 \vec{G}_v along the three orthogonal directions in space.

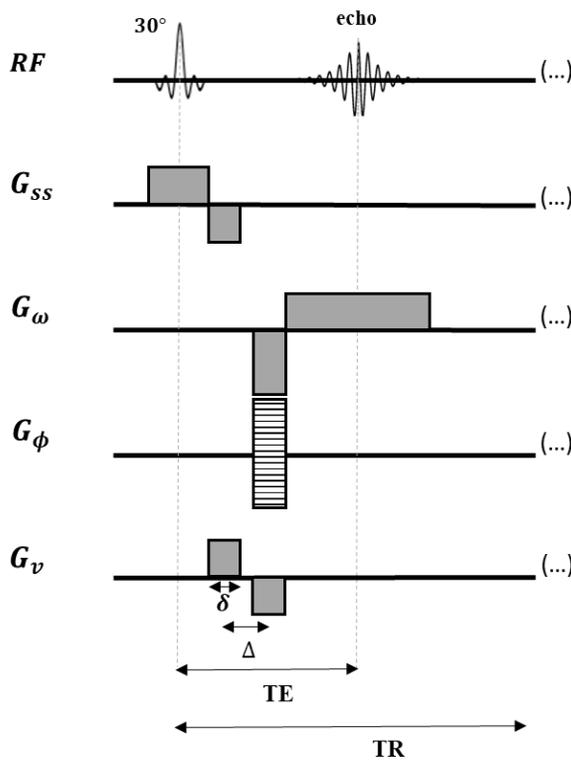

Figure 3: Acquisition protocol of 2D MRI velocity maps, based on the gradient echo sequence.

RF: radiofrequency pulses

G_{SS}: slice-selection gradient

G_ω: frequency-encoding gradient

G_φ: phase-encoding gradient

TE: echo time

TR: repetition time

G_v: velocity-encoding gradient

162 To perform the MR velocimetry experiments, the micromixer was integrated inside a home-
163 made specific radiofrequency (RF) coil which was used for both the RF emission and the reception
164 of the NMR signals. The assembly was placed in a gradient imaging system delivering a maximum
165 magnetic field gradient intensity of 150 G/cm .

166 2.2.2. *Specific MRI instrumentation*

167 The developed radiofrequency milli-coil was adapted to the geometry and dimensions of the
168 micromixer (Figure 1 (b) and Figure 1(c)). The geometry chosen for this study was a Helmholtz
169 coil composed of a pair of copper loops placed face to face and 2.5 mm apart. The diameter of
170 each loop was 5 mm . The fabrication of the milli-coil was realized using an etching process on a
171 DuPontTMPyralux[®]AC flexible copper/Kapton polyimide substrate. The width of the copper strip
172 etched on the polyimide substrate was 0.4 mm and its thickness was $45\text{ }\mu\text{m}$. The fabricated milli-
173 coil was connected to an electronic circuit composed of capacitors so that the resulting RLC circuit
174 resonated at the proton (^1H) resonance frequency of 600 MHz (tuning) and its impedance matched
175 the characteristic impedance of the coaxial cable used for the transmission of the generated RF
176 pulses and the received NMR signal (matching). For tuning and matching, a commercial
177 exchangeable surface coil head Bruker MicWB40 was re-used. A pre-tuned circuit was added to
178 complete the tuning with a set of fixed capacitors: ($C_{\text{tuning}} = 2.7\text{ pF}$, $C_{\text{matching}} = 1.2\text{ pF}$).

179 Electromagnetic simulations were carried out in order to determine the distribution of the
180 radiofrequency field generated at 600 MHz by the fabricated milli-coil. The simulations were
181 performed with COMSOL multiphysics[®] and allowed computing the normalized radiofrequency
182 field intensity over a 5.7 mm distance in the direction of the outlet of the micromixer. The
183 measurement of the NMR signal intensity map (Figure 4 (b)), performed on the micromixer filled
184 with the copper sulfate solution is in very good agreement with this simulation (Figure 4 (c)).

185 According to these results, the profiles present a plateau where the radiofrequency field is
186 homogeneous. The deviation from homogeneity over a length of 2 mm is only 1.3 % on the profile
187 obtained by the electromagnetic simulation and 3 % on the MRI profile.

188 For a detailed and accurate study of the hydrodynamics occurring in the micromixer, the MRI
189 velocity measurements presented in this work were located within the homogeneity zone of the
190 radiofrequency field produced by the milli-coil.

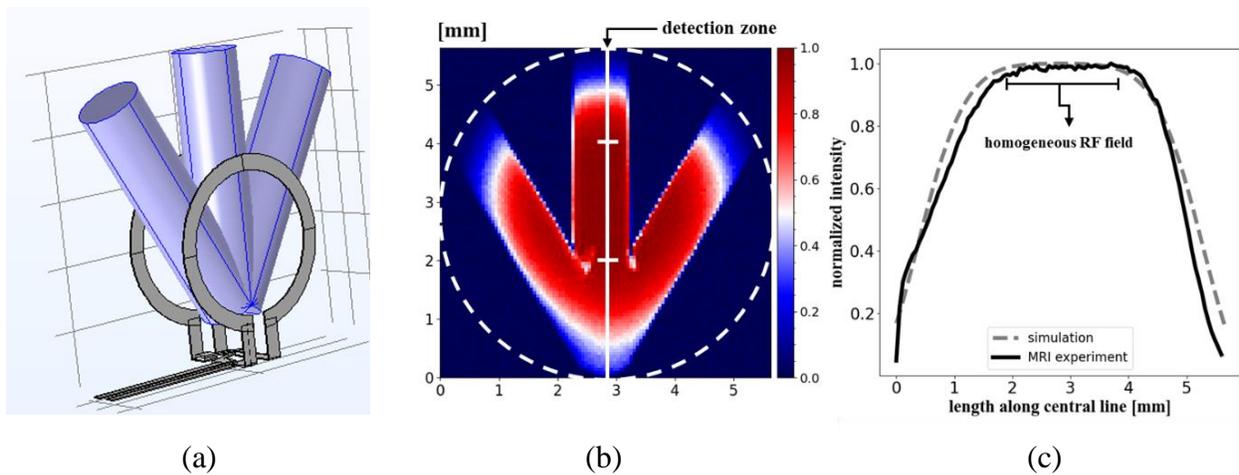

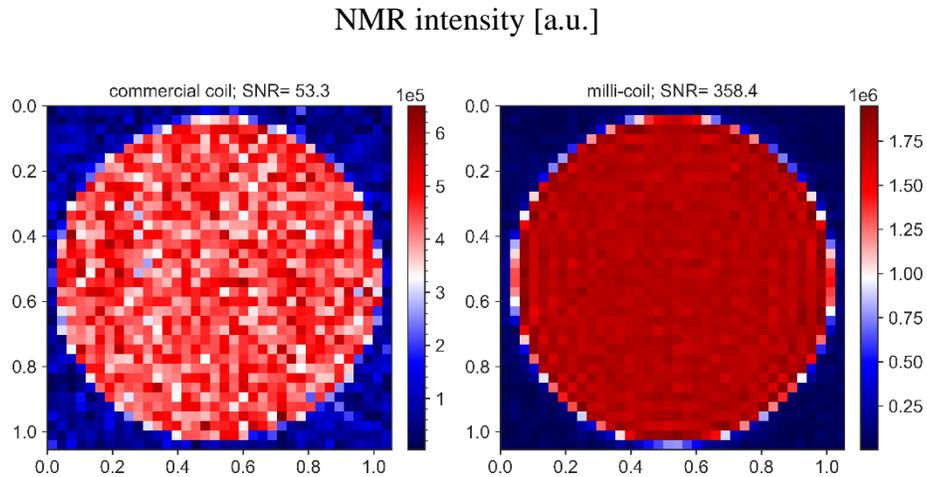

Figure 4: (a) Schematics of the Helmholtz NMR coil, composed of a pair of copper loops placed face to face on either side of the mixing zone. (b) Normalized 2D MR image of the CuSO_4 solution in the mixer. (c) Comparison of the experimental and simulated normalized NMR intensity profiles along the centerline of the outlet channel showing a homogeneous intensity plateau of about 2 mm in length.

191
192 In order to evaluate the improvement of the signal-to-noise ratio (SNR), MRI measurements
193 were performed on both the milli-coil and the commercial coil Bruker MicWB40 (with a detection
194 volume 10 times larger) in similar conditions.

195 An axial NMR signal intensity map (measured in the plane orthogonal to the main flow
196 direction) was performed with the milli-coil considering a field of view of $7.5 \times 7.5 \text{ mm}^2$,
197 corresponding to a spatial resolution of $30 \times 30 \mu\text{m}^2$ per pixel. The NMR signal was averaged
198 over a slice thickness of $200 \mu\text{m}$ and accumulated 8 times. The slice position considered is at 3 mm
199 from the mixing point. A similar measurement was performed with the commercial coil Bruker
200 MicWB40. The results demonstrate a ~ 7 fold improvement of the SNR, evaluated by dividing the
201 mean value of the signal (in the channel) by the mean value of the noise (outside the channel). The
202 improvement of the signal-to-noise ratio with the developed milli-coil allows, with a higher image
203 quality, a detailed characterization of the velocity field in the micromixer (Figure 5).

(a)

(b)

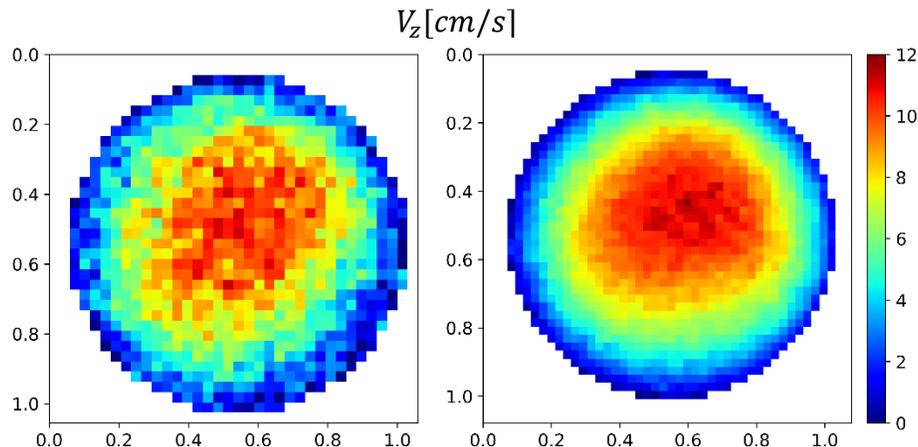

Figure 5: comparison of the MRI measurements performed with the commercial coil and with the milli-coil showing the improvement of the signal to noise ratio and the image quality. (a) 2D NMR signal intensity maps (b) 2D velocity map of the z component (flow rate 1.4 ml/min per inlet, slice thickness 0.2 mm, slice position at 3 mm from the mixing point) obtained with the commercial coil Bruker MICW40 (25 mm ID), in-plane resolution $30 \times 30 \mu\text{m}^2$ and 8 accumulations of the NMR signal) and with the developed milli-coil (in-plane resolution $24 \times 24 \mu\text{m}^2$ and 4 accumulations). The distances on the axes are in millimeters.

204

205 2.2.3. Parameters and conditions for MRI velocity measurements

206 The fluid flowing through the micromixer was an aqueous CuSO_4 solution 0.01 M characterized
207 by a longitudinal relaxation time $T_1 \sim 100$ ms. This concentration is adequate to significantly
208 shorten the NMR relaxation times while remaining sufficiently low to not alter the physical
209 properties of the water phase, including the self-diffusion coefficient. The water flow was achieved
210 through 1 mm ID PTFE tubings using a multi-channel peristaltic pump (Ismatec Reglo ICC
211 Digital) used with Tygon® S3™ E-LFL, 1.52 mm ID pump tubing. The peristaltic pump ensures
212 that a same flow rate was injected at each inlet during all the experiments. Experiments were
213 conducted for eight different flow rates ranging from 1.4 to 4.2 ml/min at each inlet (see Table
214 1), corresponding to outflow Reynolds numbers in the range [59 – 178] (note that the outflow
215 Reynolds number is the double of that of the inflow).

216 The protocol described earlier (gradient echo sequence with phase encoding) was used to measure
217 both axial (in planes orthogonal to the main flow direction) and sagittal velocity maps (in a plane
218 orthogonal to the axial images containing all three channels of the micro-mixer). The measurements
219 were carried out using the parameters summarized in Table 2. Each velocity component was
220 mapped separately, the z -component corresponding to the main flow direction. In order to check

221 the accuracy of the measurements, the average flow rate was calculated from the velocity images
 222 in several sections and for the different flow rates supplied by the pump. The results agree over the
 223 entire measurement range, with an error of less than 5%. The reconstruction of the velocity field
 224 was made with Paravision 5.1 software. The presentation of the maps and the comparison with the
 225 CFD results were done using Python 3.7 in Jupyter Notebook 6.0.1.

Table 1: flow conditions in the micromixer

Flow rate per inlet (<i>ml/min</i>)	Reynolds number (outflow)	Maximum velocity (Poiseuille flow) (<i>cm/s</i>)
1.4	59	12
1.9	80	16
2.4	102	20
2.9	123	25
3.2	136	27
3.4	144	28
3.9	165	30
4.2	178	32

Table 2: parameters for MRI velocity measurements

	Parameter	Characteristics
	<i>TR</i>	300 <i>ms</i>
	<i>TE</i>	5 <i>ms</i>
	Δ	2.16 <i>ms</i>
	δ	2.05 <i>ms</i>
	acquisition time	300 s
	accumulations	4
	thickness	200 μm
axial images	field of view	$6 \times 6 \text{ mm}^2$
	spatial resolution	$24 \times 24 \mu\text{m}^2$
	thickness	400 μm
sagittal images	field of view	$1 \times 1 \text{ cm}^2$
	spatial resolution	$39 \times 39 \mu\text{m}^2$

226
227

228 2.3. CFD modeling and simulation

229 2.3.1. Geometry and mesh

230 Modeling and CFD simulations of the hydrodynamics in the micromixer were conducted using
 231 the ANSYS 2019 commercial software package (including ANSYS Fluent). A first geometry was
 232 drawn using ANSYS Design Modeler following the dimensions presented in Figure 1 (a), i.e. a
 233 diameter of 1 *mm* with inlets and outlet pipes of 10 *mm* length each. This design will be referred
 234 through the remaining of this paper as “ideal geometry”. ANSYS Meshing software was used for
 235 meshing the numerical domain. Given the form of the micromixer, the mixing zone was meshed
 236 using tetrahedral cells while the remaining parts, consisting of the inlets and outlet channels, were

237 discretized using hexahedral elements (Figure 6). A total of about 13.4×10^6 cells was employed
238 for ensuring a mesh-independent solution for all the cases studied.

239 As discussed later in this paper, numerical results obtained using the “ideal geometry” did not
240 allow reproducing the experimental velocity fields. Accordingly, as explained in Section 2.1, the
241 real micromixer geometry has been identified through X-ray μ CT scanning. This second design
242 will be referred through the remaining of this article as “real geometry”. As mentioned earlier and
243 detailed in the Supplementary material section, compared to the “ideal geometry”, the real one
244 involves a slight misalignment of the inlets and outlet microchannels and includes two relatively
245 large machining chips nearby the mixing zone. The “real geometry” was first meshed via Avizo
246 software and then exported toward ANSYS Meshing where the mesh was further refined reaching
247 a total of about 7.9×10^6 tetrahedral elements (Figure 6). Such a large number of computational
248 cells is necessary for reaching mesh-independent solutions given the significant levels of numerical
249 diffusion of tetrahedral elements.

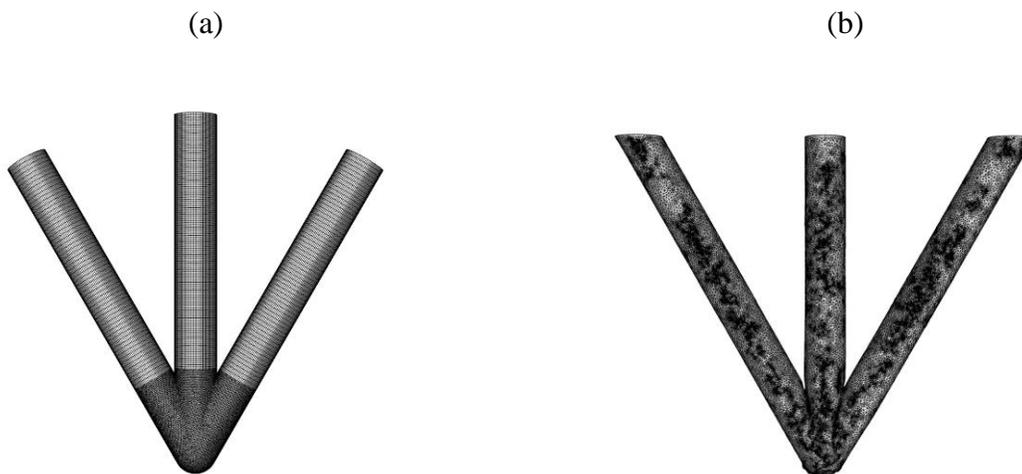

Figure 6: Mesh used for the CFD simulations corresponding to the “ideal geometry” (a) and the “real geometry” (b) of the micromixer.

250 2.3.2. *Hydrodynamics modeling*

251 For both ideal and real geometries, the flow field has been determined by solving the Navier-
252 Stokes equations assuming an incompressible and isothermal flow (and hence, uniform water
253 properties):

254
$$\text{div}(\vec{u}) = 0 \quad (1)$$

255
$$\rho \frac{\partial \vec{u}}{\partial t} + \rho \overrightarrow{\text{div}}(\vec{u} \otimes \vec{u}) = -\vec{\nabla} p^* + \mu \vec{\Delta} \vec{u} \quad (2)$$

256 where t denotes time, \vec{u} the velocity vector, ρ the water density, μ its dynamic viscosity and p^* the
257 driving pressure.

258 The first term in Equation 2 describes transient flow behavior. Since this study focuses on the
259 steady-state regime only, this term has been considered null and a steady-state solver has been used
260 to compute the steady-state solution. However, for the “real geometry” case under a flow rate of
261 4.2 ml/min at each inlet, convergence could not be achieved this way. Indeed, under these
262 operating conditions, the machining chips led to some low amplitude vortex shedding phenomena.
263 Hence, for this case only, the full unsteady Navier-Stokes equations were solved until reaching the
264 permanent flow regime where the time-averaged solution was computed. Advancement in time
265 was achieved through a second-order implicit scheme with time steps of 10^{-4} s.

266 Simulations were conducted considering uniform velocity profiles at the inlets, uniform pressure
267 at the outlet and no-slip condition at the wall. The advective terms have been discretized using the
268 QUICK scheme and the diffusion terms were central-differenced.

269 Since MRI measurements correspond to space-averaged (namely along the depth of the sample
270 slices) velocities, in order to allow reliable comparison, CFD data were interpolated over a coarser

271 grid corresponding to the MRI slice thickness in order to achieve the same spatial resolution
272 between experimental and numerical results (see Fig.S4).

273 2.3.3. CFD investigation of mixing efficiency

274 As detailed later in the results section, flow simulations revealed that manufacturing defects and
275 the presence of residual machining chips have significant effects on the hydrodynamics in the
276 micromixer, which is expected to substantially impact the mixing efficiency. Accordingly, mixing
277 simulations were conducted using both the “ideal” and “real” geometries, and that for all of the 8
278 flow rates investigated in this study (

279).

280 These simulations consist in continuously injecting a tracer (i.e. a passive scalar) at one
281 inlet where its concentration is assumed to be uniform and equal to C_{max} , whereas at the second
282 inlet, its concentration is considered to be zero, i.e. tracer-free water is injected. It should be
283 underlined that the value of C_{max} is arbitrarily chosen as it does not influence the mixing quality.
284 Indeed, the tracer concentration is assumed to have no effect on the water density or
285 physiochemical properties.

286 The concentration field is determined by solving the mass transport equation:

$$287 \quad \frac{\partial C}{\partial t} + \text{div}(C \vec{u}) = D \Delta C \quad (3)$$

288 where C is the tracer local concentration and D its molecular diffusivity in the liquid, taken here as
289 $2 \times 10^{-9} \text{ m}^2 \text{ s}^{-1}$ which corresponds to water self-diffusion coefficient at 20 °C. At the outlet
290 section, a zero normal-concentration-gradient boundary condition is assumed.

291 The first term in Equation 3 corresponds to temporal variations. As for the flow simulations
292 (Section 2.3.2), it was considered null apart for the case involving the “real geometry” under a flow
293 rate of 4.2 ml/min at each inlet where no steady-state solution could be achieved. For this case,
294 Equations (1), (2) and (3) are simultaneously solved using a time step of 10^{-4} s until reaching the
295 permanent flow regime where the time-averaged solution is computed.

296 Mixing quality can be quantified by computing the concentration standard deviation at the outlet
297 or more correctly, the concentration mass-weighted uniformity index. However, because of the low
298 diffusivities of liquids, when dealing with laminar or transitional flows as in this study, numerical
299 diffusion effects become significant and may even exceed molecular diffusion effects. This is
300 particularly true when the computational domain involves tetrahedral cells. Therefore, despite the
301 large number of computational elements used (Section 2.3.1) which sufficiently reduces numerical
302 diffusion, mixing simulations will be only qualitatively analyzed in this article. No quantification
303 of the mixing quality will be presented so as to not cumbersome the paper with discussions on
304 numerical diffusion effects especially since no experimental measurements are available for
305 supporting mixing simulations results.

306 **3. Results and discussion**

307 3.1. *Hydrodynamics in the micromixer*

308 3.1.1. *CFD simulations with the “ideal geometry”*

309 CFD simulations carried out using the “ideal geometry” revealed similar flow behavior
310 (presented in Figure 7 and Fig.S5 to Fig.S11 in the supplementary material) for all eight flow rates
311 investigated (

312). The flow remains steady and preserves its double symmetry along the zy and zx planes. At
313 the entrance of the outlet channel (i.e., in the vicinity of the mixing zone), four vortices develop in
314 the cross-stream direction, and their intensity increases with increasing flow rate. Indeed, once
315 inertial effects are sufficient, secondary flow structures are known to form in the mixing channel
316 (Bothe et al., 2006; Lobasov et al., 2018). These vortices promote lateral displacement of the fluid
317 parcels and thus enhance the mixing quality. When progressing downstream toward the outlet, the
318 secondary flow intensity attenuates (and thus the cross-stream velocity components) as the flow
319 becomes increasingly axisymmetric and tends to fully develop into a classic Poiseuille profile. As
320 could be expected, the development length increases with the flow rate.

321 3.1.2. *MRI velocity measurements vs CFD results*

322 MRI velocity measurements along the outlet channel confirmed some of the general flow
323 features predicted by the CFD simulations with the “ideal geometry” (Section 3.1.1) such as the
324 presence of secondary flows. Nonetheless, major differences existed between experimental and
325 numerical results. Indeed, MRI revealed that even for the lowest flow rates investigated, the double
326 symmetry of the flow is not preserved (Figure 7 and Fig. S12 to Fig. S15 in the supplementary
327 material). The secondary flows consisted of one or two asymmetric cells rather than four vortices
328 as predicted by the simulations.

329 As discussed in Section 2.1, these large differences between numerical and experimental data
330 raised doubts about the presence of manufacturing defects in the prototype. Accordingly, the real
331 geometry of the micromixer was recorded using X-ray CT which revealed some minor defects as
332 well as the presence of two machining chips that were not removed during the milling process as
333 explained earlier.

334 CFD results obtained using the “real geometry” are in very good agreement with experimental
335 measurements as can be seen in Figure 7 (and Fig. S16 to Fig. S22 in the supplementary material),
336 and allow reproducing the high asymmetry of the velocity fields as revealed by the MRI, which
337 proves that even small defects may have a big impact on the hydrodynamics and hence on the
338 mixing efficiency in micromixers. We note that the velocity map presented on Figure 7a shows
339 important phase wrapping in the mixing zone (V_x component), manifested by an abrupt change in
340 velocity for small lateral displacements. We have not tried to correct this artifact because the axial
341 maps discussed in this paper are measured well above the mixing zone.

342 For the lowest flow rate investigated, CFD results are in excellent agreement, qualitatively and
343 quantitatively, with experimental data (Figure 8). As the flow rates is increased, although it remains
344 acceptable, the agreement between the two sets of results tends to decrease, and this for different
345 reasons. Indeed, with increasing flow rates, larger velocity gradients occur in the mixing zone, i.e.
346 velocity values vary more and more significantly along the axial position along the outlet channel,
347 in particular in the vicinity of the mixing zone. Accordingly, a small uncertainty in the exact
348 location of the MRI measurement section may lead to large differences with the numerical results
349 as the flow becomes very sensitive to axial position. Moreover, MRI images accuracy deteriorates
350 as the velocities are gradually increased. For instance, from a flow rate of 3.9 ml/min at each inlet
351 (corresponding to axial velocities in the mixing channel reaching about 30 cm/s , see Table 1),
352 measurements using the current experimental apparatus are no longer reliable as the signal-to-noise
353 ratio becomes very low (Fig. S23 in the supplementary material). The effect of temporal averaging
354 during the observation time Δ should also be considered to better understand the limitations of the
355 measurements. Indeed, when the flow rate is high, the average fluid displacement during Δ can be
356 much larger than the voxel sizes which can lead to significant image distortions. This should be

357 taken into consideration for further comparison and to better delimit the range of velocities
358 accessible to the experiment.

359 In any case, in the range of the measurable velocities, the successful comparison between MRI
360 measurements and CFD data allows validating the presence of complex flow features in the mixing
361 channels and reveals the great impact that small manufacturing defects may have on the
362 hydrodynamics in micromixers.

369

370 3.1.3. Effects of manufacturing defects on the mixing efficiency

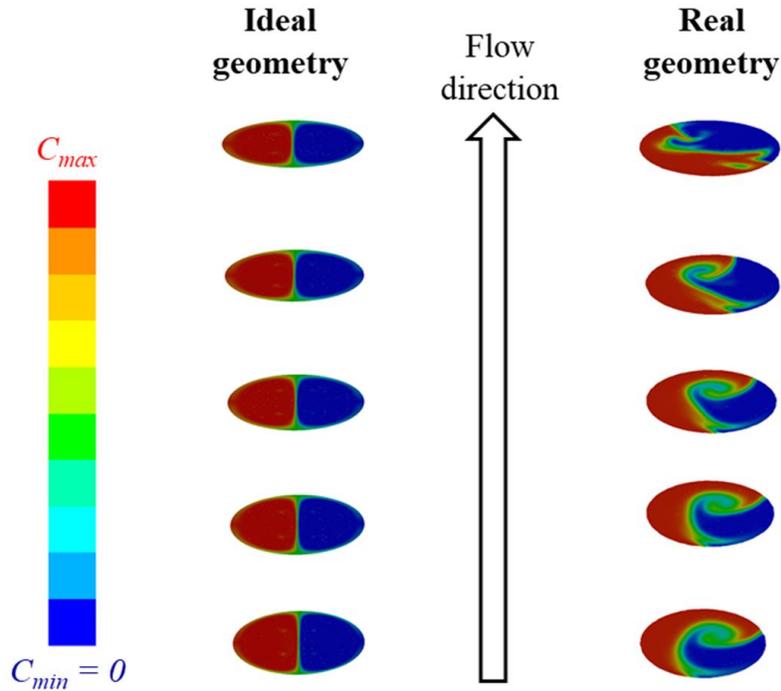

371 In the previous sections, it has been shown that manufacturing defects have a great impact on
 372 the hydrodynamics downstream the mixing zone, and thus, they are expected to significantly
 373 influence the mixing efficiency. Mixing simulations (Section 2.3.3) were conducted in order to
 374 check this eventuality.

375 Simulations revealed that the exact micromixer geometry has a great impact on the mixing
 376 efficiency as can be seen from Figure 10. Indeed, in the case of the “ideal” geometry (and for all
 377 eight flow rates investigated), despite the presence of secondary flows, given the double symmetry

378 of the flow, the main contact zone between the two fluid streams remains quasi-planar which
379 practically limits mixing to the sole effects of diffusion. In the case of the “real” geometry, the flow
380 perturbation induced by the manufacturing defects engenders a larger contact zone between the
381 two streams which is supposed to increase diffusive mixing (note that simulations probably
382 overestimate the thickness of the mixing front because of numerical diffusion effects).
383 Additionally, the large secondary flow cells engender engulfment of the two streams which is
384 expected to enhance the mass-transfer efficiency. Hence, it is clear that these non-voluntary
385 manufacturing defects have a positive impact on the mixing quality although they generate
386 additional mechanical energy dissipation.

387 When increasing the flow rate, as inertial effects becomes larger, mixing efficiency is improved
388 in both geometries. However, while this enhancement remains insufficient with the ideal design as
389 the main contact zone remains quasi-planar, it is much more pronounced in the case of the real
390 geometry as the contact zone becomes larger. Moreover, as mentioned in the previous section, for
391 a flow rate of 4.2 ml/min , in the case of the real geometry, the presence of manufacturing chips
392 induces some unsteadiness in the flow which is expected to further enhance the mixing quality.

393

394

395 *Figure 9: Concentration field at sections located 3, 4, 5, 6 and 7 mm downstream of the mixing*
 396 *point: case where the flow rate at each inlet is 3.4 ml/min.*

397

398 **4. Conclusion**

399 In this study, NMR imaging methods were used to study the hydrodynamics occurring in the
 400 mixing channel of a micromixer in an arrow configuration. A specific device was set up including
 401 a home-made radiofrequency coil with reduced dimensions and adapted to the geometry and the
 402 dimensions of the manufactured micromixer. In the homogeneity zone of the radiofrequency field
 403 generated by the developed milli-coil, the signal-to-noise ratio was improved by a factor 7 in
 404 comparison with a standard commercial hardware.

405 MRI measurements were performed for the imaging of the 3D velocity field in the micromixer.
 406 On another hand, computational fluid dynamics (CFD) simulations of the hydrodynamics in the

407 device were carried out. The 2D velocity maps obtained by MRI measurements showed some
408 different symmetries on the fluid flow evolution and on the development of the secondary flows
409 compared to the CFD simulations performed on an “ideal” geometry of the micromixer. This
410 comparison revealed that the flow field was sensitive to the presence of small manufacturing
411 defects. Accounting for these imperfections in the numerical model (real geometry of the
412 micromixer extracted by X-ray μ CT) allowed obtaining, in the range of the flow rates investigated,
413 a good agreement between experimental results and numerical data, hence confirming the
414 potentiality of the developed NMR instrumentation for characterizing flow phenomena in
415 millimetric devices.

416 As the flow field was very sensitive to the manufacturing defects, the mixing efficiency was
417 also impacted. The simulations on the real geometry revealed that the defects engendered a larger
418 contact zone between the two fluid streams and their engulfment. This is expected to enhance both
419 mass-transfer and diffusive mixing.

583 **Acknowledgements**

584 The authors would like to thank Fadi Sharif (GREEN laboratory, Université de Lorraine) for his
585 help during the fabrication of the NMR microcoil, and specifically during the etching on Kapton
586 substrate.

587 **Funding**

588 This study was partially funded by the “pôle EMPP” and Fédération de recherche Jacques
589 Villermaux, Université de Lorraine, “Micro-MIX” project.

3D Magnetic resonance velocimetry for hydrodynamics characterization in microdevices: application to micromixers and comparison to CFD simulations

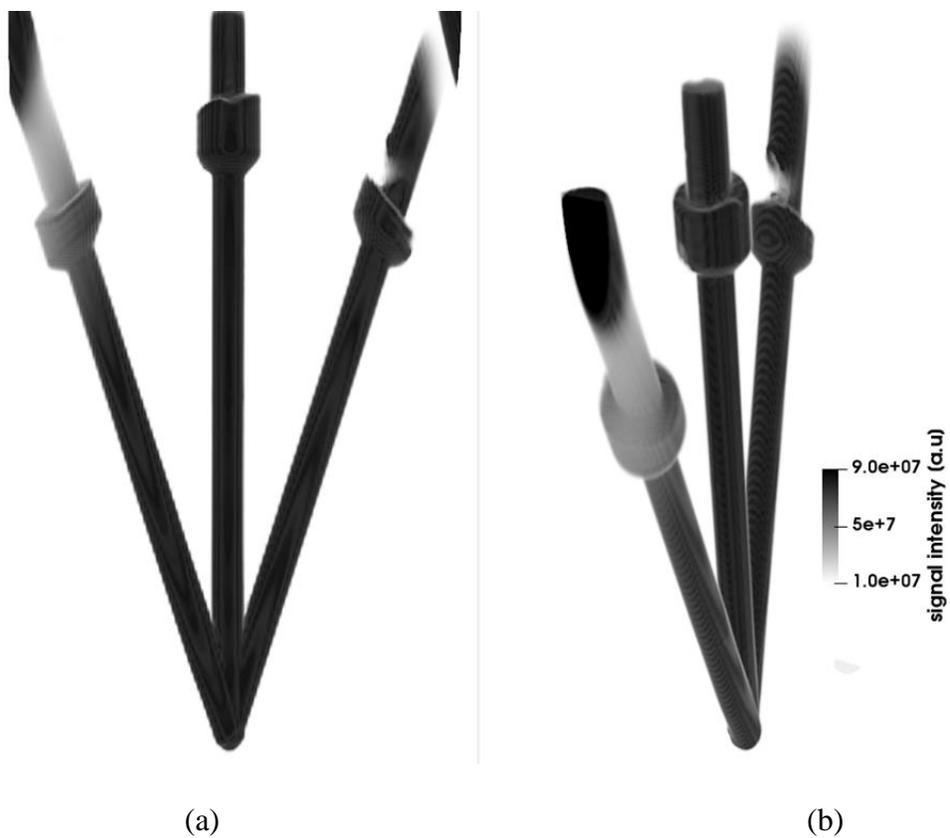

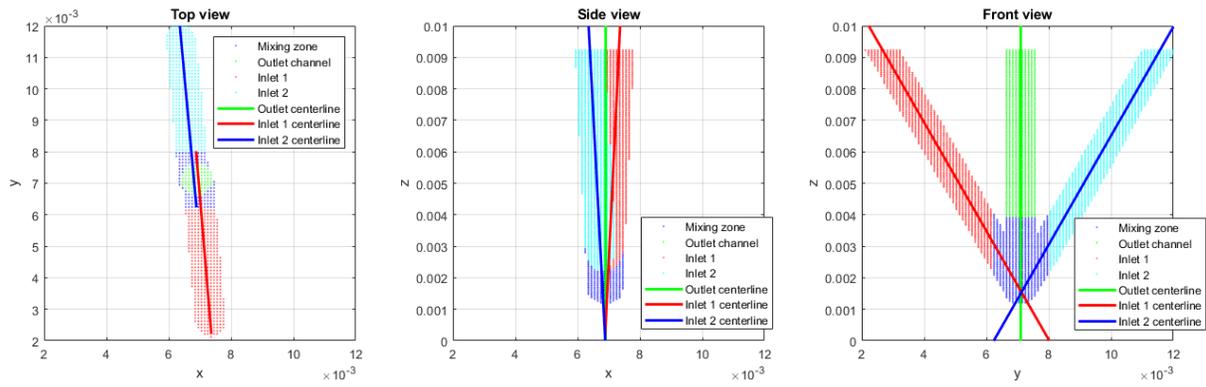

Fig.S1: visualization of the 3D NMR signal intensity image on the Paraview software. Front view (a) and side view (b) of the machined micromixer filled with the copper sulfate solution

(a)

(b)

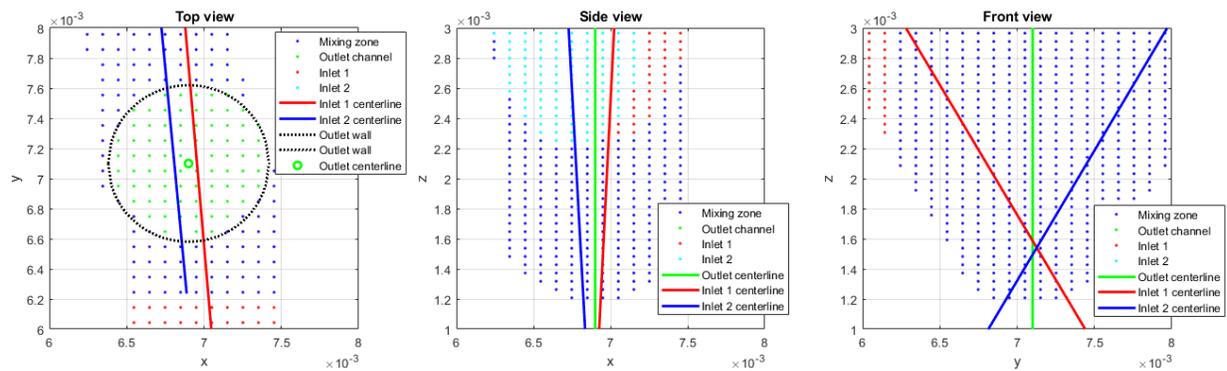

Fig.S2 : analysis and quantification of the misalignment of the three axes of the micromixer channels. (a) Views in 3 cross-sectional planes of the projections of the points in each channel and of the centerlines which constitute the axes of the microchannels. (b) Zooms on the three views near the mixing point, showing misalignment of the three microchannels: the two inlet centerlines and the outlet centerline did not meet exactly at the mixing point. The measured distances between the axes were about 90 μm and 55 μm

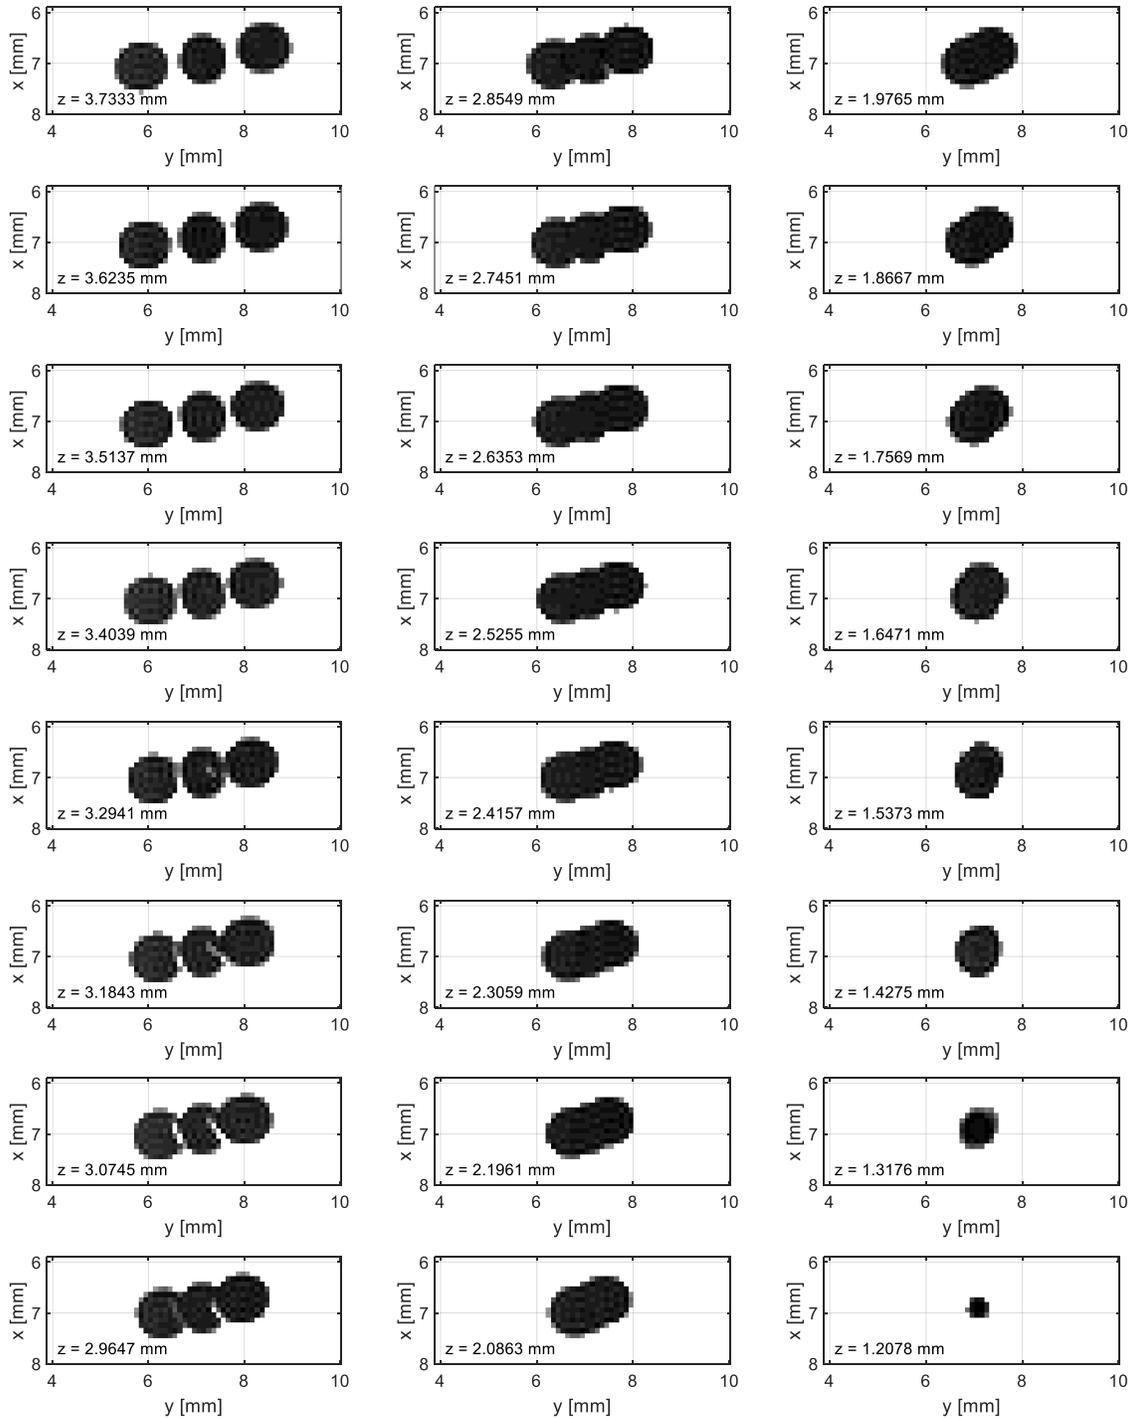

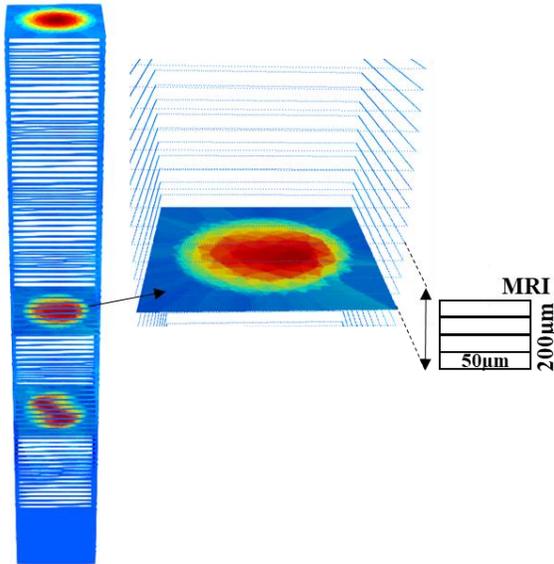

Fig.S3: Analysis of the images near the intersection of the 3 microchannels. Views of the sections of the 3 channels at different heights from the bottom of the micromixer, showing the presence of PMMA residues.

(b)

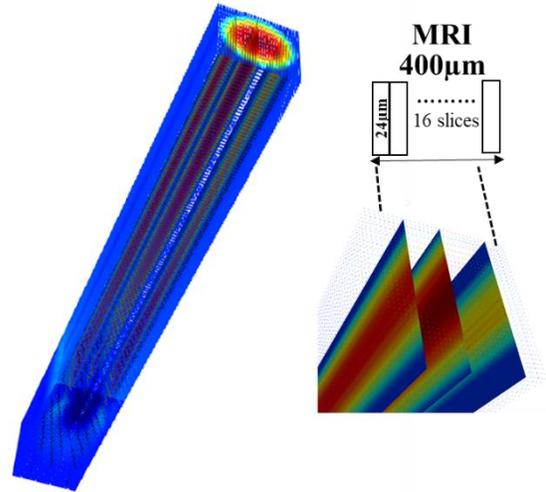

Fig.S4: interpolation of CFD data over coarser grid to correspond to MRI measurement conditions. (a) for axial images and (b) for images in planes orthogonal to the axial images. Construction of a uniform mesh with the "PointVolume Interpolator" function of Paraview. Reconstruction of the resampled data with Python as 3D matrices for each velocity component to perform averaging and display the results.

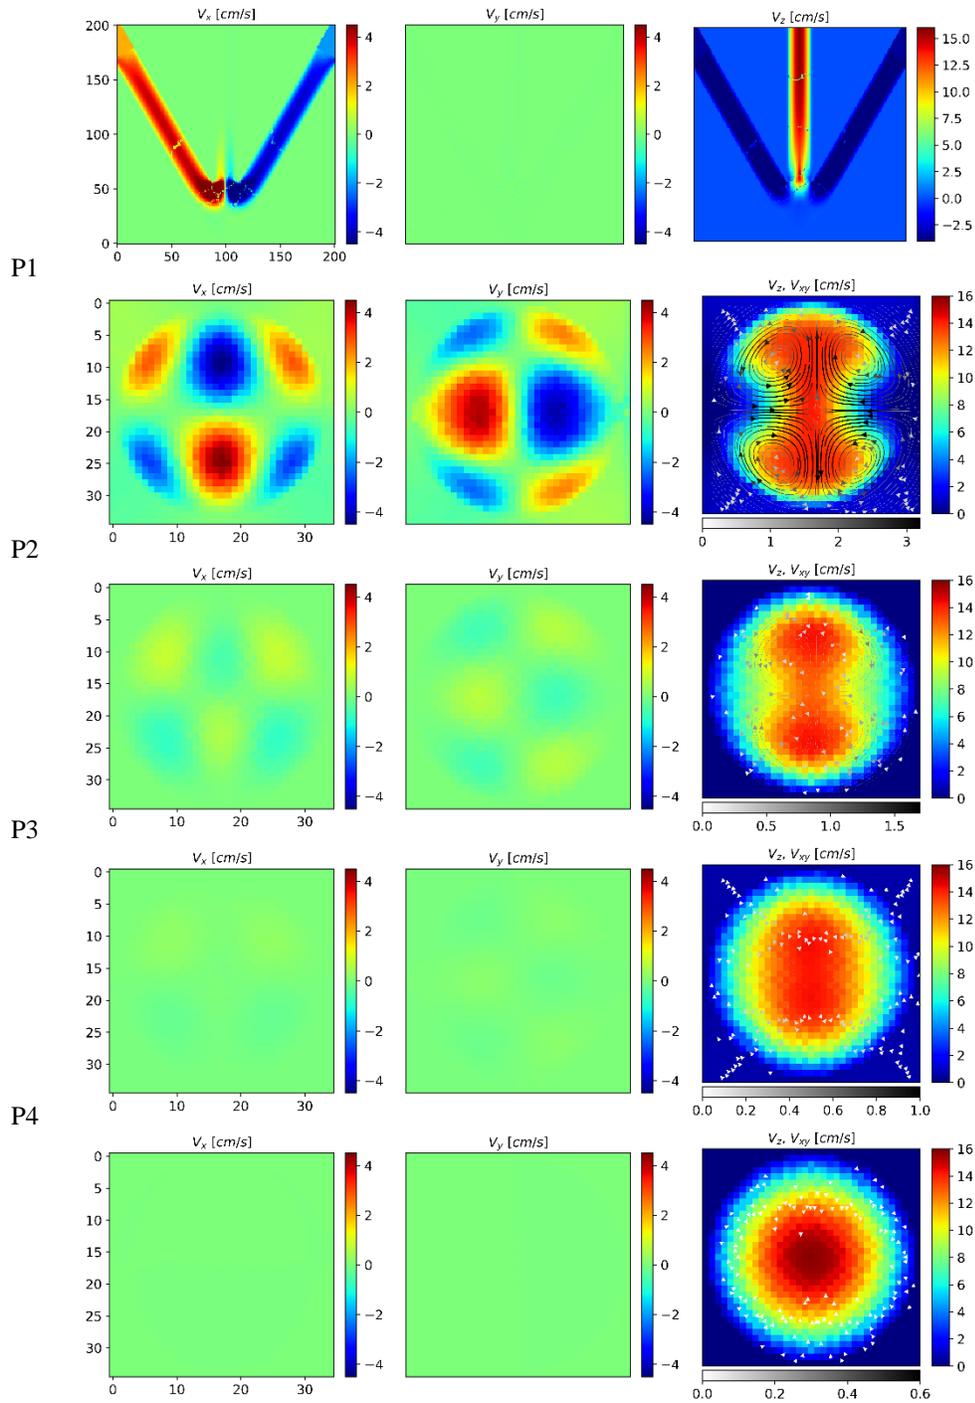

Fig.S5: 3D velocity maps obtained with CFD simulation on ideal geometry of the micromixer. The flow rate on each inlet is 1.9ml/min corresponding to Re_{outlet} of 80. The velocity maps in the orthogonal plane to the main flow direction are obtained at slice positions P1, P2, P3 and P4 corresponding respectively to 2mm, 3mm, 4mm and 7mm from the mixing point.

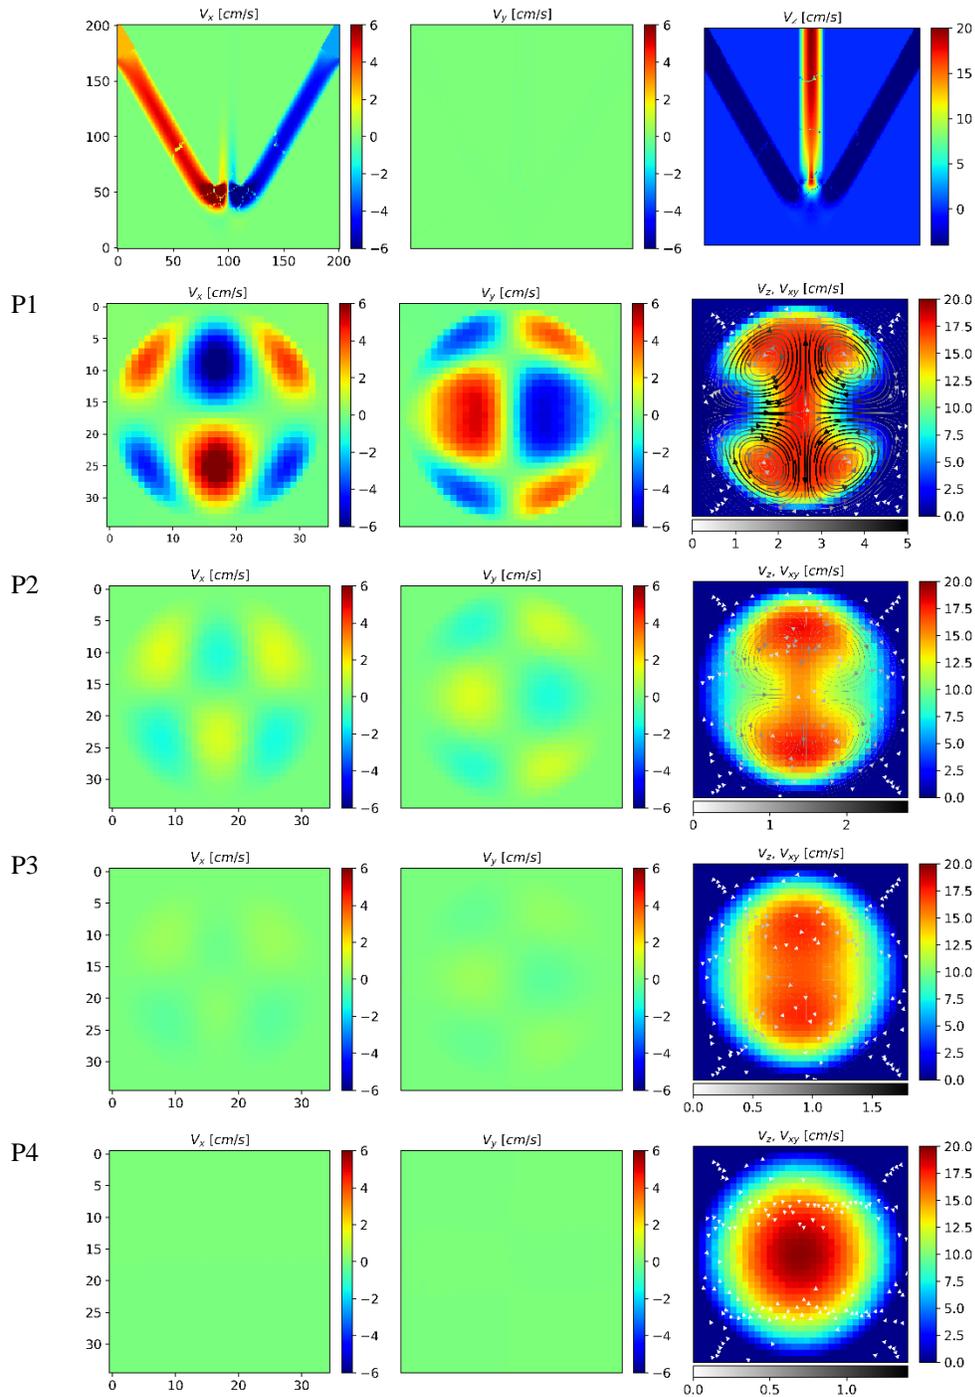

Fig.S6: 3D velocity maps obtained with CFD simulation on ideal geometry of the micromixer. The flow rate on each inlet is 2.4ml/min corresponding to Re_{outlet} of 102. The velocity maps in the orthogonal plane to the main flow direction are obtained at slice positions P1, P2, P3 and P4 corresponding respectively to 2mm, 3mm, 4mm and 7mm from the mixing point.

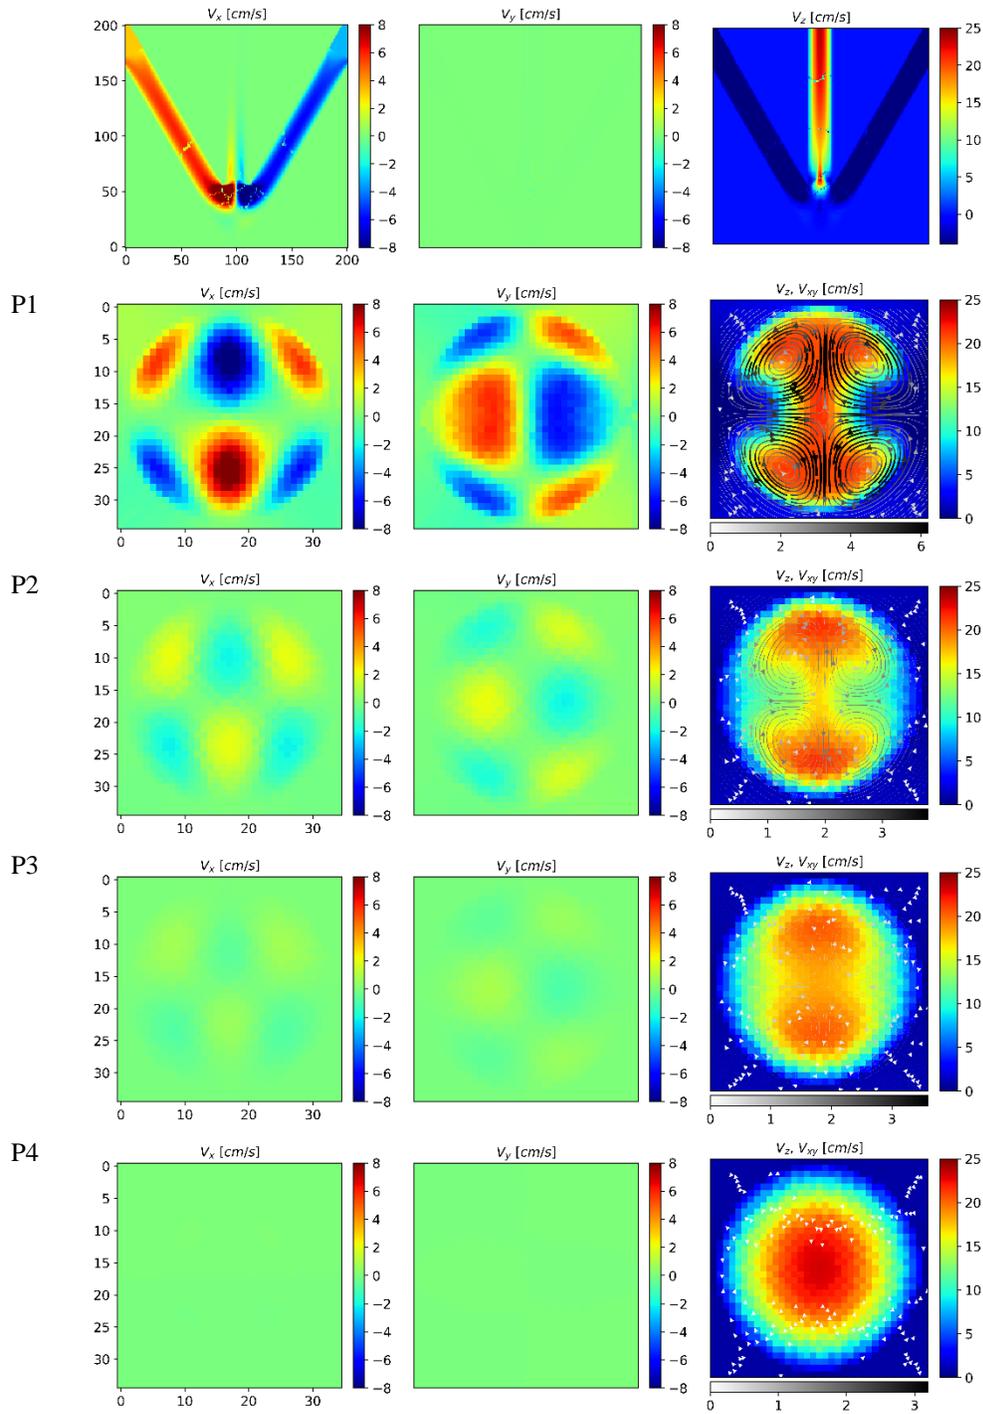

Fig.S7: 3D velocity maps obtained with CFD simulation on ideal geometry of the micromixer. The flow rate on each inlet is 2.9ml/min corresponding to Re_{outlet} of 123. The velocity maps in the orthogonal plane to the main flow direction are obtained at slice positions P1, P2, P3 and P4 corresponding respectively to 2mm, 3mm, 4mm and 7mm from the mixing point.

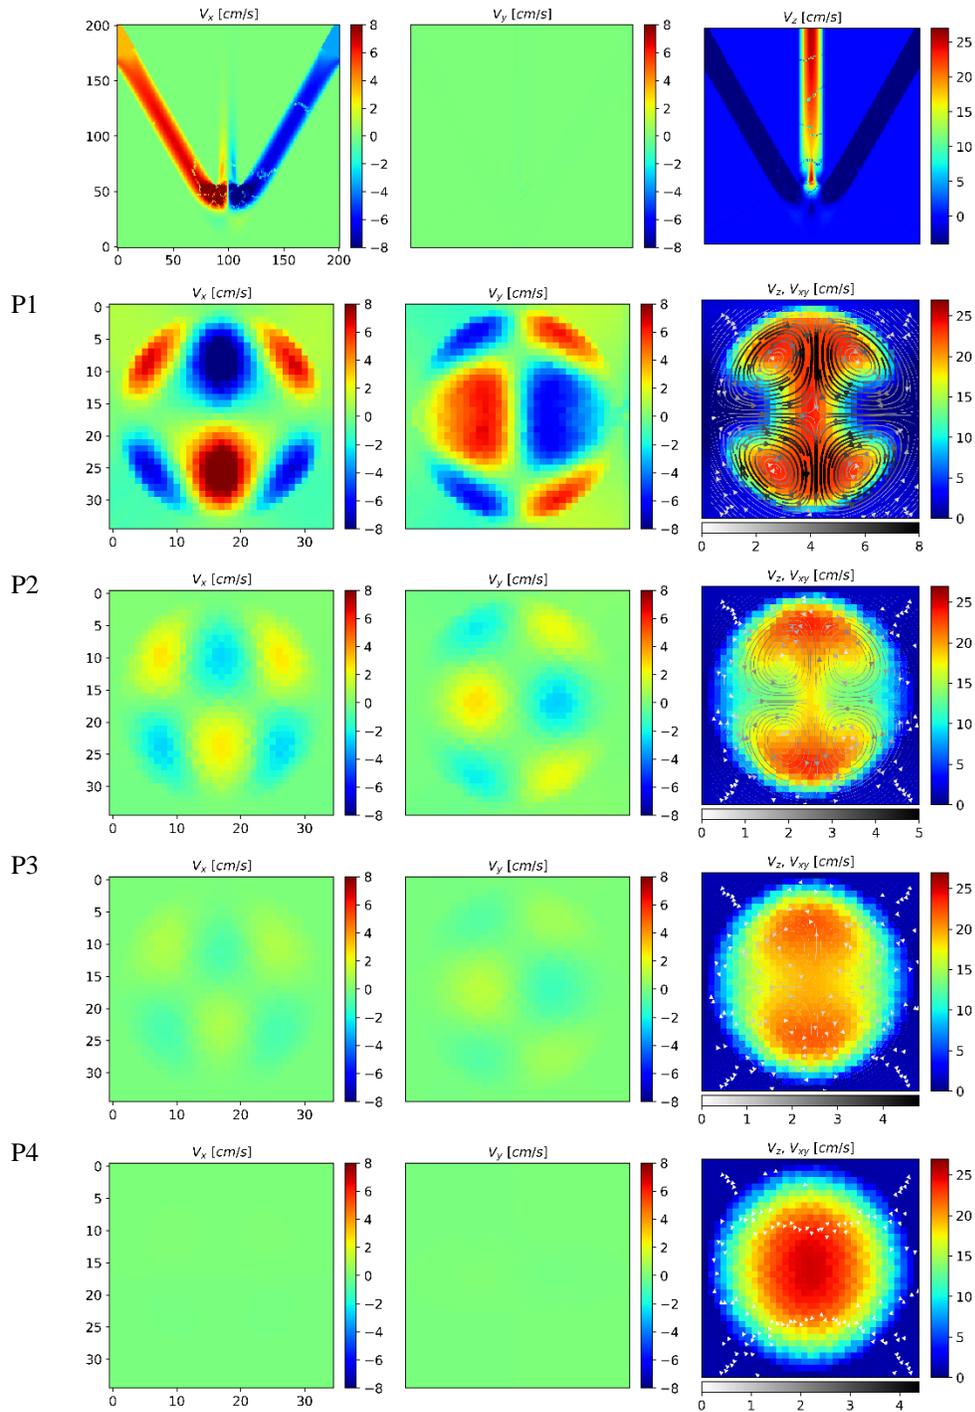

Fig.S8: 3D velocity maps obtained with CFD simulation on ideal geometry of the micromixer. The flow rate on each inlet is 3.2ml/min corresponding to Re_{outlet} of 136. The velocity maps in the orthogonal plane to the main flow direction are obtained at slice positions P1, P2, P3 and P4 corresponding respectively to 2mm, 3mm, 4mm and 7mm from the mixing point.

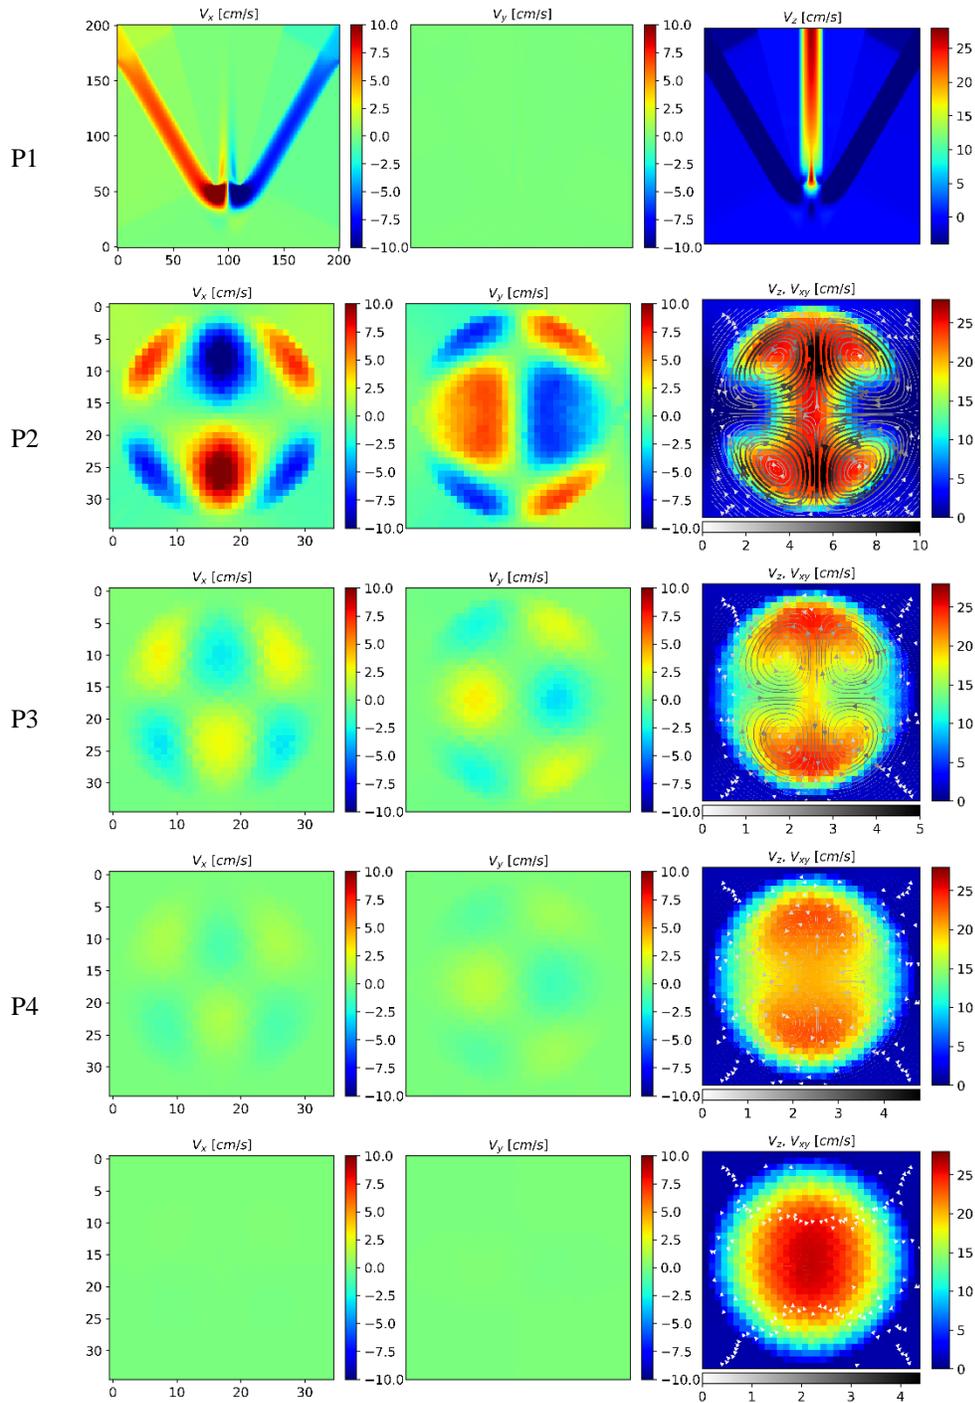

Fig.S9: 3D velocity maps obtained with CFD simulation on ideal geometry of the micromixer. The flow rate on each inlet is 3.4ml/min corresponding to Re_{outlet} of 144. The velocity maps in the orthogonal plane to the main flow direction are obtained at slice positions P1, P2, P3 and P4 corresponding respectively to 2mm, 3mm, 4mm and 7mm from the mixing point.

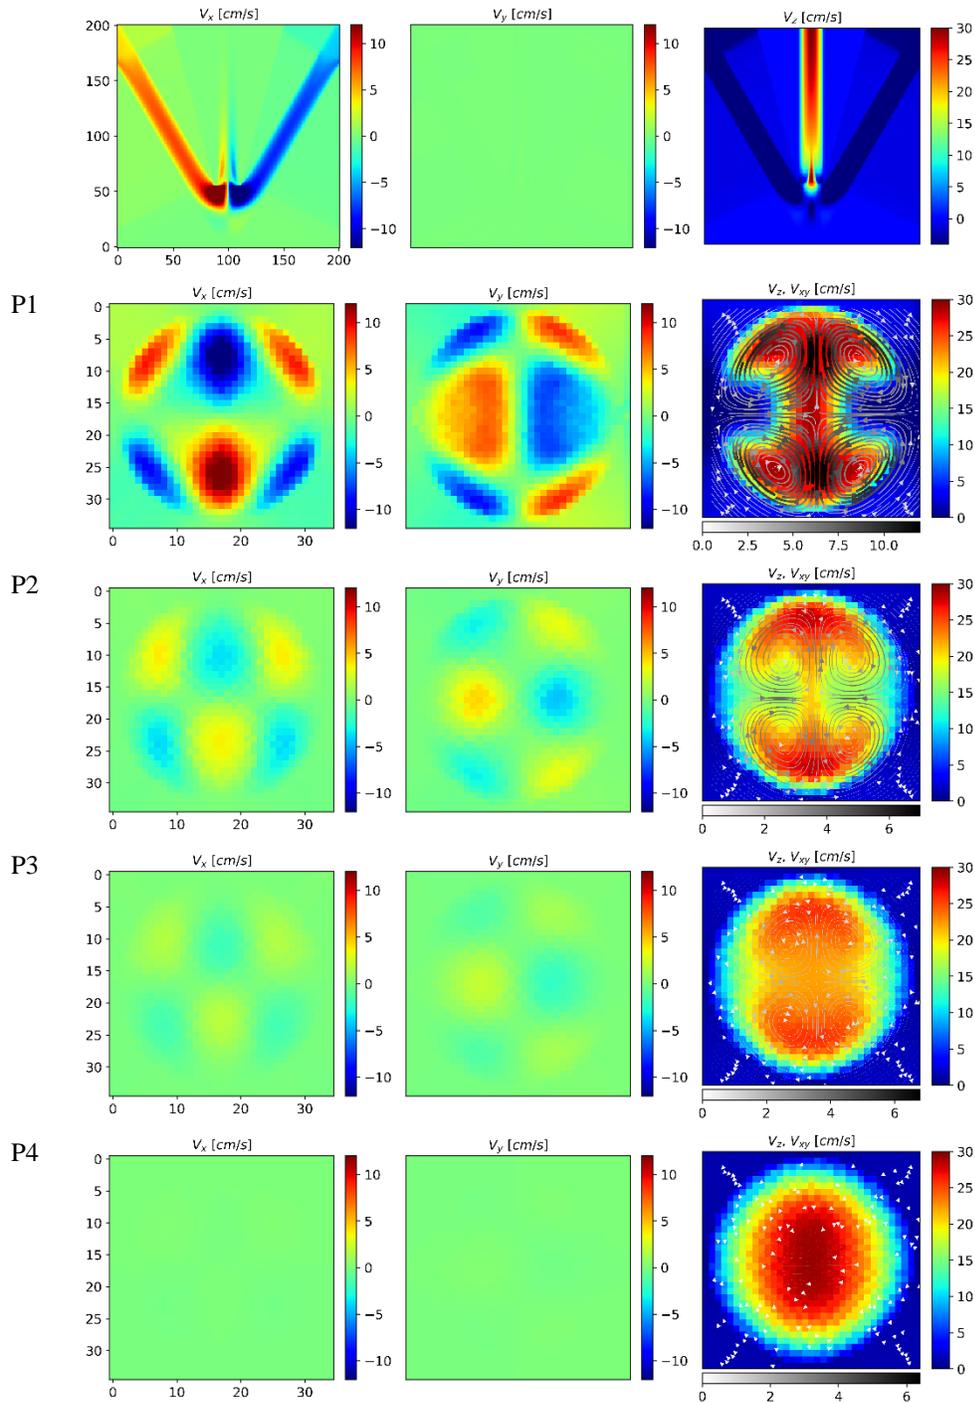

Fig.S10: 3D velocity maps obtained with CFD simulation on ideal geometry of the micromixer. The flow rate on each inlet is 3.9ml/min corresponding to Re_{outlet} of 165. The velocity maps in the orthogonal plane to the main flow direction are obtained at slice positions P1, P2, P3 and P4 corresponding respectively to 2mm, 3mm, 4mm and 7mm from the mixing point.

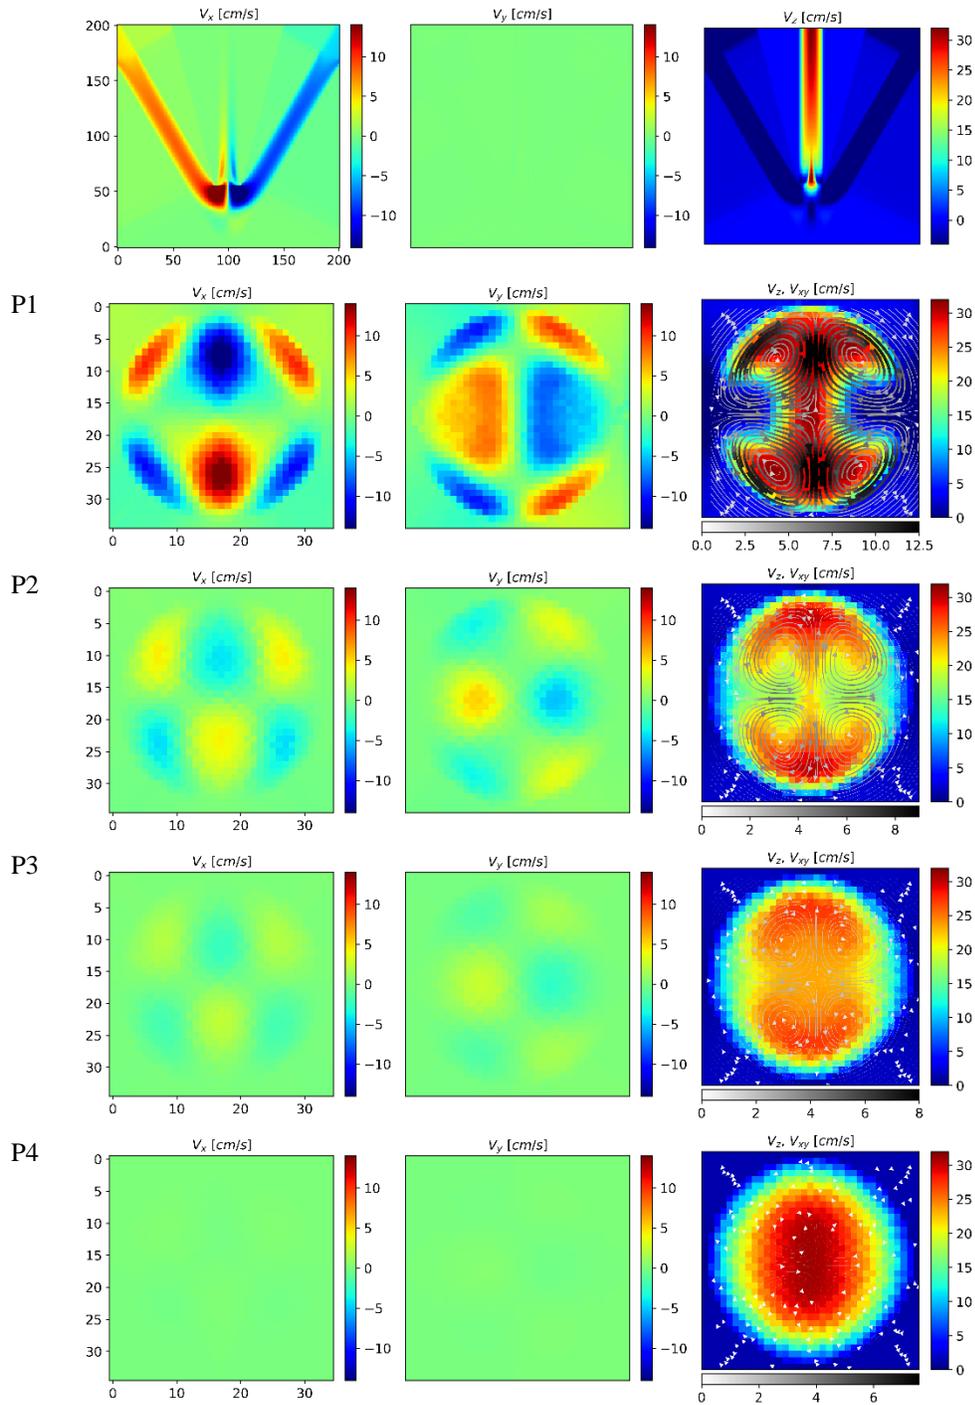

Fig.S11: 3D velocity maps obtained with CFD simulation on ideal geometry of the micromixer. The flow rate on each inlet is 4.2ml/min corresponding to Re_{outlet} of 178. The velocity maps in the orthogonal plane to the main flow direction are obtained at slice positions P1, P2, P3 and P4 corresponding respectively to 2mm, 3mm, 4mm and 7mm from the mixing point.

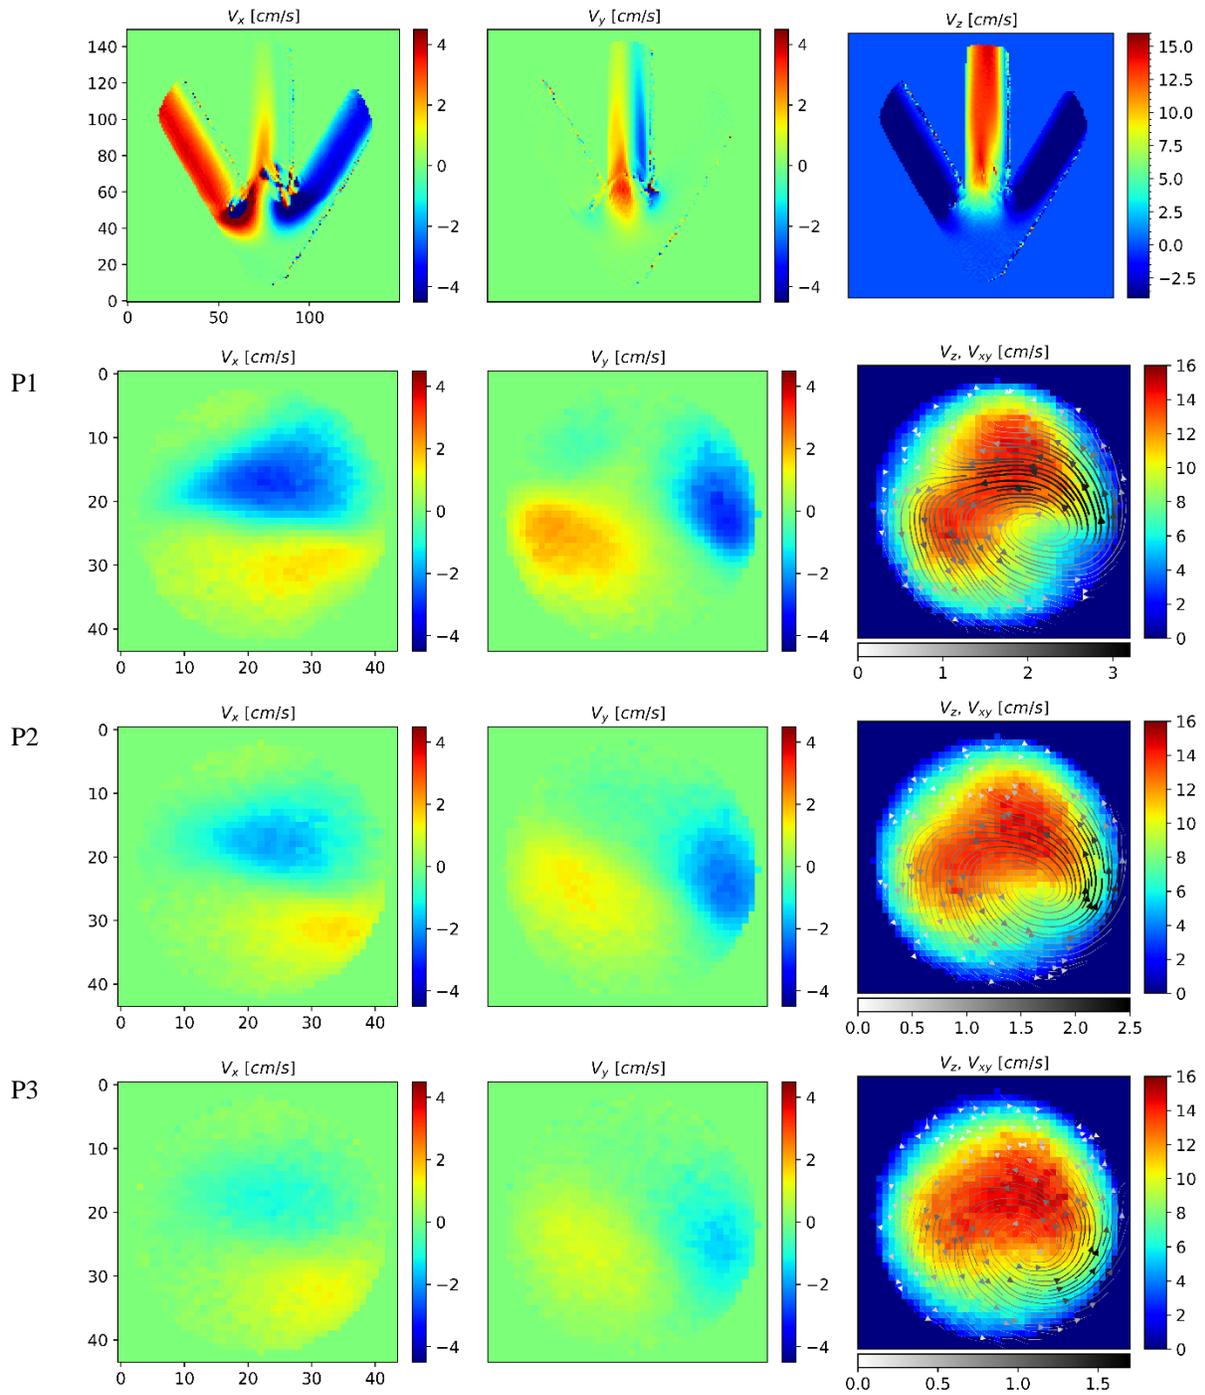

Fig.S12: 3D velocity maps obtained with the developed milli-coil. The flow rate on each inlet is 1.9ml/min corresponding to Re_{outlet} of 80. The velocity maps in the orthogonal plane to the main flow direction are obtained at slice positions P1, P2 and P3 corresponding respectively to 2mm, 2.5mm and 3mm from the mixing point.

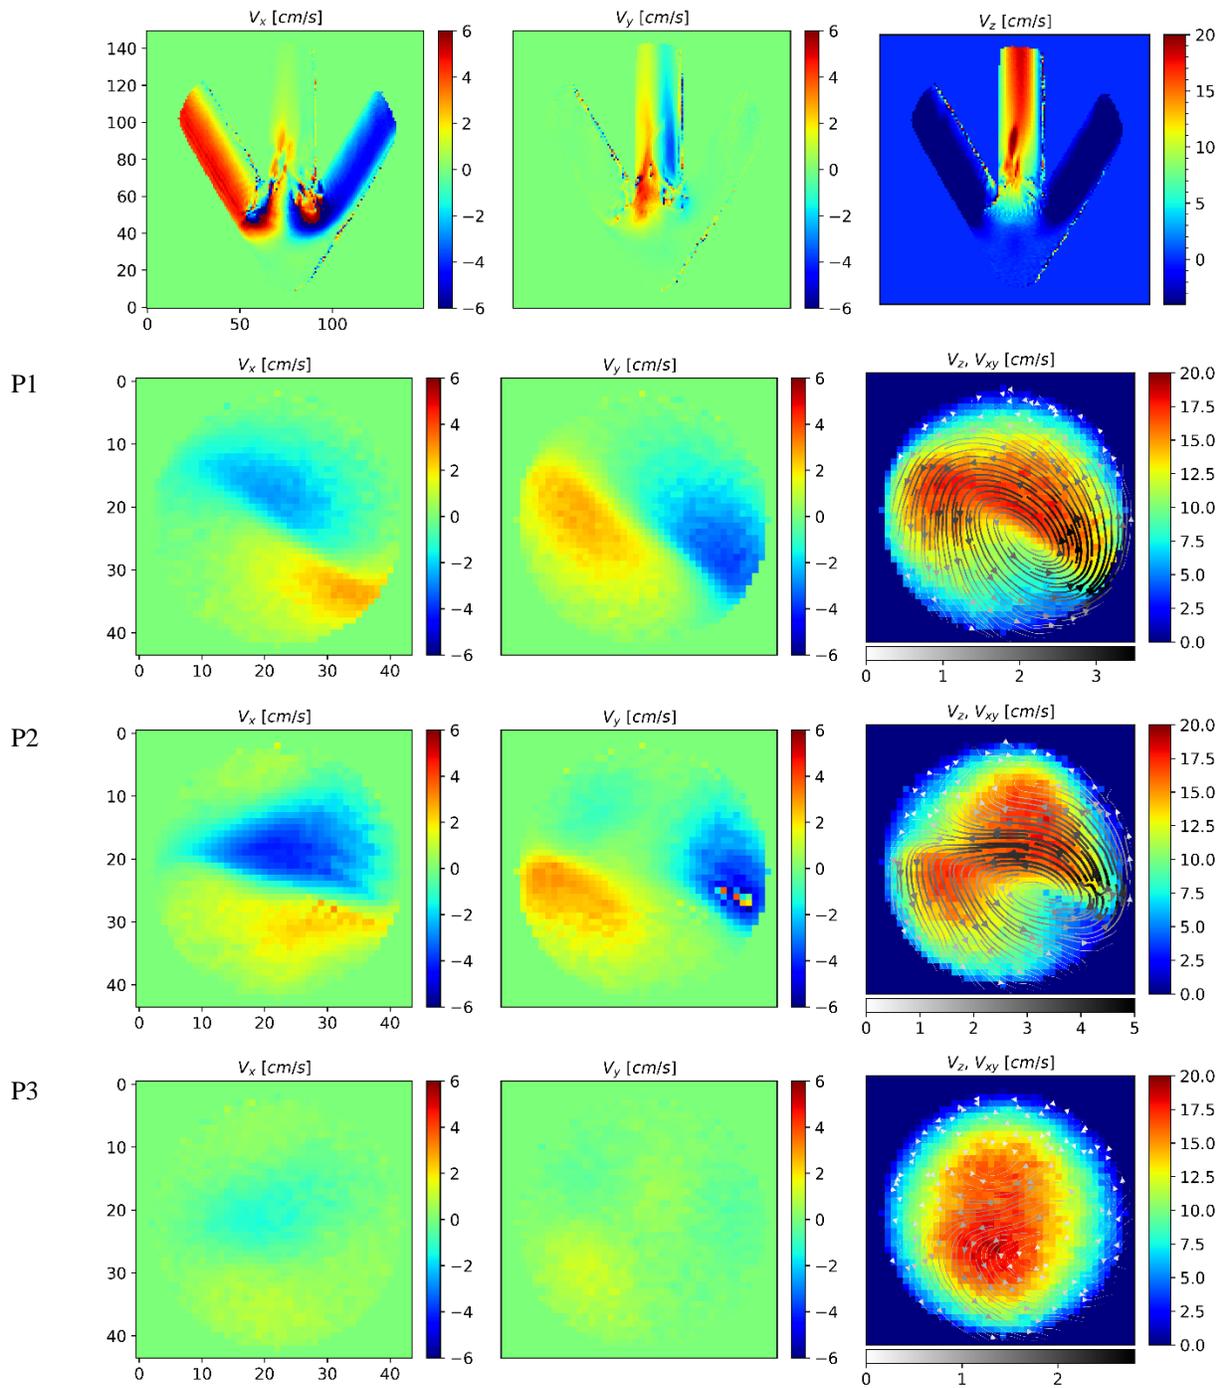

Fig. S13: 3D velocity maps obtained with the developed milli-coil. The flow rate on each inlet is 2.4ml/min corresponding to Re_{outlet} of 102. The velocity maps in the orthogonal plane to the main flow direction are obtained at slice positions P1, P2 and P3 corresponding respectively to 2mm, 2.5mm and 3mm from the mixing point.

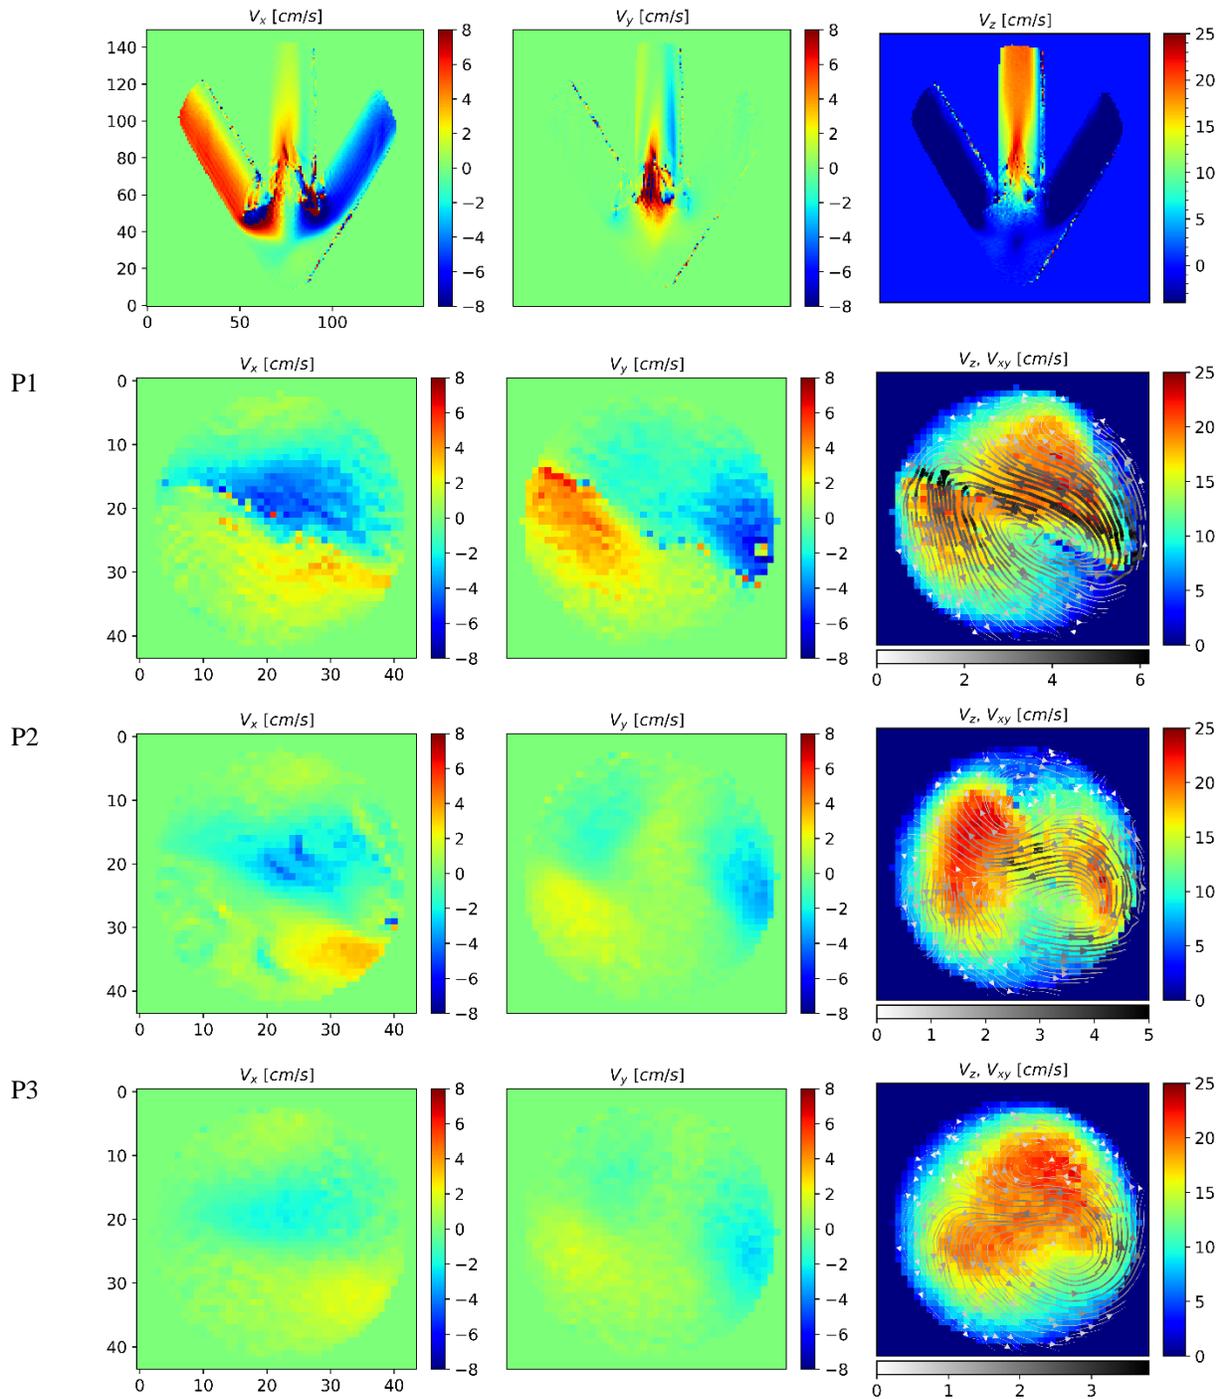

Fig.S14: 3D velocity maps obtained with the developed milli-coil. The flow rate on each inlet is 2.9ml/min corresponding to Re_{outlet} of 123. The velocity maps in the orthogonal plane to the main flow direction are obtained at slice positions P1, P2 and P3 corresponding respectively to 2mm, 2.5mm and 3mm from the mixing point.

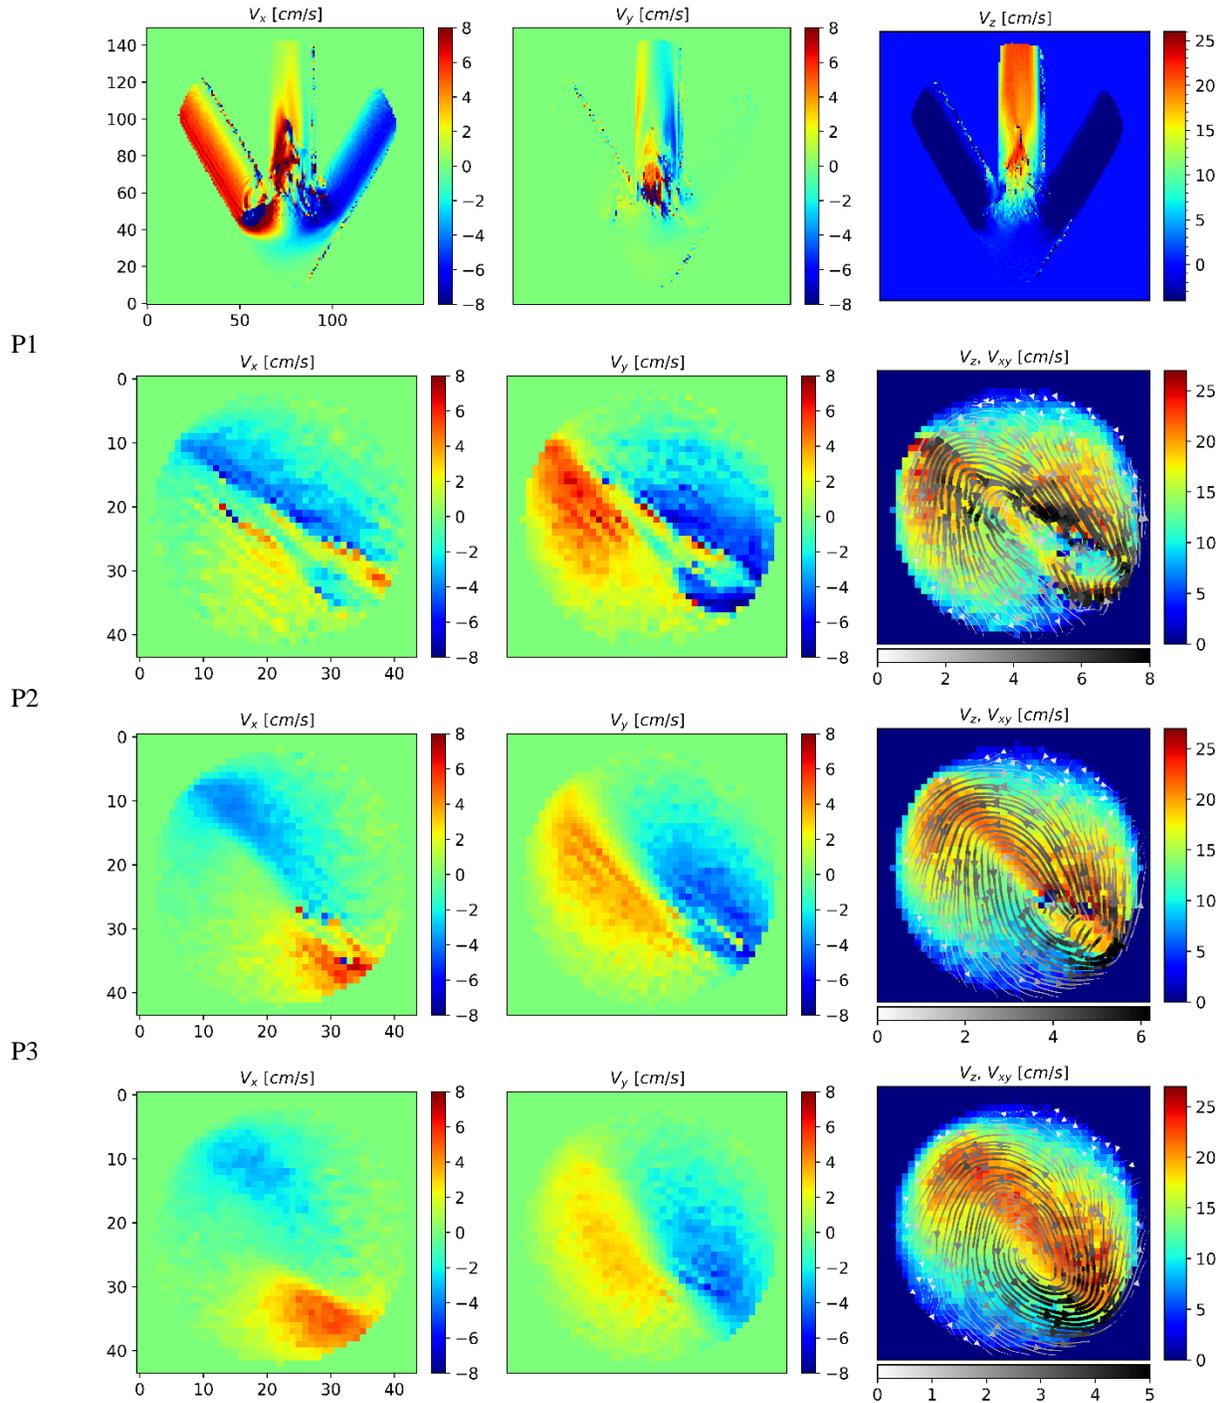

Fig. S15: 3D velocity maps obtained with the developed milli-coil. The flow rate on each inlet is 3.2ml/min corresponding to Re_{outlet} of 136. The velocity maps in the orthogonal plane to the main flow direction are obtained at slice positions P1, P2 and P3 corresponding respectively to 2mm, 2.5mm and 3mm from the mixing point.

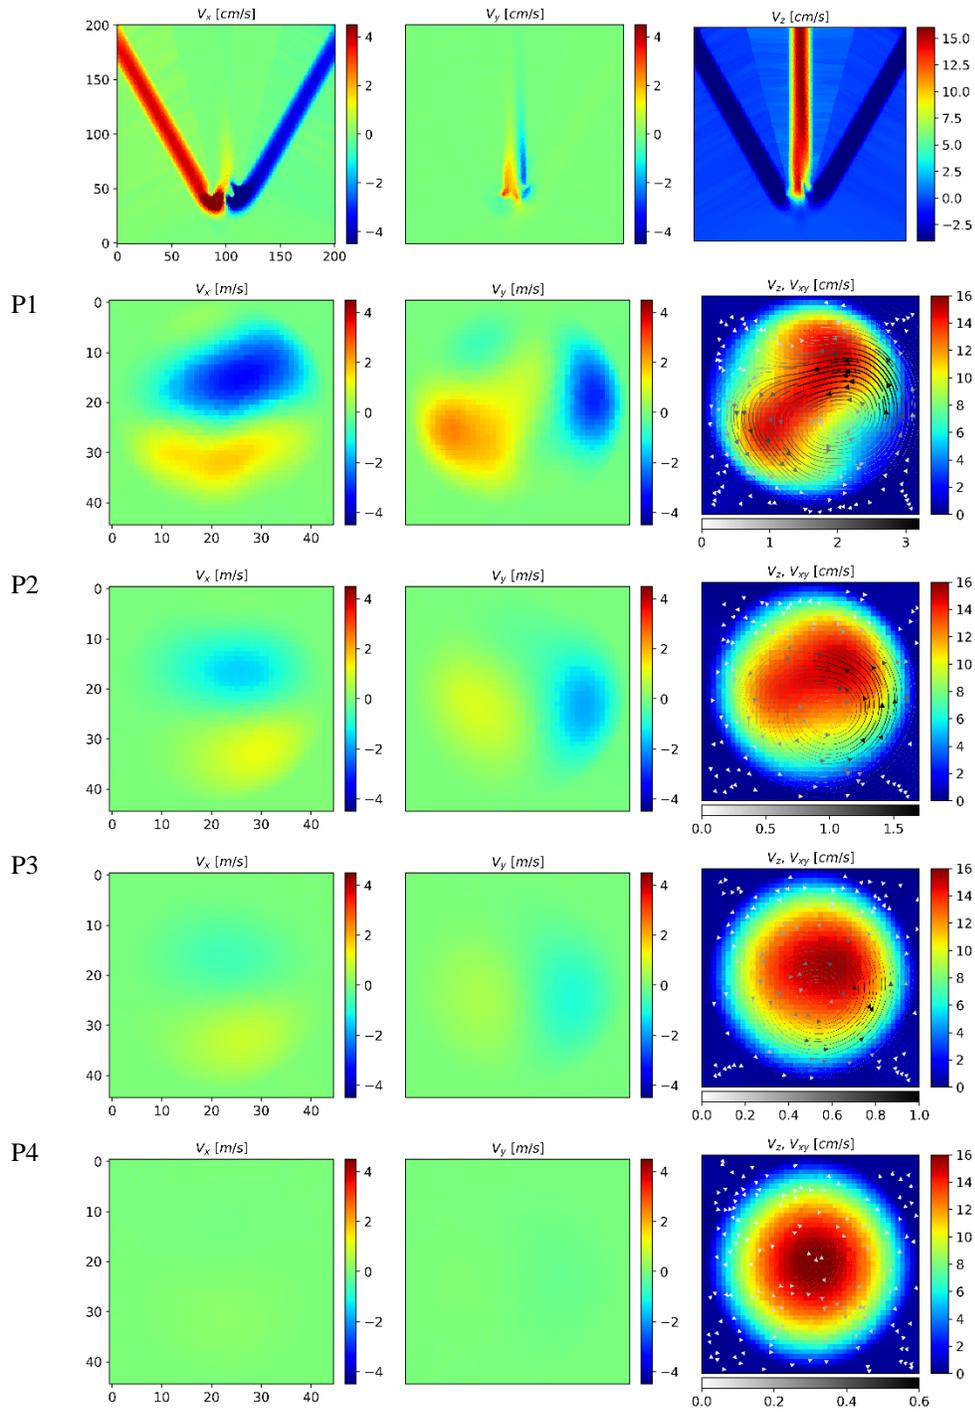

Fig. S16: 3D velocity maps obtained with CFD simulation on real geometry of the micromixer. The flow rate on each inlet is 1.9 ml/min corresponding to Re_{outlet} of 80. The velocity maps in the orthogonal plane to the main flow direction are obtained at slice positions P1, P2, P3 and P4 corresponding respectively to 2mm, 3mm, 4mm and 7mm from the mixing point.

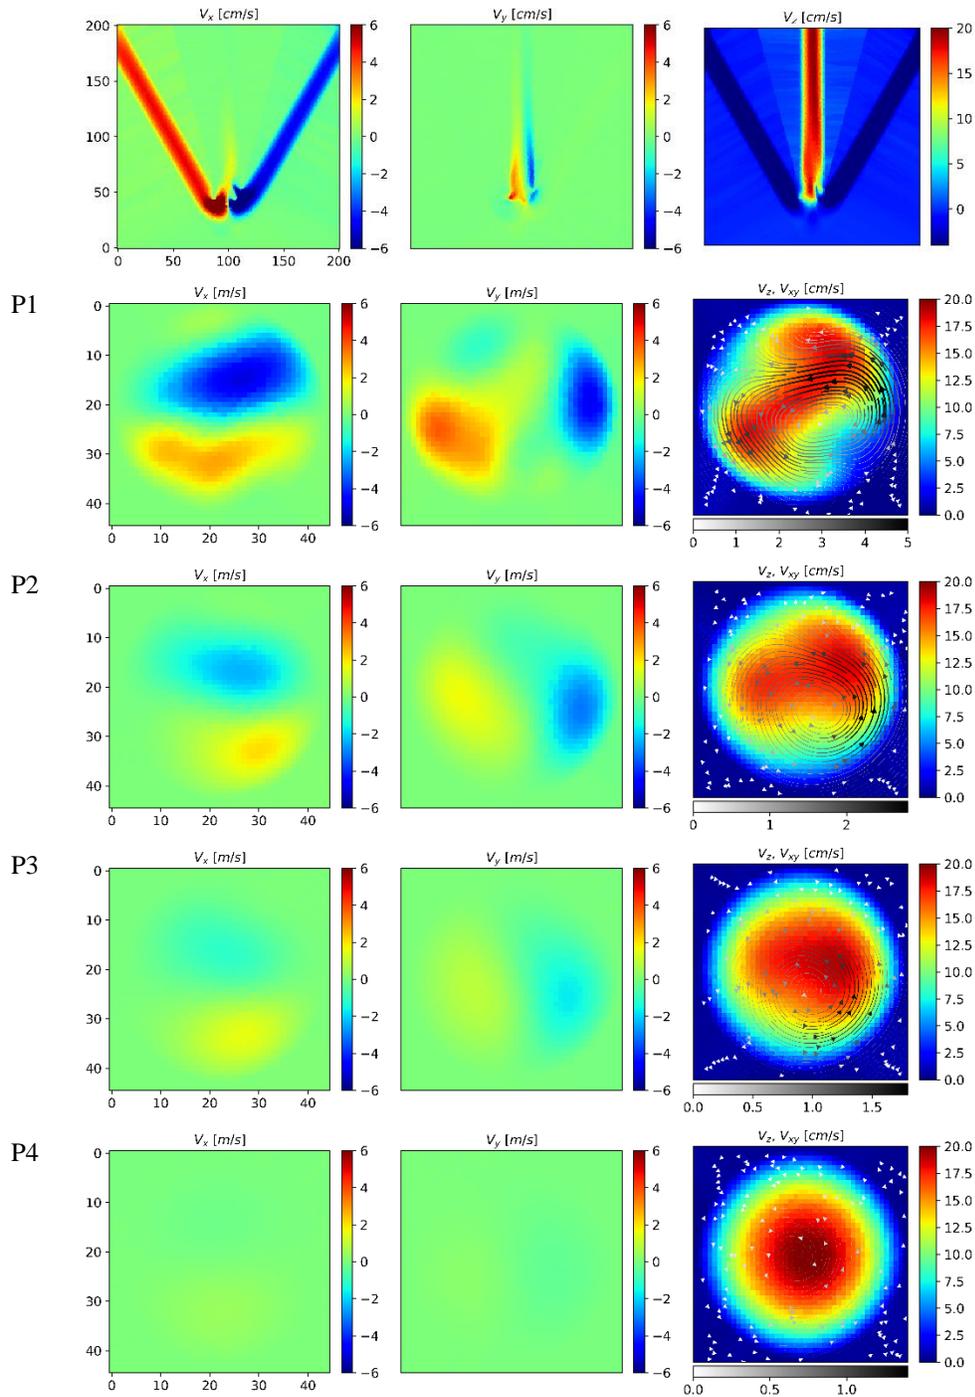

Fig. S17: 3D velocity maps obtained with CFD simulation on real geometry of the micromixer. The flow rate on each inlet is 2.4 ml/min corresponding to Re_{outlet} of 102. The velocity maps in the orthogonal plane to the main flow direction are obtained at slice positions P1, P2, P3 and P4 corresponding respectively to 2mm, 3mm, 4mm and 7mm from the mixing point.

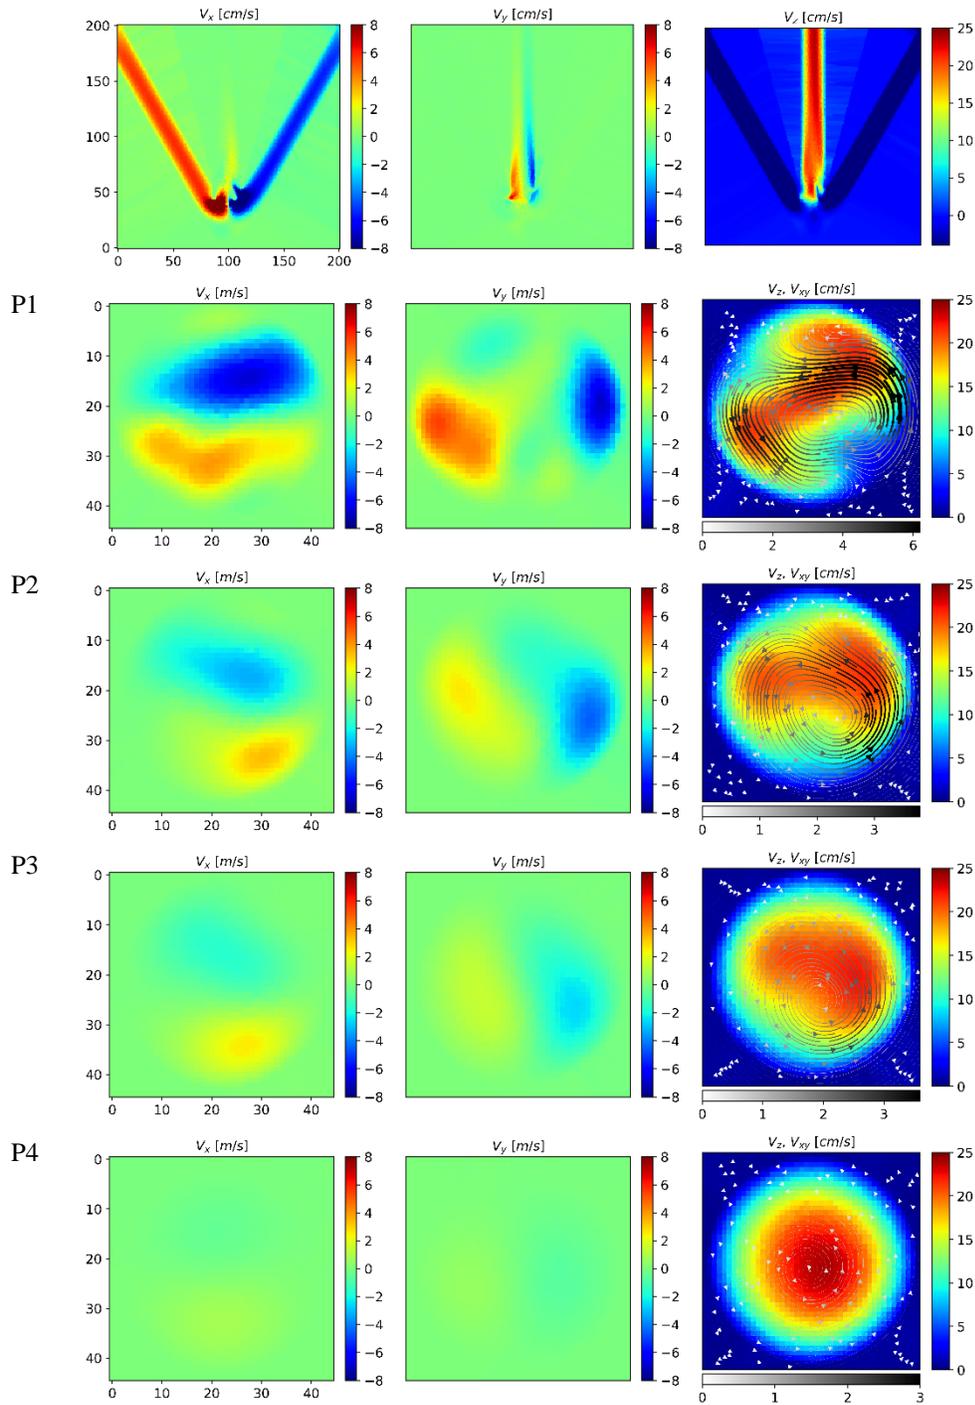

Fig. S18: 3D velocity maps obtained with CFD simulation on real geometry of the micromixer. The flow rate on each inlet is 2.9 ml/min corresponding to Re_{outlet} of 123. The velocity maps in the orthogonal plane to the main flow direction are obtained at slice positions P1, P2, P3 and P4 corresponding respectively to 2mm, 3mm, 4mm and 7mm from the mixing point.

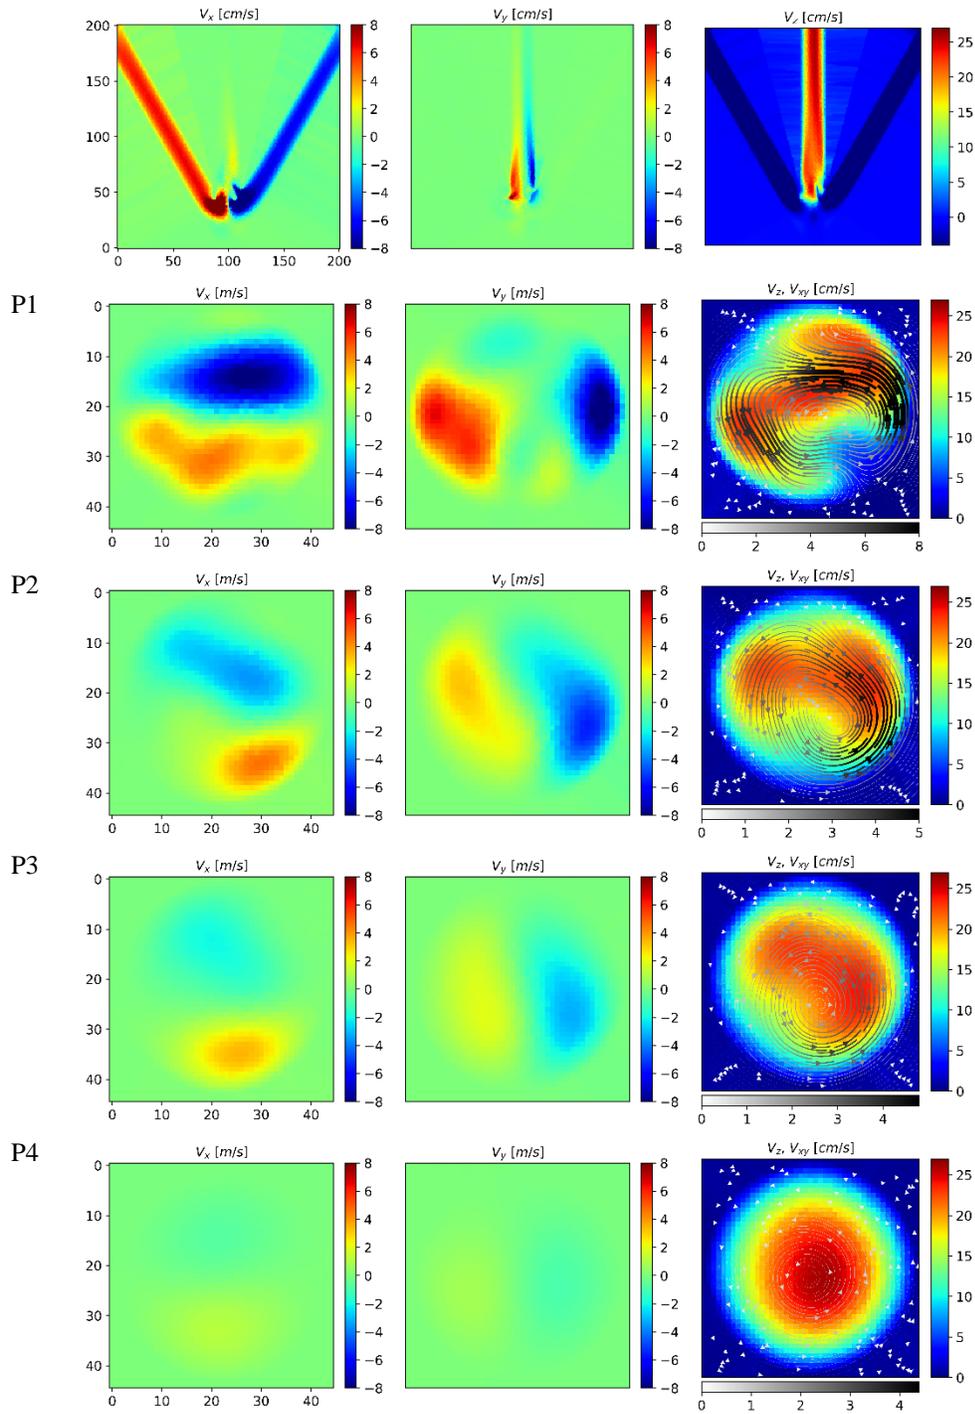

Fig. S19: 3D velocity maps obtained with CFD simulation on real geometry of the micromixer. The flow rate on each inlet is 3.2 ml/min corresponding to Re_{outlet} of 136. The velocity maps in the orthogonal plane to the main flow direction are obtained at slice positions P1, P2, P3 and P4 corresponding respectively to 2mm, 3mm, 4mm and 7mm from the mixing point.

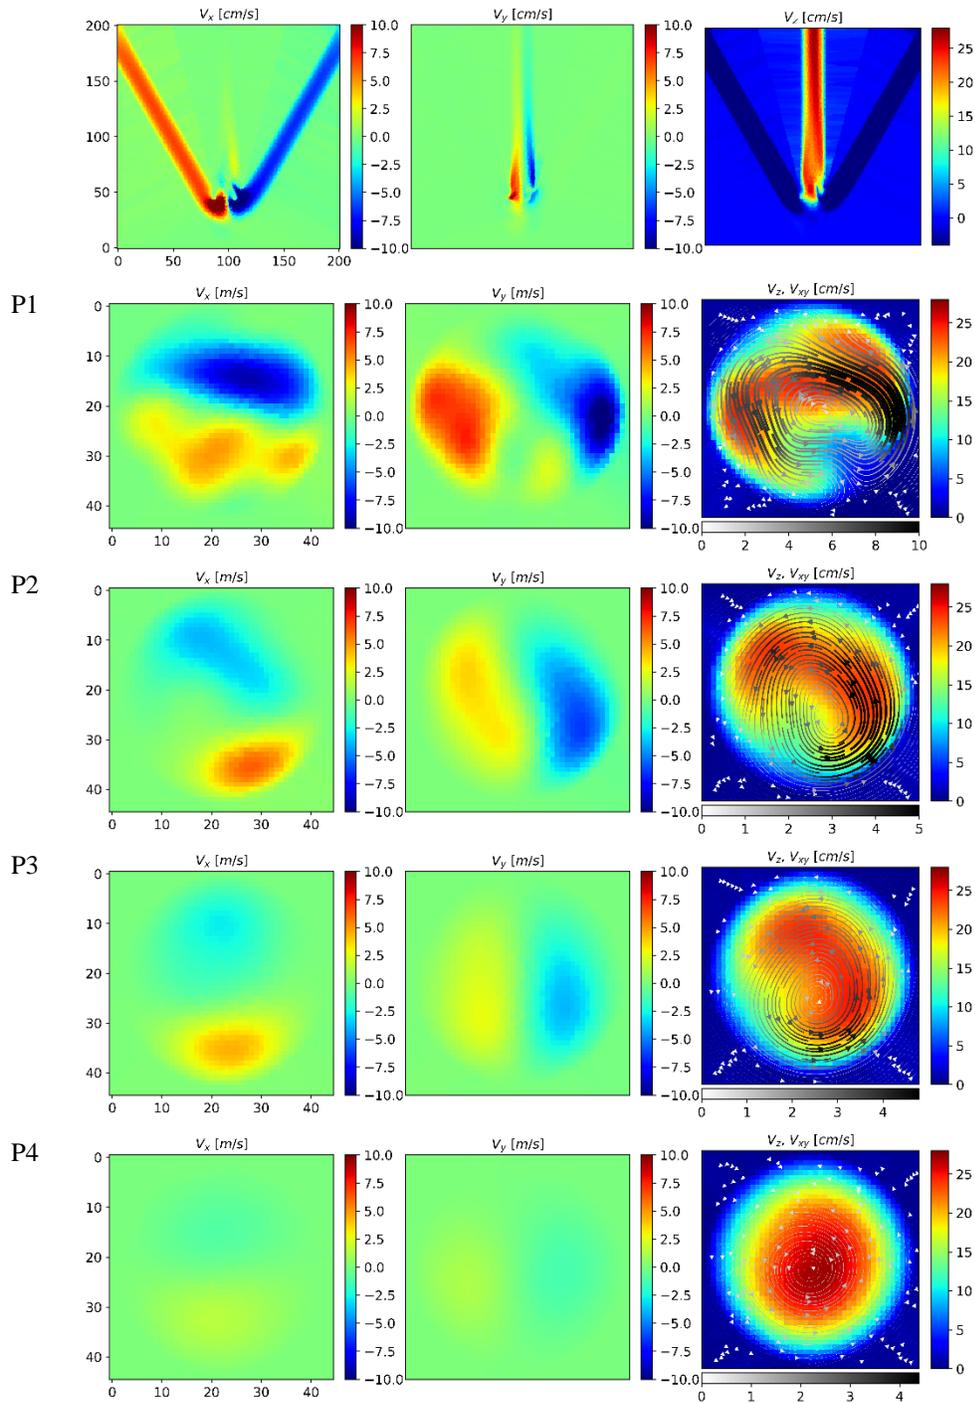

Fig. S20: 3D velocity maps obtained with CFD simulation on real geometry of the micromixer. The flow rate on each inlet is 3.4 ml/min corresponding to Re_{outlet} of 144. The velocity maps in the orthogonal plane to the main flow direction are obtained at slice positions P1, P2, P3 and P4 corresponding respectively to 2mm, 3mm, 4mm and 7mm from the mixing point.

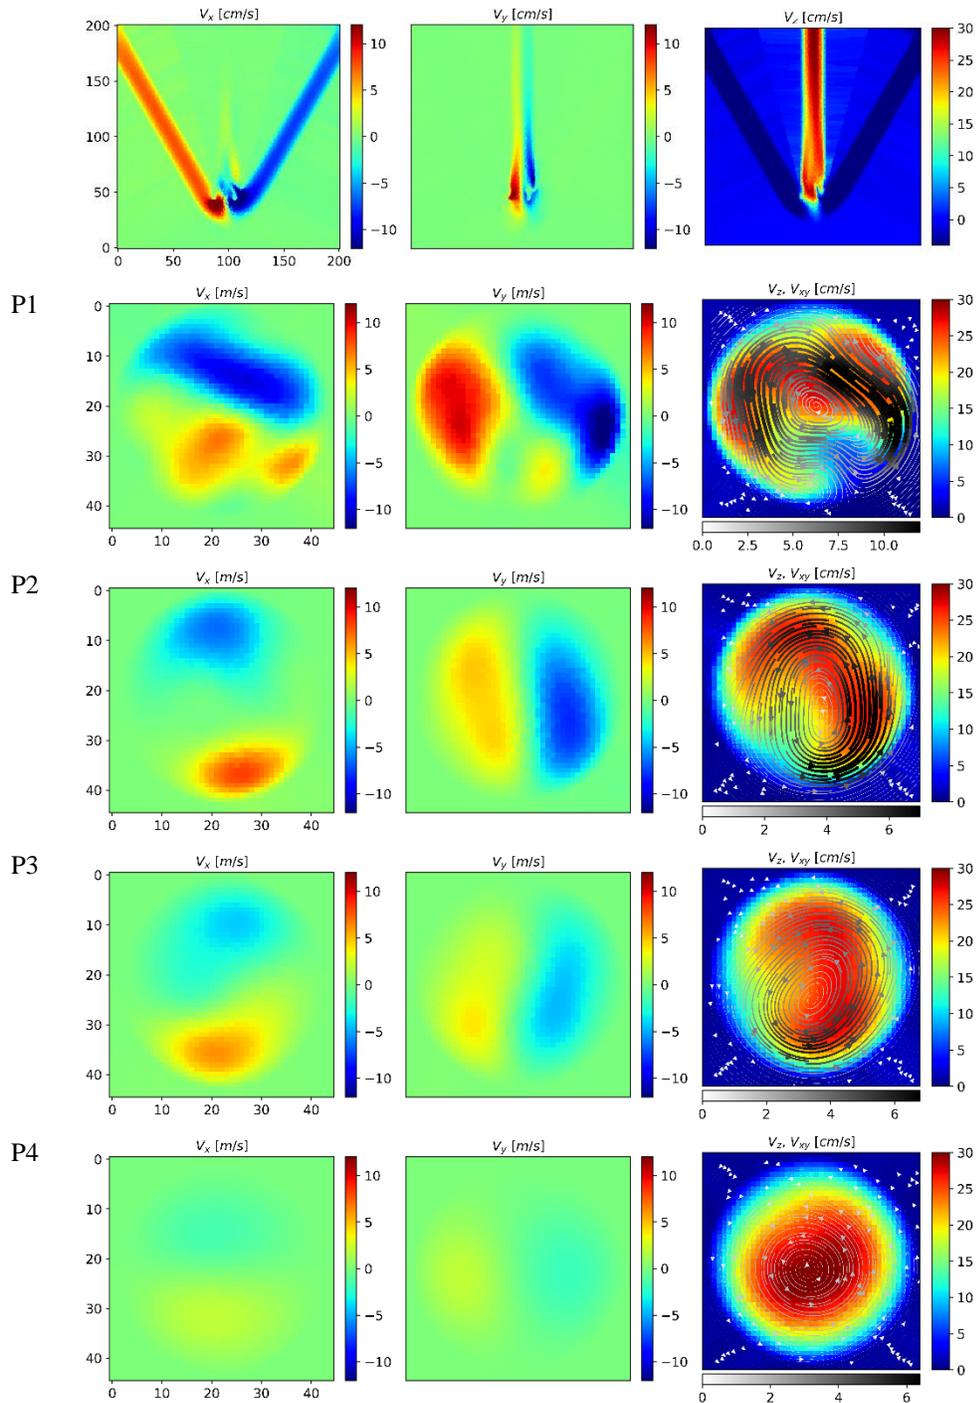

Fig. S21: 3D velocity maps obtained with CFD simulation on real geometry of the micromixer. The flow rate on each inlet is 3.9 ml/min corresponding to Re_{outlet} of 165. The velocity maps in the orthogonal plane to the main flow direction are obtained at slice positions P1, P2, P3 and P4 corresponding respectively to 2mm, 3mm, 4mm and 7mm from the mixing point.

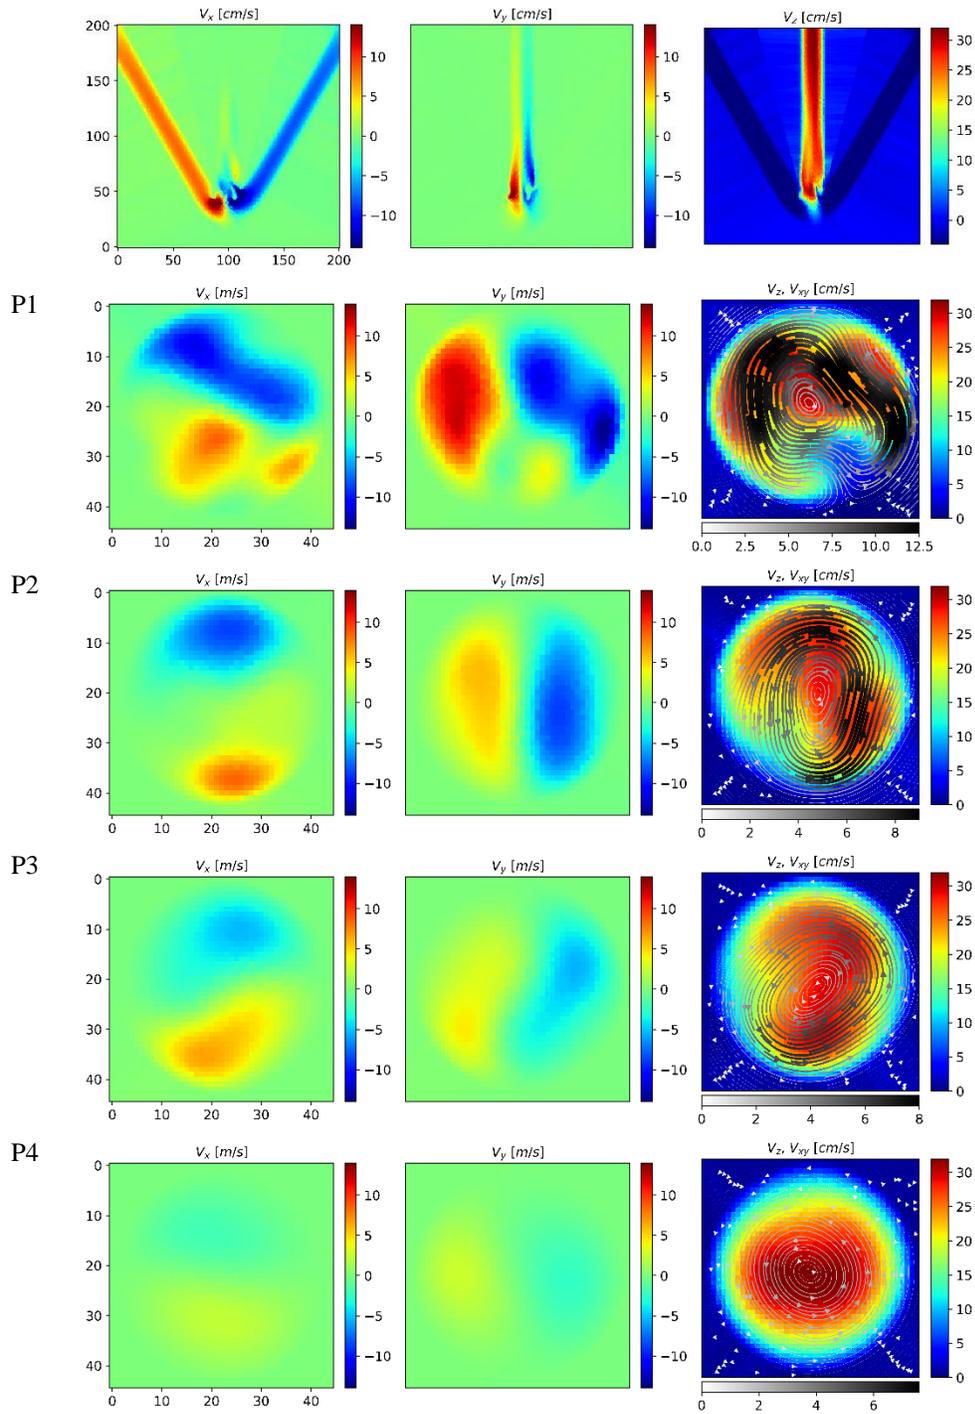

Fig. S22: 3D velocity maps obtained with CFD simulation on real geometry of the micromixer. The flow rate on each inlet is 4.2 ml/min corresponding to Re_{outlet} of 178. The velocity maps in the orthogonal plane to the main flow direction are obtained at slice positions P1, P2, P3 and P4 corresponding respectively to 2mm, 3mm, 4mm and 7mm from the mixing point.

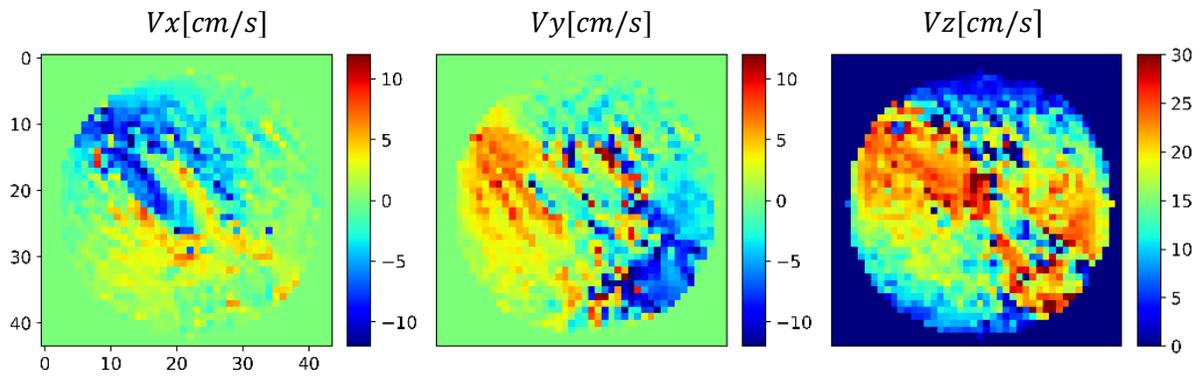

Fig. S23: 3D velocity maps obtained with the developed milli-coil (3.9 ml/min per inlet corresponding to Re_{outlet} of 165) illustrating the limit of the MRI measurement
