HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Context
Among the intrinsic factors to the risk of falling in the elderly, the alteration of visual capacities is central. Paradoxically, this modality remains preferentially used for their postural control as proved their high field dependence. This perceptual style is known to reduce sensorimotor adaptability¹. Many studies consider that increased postural variability is a marker of aging. In addition, the entropy-based complexity metrics that relate to the information content of a signal by quantifying the degree of regularity allowed detecting an exacerbated degradation of complexity in postural sway in aged people, thus indicating a failure in the dynamic re-organization of control². These metrics may provide a window on the interactions across scale supporting engaged cognitive processes and might offer an original approach to the concept of adaptability³.

The aim of this study was twofold: i) to analyze the variability and complexity of the cognitivo-postural behaviour during different suprapostural tasks in young and over 65 yo adults; and ii) to explore how field dependence level and behavioural adaptation ability are linked in elderly.

Method
Two 12-healthy-subject groups:
• Adult over 65 (75.4 ± 5.1)
• Young Adult (21.9 ± 2.4)

Four 51.2s-suprapostural tasks
Visual Fix:
• To focus a dot (VFix)
Visual Disc:
• To mentally count C-letters projected in front of them as fast and as efficiently as possible (VDis_Lev1)...
  • … with added A-letters (VDis_Lev2)
  • … with added A- and G-letters (VDis_Lev3)

Linear and non-linear analysis methods of kinetic data acquired via force platform (SATEL®, 100Hz):
• Standard deviation of CoP signal (SD).
• Entropy index (EI) calculated from the refined composite multiscale entropy curves (RCMSE).

Results & Discussion

Regardlesss of group, the significant decrease in cognitive performance in the two highest difficulty levels (VDis_Lev2 / VDis_Lev3) is not associated with a decrease in complexity. The significant differences in cognitive and postural performances between groups suggest that:
• standing is easy for young adults despite the difficulty of the cognitive task.
• cognitivo-postural tasks are too difficult for older adults.
• The behavioral adaptability of older adults is not related to their level of visual field dependence.
