Focus : Incompressible mixing at infinite Froude numbers

$$d_t \varrho = a \Delta \varrho = -d \quad \varrho = \ln \rho, \quad d = \nabla \cdot \mathbf{u}$$

$$d_t \mathbf{u} = -\nabla \pi - \pi \nabla \varrho + \nu \Delta \mathbf{u} \quad \pi = p/\rho$$

$$d_t \boldsymbol{\omega} = (\boldsymbol{\omega} \cdot \nabla) \mathbf{u} - d \boldsymbol{\omega} - \nabla \pi \times \nabla \varrho + \nu \Delta \boldsymbol{\omega}$$

$$\frac{d\boldsymbol{\omega}}{dt} = \underbrace{(\boldsymbol{\omega} \cdot \nabla) \mathbf{u}}_{\text{green}} - \frac{1}{\rho^2} \nabla P \times \nabla \rho - \underbrace{d \boldsymbol{\omega}}_{\text{blue}} + \underbrace{\nu \Delta \boldsymbol{\omega}}_{\text{yellow}}$$

Inviscid incompressible inhomogeneous flows

$$d_t \rho = 0$$

$$d_t \mathbf{u} = -g' \mathbf{i}_z - \dot{\mathbf{u}}_r - \frac{1}{\rho} \nabla p$$

$$g' = \frac{g}{\rho_0} (\rho - \rho_{\text{hydro}}) = g \frac{\rho'}{\rho_0} \sim \mathcal{O}(g C_\rho)$$

$$\mathbf{a} = \underbrace{d_t \mathbf{u}}_{\text{II}} + \underbrace{g' \mathbf{i}_z + \dot{\mathbf{u}}_r}_{\text{I}} = -\frac{1}{\rho} \nabla p$$

$$\text{Ba : } -\frac{1}{\rho} \nabla p \times \nabla \varrho \equiv \mathbf{a} \times \nabla \varrho$$

A set of scales

$$\mathbf{u} \sim u, \quad x, y, z \sim \ell, \quad \pi \sim u^2$$

$$\rho \sim \rho_0, \quad d\rho \sim \Delta\rho$$

$$\underbrace{\frac{d_t \mathbf{u}}{u^2}}_{\frac{1}{\ell}} = - \underbrace{\frac{\nabla \pi}{u^2}}_{\frac{1}{\ell}} - \underbrace{\frac{\pi \nabla \varrho}{u^2 \Delta \rho}}_{\frac{1}{\ell} \frac{1}{\rho_0}} + \underbrace{\frac{\nu \Delta \mathbf{u}}{\nu \frac{u}{\ell^2}}}$$

$$\underbrace{\frac{d_t \boldsymbol{\omega}}{u^2}}_{\frac{1}{\ell^2}} = \underbrace{(\boldsymbol{\omega} \cdot \nabla) \mathbf{u}}_{\frac{u^2}{\ell^2}} - \underbrace{\frac{d \boldsymbol{\omega}}{Ma^2 \frac{u^2}{\ell}}}_{\frac{1}{\ell}} - \underbrace{\frac{\nabla \pi \times \nabla \varrho}{u^2 \Delta \rho}}_{\frac{1}{\ell^2} \frac{1}{\rho_0}} + \underbrace{\frac{\nu \Delta \boldsymbol{\omega}}{\frac{u}{\ell^3}}}$$

$$d_t \varrho = \frac{1}{Re Sc} \Delta \varrho = - \frac{1}{C_\rho} d$$

$$d_t \mathbf{u} = - \nabla \pi - C_\rho \pi \nabla \varrho + \frac{1}{Re} \Delta \mathbf{u}$$

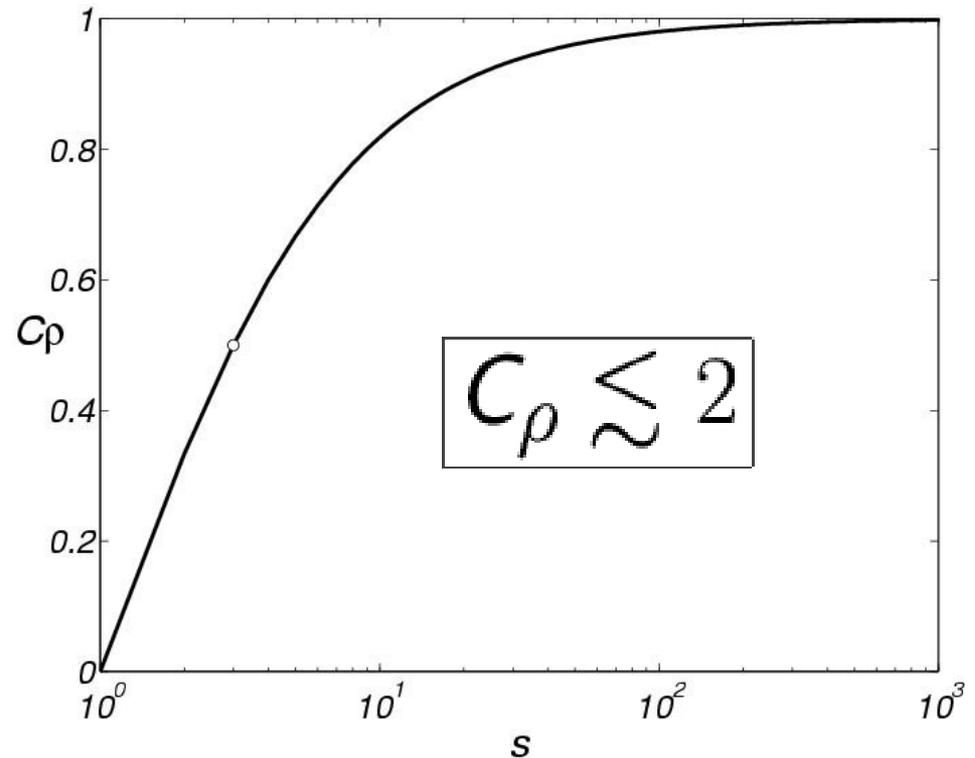

$$C_\rho = \frac{\Delta \rho}{\rho_{\text{mean}}} = \frac{\rho'}{\bar{\rho}}$$

$$s = \rho_2 / \rho_1$$

$$C_\rho = \frac{\rho_2 - \rho_1}{\rho_2 + \rho_1}$$

$$C_\rho = (s - 1) / (1 + s)$$

Condition : $2\rho_m - \Delta\rho > 0$

$$d_t \varrho = \frac{1}{ReSc} \Delta \varrho = -\frac{1}{C_\rho} d$$

$$d_t \mathbf{u} = -\nabla \pi - \underline{C_\rho \pi \nabla \varrho} + \frac{1}{Re} \Delta \mathbf{u}$$

$$d_t \boldsymbol{\omega} = \underbrace{(\boldsymbol{\omega} \cdot \nabla) \mathbf{u}}_{\text{Vs}} - d \boldsymbol{\omega} - \underbrace{\nabla \pi \times \nabla \rho}_{\text{Ba}} + \nu \Delta \boldsymbol{\omega}$$

$$\text{Vs} \quad (\boldsymbol{\omega} \cdot \nabla) \mathbf{u} \sim \mathcal{O}\left(\frac{u^2}{\lambda^2}\right)$$

$$\text{Ba} \quad \nabla \pi \times \nabla \rho \sim \mathcal{O}\left(\frac{u^2}{\ell} \frac{C_\rho}{\lambda_\rho}\right)$$

$$\frac{\text{Ba}}{\text{Vs}} \sim C_\rho \cdot \frac{\lambda}{\lambda_\rho} \cdot \frac{\lambda}{\ell}$$

$$d_t \boldsymbol{\omega} = \underbrace{(\boldsymbol{\omega} \cdot \nabla) \mathbf{u}}_{\text{blue underline}} - d \boldsymbol{\omega} - \underbrace{\nabla \pi \times \nabla \rho}_{\text{red underline}} + \nu \Delta \boldsymbol{\omega}$$

$$V_s \quad (\boldsymbol{\omega} \cdot \nabla) \mathbf{u} \sim \mathcal{O}\left(\frac{u^2}{\lambda^2}\right)$$

$$Ba \quad \nabla \pi \times \nabla \rho \sim \mathcal{O}\left(g \frac{C_\rho}{\lambda}\right)$$

$$\frac{Ba}{V_s} \sim g \cdot C_\rho \cdot \frac{\lambda}{u^2} \sim Ri$$

$$\frac{Ba}{Vs} \sim C_\rho \cdot \frac{\lambda}{\lambda_\rho} \cdot \frac{\lambda}{\ell}$$

- Fully developed 3D turbulence

$$\frac{Ba}{Vs} \sim \frac{\lambda}{\lambda_\rho} \cdot \frac{C_\rho}{Re_\lambda}$$

High Reynolds number turbulence insensitive to density variations

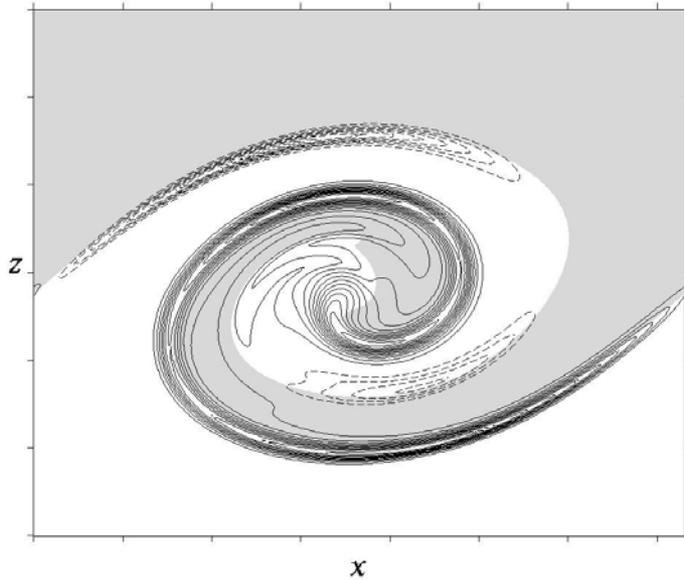

- Two-dimensional flows : no vortex stretching $\boldsymbol{\omega} \perp \nabla \mathbf{u}$

No vortex stretching, baroclinic torque only source/sink of vorticity

- Transition flows $\frac{\lambda}{\ell} \sim \mathcal{O}(1)$

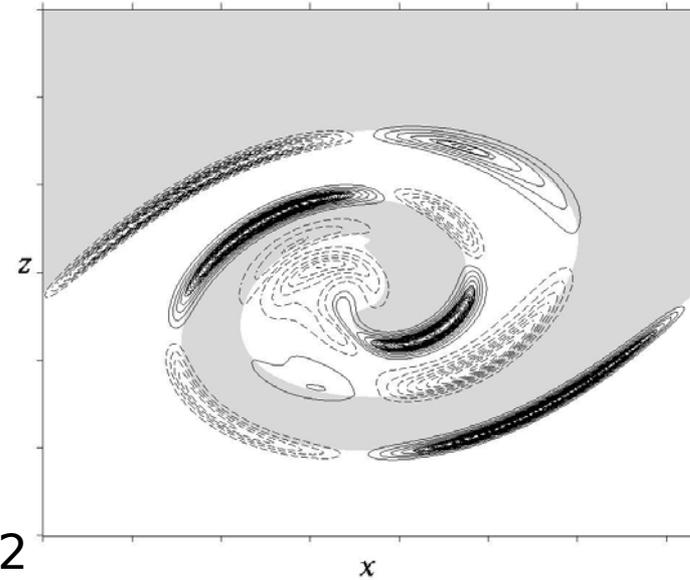

The baroclinic torque may bias the transition

Kelvin-Helmholtz instability $s=3$, $Re = U\delta/\nu = 1500$

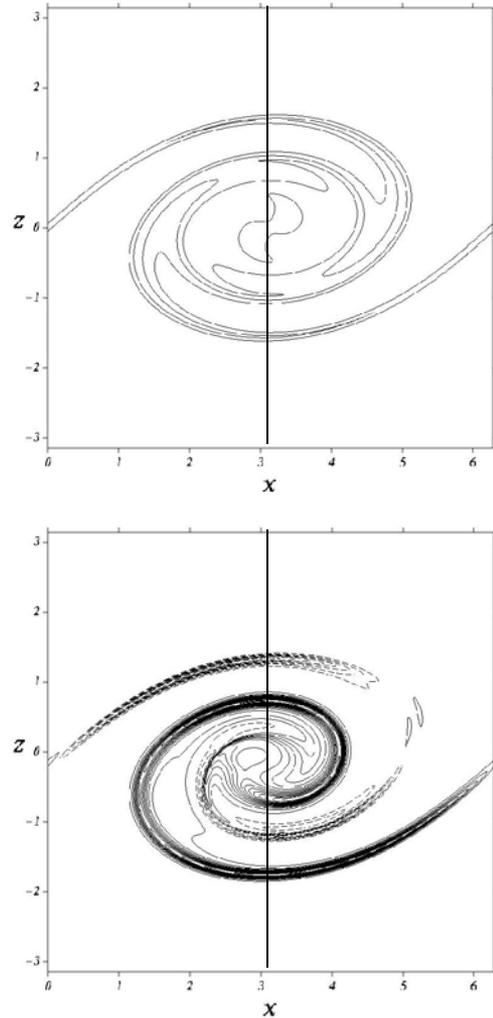

Vorticity

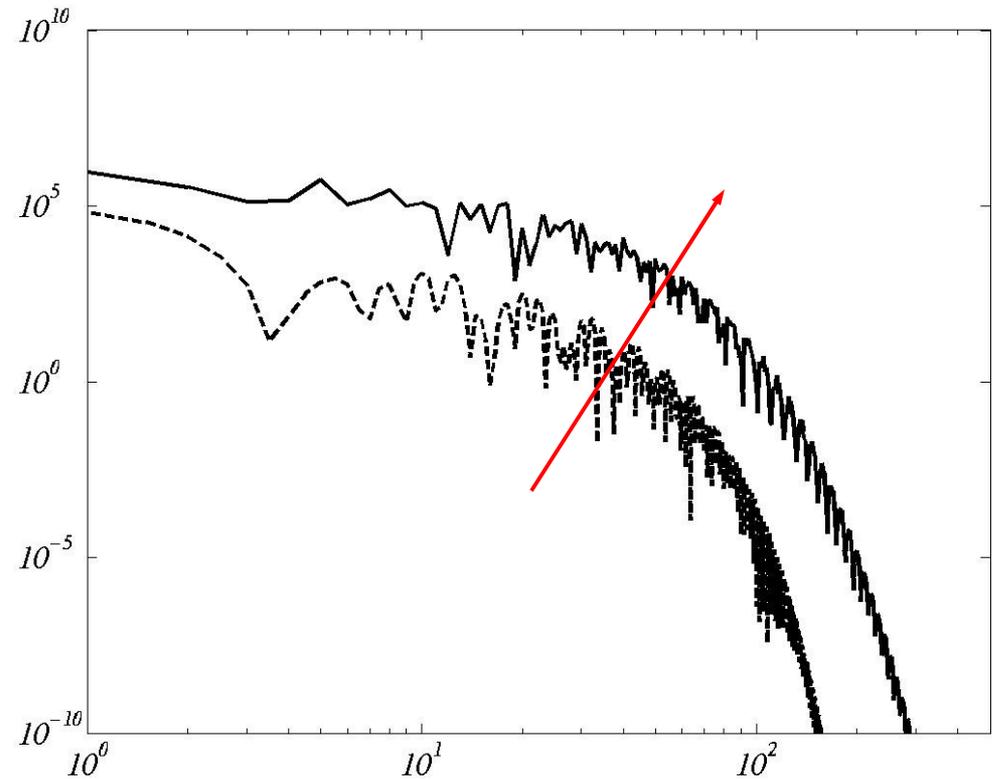

$t=12$

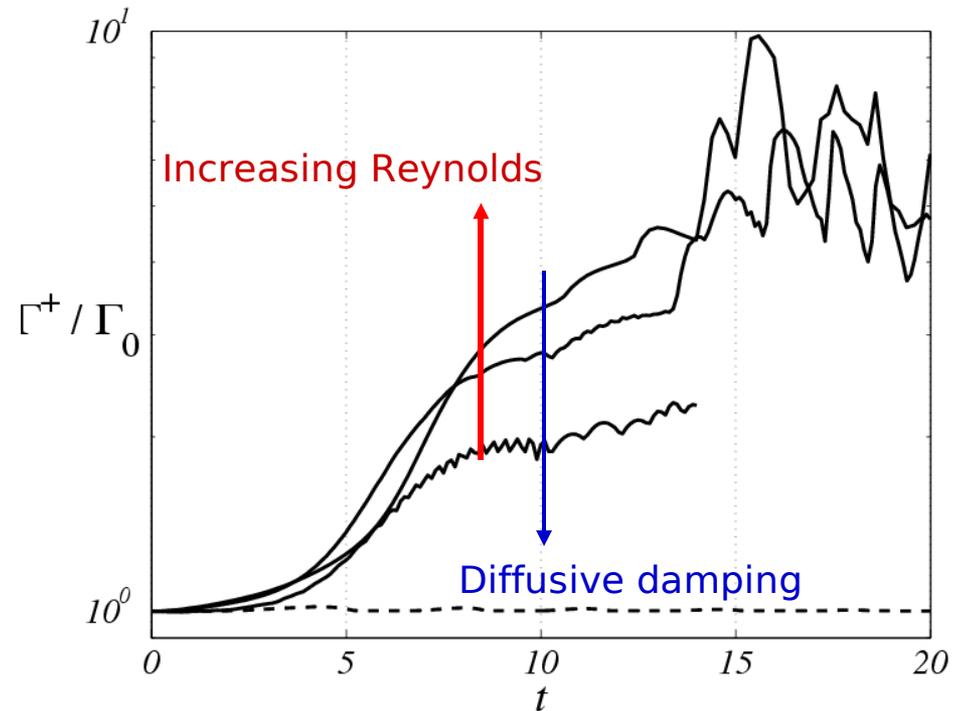

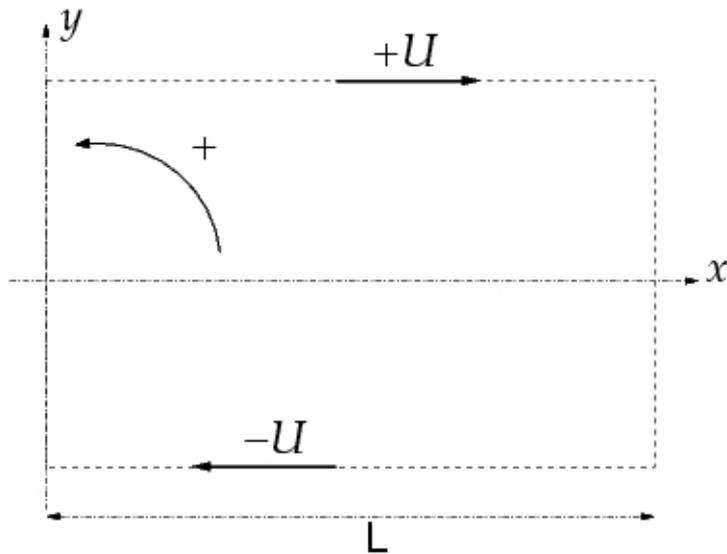

Baroclinic torque

Mixing layer $s = 1$ or 3 , $Re = 3000$, $t=12$

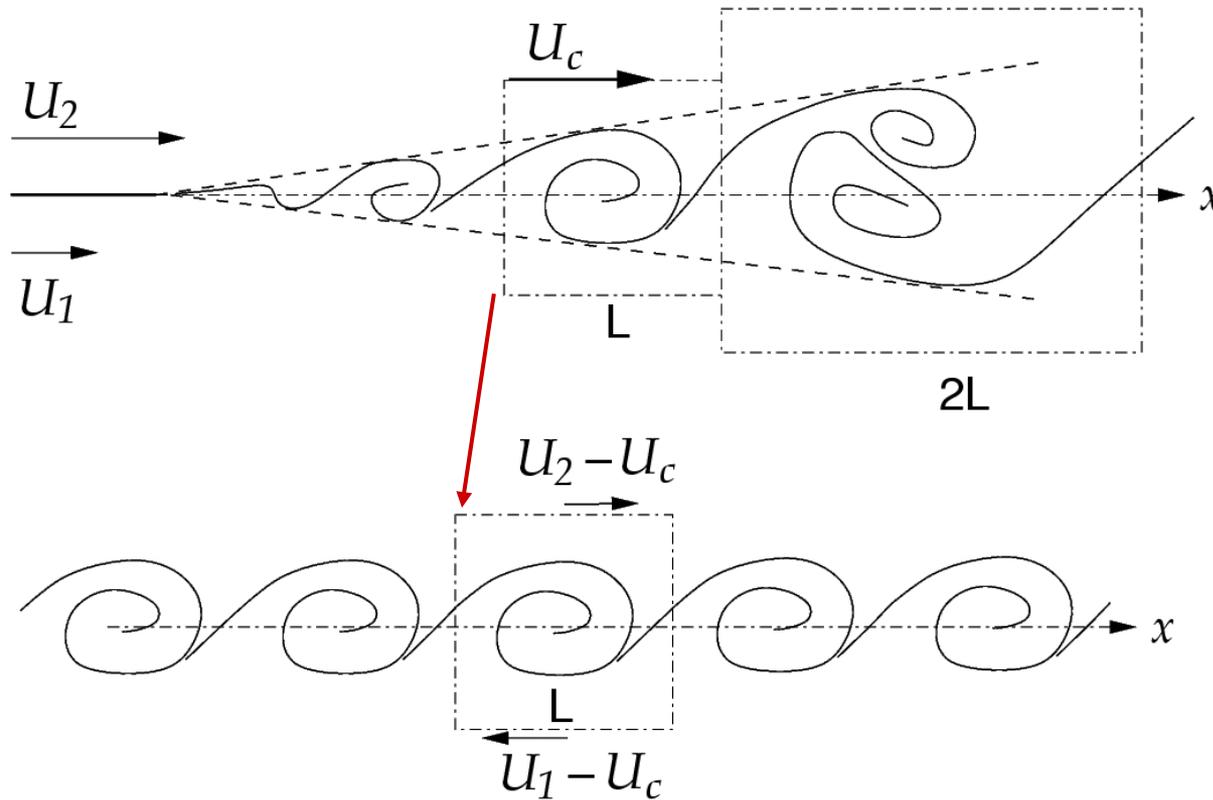

Temporal mixing layer $s=3$, $Re = U\delta/\nu = 500, 1500, 3000$

$$\Gamma_0 = -2UL$$

$$\Gamma^+ = \int_{\text{period}} (\omega < 0) d\sigma$$

...Break...
5. *Transition of the inhomogeneous mixing-layer and the 2D secondary baroclinic instability*

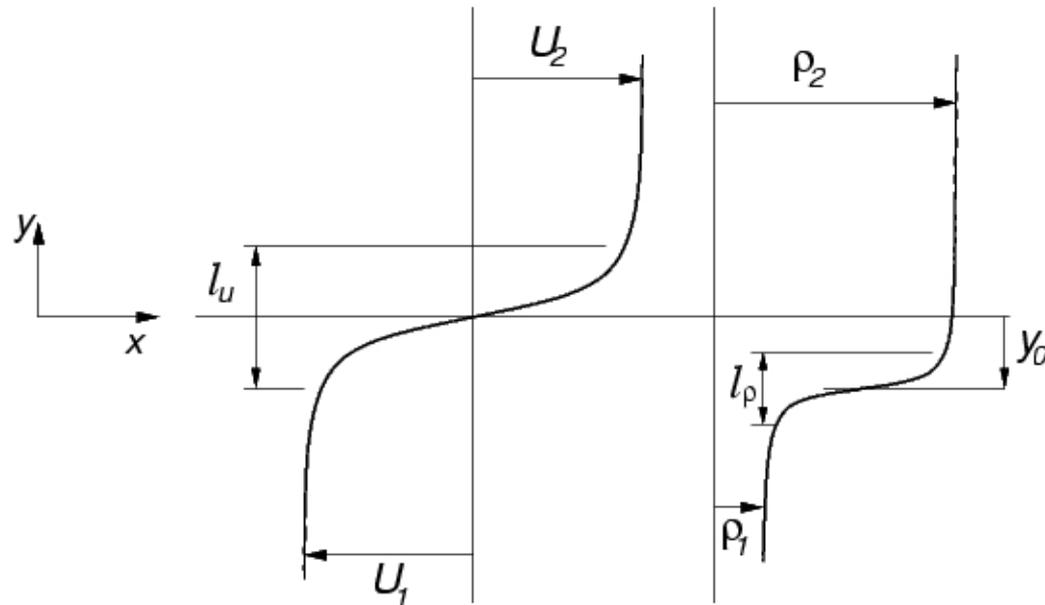

The real flow : the spatially developing mixing-layer

The temporally developing mixing-layer

The temporal approximation :

- The frame of reference is moving with the convection velocity of the large structures
- The flow is considered parallel
- The chosen subharmonic of the primary mode is periodized in the streamwise direction

Due to the temporal approximation, the difference between cogradient and countergradient situations is lost

$$U(y) = U \tanh(y/l_u)$$

$$R(y) = \rho_m + \frac{\Delta\rho}{2} f\left(\frac{y - y_0}{l_\rho}\right)$$

- Decomposition of flow variables

$$\mathbf{u}(\mathbf{x}, t) = U(y)\mathbf{e}_x + \hat{\mathbf{u}}(\mathbf{x}, t)$$

$$\rho(\mathbf{x}, t) = R(y) + \hat{\rho}(\mathbf{x}, t)$$

- Linearization of the Euler equations : perturbation equations

$$\begin{aligned} D_t \hat{\rho} + \hat{v} R' &= 0 \\ RD_t \hat{\mathbf{u}} + RU' \hat{v} \mathbf{e}_x &= -\nabla \hat{p} \\ \nabla \cdot \hat{\mathbf{u}} &= 0 \end{aligned}$$

- The Rayleigh equation for the crosswise perturbation velocity

$$\left[RD_t \nabla^2 - (RU')' \partial_x + R' D_t \partial_y \right] \hat{v} = 0$$

- Perturbations are given the 2D wavelike form

$$\begin{aligned} [\hat{\mathbf{u}}, \hat{\rho}, \hat{p}](\mathbf{x}, t) &= [\tilde{\mathbf{u}}, \tilde{\rho}, \tilde{p}](y) e^{i(\alpha x - \alpha c t)} \\ &= [\tilde{\mathbf{u}}, \tilde{\rho}, \tilde{p}](y) e^{\alpha c_i t} e^{i\alpha(x - c_r t)} \end{aligned}$$

α Streamwise wavenumber

$\sigma = \alpha c_i$ Growth rate

c_r Phase velocity

- Decomposition of the vorticity field

$$\boldsymbol{\omega}(\mathbf{x}, t) = -U'(y)\mathbf{e}_z + \hat{\boldsymbol{\omega}}(\mathbf{x}, t)$$

$$\hat{\boldsymbol{\omega}} = (\hat{\xi}, \hat{\eta}, \hat{\zeta})$$

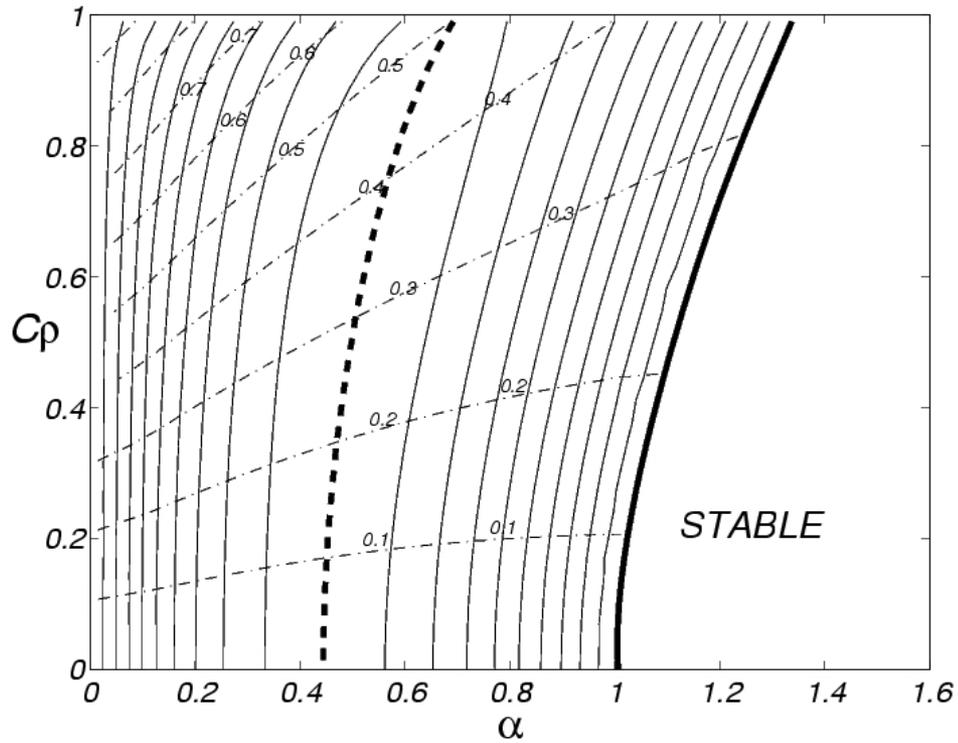

- Linearized equation for the normal vorticity perturbation (2D)

$$D_t \hat{\zeta} = U'' \hat{v} - U' \partial_z \hat{w} - \frac{R'}{R^2} \partial_x \hat{p}$$

The linearized baroclinic torque is responsible for the differences between the stability of the variable-density and the homogeneous shear flows.

$$\hat{a}_x = \frac{1}{R} \partial_x \hat{p} \quad \left| \quad \right| \quad \hat{b} = -\frac{R'}{R} \hat{a}_x$$

Kelvin-Helmholtz instability $s=3$, $Re = U\delta/\nu = 1500$

Vorticity

Baroclinic torque

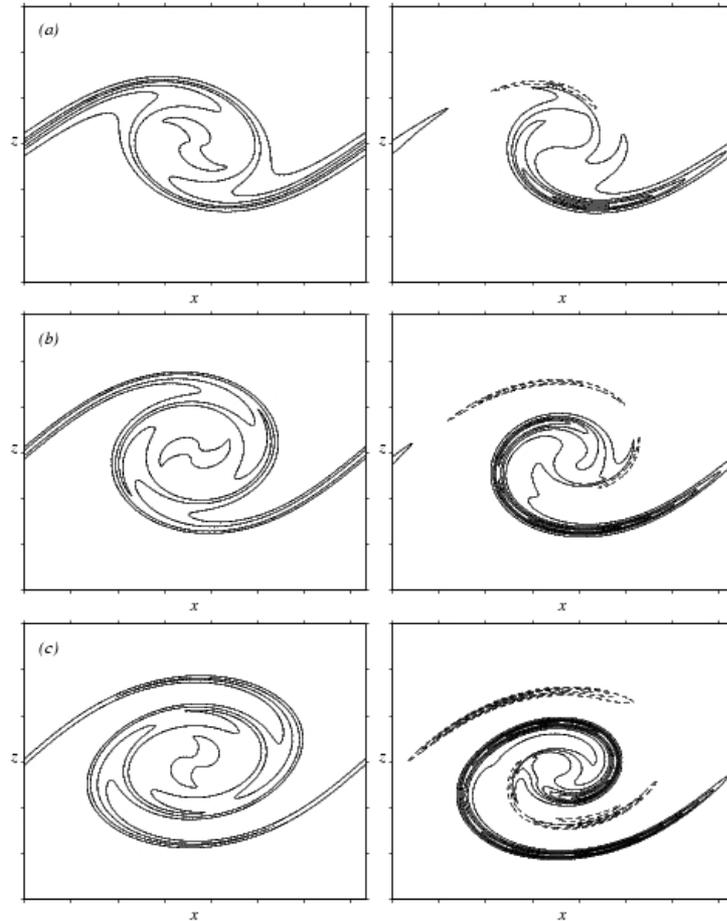

Figure 3.2: Vorticity ω_y contours of the two-dimensional variable density mixing-layer at $Re = 3000$. Left column : passive-scalar case, right column : variable-density situation with density ratio of $S_\rho = 3$. The time normalized by τ , is (a) $t = 8$, (b) $t = 10$, (c) $t = 12$. Contour increment is $1/2\tau$ for the passive-scalar case and twice that value for the variable-density case. The negative contours are drawn with dashed lines; tic marks along x and z coordinates are every δ_ω^0 .

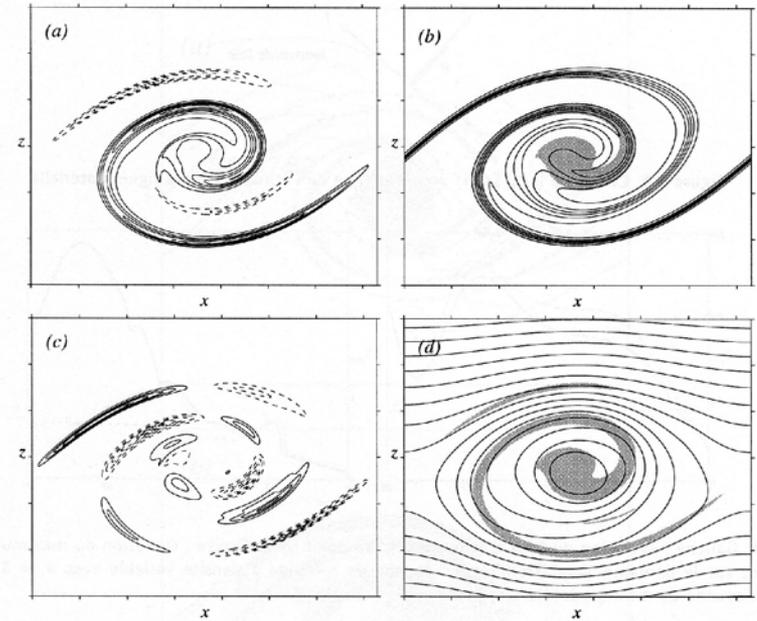

Figure 3.5: Description de la couche de mélange à densité variable à $s = 3$, $Re = 1500$ à l'instant $t = 12$. (a) contours iso-vorticité (incrément U/δ_ω^0), (b) contours iso-densité (incrément $\Delta_\rho/6$), (c) barocline couple (incrément $0.5\delta_\omega^0{}^2$), (d) lignes de courant. Les contours négatifs sont en pointillés; dans les figures (b) et (d), la région grisée correspond à des niveaux de vorticité au-delà de $2U/\delta_\omega^0$; les axes sont gradués tous les δ_ω^0 .

Normalized vorticity along the central material line

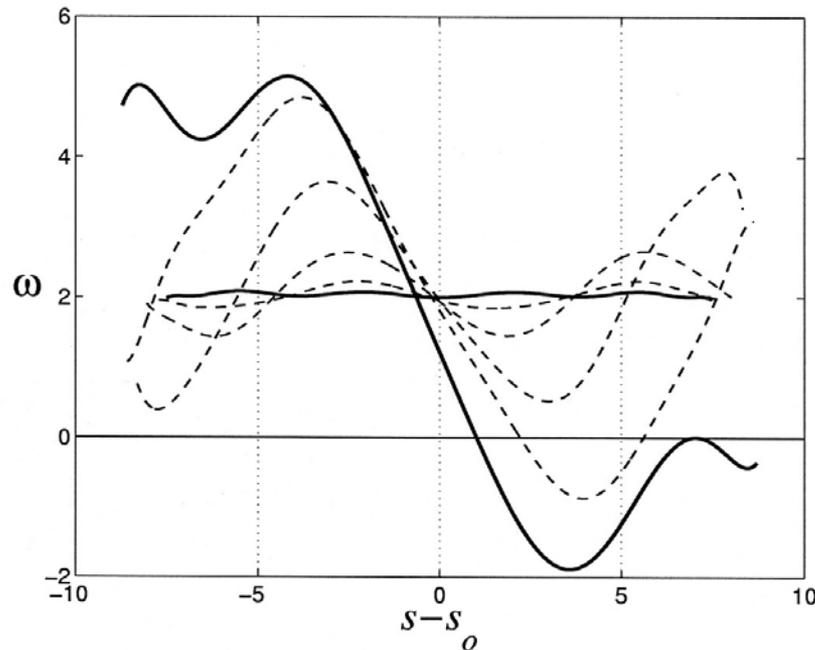

Figure 3.3: Normalized vorticity $\omega \times \tau$ along the central material line (where $\rho = (\rho_{\text{upper}} + \rho_{\text{lower}})/2$) of the variable density mixing layer with $Re = 1500$ and density ratio $S_\rho = 3$. The solid curves are the initial vorticity level and the one at $t=10$. Dashed lines are every $\Delta t = 2$ and the dot-dashed line marks the zero threshold. The abscissa is given along the normalized curvilinear coordinate s/δ_ω^0 associated to the material line, s_o being the origin at the saddle point.

The stretched vorticity filament, Dritschel et al. JFM 230 (1991)

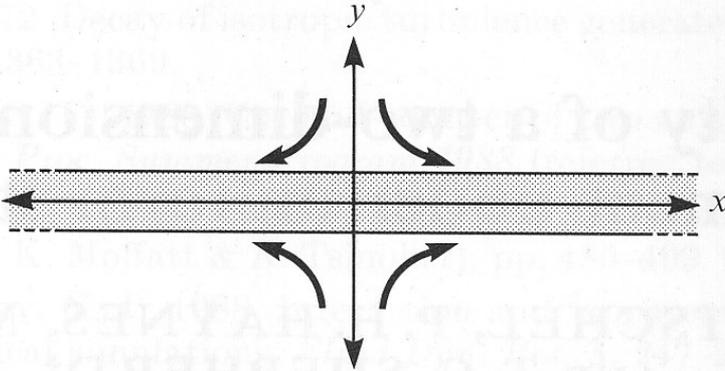

The strain rate has a twofold stabilizing effect :

2. Compresses disturbances in the transverse direction
3. Cause the disturbance wavelength to increase with time

Transient growth before inevitable decay depending on the ratio of strain rate to vorticity

A criterion based on γ/ω :

- more than 0.25 suppresses amplification
- Around 0.065 allows for transient growth rate of three, (passive behaviour of vorticity filaments in 2D turbulence)

Dynamics of unstable stratified mixing layers, Corcos et Sherman JFM 73 (1976),

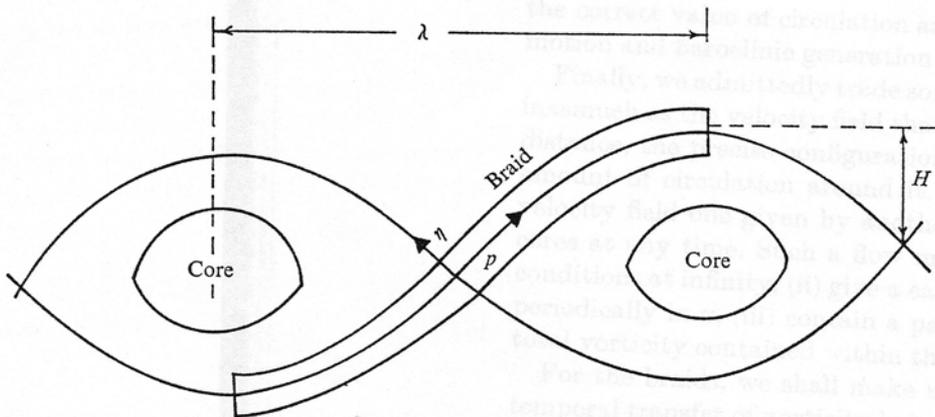

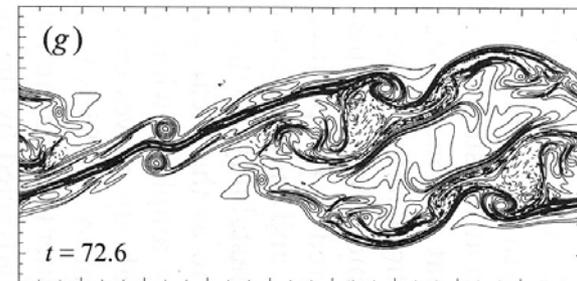

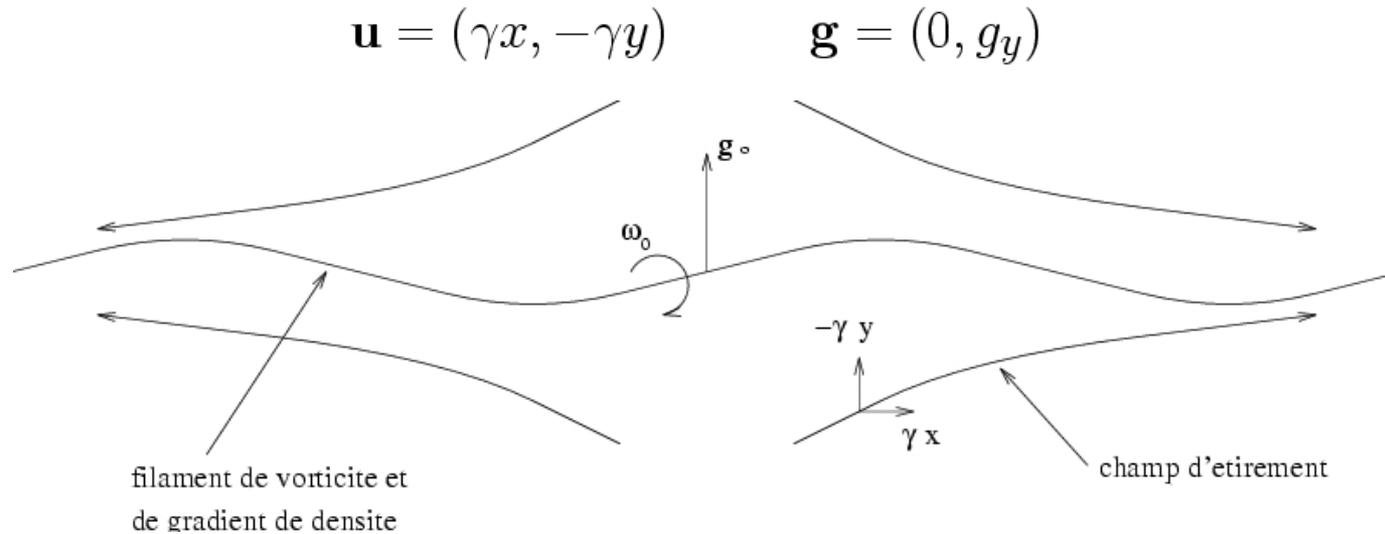

FIGURE 6. Co-ordinates for braid analysis.

Staquet JFM 296 (1995)

The stretched density-gradient and vorticity filament,

Reinaud, Joly et Chassaing PoF (2002)

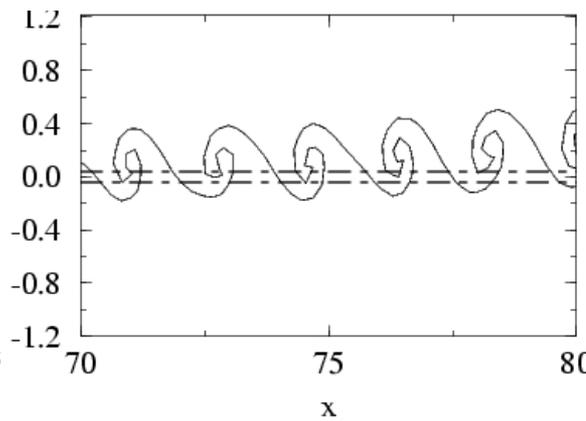

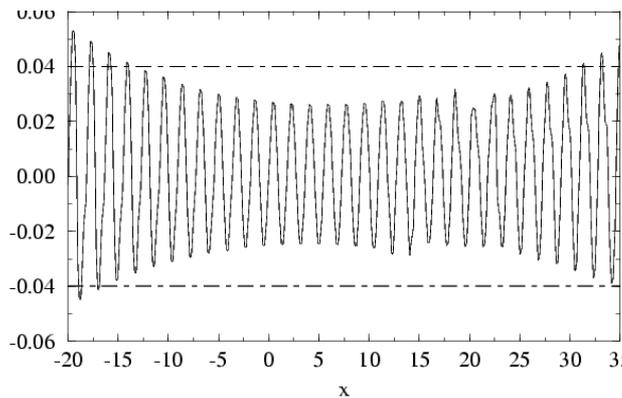

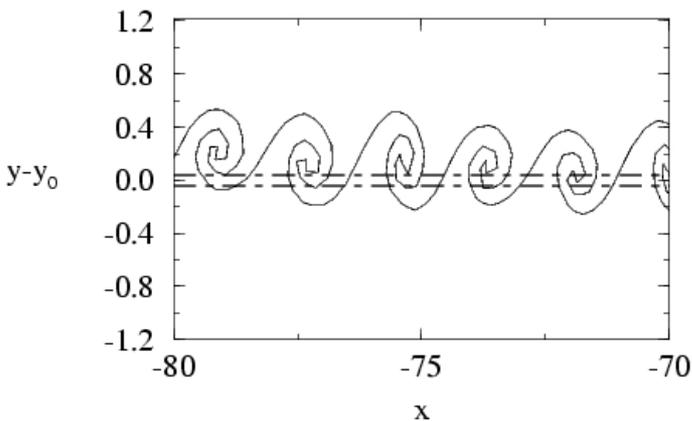

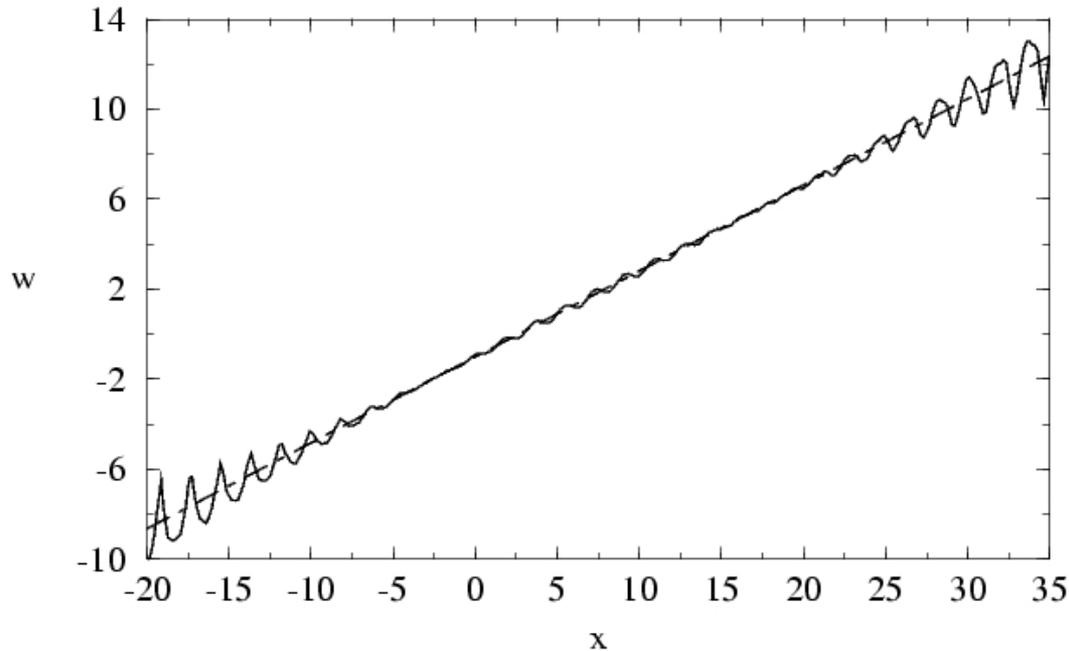

$$d_t g_y = \gamma g_y \quad \rightarrow \quad g_y(x, t) = g_0 \exp(\gamma t)$$

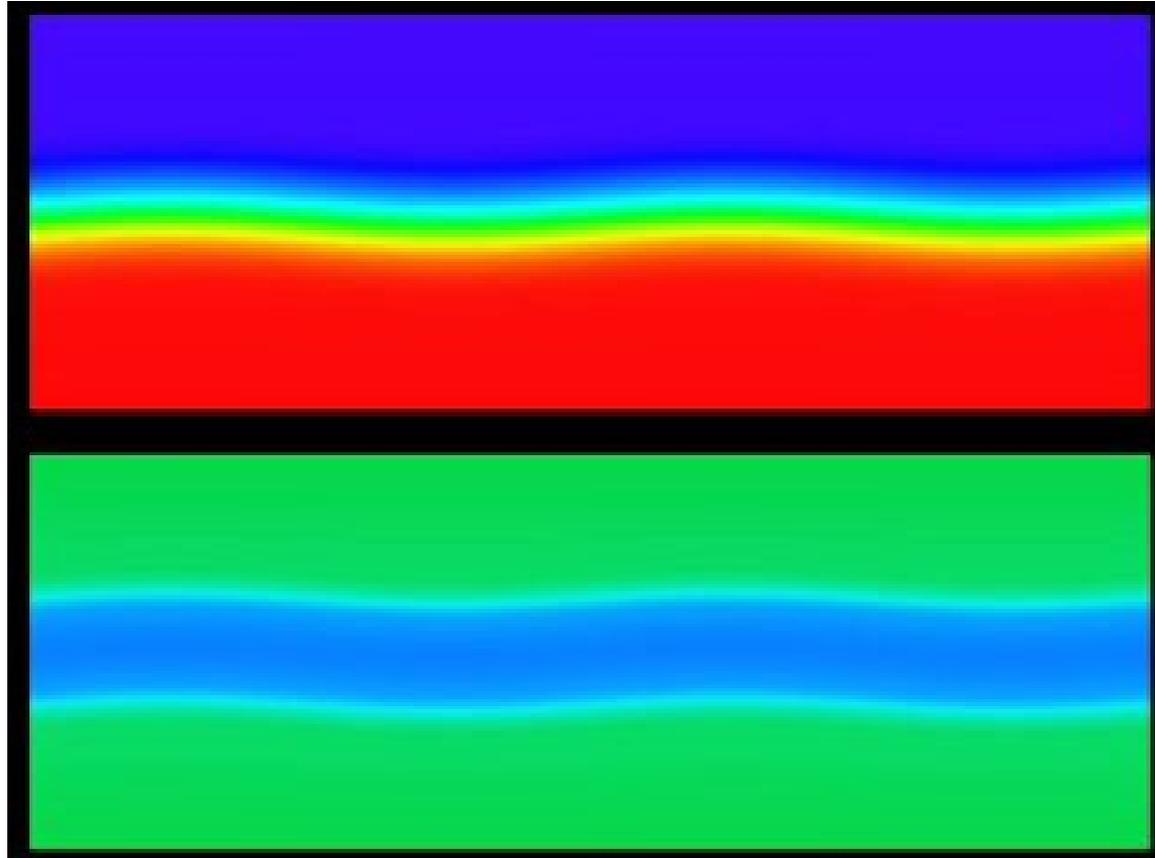

$$d_t \omega = d_t u \frac{g_y}{\rho_0} = \gamma^2 x \frac{g_0}{\rho_0} \exp(\gamma t) \quad \rightarrow \quad \omega(x, t) = \gamma x \frac{g_0}{\rho_0} \sinh(\gamma t) + \omega_0$$

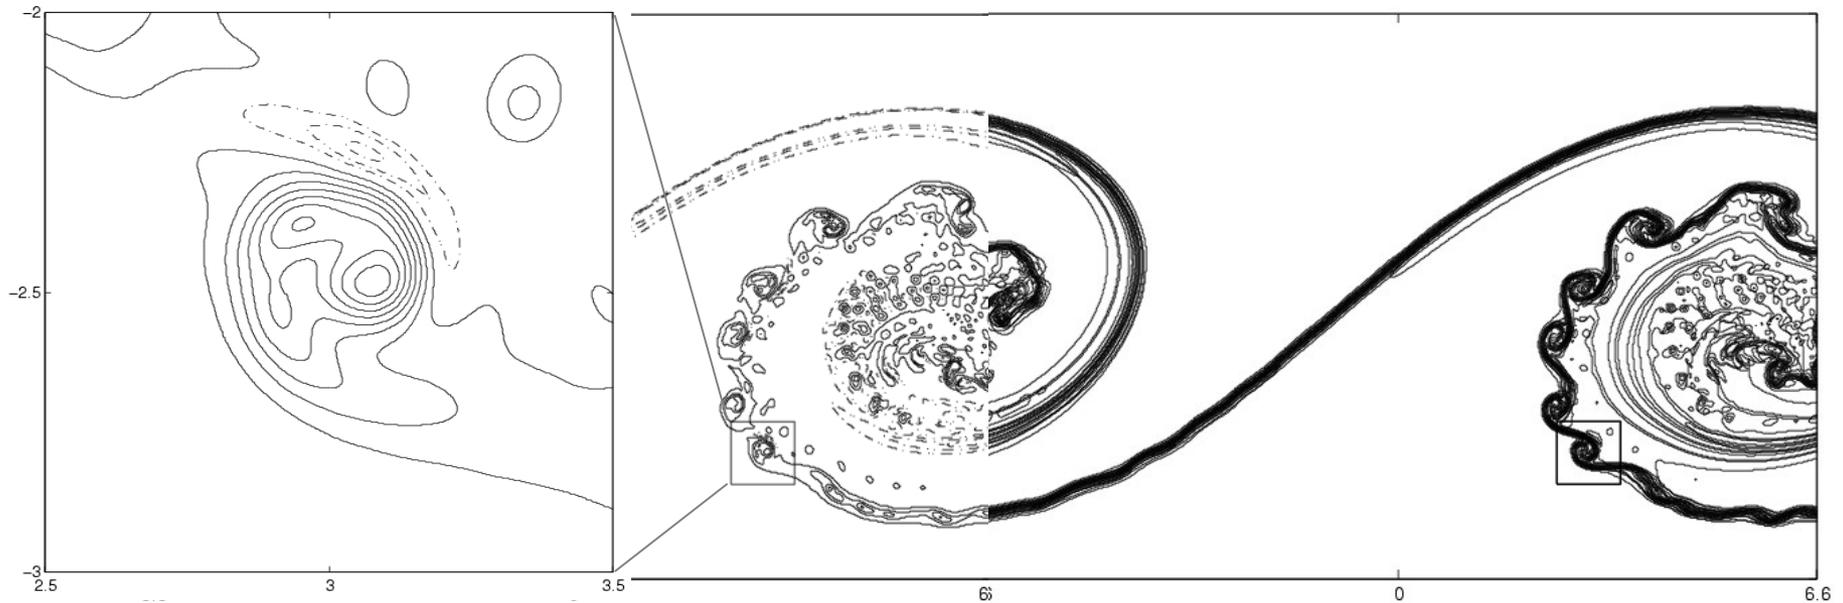

$$\frac{\omega(x, t)}{\gamma} = -\frac{g_0}{\rho_0} x \sinh(\gamma t) + \frac{\omega_0}{\gamma}$$

The stretched density-gradient and vorticity filament,
Reinaud, Joly et Chassaing PoF (2002)

$$\frac{\omega(x, t)}{\gamma} = -\frac{g_0}{\rho_0} x \sinh(\gamma t) + \frac{\omega_0}{\gamma}$$

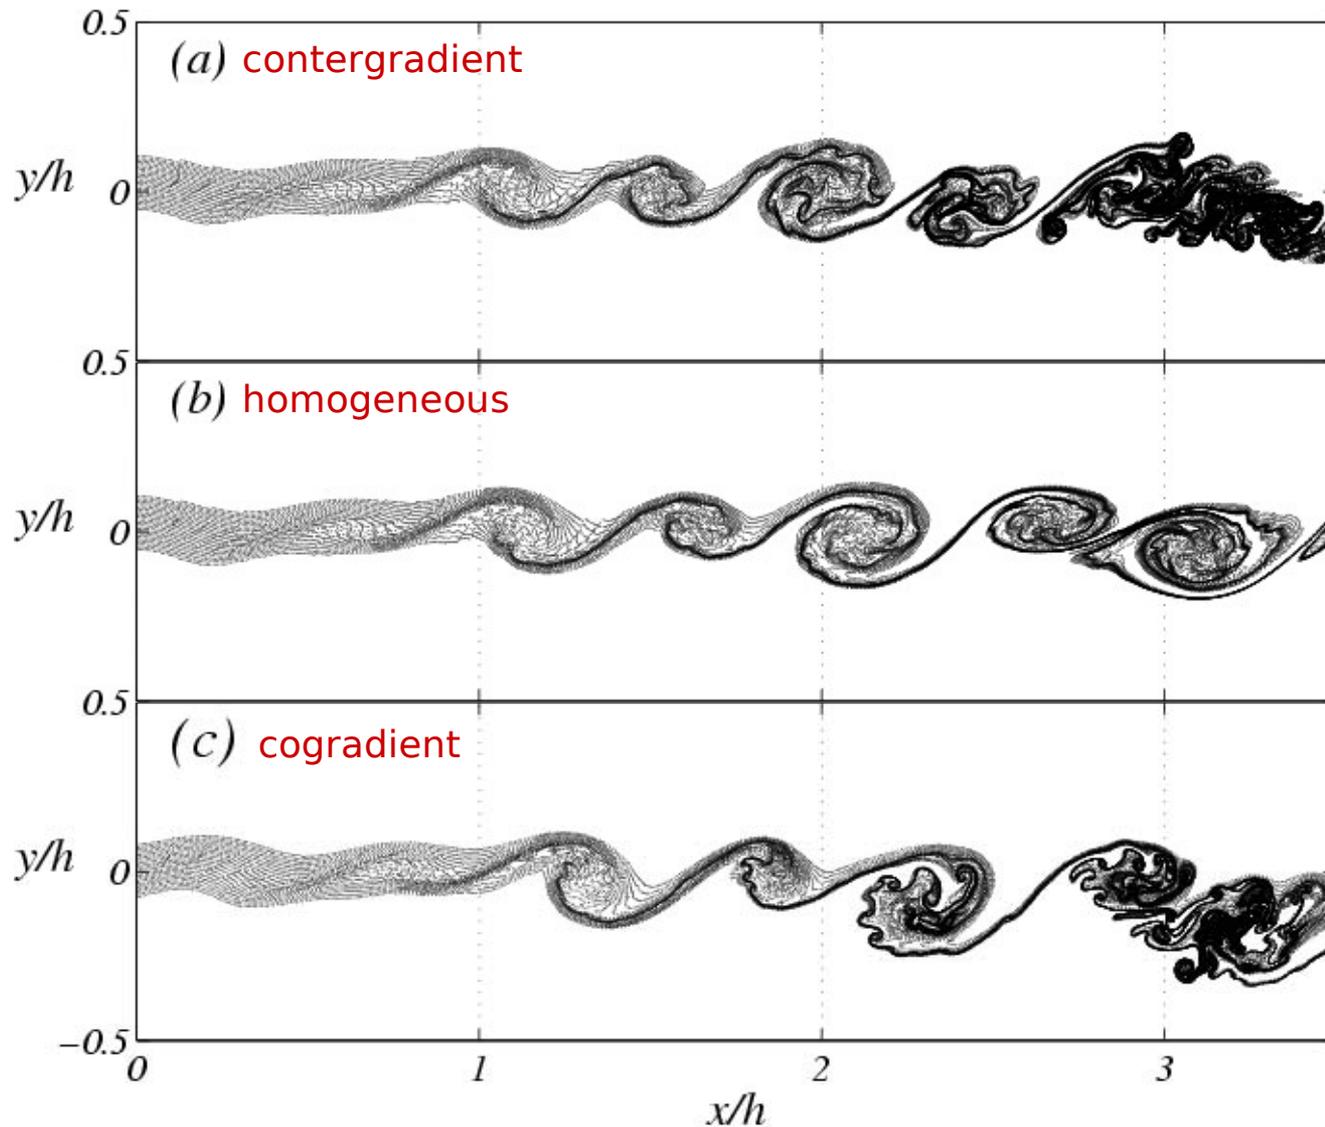

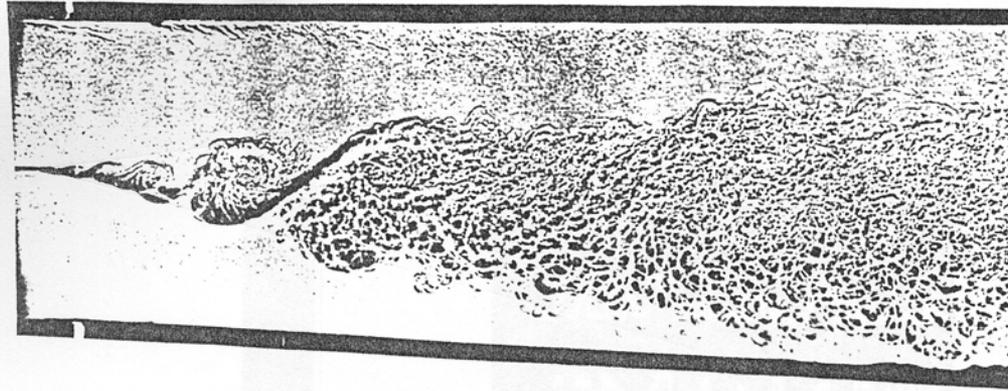

- A **specific transition mechanism** of the inhomogeneous shear flow;
- **Two-dimensional** secondary mode;
- The vorticity **pattern** is repeated in second generation structures, and so on until viscosity prevents baroclinic vorticity generation.

Forced spatially developing mixing-layer (simulations with a variable density vortex method)

1. *The 2D mixing-layer in the nonlinear regime and the secondary baroclinic instability*
2. *The strain field of 2D light jets*

- *The strain fields of light jets present a folded layered structure,*
- *Much higher strain rates may be produced in the baroclinically modified roll-up,*
- *High strain rates are to be expected « inside » the light jet and close to favored leg of the vorticity braid.*

- *Transition to three-dimensionality in light jets and **the question of side-jets***
- *Baroclinic instability of heavy vortices and some elements on vortex interaction in inhomogeneous 2D turbulence*

First observation by Monkewitz & Bechert (Album of Fluid Motion - 1988)

1. Side jets occur when the jet is absolutely unstable,
2. The jet is absolutely unstable under a critical density ratio $s < 0.7$,
3. Side jets acknowledged within some range of Reynolds number,
4. Side Jets induced by counter-rotative streamwise vortices lying in the braid region between successive vortex rings (Brancher et al. Phys Fluids 1994)
5. A shorter route to the mixing transition and a large increase of the mixing rate,
6. Side Jets recovered in a pulsed homogeneous jet by Monkewitz and Pfizenmaier (1991) leading these authors to conclude that the strength and synchronization of the primary mode in the absolutely unstable light jets is the sufficient conditions for spontaneous lateral ejections of fluids.
7. Additional facts from Hermouche experiments :
 - i. Intermittent ejection,
 - ii. Unsteady number and azimuthal position,
 - iii. Quasi-steady streamwise position,
 - iv. Life time of several PM periods
9. Remaining questions

Side ejections on $Re = 1000$ helium jets from Hermouche, *Imft* (1996)

Paradigm of secondary 3D mode yielding counter-rotative vortices lying between adjacent distorted rings

Side jets induced by pairs of counter-rotative streamwise aligned vortices

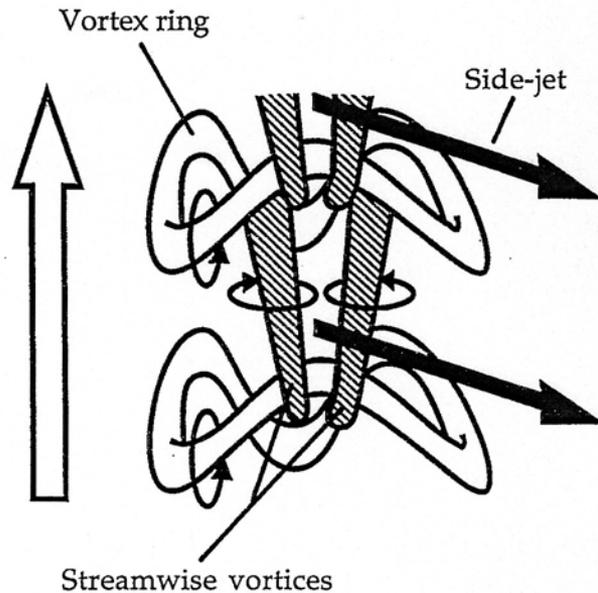

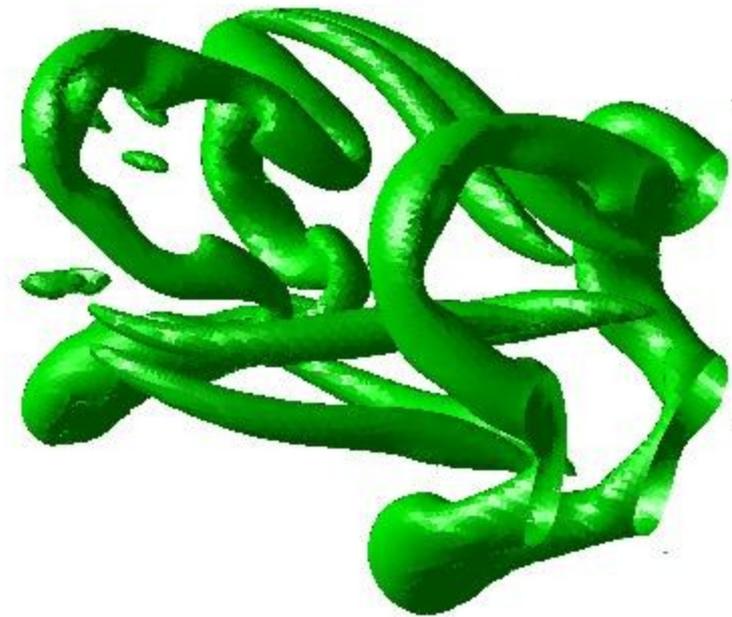

FIG. 6. Vortical structures involved in the side-jet generation process. Only a single streamwise pair is represented (hatched structures) while two consecutive vortex rings are sketched (white structures). The radial ejection of fluid is symbolized by the two black arrows emerging from the streamwise pair.

Brancher, Chomaz & Huerre (1994)

Lambda2 probe of coherent structures in a DNS of a homogeneous 3D temporal jet with a 3-lobe corrugation of the initial vorticity tube.

Two-dimensionnal Heated jets from Yu and Monkewitz JFM 255 (1993)

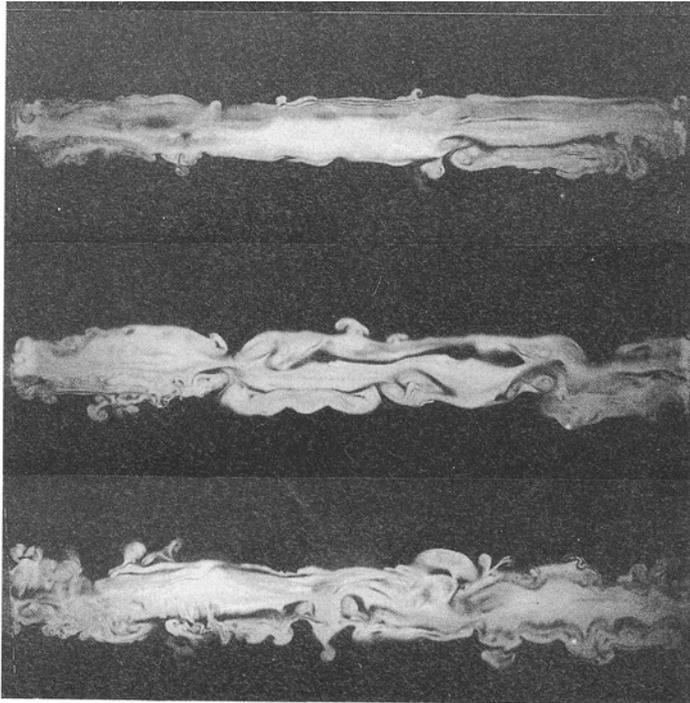

FIGURE 20. Cross-sectional views of the cold jet with $q_j = 1.25 \text{ mmH}_2\text{O}$, at $x = 1, 2, 3, 4, 5, 6, 7$ (from top to bottom).

Cold (homogeneous) jet

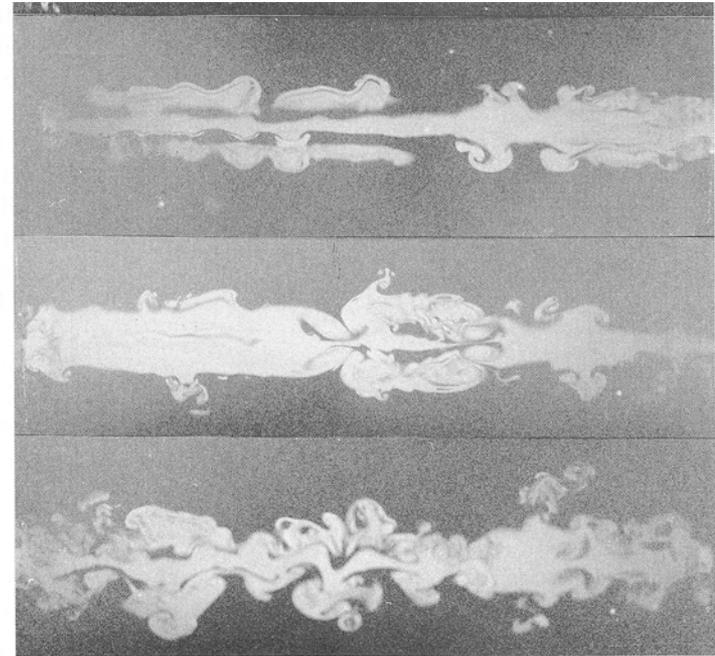

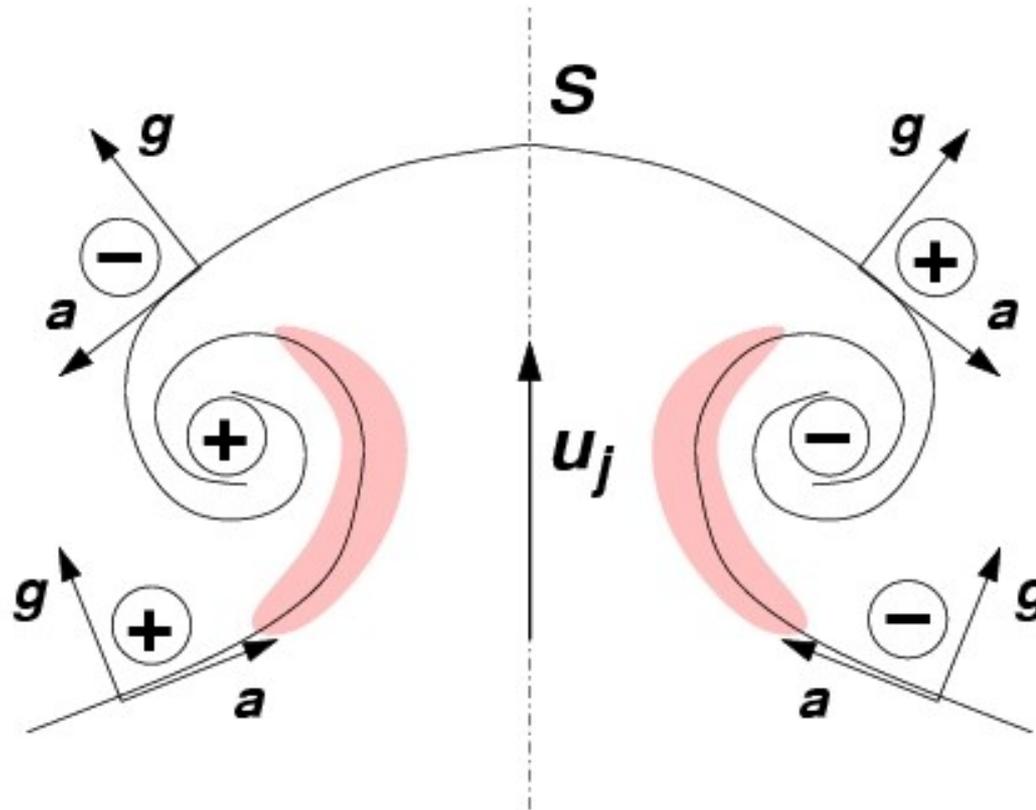

FIGURE 21. Cross-sectional views of the hot jet with $S = 0.76$ and $q_j = 1.25 \text{ mmH}_2\text{O}$, at $x = 1, 2, 3, 4, 5, 6, 7$ (from top to bottom).

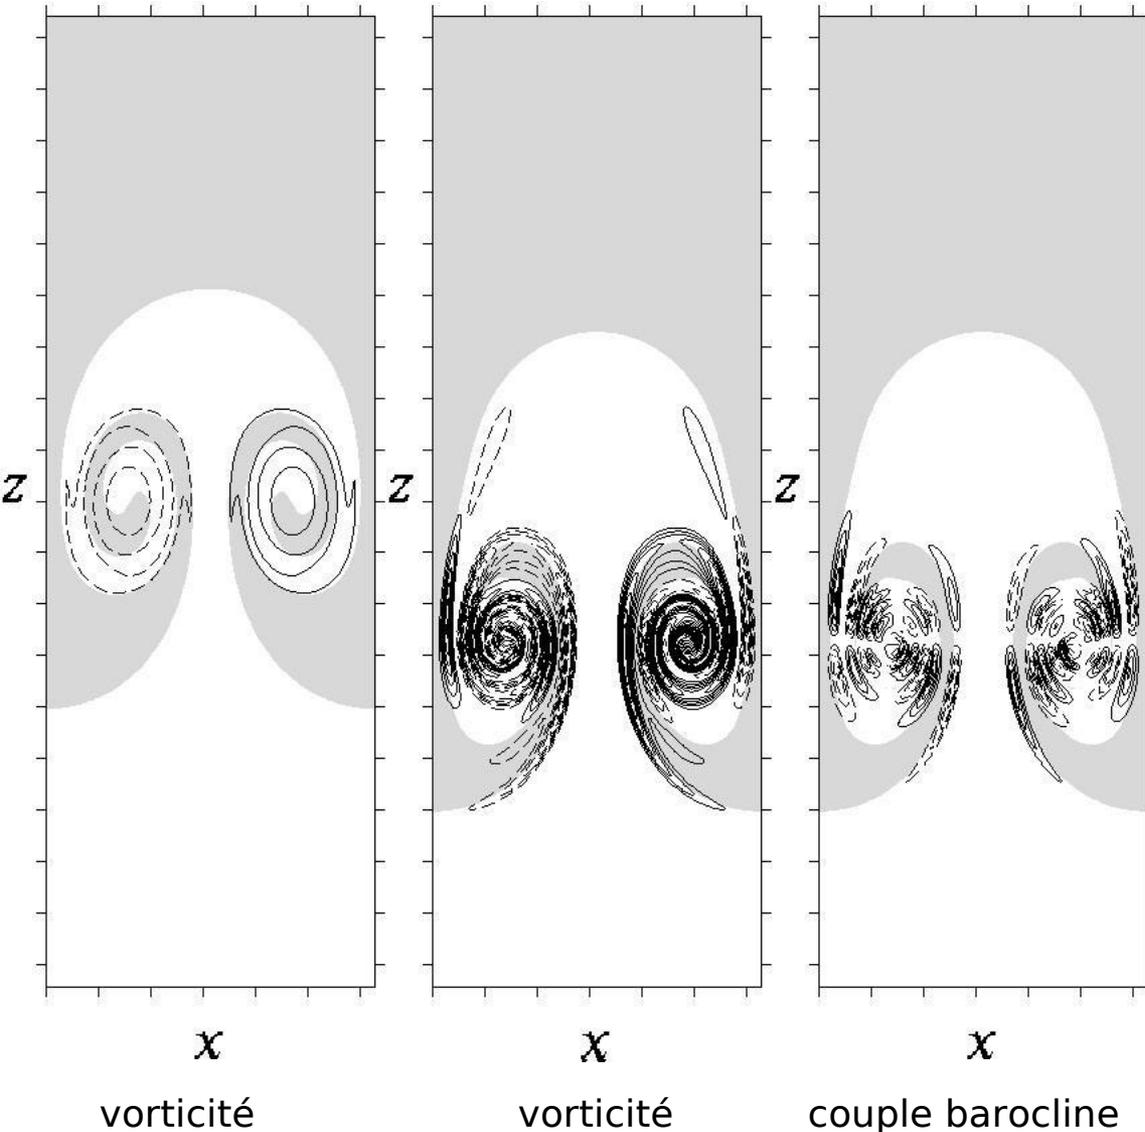

Hot (light) jet

A first guess : the strain rate in the 2D light jet and predicted growth rates

	Before the pairing - $t = 4.5\tau$				During the pairing - $t = 12.0\tau$			
	Homogeneous jet							
Elliptic	$\sigma \sim \gamma_{ck}$	0.52			$\sigma \sim$	0.57		
Hyperbolic	$\sigma_{tr} \leq 2\gamma_{ck}$	2.44	$\sigma_{as} \sim 2\Delta$	1.5	$\sigma_{tr} \leq$	0.54	$\sigma_{as} \sim$	0.5
	Light Jet							
Elliptic	$\sigma \sim$	0.71			$\sigma \sim$	0.34		
Hyperbolic	$\sigma_{tr} \leq$	2. to 5.	$\sigma_{as} \sim$	1. to 1.46	$\sigma_{tr} \leq$	0.98	$\sigma_{as} \sim$	0.36

Scheme of the vorticity generation on the model flow of unstrained counter-rotating vortices

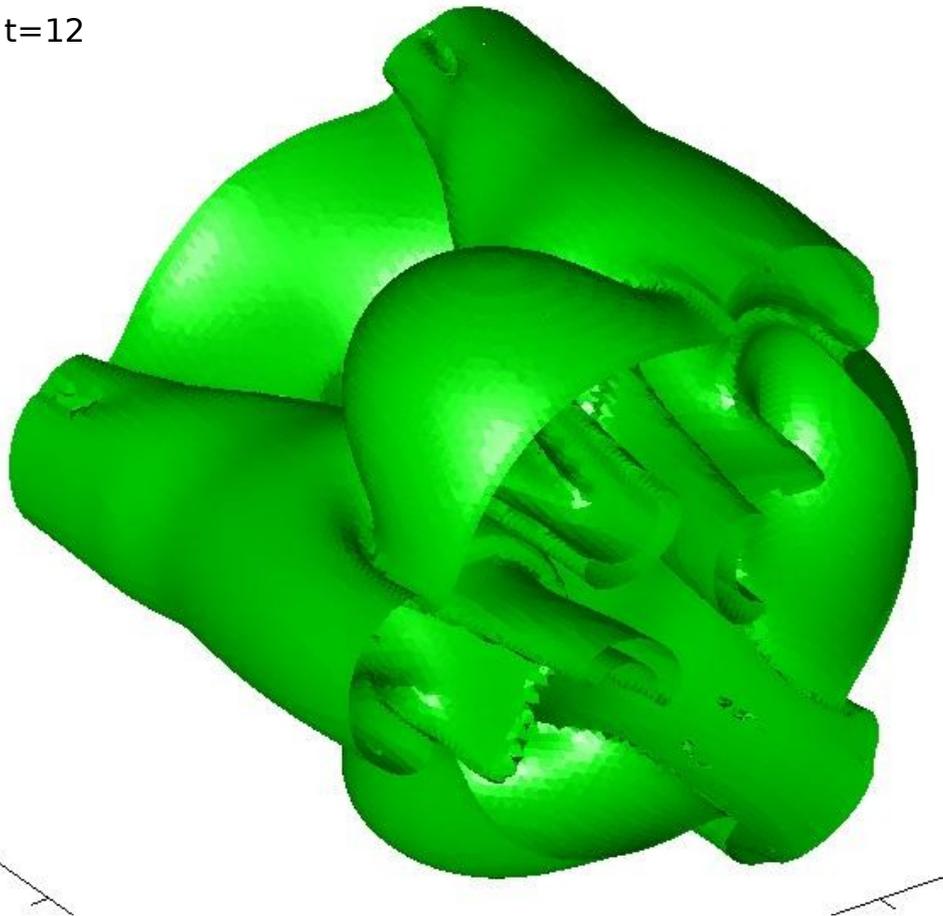

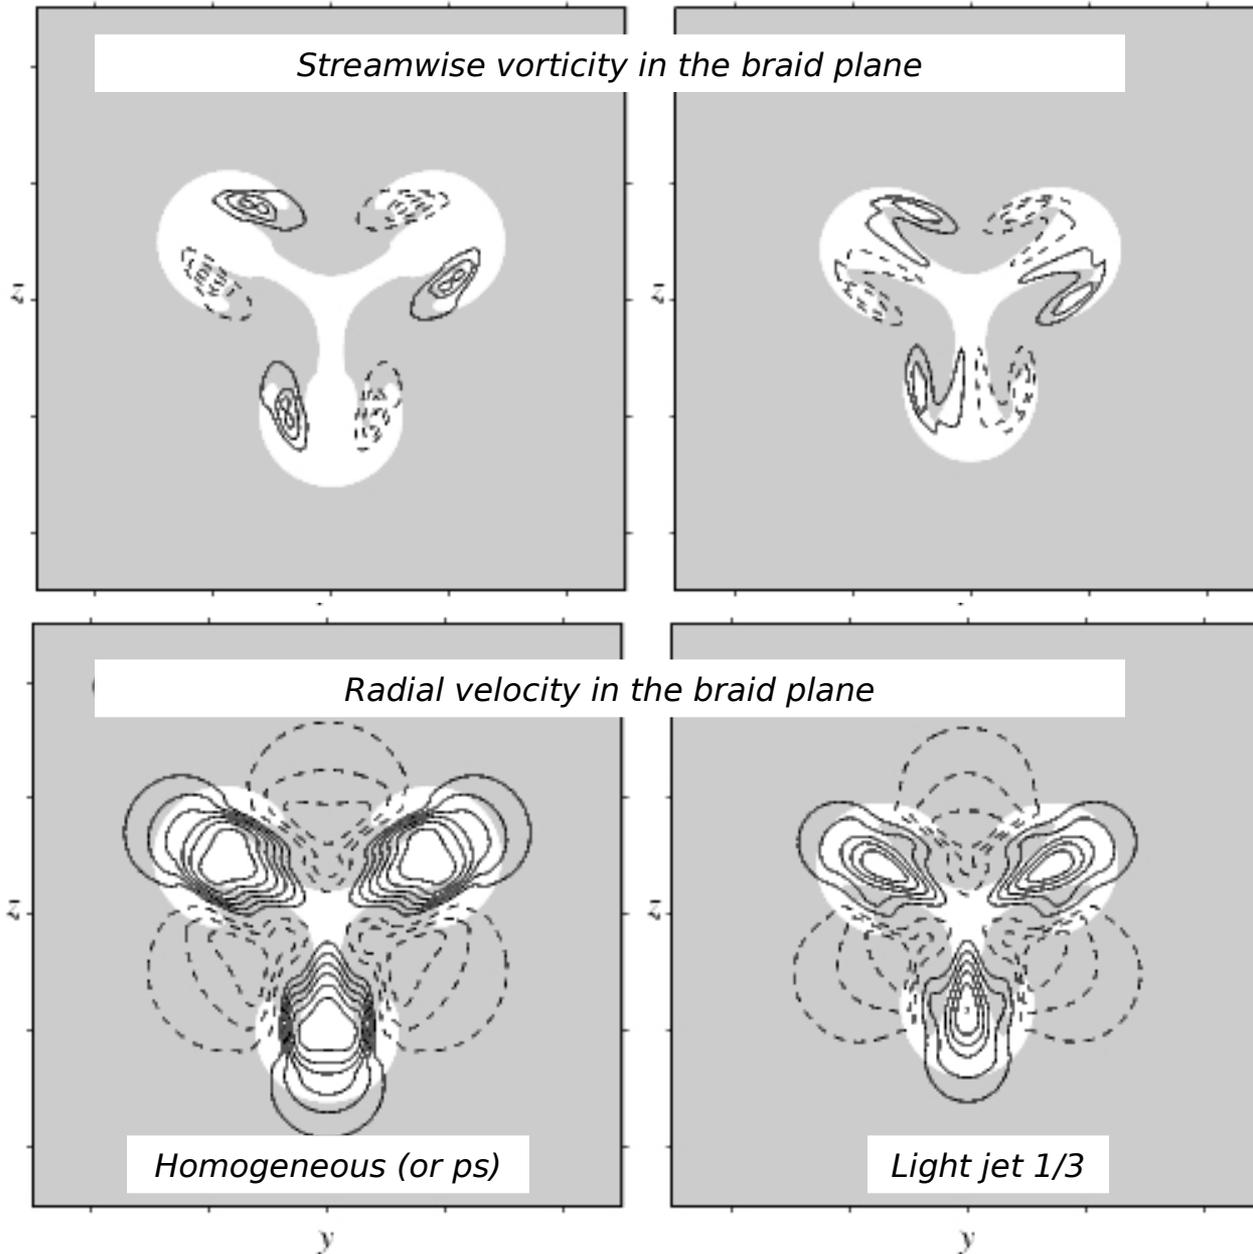

- Shift of the vortex centers toward the light side
- Asymmetric entrainment
- A trend expected to be enhanced by the underlying stretching in full configuration

Corrugated temporal jet, $Re = 1900$ et $Re_{\theta} = 170$

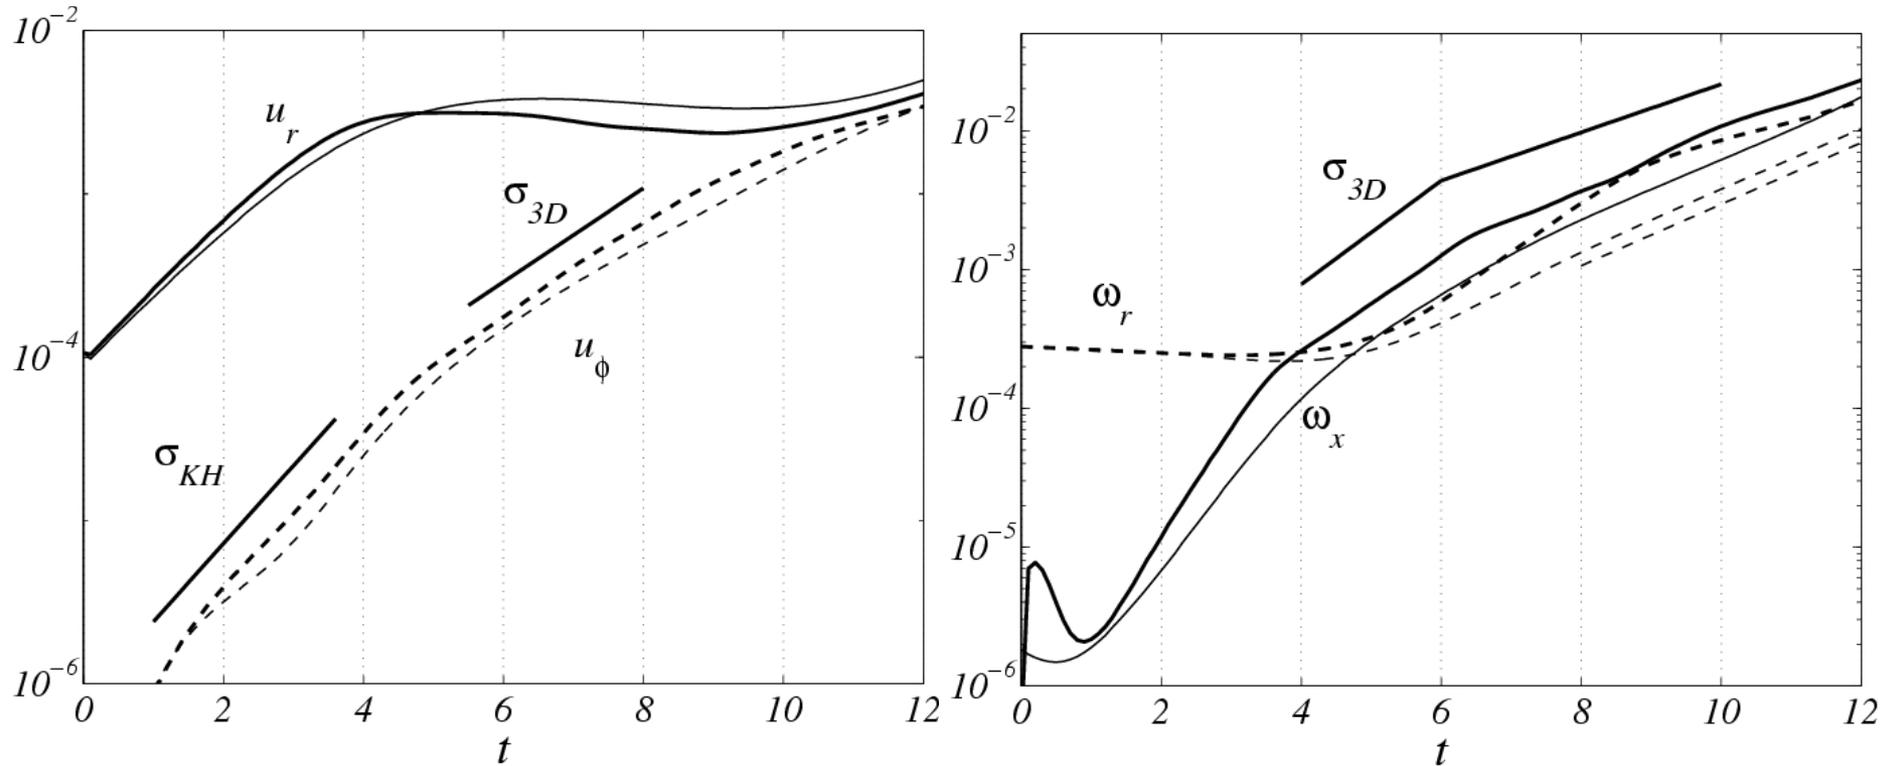

- primary mode perturbation resulting from 2D stability
- no result in 3D stability : k_{θ} ?

t=12

Growth of the energy (enstrophy) of three-dimensionnal motion

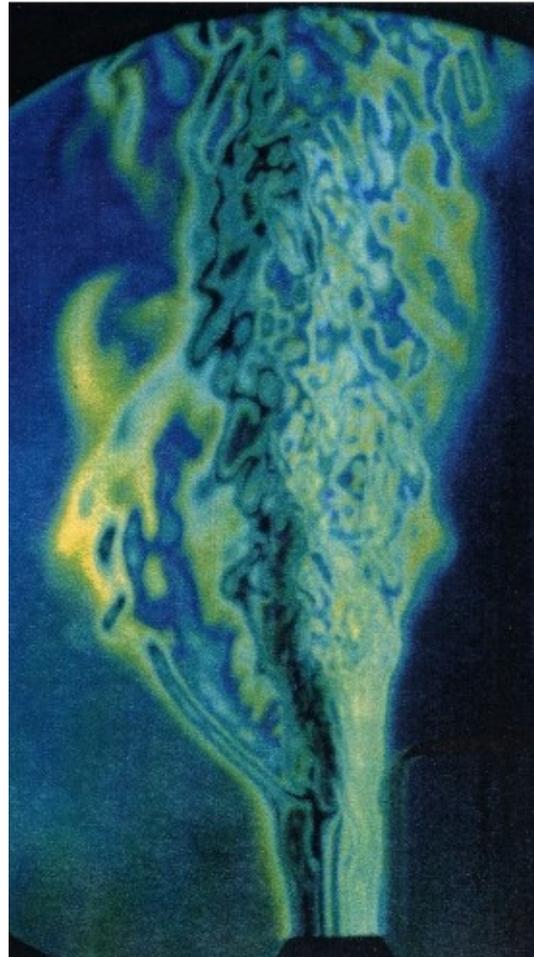

- Influence of density ratio Reynolds number and R/θ on the characteristics of the azimuthal mode;
- Higher Re_θ simulations to get the full baroclinic effect on 2D primary mode

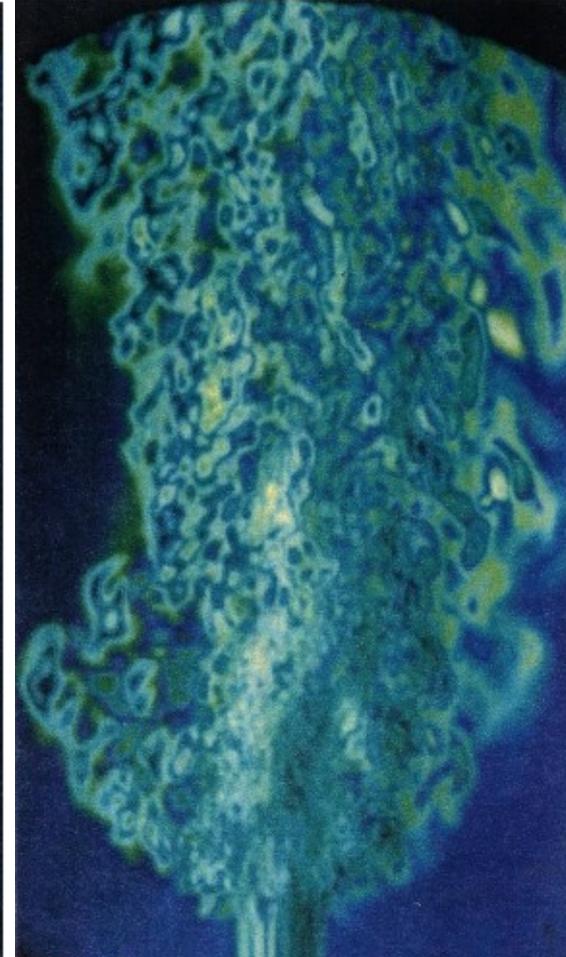

Influence of the Reynolds number

Re = 750

Re = 1000

Re = 2600

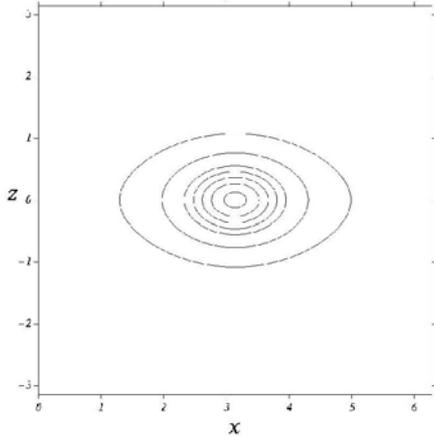

Conjecture on the transition sensitivity to the exit Reynolds number

- Viscous regime : no spontaneous side jets;
- Side jets regime;
- Secondary 2D instability regime.

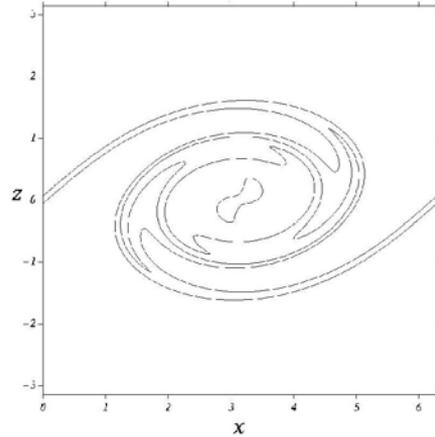

Structure of the laminar helium jet

- PIV vorticity mapping (Hermouche's test bank and Jérôme Fontane PhD);
- Primary structure of the light jet;
- 3D perturbation on the azimuthal wave number given by the 3D stability analysis;
- Impact on the mixing efficiency.

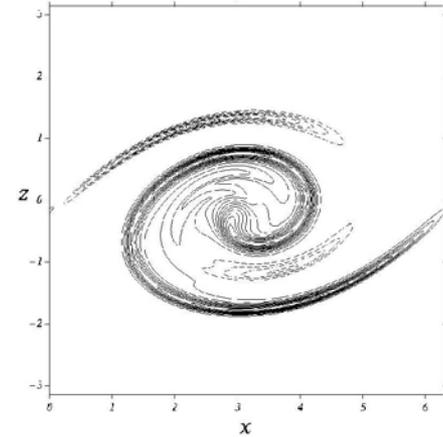

Floquet analysis of the axisymmetric jet

Vortex de Stuart, $r=0,5$

Rouleau KH homogène, $Re=1500$

Rouleau KH $s=3$, $Re=1500$

Pierrehumbert et Widnall JFM 114 (1982) : $\lambda_z = 0,6 \lambda_x$ - Klaassen et Peltier JFM 227 (1991)

$$\begin{aligned}
 D_t \hat{\rho} + \mathbf{G} \cdot \hat{\mathbf{v}} &= 0 \\
 R D_t \hat{\mathbf{v}} + R M \hat{\mathbf{v}} + \hat{\rho} M \mathbf{U} &= -\nabla \hat{p} \\
 R D_t \hat{w} &= -\partial_z \hat{p} \\
 \nabla \cdot \hat{\mathbf{v}} + \partial_z \hat{w} &= 0
 \end{aligned}$$

$$\begin{aligned}
 \hat{\mathbf{q}} &= (\hat{\rho}, \hat{\mathbf{v}}, \hat{p}) & \hat{\mathbf{q}}(\mathbf{x}, t) &= e^{ikz} \mathbf{q}(x, y, t) \\
 \partial_t \mathcal{L}_1(R, \mathbf{U}, k) \mathbf{q}(x, y, t) &= \mathcal{L}_2(R, \mathbf{U}, k) \mathbf{q}(x, y, t) \\
 \mathbf{q}(x, y, t) &= e^{\sigma t} e^{i\mu x} \tilde{\mathbf{q}}(x, y)
 \end{aligned}$$

$$\sigma \mathcal{L}_1(R, \mathbf{U}, k) \tilde{\mathbf{q}}(x, y) = \mathcal{L}_2(R, \mathbf{U}, k) \tilde{\mathbf{q}}(x, y)$$

 - *If understood may help mixing,*
 - *Experimental, Floquet analysis and DNS approach to get relevant data*
- *Baroclinic instability of **heavy vortices** and some elements on vortex interaction in inhomogeneous **2D turbulence***

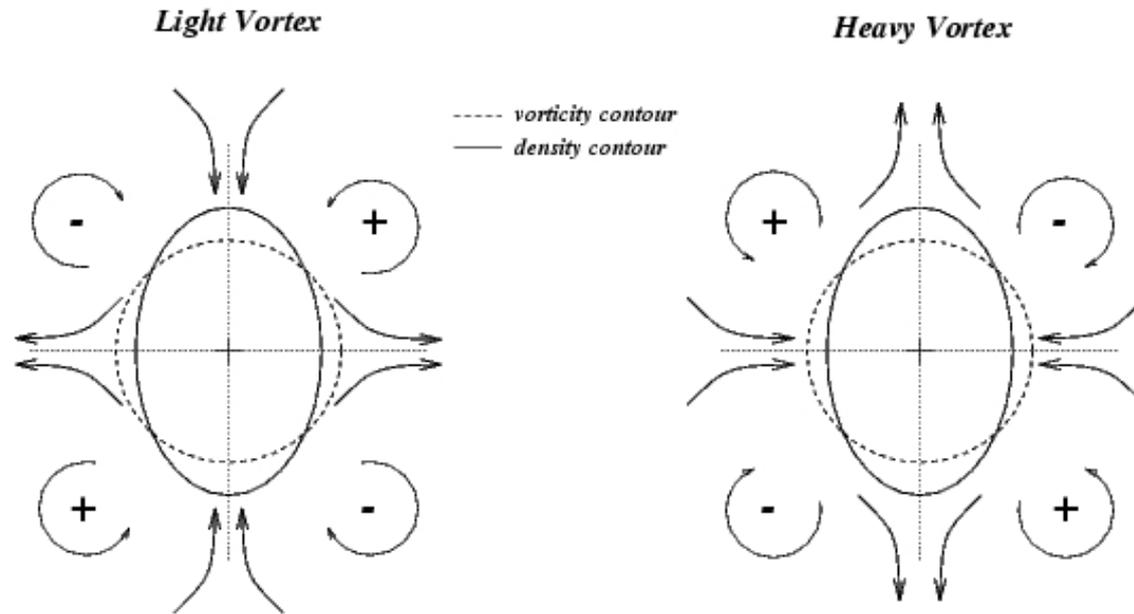

Figure 4.4: Sketch of the baroclinic effects on heavy and light vortices.

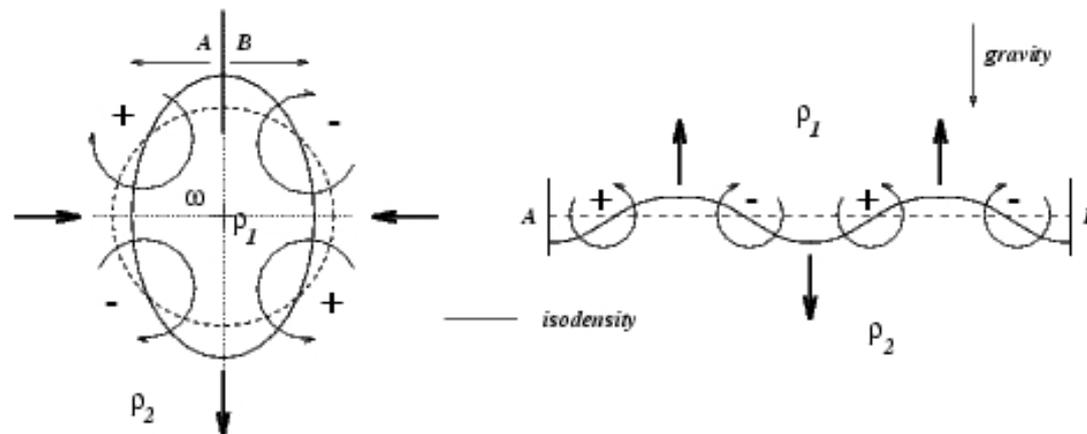

Figure 4.5: Analogy between the heavy vortex and the equivalent unrolled density stratification submitted to a downward gravity field ($\rho_1 > \rho_2$).

- *Vorticity of the gaussian vortex :* $\omega(r, \theta) = \frac{\Gamma}{\pi\delta^2} \exp(-r^2/\delta^2)$

- *Orthoradial velocity and centripetal acceleration :*
$$u_\theta = [1 - \exp(-\frac{r^2}{\delta^2})] \frac{\Gamma}{2\pi r}$$

$$a_r = -u_\theta^2/r$$

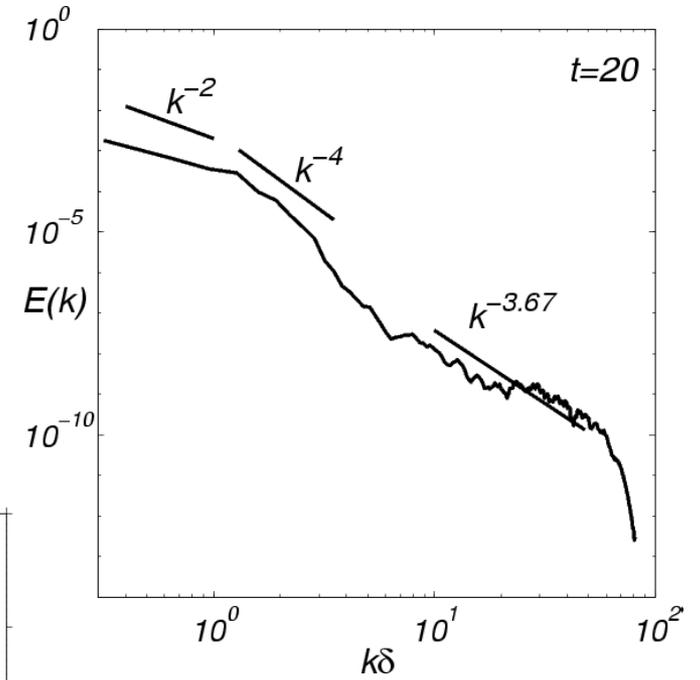

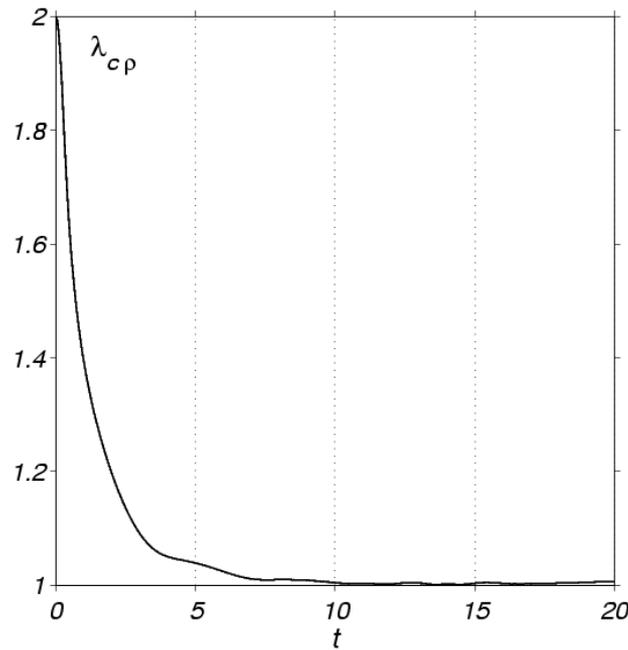

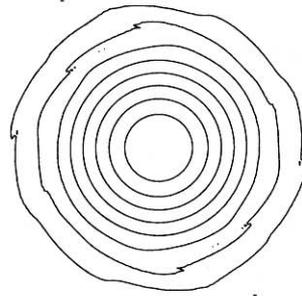

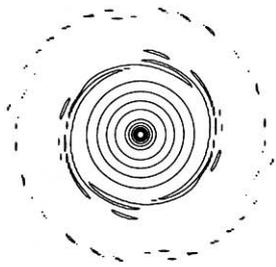

- *Density field on an elliptic patch :*

$$r_\rho^2(\theta) = r^2[1 + (e^{-2} - 1) \sin^2 \theta]$$

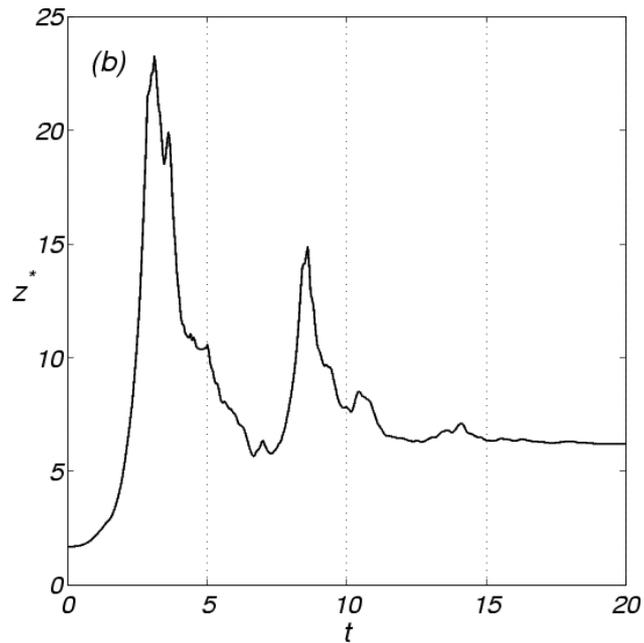

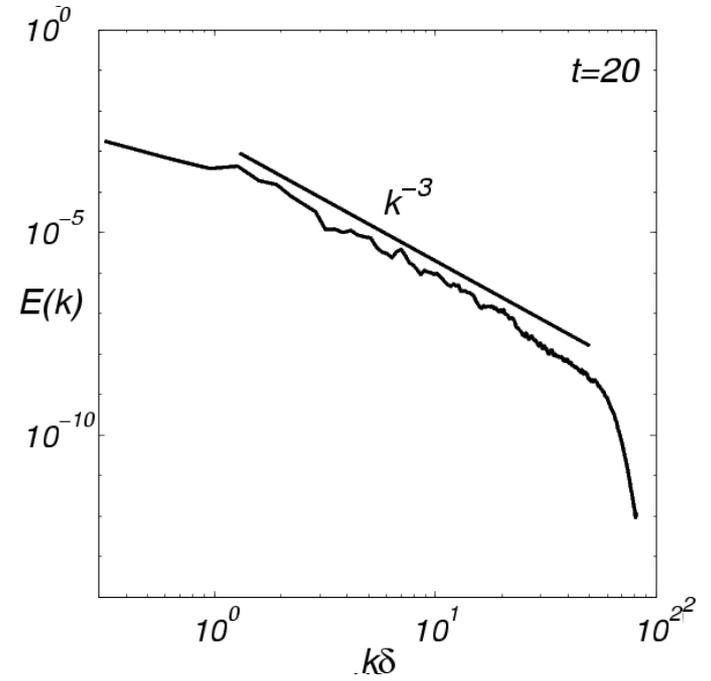

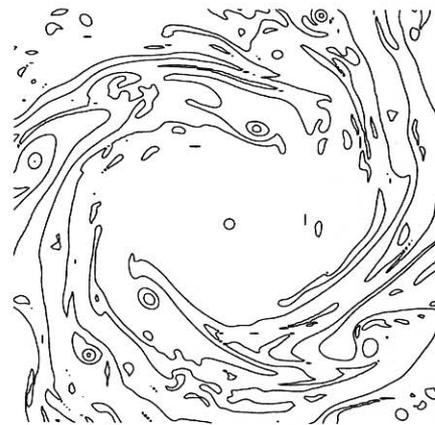

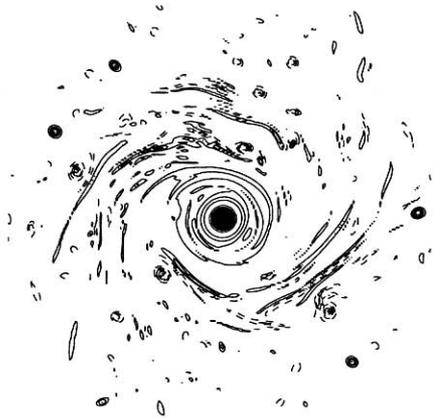

- *Density gradient vector :* $\rho(r, \theta) = \rho_e + (\rho_i - \rho_e) \exp(-\frac{r_\rho^2(\theta)}{\delta^2})$

- *Baroclinic torque :*
$$\mathbf{g} = \nabla(\ln \rho) = \begin{cases} g_r = -(1 - \frac{\rho_e}{\rho}) \frac{2r}{\delta^2} [1 + (e^{-2} - 1) \sin^2 \theta] \\ g_\theta = (1 - \frac{\rho_e}{\rho}) \frac{r}{\delta^2} (1 - e^{-2}) \sin(2\theta) \end{cases}$$

$$b = a_r g_\theta = [1 - \exp(-\frac{r^2}{\delta^2})]^2 \frac{\Gamma^2}{4\pi^2 r^2 \delta^2} (1 - e^{-2}) \frac{\rho_e - \rho}{\rho} \sin(2\theta)$$

The breakdown of an heavy vortex

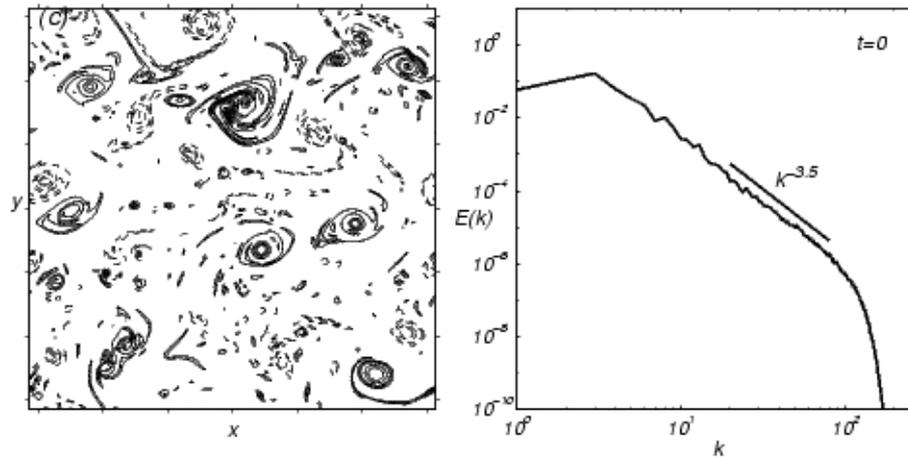

Figure 4.13: Initial vorticity field with solid positive contours and dashed negative ones, increment between contour is $\max(\omega)/2\pi$ and the zero contour is omitted (left); the corresponding energy spectrum (right).

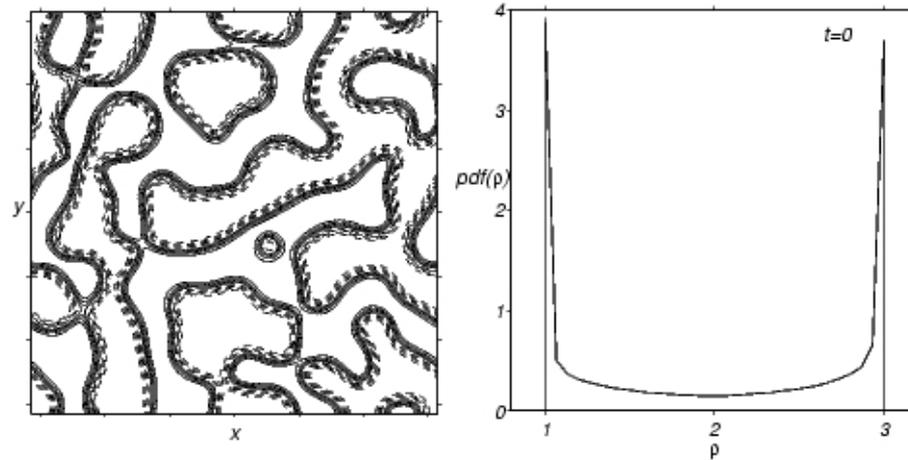

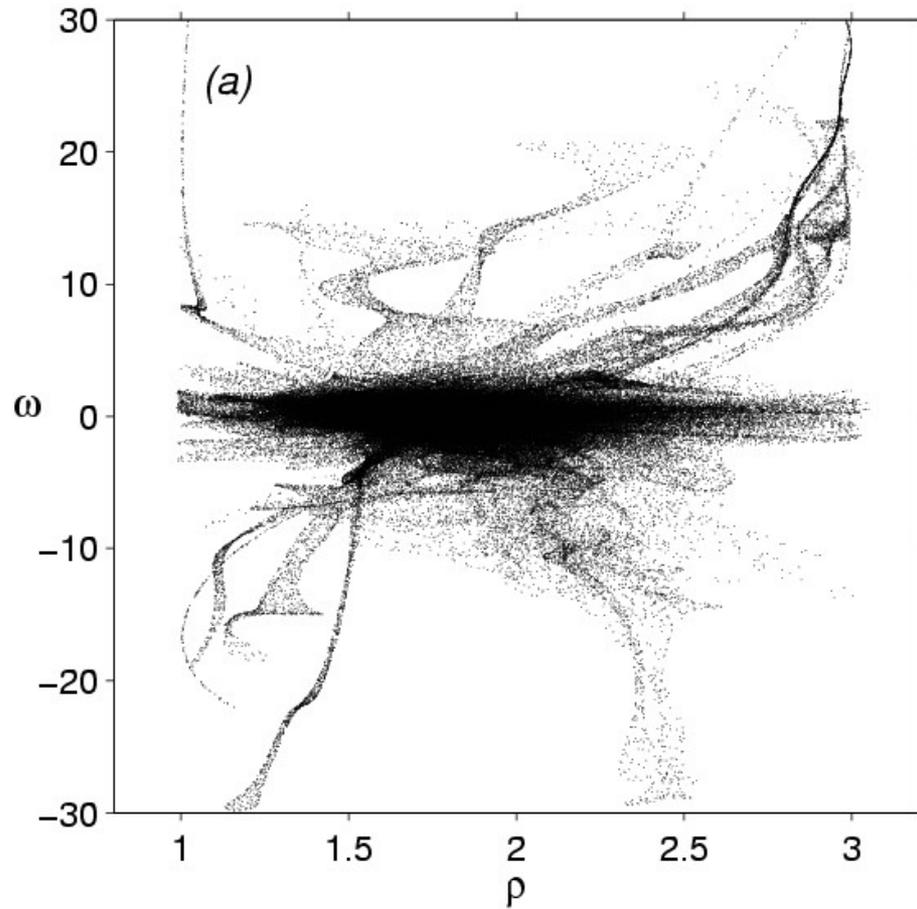

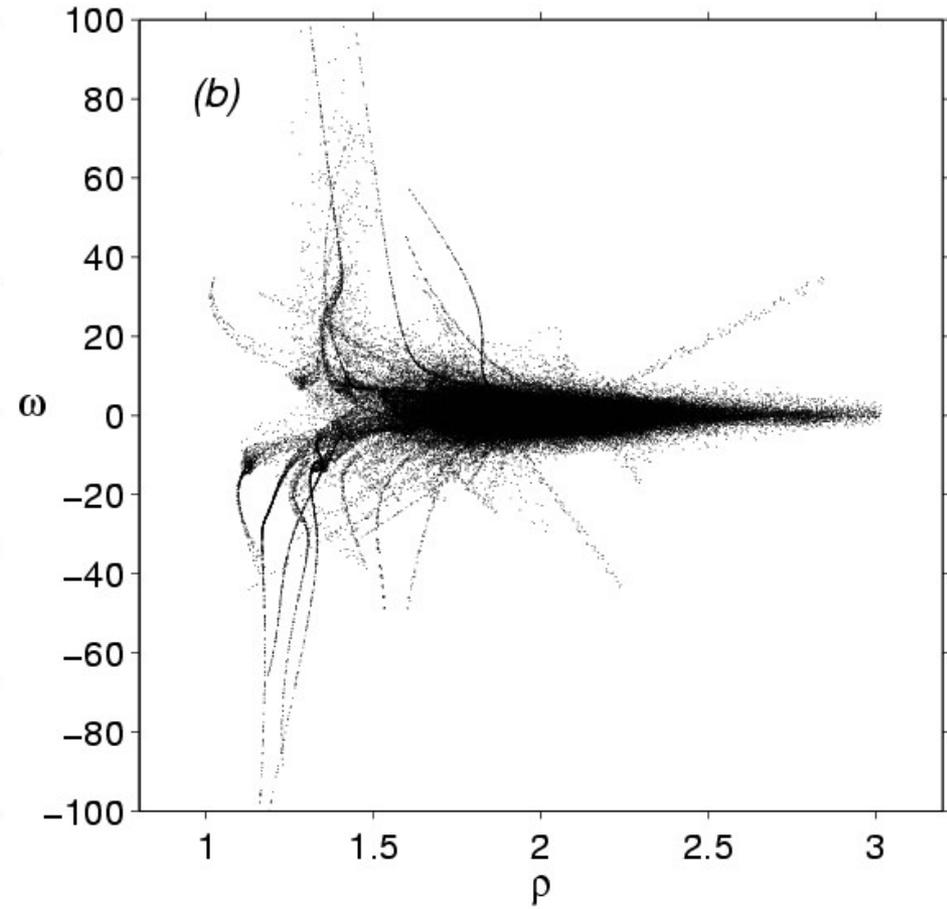

Figure 4.14: Initial density field with solid contours above mean and dashed contours beneath, increment between contour is $\Delta\rho/10$ (left); the corresponding probability density function (right).

Passive scalar 2D turbulence

Inhomogeneous 2D turbulence
