#### Abstract

Age is an important variable to describe the expected brain's anatomy status across the normal aging trajectory. The deviation from that normative aging trajectory may provide some insights into neurological diseases. In neuroimaging, predicted brain age is widely used to analyze different diseases. However, using only the brain age gap information (i.e., the difference between the chronological age and the estimated age) can be not enough informative for disease classification problems. In this paper, we propose to extend the notion of global brain age by estimating brain structure ages using structural magnetic resonance imaging. To this end, an ensemble of deep learning models is first used to estimate a 3D aging map (i.e., voxel-wise age estimation). Then, a 3D segmentation mask is used to obtain the final brain structure ages. This biomarker can be used in several situations. First, it enables to accurately estimate the brain age for the purpose of anomaly detection at the population level. In this situation, our approach outperforms several state-of-the-art methods. Second, brain structure ages can be used to compute the deviation from the normal aging process of each brain structure. This feature can be used in a multi-disease classification task for an accurate differential diagnosis at the subject level. Finally, the brain structure age deviations of individuals can be visualized, providing some insights about brain abnormality and helping clinicians in real medical contexts.

#### I **INTRODUCTION** 1

In the medical field, chronological age is widely used as an indicator to describe people. It depicts a reference curve that healthy organs should follow. The deviation from that reference may be associated with different factors such as the interaction of genes, environment, lifestyle, and diseases<sup>1</sup>. To measure this deviation, the concept of biological age (BA) has been created. It is an estimation of individual's age based on various advanced strategies<sup>2,3,4</sup> and is expected to be able to take into account all the factors mentioned above. Consequently, an accelerated (or delayed) aging process results in a higher (or lower) value of BA with respect to chronological age.

The analysis of BA can be associated with a whole-body system or a specific organ. The whole-body evaluation approaches typically use non-imaging data (e.g., DNA methylation patterns<sup>5</sup>, protein<sup>6</sup>) but often struggle to account for variations in aging among individual organs<sup>7</sup>. To this end, Tian et al. recently proposed a novel approach employing multimodal brain imaging, physiological measurements, and blood phenotypes to construct a multiorgan aging network<sup>8</sup>. Their research unveiled the heterogeneous nature of organ aging, and the multiorgan aging network could potentially facilitate early identification of individuals at risk of age-related morbidity. Besides, investigations focused on BA for specific organs are also of great interest. Le Goallec et al. proposed to use the prediction of liver and pancreas ages based on imaging data to improve the estimation of abdominal age9. In another study, Mauer et al. employed 3D knee imaging to estimate age and used it to achieve accurate majority classification (individuals older than 18 years of age)<sup>10</sup>.

Among the various organs studied, the brain emerges as a prominent subject of research. Brain structure changes are demonstrated to be mutually caused by the natural aging process and neurodegenerative diseases<sup>11,12,13,14,15,16</sup>. Cole *et al.* demonstrated that biological brain age can enable the development of treatment plans and a better understanding of disease processes<sup>17</sup>. The authors emphasized that the difference between the predicted brain age and the chronological age is a valuable bio-marker since it shows a correlation with aging as well as with diseases. This difference is denoted as BrainAGE for Brain Age Gap Estimation. Since its introduction, this new bio-marker has been widely used in many studies to analyze various diseases<sup>1</sup>. Generally, a model is trained with brain images from a healthy population and then used to estimate the age of patients with diseases.

In BrainAGE, structural magnetic resonance imaging (sMRI) is the most used modality (about 88% of studies<sup>18</sup>). It has been shown that reasonable prediction error can be achieved using this modality. Moreover, sMRI is commonly available in medical environments<sup>18</sup>. Initially, sMRI was used with some traditional machine learning algorithms such as relevance vector regression<sup>19</sup>, support vector regression<sup>20</sup>, and Gaussian process regression<sup>21</sup> to perform BrainAGE. The prediction error of these methods ranges from 4.29 to 5.02 years for the mean absolute error (MAE) metric. Since the success of deep learning in many natural image processing applications, it has also become a useful technique in various medical imaging studies. Recent studies show the capacity of deep learning algorithms in the brain age estimation task based on sMRI with an MAE ranging from 1.96 to 4.16 years<sup>7,22,23,24,25</sup>. These promising results suggest using deep learning to estimate brain age for further analysis.

These deep learning-based methods adapt famous convolutional neural network (CNN) architectures to estimate brain age. When employing a VGG-like architecture, Ueda *et al.* demonstrated that using 3D CNN can lead to better accuracy than 2D CNN for age prediction<sup>26</sup>. In another work, Cole *et al.* also used a VGG-like architecture and found that the grey matter extracted from 3D sMRI is better than white matter and raw image for age prediction<sup>17</sup>. Using a similar architecture, Bermudez *et al.* suggested additionally taking advantage of brain structure volume to improve the model performance<sup>25</sup>. Bintsi *et al.* employed ResNet architecture to predict age on several sub-volumes of brain image<sup>27</sup>. The final prediction was aggregated using a linear regression model. Armanious *et al.* proposed to use the inception module with squeeze-and-excitation module to accurately predict healthy brain age<sup>7</sup>. Bashyam *et al.* customized the inception-resnetv2 to build their model and trained it on 11729 healthy subjects.

After training a brain age prediction model, the next step is to apply it to a population of interest to compare healthy and diseased groups (*i.e.*, analysis at the population level). For example, Franke *et al.* analyzed brain maturation during childhood and adolescence<sup>28</sup>. By applying a trained model on subjects being born before the 28th and after the 29th week of gestation, they found that the BrainAGE of the first group was significantly lower than the second group, showing a delayed structural brain maturation of the first group. Applying the same technique, Koutsouleris *et al.* demonstrated an accelerated aging of 5.5 years in schizophrenia and 4.0 years in major depression patients compared to normal aging<sup>29</sup>. In another study dedicated to Alzheimer's Disease (AD), the BrainAGE was estimated at about +10 years in AD patients, implying accelerated aging of this population<sup>19</sup>.

Although BrainAGE can provide a description of a specific population, its application in individual diagnosis is still limited. Only a few works suggested performing disease detection or differential diagnosis using BrainAGE at the subject level. For instance, the BrainAGE was used as a biomarker to perform differential diagnosis between mild cognitive impairment and AD in <sup>30</sup> and to diagnose AD (*i.e.*, AD patients *vs.* healthy controls) in <sup>31,32</sup>. More recently, Cheng *et al.* used deep learning to accurately predict brain age and they use BrainAGE as the only feature for various binary diagnosis tasks (*i.e.*, diseased subjects *vs.* healthy subjects) <sup>33</sup>. Although encouraging results were obtained, these works performed only binary classification tasks but not multi-class classification. The reason for this may be due to the coarse description of the brain's state provided by the global BrainAGE. Indeed, BrainAGE can only describe the aging process of the whole brain but does not provide any details about brain structures' state. Therefore, it is difficult to use BrainAGE for involved tasks such as the differential diagnosis of multiple pathologies.

Since global age estimation, several approaches have proposed voxel-wise estimations. Beheshti *et al.* introduced a methodology that estimates brain age at the voxel level based on patch similarity<sup>34</sup>. The global brain age was subsequently deduced using a weighted average of the predicted voxels, achieving an MAE of 1.66 years. This method highlights the potential of voxel-wise age prediction. In another study, Popescu *et al.* employed a U-Net model to estimate brain age at the voxel level, using data from gray and white matter in sMRI scans<sup>35</sup>. Although their technique did not surpass other models in age estimation accuracy, this approach did reveal significant differences in local brain ages between healthy individuals and dementia patients, presenting a promising avenue for future research in brain disease diagnosis.

In this paper, we propose to extend the notion of the global brain age to local brain structure ages. Our main hypothesis is that the aging process is heterogeneous over the brain and specifically, different brain structures may present different ages. While voxel-wise age estimation methods might be valuable markers, our paper introduces a novel structure age estimation as a complementary method dedicated to interpretable computer-aided diagnosis. Structure age summarizes the brain's state into a

vector of apparent ages for multiple anatomical structures, which is easier to interpret than voxel-wise ages. This summary not only provides a quick comparative assessment of the structural impacts of diseases but also reduces the complexity of data analysis. By doing so, it helps prevent model overfitting, facilitates the integration with other structure-based biomarkers (*e.g.*, volume) in disease classification, and provides more robust estimates by averaging noisy voxel-level estimations. Consequently, we first estimate the brain age at the voxel level. This results in a 3D aging map of voxelwise brain ages. By averaging predicted brain ages by brain structure, we obtain the Brain Structure Ages, denoted as BSA. This local BSA is expected to provide more information about the subject's condition than a global age prediction of a whole subject's brain. As shown later, this novel biomarker can be used as input of a support vector regressor (SVR) to accurately estimate the subject's age. During validation, our framework showed competitive results compared to state-of-the-art methods. Furthermore, the difference between BSA and the subject's chronological age, denoted as BSAGE for Brain Structure Age Gap Estimation, can be also used with a support vector machine classifier (SVM) for multi-class classification (*i.e.*, Cognitively Normal (CN) *vs.* AD *vs.* Frontotemporal Disease (FTD) *vs.* Multiple Sclerosis (MS) *vs.* Parkinson's disease (PD) *vs.* Schizophrenia (SZ)). In our experiments, we demonstrated the important gain of using BSAGE compared to BrainAGE for the multi-disease classification task. Finally, by projecting the BSAGE on a brain atlas, we can visually observe the brain regions affected by different diseases.

# 2 MATERIALS

#### 2.1 Datasets

The data used in this study comprise 39255 images from various datasets: the Autism Brain Imaging Data Exchange (ABIDE)<sup>36,37</sup>, the Alzheimer's Disease Neuroimaging Initiative (ADNI)<sup>38</sup>, the Australian Imaging Biomarkers and Lifestyle Study of aging (AIBL)<sup>39</sup>, the International Consortium for Brain Mapping (ICBM)<sup>40</sup>, the Information eXtraction from Images (IXI)<sup>‡</sup>, the National Database for Autism Research (NDAR)<sup>41</sup>, the Open Access Series of Imaging Studies (OASIS)<sup>42</sup>, Cincinnati MR Imaging of Neurodevelopment (C-MIND)<sup>§</sup>, UKBioBank<sup>43</sup>, the Strategic Research Program for Brain Sciences (SRPBS)<sup>44</sup>, the Center for Biomedical Research Excellence (COBRE)<sup>¶</sup>, the Cambridge Centre for aging and Neuroscience (CamCAN)<sup>45</sup>, the Parkinson's Progression Markers Initiative (PPMI)<sup>46</sup>, the Frontotemporal Lobar Degeneration Neuroimaging Initiative (NIFD)<sup>#</sup>, the Observatoire Français de la Sclérose en Plaques (OFSEP)<sup>47</sup>, the National Alzheimer's Coordinating Center (NACC)<sup>48</sup>, the Dallas Lifespan Brain Study (DLBS)<sup>||</sup>, the Minimal Interval Resonance Imaging in Alzheimer's Disease<sup>49</sup>, the Minimal Interval Resonance Imaging in Alzheimer's Disease<sup>49</sup>, the T1 weighted images at the baseline were used.

#### 2.1.1 Chronological age prediction

Among available data, 32718 images were used to study the accuracy of our chronological age predictor. First, eight datasets including 2887 images (*i.e.*, ABIDE I, ADNI, AIBL, ICBM, C-MIND, IXI, NDAR, OASIS1) were used in training/validation. Second, two external datasets (*i.e.*, out-of-domain) were used for testing. Concretely, CN subjects of ABIDE II (*i.e.*, 580 images) were used to estimate the model accuracy on a young population and CN from UKBioBank (*i.e.*, 29251 images) were used to estimate the model accuracy on an older population (see Table 1). For ABIDE, we ensured that no subject in phase I was presented in phase II.

#### 2.1.2 | Multiple pathologies classification

Besides, we assessed the classification performance using BSAGE on 6537 images composed of 6 classes (*i.e.*, CN, AD, FTD, MS, PD and SZ). Eight datasets including 1992 images (ADNI, AIBL, SRPBS, COBRE, CamCAN, PPMI phase 1, NIFD and OFSEP centers 1-2) were used to perform a 10-fold cross validation (in-domain validation) (see Table 2). Then, we constructed

an out-of-domain dataset including 4545 images using seven cohorts (*i.e.*, NACC, DLBS, MIRIAD, OASIS3, BrainGluShi, PPMI phase 2 and OFSEP-other-centers) to assess the generalization capacity of such models. For the OFSEP, we used the acquisition sites to split this global dataset into two non-overlapping domains. For PPMI, we ensured that no subject in phase I was presented in phase II.

Usage	Dataset	Male/Female	Age (Mean $\pm$ Std)			
	ABIDE I	408/84	$17.5 \pm 7.8$			
	ADNI	201/203	$74.8 \pm 5.8$			
Age prediction	AIBL	112/120	$72.3 \pm 6.7$			
training	ICBM	112/182	$33.7 \pm 14.3$			
	C-MIND	107/129	$8.4 \pm 4.3$			
	IXI	242/307	$48.8 \pm 16.5$			
	NDAR	208/174	$12.4 \pm 6.0$			
	OASIS1	111/187	$45.3 \pm 23.8$			
Young population testing	ABIDE II	403/177	$14.8 \pm 9.3$			
Older population testing	UKBioBank	14917/14334	$64.2 \pm 7.9$			
	Total	16821/15897	$14.8 \pm 9.3$

intracranial cavity (ICC) extraction<sup>55</sup>. After preprocessing, we used AssemblyNet <sup>\*\* 56</sup> to get the parcellation of the brain into 133 structures (see Figure 1). This brain structure segmentation is then used to compute the BSA for further analysis.

## 3 METHOD

# 3.1 | Method overview

Figure 1 provides an overview of our method. First, we estimate the brain ages map at voxel level from a preprocessed T1 image using a large number of U-Nets. Then, this 3D map is used with a segmentation mask to compute the BSA features (Section 3.1.1). Finally, the BSA features can be employed to estimate the chronological age using an SVR model or combined with brain structure volumes to perform multi-disease classification using an SVM classifier (Section 3.1.2).

### **3.1.1** | Brain structure age estimation

In order to produce the 3D aging map, we extracted  $m = k^3$  overlapping 3D sub-volumes of the same size for each T1w MRI. Next, we trained *m* U-Nets to predict age at voxel level with these *m* 3D sub-volumes. The goal of this training strategy is dual. First, as the size of a sub-volume is relatively small compared to the original image, it can be trained with a lighter weight model and thus, require only a low computation capacity. Second, we limit the receptive field of each model to a local brain region in order to force it to locally describe the brain age. The outputs were then used to reconstruct a 3D brain age map. Finally, the

<sup>\*\*</sup> Available at https://github.com/volBrain/AssemblyNet

FIGURE 2 Architecture of an unit U-Net used for voxel-level age prediction. The number above each block is the number of channel.

BSA was computed with the help of an AssemblyNet-based brain segmentation<sup>56</sup>. In practice, we estimated the mean value of voxel-wise age estimation for each structure segmentation.

#### 3.1.2 Application to chronological age prediction and multi-disease classification

To demonstrate different use cases of the BSA, we performed two experiments using this biomarker: chronological age prediction which can help to briefly describe a population and multi-disease classification which can guide clinicians to focus on certain pathologies.

To predict the chronological age of healthy people, we employed a classical SVR and used the predicted BSA as its input. For the multi-disease classification, we first computed the BSAGE (*i.e.*, the difference between BSA and the subject's chronological age) and then used it as input of an SVM classifier to address the 6-class problem CN vs. AD vs. FTD vs. MS vs. PD vs. SZ. Moreover, structure volume is used as additional feature of BSAGE for SVM-based classification.

### **3.2** | Implementation details

First, a preprocessed T1w MRI in the MNI space of size  $181 \times 217 \times 181$  voxels at  $1mm^3$  was downscaled with a factor of 2 to the size of  $91 \times 109 \times 91$  voxels. After that, we extract  $k^3$  (*i.e.*, k = 5) overlapping sub-volumes of the same size  $32 \times 48 \times 32$  voxels and evenly distributed along the 3 image's dimensions from the downscale image. We trained  $m = k^3$  (*i.e.*, m = 125) U-Nets to predict age at voxel level with these *m* sub-volumes. Figure 2 shows the architecture of our unit U-Net used for voxel-level age prediction. The *m* outputs were then used to reconstruct a 3D age map of size  $91 \times 109 \times 91$  voxels. Of note, the predicted brain age located at overlapping voxel positions of more than 1 sub-volume was averaged. The reconstructed image was upscaled using trilinear interpolation to the same spatial size as the original input. This 3D map was used to compute BSA and then BSAGE features.

For training the U-Nets, each voxel inside the ICC is assigned the subject's chronological age as its ground truth value, while all other voxels are set to zero. During training, we use the mean absolute error (MAE) as loss function and SGD optimizer. The batch size is set to 8 and the training was terminated after 20 epochs without any improvement on validation loss. The first U-Net was trained from scratch and other U-Nets were trained with transfer learning from their adjacent U-Net (see <sup>56</sup> for more details). The training data is split into training/validation sets with a ratio of 80%/20% (see Table 1). In addition, when a new U-Net was trained, the training and validation data were gathered and re-split to exploit the maximum information from available data. Finally, we employed different data augmentation techniques to alleviate the overfitting problem. Concretely, we

randomly shifted a patch by  $t \in \{-1, 0, 1\}$  voxel in each dimension (denoted as random shift technique) and then applyed mixup data augmentation<sup>57</sup>.

Before using BSA features, we applied an age correction technique for each of their elements. We followed a simple method of Smith *et al.*<sup>58</sup> to eliminate bias in each structure brain age. Concretely, we denoted the actual age as Y (an  $N_{subjects} \times 1$  vector), the brain age as  $Y_B$ , a brain structure age as  $X_s$  (an  $N_{subjects} \times 1$  vector) and the bias term  $\delta$ . So, we predicted  $Y_B$  from  $X_s$ :  $Y_B = Y + \delta = X_s\beta$ . This is equivalent to  $Y = X_s\beta - \delta$ . This regression can be solved with  $\beta = (X_s^T X)^{-1} X_s^T Y$ . Finally,  $Y_B = X_s (X_s^T X_s)^{-1} X_s^T Y$ .

When training the SVR to estimate chronological age, three kernels were used to select the best model through our crossvalidation: linear, polynomial and radial basis function. Five values of C and epsilon in [0.1, 1, 10, 100, 1000] were used in the hyper-parameter search. We performed a grid-search for the kernel and the hyper-parameters C, epsilon.

When training the SVM for multi-disease classification, "one vs rest" was used as the decision function shape, three kernels were used to select the best model through our cross-validation: linear, polynomial and radial basis function. One hundred values of C in the log-space [-1.5; 0.5] were used in the hyper-parameter search. We performed a grid-search for the kernel and the hyper-parameter C.

#### 3.3 Validation Framework

For chronological age prediction, we compute the BSA features of U-Nets' training subjects. This data is used to train the SVR-based regression (10-fold cross-validation). This results in 10 SVR models. We used two separate out-of-domain datasets to assess our method accuracy (see Table 1). When evaluating the framework for this data (young and old populations), we used these 10 models to predict the individual chronological age and then averaged the 10 obtained results to make only one prediction per subject.

For multi-disease classification, we employed a 10-fold cross-validation for training our SVM classifier, as outlined in Table 2. Each of the 10 models was evaluated using its corresponding test fold. Consequently, each test sample was assessed once, yielding a single global final prediction. We concatenated the results across 10 test folds to determine the in-domain performance of our model. Furthermore, we examined the model's generalizability by testing it on an out-of-domain dataset, also detailed in Table 2. For this external data set, each test sample was evaluated using all 10 cross-validated models, and their outputs were averaged to enhance model generalization. This resulted in one final prediction for each test sample in the out-of-domain dataset.

#### 4 | EXPERIMENTAL RESULTS

#### 4.1 Chronological age estimation

#### 4.1.1 Ablation study

In this part, we aim at studying different factors influencing the model performance: Data amount, different augmentation strategies (*e.g.*, random shift, mixup<sup>57</sup>), age correction technique (see Section 3.2) and regressor (*e.g.*, Multi-Layer Perceptron (MLP), SVR). Table 3 shows the comparison results. The regression lines are provided in the Annexes.

First, we can observe that increasing the data amount (exp. 1, 2, 3) consistently improve the model accuracy on both young and old population in all metrics (*i.e.*, MAE,  $R^2$  and their corresponding CI). Second, applying different data augmentation techniques (*i.e.*, random shift, mixup in exp. 4, 5) can slightly improve the mentioned metrics and their CI. This is in line with the finding of<sup>59</sup>. Third, many studies have shown the advantages of using age correction techniques. In our case, the implemented technique does not show improvements (exp. 6). However, this technique can enhance the discriminative capacity of BSA for better disease classification (see Section 4.2.1). Finally, using SVR improves our model accuracy over MLP (exp. 7). Overall, each factor contributes to our model accuracy. In the rest of the paper, BSA is computed using 100% data, random shift, mixup, structural age correction techniques, and SVR regressor unless otherwise specified.

**TABLE** 3 Ablation study for the chronological age estimation. Red: best result, Blue: second best result. Text or symbols in black: Changes compared to the previous experiment. Text or symbols in gray: No change compared to the previous experiment. The model performance is estimated by different metrics: Mean absolute error (MAE) and the coefficient of determination ( $R^2$ ). The validation procedure is presented in Section 3.3. We denote MLP, SVR and CI for Multi-layer perceptron, Support Vector Regressor and Confidence Interval. The CI is estimated at 95% confidence level using boostraping.

No.	Data amount	Random Shift	MixUp	Structural Age Correction	Regressor		Young po	pulation			Old pop	oulation

# 4.1.2 Comparison with state-of-the-art methods

In this part, we compare our method with different state-of-the-art methods. For each method below, we used the code available <sup>††</sup> <sup>‡‡</sup> and retrained the model using the same data split as in our training process. The first method by Jonsson *et al.* uses a ResNet-like architecture and demonstrated promising results in age prediction<sup>24</sup>. More recently, Peng *et al.* presented a lightweight architecture named Simple Fully Convolutional Network (SFCN) for this problem<sup>59</sup>. They considered age prediction as a classification problem. To introduce a relationship between close classes, they used a soft label during training. The soft label is a probability distribution centered around the ground-truth age. In another work, Leonardsen *et al.* reused the SFCN backbone and demonstrated that the soft label can lead to better accuracy with in-domain data but the regression version presents a better generalization capacity on out-of-domain data<sup>60</sup>. Table 4 shows the results of the comparison. For the young population, we can remark that our method presents a very low MAE (1.88 years) and very high *R*<sup>2</sup> (0.91) compared to other state-of-the-art methods. For the older population, all methods present a drop in performance. In this case, our method shows *MAE* = 3.83 years and *R*<sup>2</sup> = 0.62, presenting the best prediction error over all methods. Finally, our method shows better and non-overlapping CI compared to other methods, demonstrating superior performance on chronological age estimation.

#### 4.2 Disease classification

#### 4.2.1 Ablation study for binary classification tasks

In this part, we aim at assessing the BSAGE (*i.e.*, the difference between BSA and the chronological subject's age) feature in the context of specific disease detection (binary classification). To do it, we compare this feature with the brain structure volume feature (denoted as V). We denote BSAGE<sub>nc</sub> as the BSAGE without age correction (see Section 3.2). Finally, we propose to take advantage of both BSAGE and structure volume biomarker to improve the discriminative capacity of our model.

Table 5 shows the results of the comparison between different features for different classification problems. The balanced accuracy (BACC) is presented. Other metrics are provided in the appendix. First, we can remark that BSAGE (exp. 2, 6) shows better results in BACC and the CI associated than the non corrected version  $BSAGE_{nc}$  (exp. 1, 5) in most classification problems (*i.e.*, AD, FTD and MS detection). Only in case of PD detection, the version without age correction shows better results than the

corrected version in the out-of-domain dataset. Second, we observe that BSAGE (exp. 2, 6) shows high BACC in FTD detection and MS detection while the results of structure volume shows its effectiveness in AD detection, FTD detection and SZ detection. In other cases (*i.e.*, PD detection), both features moderately perform on in-domain data and poorly perform on out-of-domain data. From this observation, both the BSAGE and the structure volumes demonstrate discriminative power for different disease detection tasks. Thus, it should be beneficial to combine them for a better discriminative capacity. As a result, the combination of BSAGE and structure volume (exp. 4, 8) shows most of the time the best or the second best BACC.

# 4.2.2 | Multi-disease classification

Table 6 shows the results for the multi-disease classification problem. We estimated the balanced accuracy (BACC), accuracy (ACC) and area under curve (AUC) of our model. We performed classification using the true age (exp. 1, 7) and the predicted subject's age (exp. 2, 8) to confirm that estimating brain age at structure level provides better results than using a global age estimation with real or estimated values. Moreover, these baseline methods enable to estimate the biases present between populations in terms of age. Indeed, there was some bias in age distribution between diseases since for instance the SZ patients were young while compared to the AD patients. Thanks to this analysis, we can observe that BSAGE (exp. 4, 10) and V feature (exp. 5, 11) presents far higher performances and better CIs than the true age and the predicted subject's age. This suggests that

the structure-related information is valuable in classification context. Furthermore, we compared BSAGE with the BrainAGE (*i.e.*, the difference between the predicted subject's age and the true age) for multi-disease diagnosis (exp. 3, 9). Experimental results suggested that using local brain ages gap estimation (*i.e.*, BSAGE) is more beneficial than the global BrainAGE in multi-disease detection. Besides, although the BSAGE (exp. 4, 10) presents lower performance than the V feature (exp. 5, 11), the two biomarkers can be mutually used to achieve better classification performance. Indeed, their combination (exp. 6, 12) shows the best performance of CN vs. AD vs. FTD. This is presented alongside results from state-of-the-art methods, demonstrating the efficiency of our framework in varied diagnostic scenarios.

**TABLE** 6 Multi-disease classification results. **Red**: best result, **Blue**: second best result. The results are presented in %. We denote BrainAGE for the difference between the predicted age and the true age, BSAGE, V and CI for BSAGE with correction, structure volume and Confidence Interval. The CI is estimated at 95% confidence level using boostraping. The validation procedure is presented in Section 3.3.

To better confirm the advantages of BSAGE over BrainAGE, we conducted an analysis of their respective confusion matrices using out-of-domain data (independent testset). These matrices are presented in Figure 3. Notably, when employing BSAGE features, the SVM classifier is capable of generating predictions for all classes. Although the precision for certain classes, such as PD and SZ, may not be ideal, it is still better BrainAGE features, where the SVM fails to generate predictions for the FTD, PD, and SZ classes. Instead, these classes are frequently misclassified as CN, AD, or MS. This misclassification may be attributed to a overlap in the BrainAGE distribution between the (FTD, PD, SZ) and (CN, AD, MS) classes (see Section 4.3).

### 4.3 | Predicted brain age gap of different populations

In this section, we compare the predicted brain age gap between different populations (*i.e.*, CN, AD, FTD, MS, PD and SZ). Figure 4 summarizes the distribution of predicted brain age gap for six considered populations. The median and mean predicted brain ages of CN, AD, FTD, MS, PD and SZ are respectively (-1.1, -1.0), (3.3, 3.4), (8.3, 9.2), (11.2, 11.8), (1.0, 1.0) and (6.2, 6.1). First, we observe that the CN class has the mean and median closest to 0 as expected. Second, the BrainAGE of all patient groups is significantly higher than the cognitively normal group (p < 0.0001 with T-test). Third, PD pathology seems to be closest to healthy people. Indeed, although T1 weighted MRI presents high contrast of grey/white matter, poor contrast may be found in structures related to PD (*e.g.*, subthalamic nuclei)<sup>61</sup>. This may explain the proximity of this class with CN class and the poor performance in PD detection (see Table 5). Fourth, the FTD group presents a more advanced aging process than AD group which is in line with the finding of Lee *et al.*<sup>62</sup>. Finally, we found the same magnitude of BSAGE for MS (11.2 years) as Cole *et al.* (about 10.8 years)<sup>63</sup>, for AD (3.3 years) as Sendi *et al.* (2.1 years)<sup>64</sup> and for SZ (6.2 years) as Koutsouleris *et al.* (5.5 years)<sup>29</sup>.

**FIGURE 3** Confusion matrix associated with BSAGE features (left) and BrainAGE features (right) computed on out-of-domain data (independent testset).

**FIGURE 4** Predicted brain age of different populations in out-of-domain data (independant testset). The white point presents the position of the mean value.

#### 4.4 Interpretation of brain structure age gap estimation

In this section, we propose to visualize the variation of the age gap between brain structures. The presented results in Figure 5 correspond to the average BSAGE value for each structure on different populations of our out-of-domain datasets. We use the same color bar for all populations to compare the impact of each disease on the aging process.

For the AD group, the region surrounding the hippocampus is highlighted as the most accelerated aging area. This region is well-known to be related to AD<sup>65,66,67,68</sup>. For the FTD group, the accelerated aging pattern is mainly located in the temporal and

FIGURE 5 BSAGE of different populations in out-of-domain data (independant testset).

frontal lobes which are in line with current literature<sup>69,70</sup>. For the MS group, the area with the highest accelerated aging pattern is similar to the finding of Cortese *et al.* (*i.e.*, thalamus and global cortical grey matter)<sup>71</sup>. For the PD group, all regions seem to be close to healthy people as discussed in Section 4.3. Finally, for the SZ group, the prefrontal and medial temporal lobe regions are highlighted which is coherent with several studies<sup>72,73</sup>.

We further analyzed the brain structures showing the most significant age differences for each disease, as outlined in Table 7. Firstly, many of the brain structures we previously mentioned also appear on this list, which is consistent with our expectations. Secondly, there's a variation in the ranking of brain structures based on their mean age differences across diseases. This distinction highlights the reason our BSAGE features are more insightful than the overall brain age gap (BrainAGE) for multi-disease diagnosis.

#### 5 DISCUSSION

In this work, we proposed an approach to estimate brain age at structure level. We showed that this feature can be used for different purposes. First, it can be directly used to accurately estimate the chronological age. Second, this can be used to compute the BSAGE (*i.e.*, the difference between brain structure ages and the chronological age). This biomarker presents discriminative patterns which are useful for the multi-disease classification problem (*i.e.*, CN vs. AD vs. FTD vs. MS vs. PD vs. SZ).

For the problem of chronological age estimation, we observed that the model accuracy was heavily influenced by different factors: data amount and data augmentation techniques. In our experiments, the model accuracy was consistently improved when the data amount was increased and we did not observe saturation. This suggests that training our framework on more data could yield higher accuracy. In this study, due to the limited training data, we instead applied several data augmentation techniques to improve the generalization capacity of our model. Experimental results showed that the random shift and mixup techniques have a huge impact on our model performance (see Table 3). Moreover, the resulting BSA can enable a more accurate subject's age prediction. While our framework was training over a large range of ages (*i.e.*, 0 to 95 years old), it achieved higher accuracy when predicting on young population (*i.e.*, ABIDE dataset MAE = 1.88 years) than on older population (*i.e.*, UKBioBank dataset MAE = 3.83 years). Our approach outperformed other state-of-the-art methods with 1.20 years MAE lower on the young population and 0.99 year MAE lower on the old population. When evaluating our approach on different disease populations (*i.e.*, AD, FTD, MS, PD, SZ), our findings were in line with current knowledge in the literature (see Section 4.3 for more details).

Finally, we observed that the predicted age distributions are different between diseases, suggesting a discriminative power of our BSA feature.

While most papers used the global BrainAGE to show that a disease can present an accelerated or delayed aging process on a population<sup>28,29,19</sup>, only a few approaches have proposed to use it for classification<sup>30,31,32,33</sup>. Moreover, these studies dedicated to classification had a common limitation. Indeed, it might exist a range of global BrainAGE values that is presented in different populations. In our case, all populations had global BrainAGE values in range [-5, 10] (see Figure 4). When the number of classes is increased, this limitation becomes more challenging. This might explain why existing BrainAGE-based algorithms only address classification problems with a low number of class (*e.g.*, binary classification). This raises the need for other features better describing the brain aging process for classification. Thus, we propose to extend the notion of BrainAGE to BSAGE . This local feature offers a richer representation of the brain aging process than global BrainAGE estimation. Consequently, this information is important for improving the multi-disease classification as analyzed in Section 4.4.

In addition to improve classification performance, BSAGE can be projected into a brain segmentation for visualization purpose. Principal remarks for each population were discussed in Section 4.4. Overall, it gives some insights about the specific structures impacted by each disease. The main patterns of each disease highlighted by our color maps are coherent with current literature (as discussed in Section 4.4). This presents an important clinical value of our framework in a real medical context.

Based on brain age prediction, several methods have been developed that can potentially identify brain regions affected by diseases. For example, Levakov *et al.* proposed using Explainable AI maps of CNNs to emphasize brain regions that significantly contribute to brain age prediction<sup>74</sup>. Hypothetically, if such techniques were applied to populations with brain disorders, they might uncover regions associated with signs of either accelerated or delayed brain aging due to the disorder. In our method, the BSAGE maps exhibit other interesting properties. Specifically, our BSAGE maps offer a quantitative measure that captures the abnormality of brain structure at the subject level. In contrast, explanation maps present a more qualitative insight into the relative significance of each feature during the decision-making phase. For instance, within an explanation map of an AD patient, it remains uncertain whether the non-emphasized regions (areas the models did not consider important for their decision) are in a healthy state or just non-informative (either redundant with other structures, or possibly too noisy across subjects, etc.). Additionally, explanation maps typically normalize values within a same range of values, making any comparison between two maps purely qualitative.

One limitation of our study is the lack of an independent in-domain testset for evaluating multi-disease classification. Typically, leveraging a separate in-domain testset would enable a more rigorous analysis of performance differences between in-domain

and out-of-domain settings. In our case, however, the use of a small testset could compromise the representativeness of the data, affecting the reliability of performance estimates. Conversely, using a large portion of the data for testing could reduce the amount of data available for effective model training. To balance these competing needs, we proposed to use a cross-validation strategy. While this approach offers a reasonable compromise between performance estimation and training robustness, it admittedly limits our ability to investigate performance disparities between in-domain and out-of-domain scenarios explicitly.

Finally, some diseases such as Parkinson's Disease cannot be easily detected using T1 weighted MRI. Future works should focus on the multi-modal input to either accurately estimate brain age or produce a more discriminative BSAGE feature. In addition, we use the same CNN architecture to analyze different brain locations. This can be not optimal due to the fact that different brain locations may have a specific set of patterns. An auto-search algorithm to select an optimal architecture for each brain region would be beneficial for further analysis.

#### 6 CONCLUSION

In this paper, we propose to extend the notion of brain age by estimating the brain age at voxel level. This voxelwise brain age map is then used to compute BSA. This biomarker can be used for different purposes. First, it can be used to predict the chronological age of people. The deviation of the predicted age from the subject's age can provide insight about the individual brain status. Second, by subtracting the subject's age from the BSA, we obtain a BSA gap estimation (*i.e.*, BSAGE). This feature can be mutually used with other biomarkers such as structure volume for disease detection. Finally, this feature can be also visualized to detect brain abnormality in MRI. Such a tool can help clinicians in making more informed decisions.

#### ACKNOWLEDGMENTS

This work benefited from the support of the project DeepvolBrain of the French National Research Agency (ANR-18-CE45-0013). This study was achieved within the context of the Laboratory of Excellence TRAIL ANR-10-LABX-57 for the BigDataBrain project. Moreover, we thank the Investments for the future Program IdEx Bordeaux (ANR-10-IDEX-03-02 and RRI "IMPACT"), the French Ministry of Education and Research, and the CNRS for DeepMultiBrain project.

TLDNI was funded through the National Institute of Aging, and started in 2010. The primary goals of FTLDNI were to identify neuroimaging modalities and methods of analysis for tracking frontotemporal lobar degeneration (FTLD) and to assess the value of imaging versus other biomarkers in diagnostic roles. The Principal Investigator of NIFD was Dr. Howard Rosen, MD at the University of California, San Francisco. The data are the result of collaborative efforts at three sites in North America. For up-to-date information on participation and protocol, please visit http://memory.ucsf.edu/research/studies/nifd. Data collection and sharing for this project was funded by the Frontotemporal Lobar Degeneration Neuroimaging Initiative (National Institutes of Health Grant R01 AG032306). The study is coordinated through the University of California, San Francisco, Memory and Aging Center. FTLDNI data are disseminated by the Laboratory for Neuro Imaging at the University of Southern California.

The C-MIND data used in the preparation of this article were obtained from the C-MIND Data Repository (accessed in Feb 2015) created by the C-MIND study of Normal Brain Development. This is a multisite, longitudinal study of typically developing children from ages newborn through young adulthood conducted by Cincinnati Children's Hospital Medical Center and UCLA and supported by the National Institute of Child Health and Human Development (Contract #s HHSN275200900018C). A listing of the participating sites and a complete listing of the study investigators can be found at https://research.cchmc.org/c-mind. The NDAR data used in the preparation of this manuscript were obtained from the NIH-supported National Database for Autism Research (NDAR). NDAR is a collaborative informatics system created by the National Institute of Health to provide a national resource to support and accelerate research in autism. The NDAR dataset includes data from the NIH Pediatric MRI Data Repository created by the National Institute of Child Health and Human Development. This is a multisite, longitudinal study of typically developing hildren from ages newborn through young adulthood conducted by the Brain Development Cooperative Group and supported by the National Institute of Child Health and Human Development, the National Institute on Drug Abuse, the National Institute of Mental Health, and the National Institute of Neurological Disorders and Stroke (Contract #s N01- HD02-3343, N01-MH9-0002, and N01-NS-9-2314, -2315, -2316, -2317, - 2319 and -2320). A listing of the participating sites and a complete listing of the true.

The NACC database was funded by NIA/NIH Grants listed at https://naccdata.org/publish-project/authors-checklist# acknowledgment.

This research has been conducted using data from UK Biobank, a major biomedical database. . See https://www.ukbiobank.ac. uk/ for further details.

Data collection has been supported by a grant provided by the French State and handled by the "Agence Nationale de la Recherche," within the framework of the "Investments for the Future" programme, under the reference ANR-10-COHO-002, Observatoire Français de la Sclérose en Plaques (OFSEP)" & "Eugène Devic EDMUS Foundation against multiple sclerosis".

Data was downloaded from the COllaborative Informatics and Neuroimaging Suite Data Exchange tool (COINS; http://coins.mrn.org/dx) and data collection was funded by NIMH R01MH084898-01A1, "Brain Glutamate and Outcome in Schizophrenia", PI: J. Bustillo.

Data were provided in part by OASIS : OASIS-1: Cross-Sectional: Principal Investigators: D. Marcus, R, Buckner, J, Csernansky J. Morris; P50 AG05681, P01 AG03991, P01 AG026276, R01 AG021910, P20 MH071616, U24 RR021382

**T A B L E** A3: Comparison of our model performance with the state-of-the-art methods for the classification CN vs. AD vs. FTD. Red: best result, Blue: second best result. The results are presented in %. The performance of the state-of-the-art methods is sourced from <sup>75</sup>. It is important to note that the in-domain data used by these methods differs from ours. Specifically, they employed the ADNI2 and NIFD datasets for training their classifiers, whereas we used CN subjects from ADNI2 for training our age prediction models. For training our classifiers, we used all available CN, AD, and FTD samples from our in-domain data. For out-of-domain data, the same dataset (*i.e.*, NACC) with the same subjects as <sup>75</sup> is employed to ensure a more equitable comparison. It is also worth noting that the table that follows is only presented to offer an overview of the classification efficacy of our framework for CN vs. AD vs. FTD.

	No.	Methods	BACC	ACC	AUC
	1	Hu et al. 2021	72.5	76.3	90.0
