25 Abstract

26 This contribution proposes answers to the question: who is where? For the first time, massive, reliable phone data
27 collected and verified at a high level of spatial and temporal precision over the entire French territory have been used
28 to address this questioning. The article raises the issue of data quality and relevance and sets out a framework which
29 focuses on the inhabitant, not just the resident or the commuter. The processing of these data allows us to challenge the
30 approximation of a home-stuck dweller and to propose a new approach. Two novel indicators (inhabitants.year and
31 attractivity index) have been designed to account for the reality of individual spatial practices and to encompass the
32 multiple ways in which a country is inhabited. Finally, maps that these data make possible are produced and analyzed.
33 A fresh portrait of France as a complexly inhabited space emerges.

34

35 Teaser

36 Comprehensive data now makes it possible to locate and count the effective population with a high space and time
37 accuracy.

38

39 MAIN TEXT

40

41 Introduction

42 It is not easy to know how many people there are in a locality, a district, a city. We have on the one hand censuses,
43 where they are reliable, and on the other hand mobility surveys. The digital world provides new sources, but they
44 remain fragmentary on this point. The main weakness of censuses is that they are based on an implicit assumption: that
45 the location of a respondent's primary residence is predictive of that person's permanent location. This is not the case.
46 Individuals move, sometimes coming from very far away, circulating in many places during the day, and may well still
47 be spend the night elsewhere.

48 Mobility surveys help enrich the picture, but they too have several weaknesses (see Materials and Methods). This article
49 presents the first set of results that originate from a different starting point: Individuals divide their time between

50 different places. They allocate their time resources to their various housings, places of work, education, personal
51 relationships, or leisure, as well as to their travel activities. On average, each person spends time in several places each
52 day, generally between 2.5 and 4 per person per day in urbanized societies: about France, see (1). For example, in
53 addition to commuting (2), 40% of working people travel for work in France. An inhabitant is not only a resident.

54 It is therefore useful to distinguish *residents*, defined by the location of their home, from *inhabitants*, who are defined
55 by the different types of places they practice, their primary home being only one of them. To avoid ambiguities, we
56 will not use the term ‘dweller’ in the remainder of this text.

57 In this perspective, the article presents the results of a research that exploited massive cell phone data covering the
58 whole of mainland France for one year. We have established indicators that allow us to answer the two questions:
59 Where are the inhabitants really located? And how does their location differ from the classic population distribution
60 based on permanent homes. This is what the first section of this paper is about. Maps draw a fresh, sometimes
61 spectacular, geography of France.

62 For personal data protection reasons, the team did not have access to mobile phone users’ personal identifiers. We have
63 nevertheless been able to answer one part of the question: who are the inhabitants? In the second part, a self-portrait of
64 the country through their inhabitants’ spatial practices shows how lifestyle choices, tourism, or the role of foreign
65 visitors contribute to define specific profiles for the different places, that constitute France, inside and outside its
66 territory.

67 This first set of results marks the beginning of a vast work program. It is also an invitation to redefine and enrich what
68 can be called *inhabiting*.

70 Results

71 Real People in Actual Places

72 A simple, versatile indicator: the inhabitant.year

73 Inhabiting is not only sleeping. As censuses suppose people remaining permanently still at their residential address, we
74 more realistically consider that each individual allocates their time in different places.

75 A inhabitant.year (IY) is a full year stay equivalent. The value of IY_i is [1]:

$$IY_i = \sum_{i=1}^n \frac{S30i}{17520}$$

76
77
78
79 [1]

80
81
82 where $S30i$ is the number of people that stayed for any of the forty-eight 30-minute time slots of a day of a determined
83 year in the i spatial unit and 17520 being the number of 30-min slots in a year (see Materials and Methods, below).

84 This indicator takes into consideration the fact that, most of the time, an individual does not stay in the same place for
85 the whole year, and what is useful to know is how much of his year he/she has spent in a particular place. This measure
86 of *full-year equivalents* also has the advantage of producing efficient results with sources that are not only anonymous
87 but also unidentified. We know that in each location, in a given timeslot, there were x people, but this does not tell us
88 anything about these people. We can, however, measure the number of people present in that location and this is a
89 major information.

90 Using 30 min-stays data all over a year (March 2022-February 2023), we have calculated the number of IY in a
91 determined space in each of the 48,589 spatial statistical units that compose the mainland France territory (see Materials
92 and Methods). The results obtained show a total population of 70,098,618 inhabitants.year divided into 65,121,201
93 subscribers of national operators (French permanent residents) and 4,977,417 roaming customers (foreign visitors).

94 Fig. 1-2 shows the spatial distribution of IYs’ density. This map appears to be close to a typical density map made from
95 census data. In fact, important differences concern the masses and their distribution.

96 The Euclidean map (Fig. 1) particularly emphasizes transportation routes, which makes sense because the measurement
97 detects moving people in proportion to the time spent in a small spatial unit. These mobile inhabitants who are missed
98 in the usual census counts now affect the density map.

99 The cartogram (Fig. 2) has a background map making the areas represented proportional to the number of IYs. This
00 shows the considerable weight of the largest urban areas. Their density reaches particularly high values in the city
01 centers. The maximum density reaches 490,676 IY/sq. km (\approx 189,400 IY/sq. mi.) in central Paris, where the average
02 residential density is 20,360 people/sq. km (27,346 in Manhattan). These scores are all the more impressive because
03 they do not reflect seasonal overrepresentation: they are full-year equivalents.

04 The non-metropolitan territory appears demographically residual, which is confirmed by comparison with census data
05 (see below).

Fig. 1. France, Density, Inhabitants.year, 2022-23, Euclidean Metric.

 16
 17

18 **Inhabitants vs. Residents: An Index of Attractiveness (A-index)**

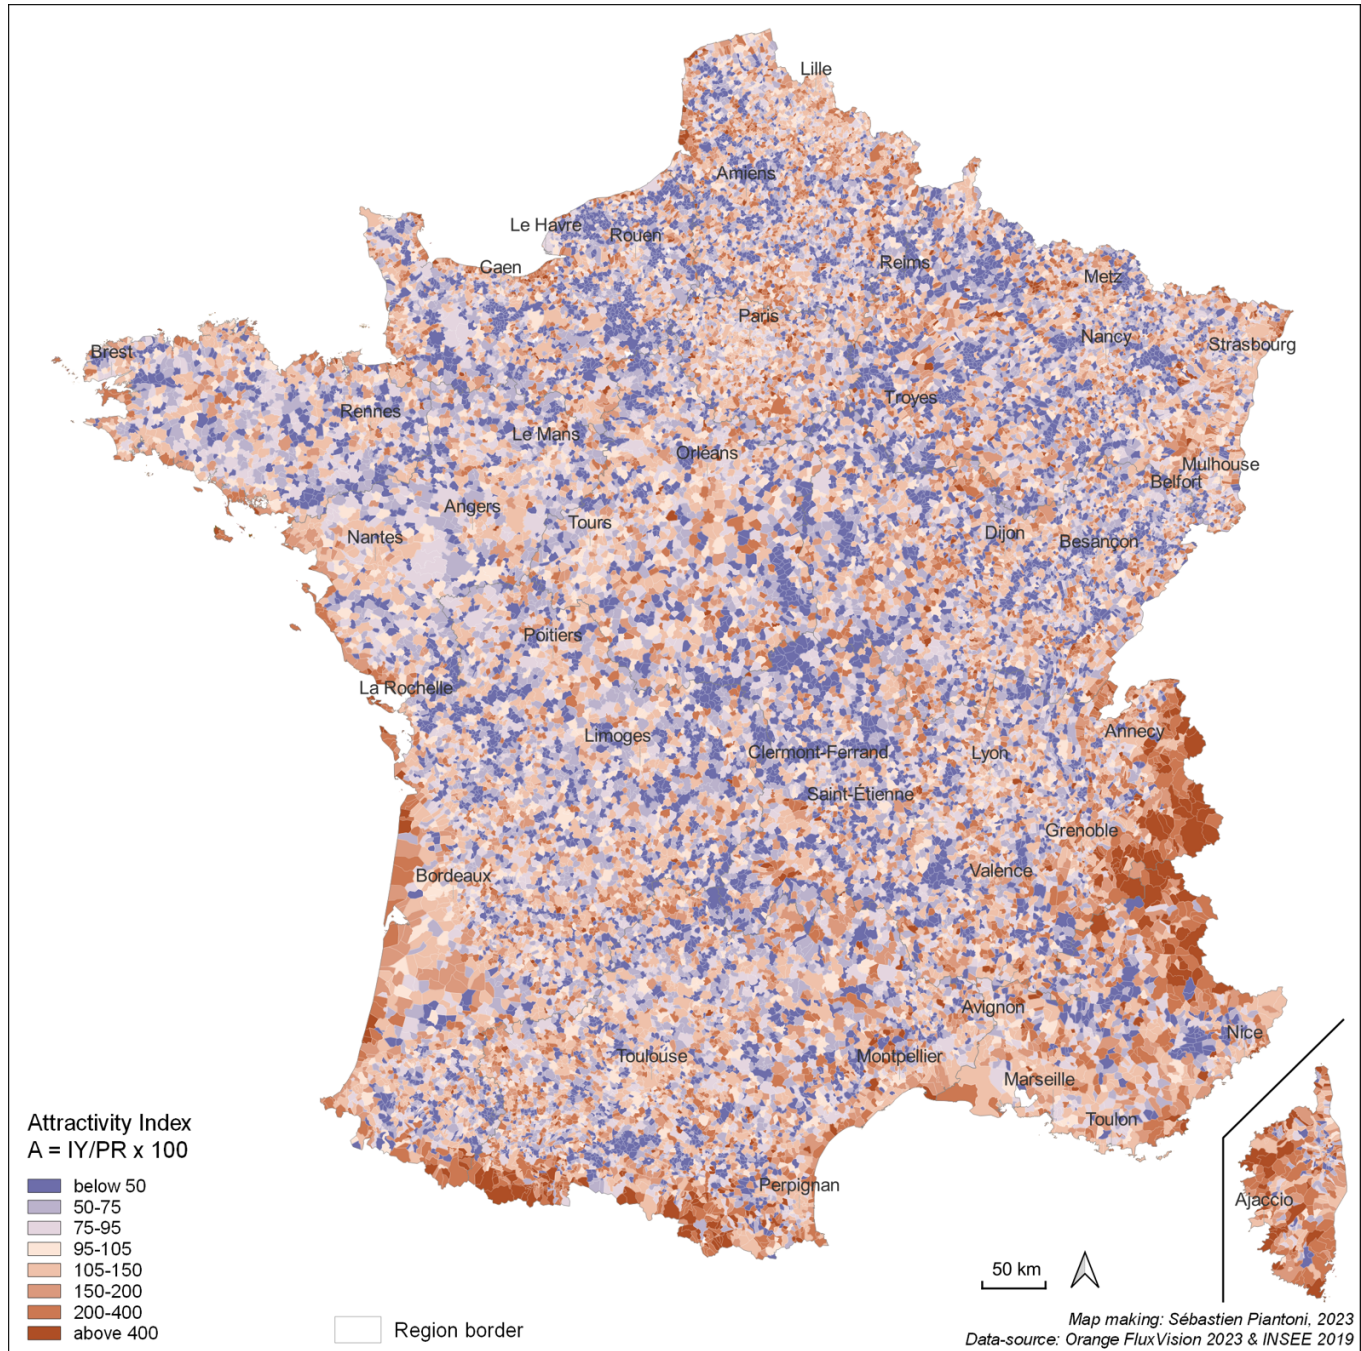

19 The comparison between the number of people counted at their primary residence (PR) of a spatial unit as measured
 20 by censuses and their actual inhabitants (IY) can be considered a simple and powerful indicator of the attractiveness of
 21 a place (see Material and Methods. The A-index [2] is a simple relation between an overall population and its residential
 22 component.
 23

$$A_i = 100 \left(\frac{IY_i}{PR_i} \right) \quad [2]$$

24 The A-index appears as a useful complement to the classic measurement of different types of mobility, on the one hand,
 25 and to economic attractiveness (e.g., with jobs or investments), on the other.
 26
 27

28 It includes those flows of people, goods, or capital but goes beyond it, offering a vision that is both synthetic and
29 comprehensive of all the logics that link one place with all the others. Moreover, the A-index makes sense at all scales,
30 from micro-local to global.
31

Two comparative maps (Euclidian and cartogram, Fig. 3-4) show the spatial significance of this index. The most populated locations show values significantly above the 100-line. Beyond the density values in a given spatial unit, the absolute value comparison between PR and IY show huge differences as the most populated areas have very few residents, sometimes none.

The contrasts between the two series of data (inhabitants vs. residents) at the national level reveals two major features: the polarization on the core areas of urban regions, especially as these are important, and an internal redistribution inside urban areas (see below). We will analyze later a third aspect: the considerable role of tourists-appealing areas.

First, the IY distribution map shows strong regularity in support of a concentric pattern. The core areas appear hyper-populated with values that no density measure had previously identified. The inner suburbs are unevenly populated, but overall, non-residential activities of various types do balance residential mass in many locations.

Conversely, predominantly residential suburban and peri-urban areas show a lower population than in the censuses: their residents spend a significant part of their time outside of their home, while their neighborhoods are unattractive to other inhabitants.

55 In large urban areas, the differentiation of spaces according to the two measurement systems (residents and IYs)
 56 generates a mosaic-style pattern. In each urban area, places with a IY surplus are next, often very close to locations
 57 with a deficit compared to census population. The places that have the most visible positive contrast are the employment
 58 areas in the historic centers, commercial or cultural attractions, mobility hubs and axes, and recreational areas (urban
 59 parks, forests, and theme parks).
 60 The zoom-in maps (Figures 5-6) show the situation in Paris urban area and in Lyon region.

In the Lyon region, Auvergne-Rhône-Alpes (Fig 7-8), the weight of the Lyon core urban area is less marked, competing with suburban industrial districts, business parks, shopping malls, or leisure areas. This phenomenon is also visible in Grenoble, Clermont-Ferrand, and Annecy, and even more in Saint-Étienne a ‘rust belt’ city that is struggling to bounce back in a post-industrial context. The blue dominant of the residential suburbs, exurbs, and remote countryside appear as a ‘background noise’, while, on the other hand, the red zone of Alpine resorts forms a spectacular cluster.

The case of Roanne helps us understand how these new data make more visible the strengths and weaknesses of a given place. This city has an urban area of 141,000 residents (2020 census), but, in the same territory, to only 134,000 IYs. This means that it is slightly more repulsive than attractive. Simultaneously, the core municipality contains only 15,000 IYs, or only 44% of its 34,000 census-counted residents. On the other hand, the peri-urban area shows a higher

11 population (98,000) of inhabitants.years than of residents (81,000). This reflects the fact that employment and
 12 commercial activities tend to flee the historical center and settle outside. This is the typical situation in which the
 13 stagnation of the overall urban area is correlated with a loss of substance in its central area, where non-residential
 14 functions are tendentially evaporating. By crossing our two indicators (IY and A-index), we understand that it is not a
 15 simple coincidence: the single cause is a declining attractiveness that affects, in two ways, the whole area and its central
 16 district. As we will see later ('Large Cities' Cores Upgraded'), this is a problem common to most small and medium-
 17 sized French cities.

Map making: Sébastien Piantoni, 2023
 Data-source: Orange FluxVision 2023 & INSEE 2019

Base map: surfaces on the map are proportional to foreign visitors IYs in each of the 35,048 municipalities, *arrondissements*, or *quartiers*.

A Country's Self-Portrait

The data allows us to explore in detail the different types of localities that make up France. Attractive city centers are experiencing centripetal movements as centrifugal forces affect enlarged low-density areas. Mobility turns out to be a

28 central feature of the inhabiting process. The major role of foreigners and tourists is made visible. Exploring places
29 leads to focus on the diversity of spatial lifestyles.

31 **Paris area and Large Cities' Cores Upgraded**

32 If we adopt districting of *aires d'attraction des villes* ('city attraction areas') set up by Insee, the French statistical
33 office, Paris urban area has 14.790 million IYs (vs. 13.114 million residents) and the core area (the municipality of
34 Paris) 3.663 million IYs (vs. 2.166 million residents). The IYs count thus reinforces both the weight of France's largest
35 urban area and that of its core.

36 Paris' core area has an A-index of 169.1. The core municipalities of the six other areas with more than one million IYs
37 have an average A-index of 120, those of 12 areas with 500,000-1 million IYs a 101.3 average. and those of the 92
38 areas of 100,000-500,000 IYs a 101.2 average. This distribution means that centers of larger cities are, by and large,
39 more attractive than those of smaller ones. Said differently, we can observe positive feedback of the overall inhabiting
40 population of an urban area to the attractiveness of its core area.

41 The attractiveness of areas characterized by a strong urban character (density + diversity, reinforced by urban mass) is
42 thus confirmed by the new data. City centers turn out to be much more inhabited than the census would suggest because
43 they combine and cumulate residence, employment, and all other types of activity. By and large, the classic model of
44 the European city is confirmed: a compact built-up area used by a large array of practices, from residential (and it
45 connected services) to any kind of industries, as diverse as movie theaters and redesigned, low-pollution manufacturing
46 plants.

47 In French big cities, the *hyper-cores* that get the most out of this game, are always the historic centers, which are
48 generally located at the geometric center of the built-up area. This is a confirmation of a revival of the Burgess
49 concentric model (3) based on a core-periphery pattern. This model has been disputed for a while by two others, the
50 Hoyt (4) sector (i. e. quadrant) model and the Harris and Ullman (5) multiple-nuclei model. The concentric approach
51 is regaining strength due to economical, sociological, and political rearrangement of urban societies (6, 7). Our survey
52 provides new evidence of this emerging process.

54 **Trans-Urban: Movement as a Part of the Inhabiting Process**

55 Four types of places have much more IY than residents: infrastructures of mobility, such as airports, railway stations,
56 and inter-city transportations axes; business districts and business parks; shopping centers and, in general, commercial
57 areas; leisure spots, such as forests, mountains, coastlines, and theme parks.

58 The *Métro-Boulot-Dodo* ('Subway-Work-Bed') motto was characteristic of the century-long Fordist era. It is
59 challenged by the diversification of daily lives. Professional life is no longer reduced to a workstation but encompasses
60 either an intrinsic mobile component (passenger transportation, storage, shipping, and delivery of goods), or a large
61 number of locations for meetings with customers, partners, colleagues from other companies or organizations, seminars,
62 conferences, field work, especially since professional missions include a significant element of creativity (6,7).

63 Moreover, thanks to the absolute and relative transportation cost decrease, daily life has become more mobile:
64 shopping, supervising children's multiple activities, sport, cultural consumption, discovery of new places take up time
65 and space in the schedule (8, 9).

66 These changes, which have been measurable for decades by a multitude of other tools and studies, and which are
67 becoming undeniable thanks to this work, make the classic census approach still very useful but insufficient to describe
68 the current relations between population and geography. Those who wish to understand urban and regional rationales
69 can no longer be satisfied with the implicit postulate of an imaginary immobility in the place of residence and a mobility
70 reduced to commuting between an exclusive home and a single workplace.

71 The importance of non-commuting, non-work-related mobility invites us to take these new mobility issues seriously.
72 Inhabiting means *staying*, but also *crossing*. Trips and all aspects of 'motility' (10) that goes with them (preparation,
73 impact, technical mastery, travel imaginations) should no longer be seen as a suspension of inhabiting but as another
74 way of making and living an overall *inhabiting agency*.

75 Beyond commuters' daily networks, which remain powerful, a massive multi-pace intra-city and inter-city space is
76 emerging. It includes, as destination points, tourism-based places. The facilities and the flows that embody this mobility
77 is also part of the contemporary human 'habitats'.

78 Maps (Fig. 1-4 and 7-8) show the pivotal importance of tourism in the contemporary geographic layout of France. It is
79 as if a part of the lived spaces were propelled elsewhere to the point of constituting significant concentrations of
80 population, comparable to the usual cities. Moreover, the geography of foreigners (Fig. 9) shows that it is also through
81 international attractiveness that these locations are fed.

82 Of 663 mainland France, non-crossborder urban areas, 28 only have an A-index above 200, meaning they have at least
83 twice as many inhabitants (IY) as permanent residents (PR). These 28 urban areas are all, without exception, tourist
84 spots, seaside or mountain resorts, and tourism-driven medium-sized cities that are located either on the Atlantic and
85 Mediterranean coast and islands, or in the Alps.

86 Here is the list:

88 Val-d'Isère, Saint-Tropez, Chamonix-Mont-Blanc, Morzine, La Flotte, Bourg-Saint-Maurice, Carnac, Barcelonnette,
89 Saint-Gervais-les-Bains, Quiberon, Cavalaire-sur-Mer, Le Grau-du-Roi, Bormes-les-Mimosas, Crozon, L'Île-Rousse,
90 Calvi, Modane, L'Île-d'Yeu, Porto-Vecchio, Saint-Jean-de-Monts, Trouville-sur-Mer, Arcachon, Le Pouliguen, ,
91 Briançon, Port-Saint-Louis-du-Rhône, Capbreton, Ciboure, Agde.

92
93 These locations are neither central, nor suburban, nor peri-urban, nor exurban. Underlining the weight and the
94 geographical distinctiveness of tourism-driven areas, we can speak of a *trans-urban* space as a separate and alternative
95 style of urbanization. This observation is rendered by the Latin prefix *trans*, which expresses the displacement from
96 one place to another. The trans-urban rationale refers to a set of processes that project urban phenomena into new
97 locations. Instead of considering it as a seasonal event, the notion of the year-inhabitant allows it to be treated as a
98 permanent reality, which certainly varies during the year, but whose impact can be compared to standard urban
99 settlements.

00 01 **Social voids**

02 In areas of low population density, the differences are relatively small. However, the comparison between inhabiting
03 and residential maps shows a general deficit of inhabitants in low-density areas. Empty places are even emptier. The
04 'Empty Diagonal' ('*Diagonale du vide*'), an area of deep demographic decline nationwide that runs from the Ardennes
05 to the Pyrenees and also includes the Southern Alps can easily be detected on maps (Fig. 1-4). Moreover, there is a
06 vast area located in the northwestern quarter, which combines low densities and low attractiveness. All these regions
07 turn out to be even more depopulated because low residential densities are aggravated by the absence of attractiveness,
08 therefore by the absence of non-residence-driven activities. This is all the more true as commerce has moved out of
09 small towns to concentrate in shopping malls. Conversely, polarization towards a reduced number commercial and
10 employment attractive areas plays its role in these less dense areas. These zones can also benefit from the crossing of
11 major mobility routes, which is even more significant when they are located, in low-density areas, like in the southeast
12 of the Paris Basin, from Brie to Morvan.

13 In all the medium-sized and large cities, a distinction appears between exclusively residential suburban or peri-urban
14 areas that are losing inhabitants and other parts where suburban employment and leisure centers are gaining. This
15 generates a small-scale redistribution of polarities within urban areas which gives its mosaic style to A-index maps
16 (Fig. 3-8).

17 18 **A Place for Strangers**

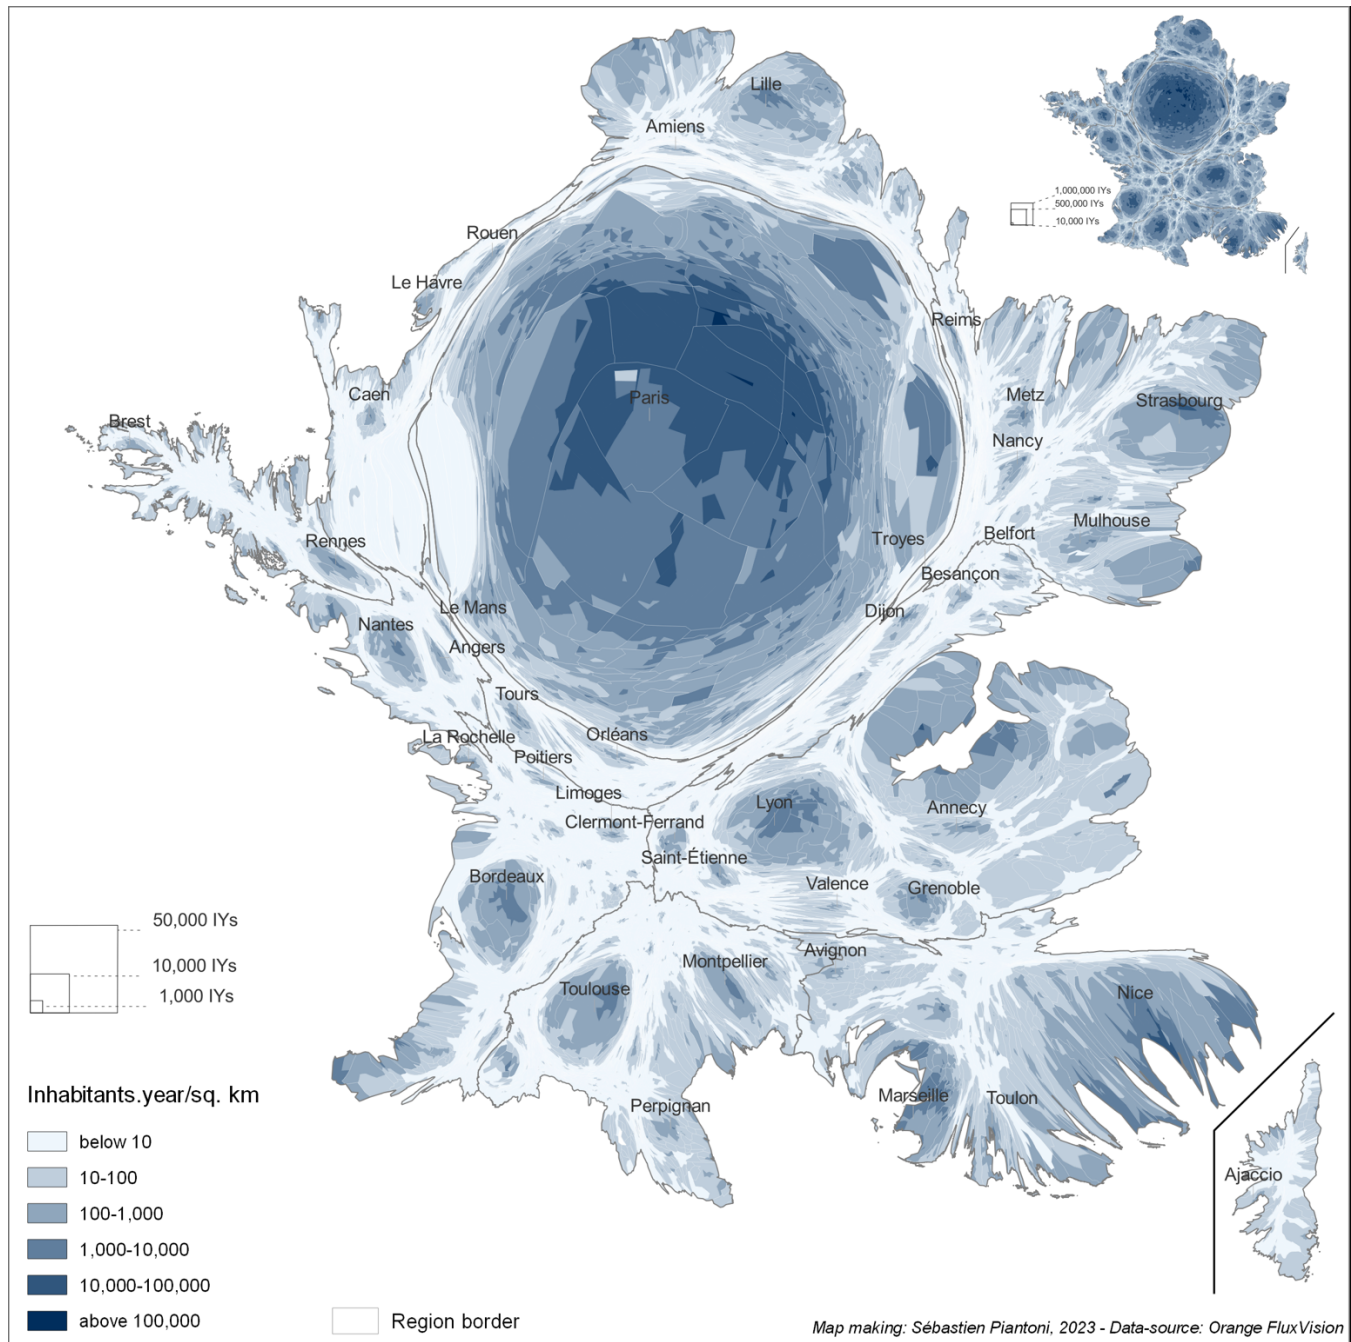

19 Our datasets use a distinction between two types of users, customers of national operators, and customers of foreign
20 operators using roaming services in mainland France. 'Nationals' users are 'French residents', which means they have
21 an address in France. They are either French citizens, or foreigners who live in France. Conversely, some French
22 expatriates who come back for a while in their country of origin appear among the roamers.

23 The 65.1 million 'nationals' that appear in our data are in fact a balance. Surveys (11-13) show that an estimated
24 800,000 French IYs have been traveling abroad or have been border workers during this period. In the opposite
25 direction, there are people not easy to evaluate, probably 100,000 to 300,000 IY, who can be I undocumented migrants
26 who are flying under radars but who are cell-phone users, and II temporary foreign residents (in business stays or in
27 second houses). Those two groups swell the numbers of 'nationals'. Taking into account the difference +800,000 –
28 200,000, we get 65.7 million IY, which is close to the official population of metropolitan France (65.6 to 65.8 million)
29 as estimated in mainland France by the French statistical institute Insee between March 2022 and February 2023.

30 The first big surprise comes from the number of foreign residents present on the French territory, close to 4,977 million
31 IYs, which is much more (at least 2 times more) than the number of IYs estimated from different tourism surveys.
32 According to official data and considering both overnight stays, with paid or free accommodation, and day trips (12,
33 14), a volume of just under 2 million IY is obtained for 2022-2023. How can this substantial difference be explained?
34 We will come back to this question below, but this dramatic difference already shows that another, partly unknown
35 France, is being unveiled thanks to these data.

36 In mainland France, those around 5 million IYs composed of customers of non-French operators provide a good proxy
37 to approach non-resident foreigners. They are composed of visitors performing business travels, cross-border trips, or
38 vacation tourism. In addition, there are also about 5.2 million foreign residents in the same territory, who generate
39 approximately 5.148 million IYs. In total there are $4.977 + 5.148 = 10.125$ million foreigners living in metropolitan
40 France. If the 2.5 million IYs corresponding to current French citizens born foreign nationals (naturalized immigrants)
41 are added, we obtain a total of 12.75 million foreigners or having a foreign origin. They represent 18% of the total
42 population of effective inhabitants. Like its European neighbors, France turns out to be a global place, a concentrate of
43 human globality, where almost one in every five inhabitants brings their share of otherness to the host society.
44

45 **Fig. 9. Density, France, Foreign Visitors (IY) 2022-23, Cartogram.**
 46 **Top right: Density, Inhabitants.year, France, 2022-23, Cartogram.**
 47

Base map: surfaces on the map are proportional to IYs in each of the 48,789 spatial units.

51 This cartogram (Fig. 9) is directly comparable to the general cartogram of IYs (Fig. 2, duplicated, top right). Here, the
 52 base-map shows the specific spatial distribution of the foreign visitors. It clearly demonstrates their extreme
 53 concentration in large cities and tourist areas, especially Paris metropolitan region and in particular its core area.
 54 Counted in IYs, foreign visitor sometimes reach astonishing densities, as on the banks of the Seine, in Marais or in the
 55 Opera district, where they can exceed 100,000 inhabitants/sq. km and in some cases outnumber the French residents.
 56 In about 2,000 spatial units out of the 50,000 that cover the French territory, they exceed 1,000 inhabitants/sq. km,
 57 which can be considered as an urban density threshold. The other major urban areas come next, with an advantage for
 58 those located close to the border, such as Lille and Strasbourg, or Toulouse, which hosts the main Airbus group site in
 59 Europe. The tourist areas are in the lead, with a preeminence of the French Riviera, a region that the French tourists are
 60 tendentially neglecting. Finally, special spots such as mobility hubs, theme parks and even places of pilgrimage (such
 61 as Lourdes) are doing well. This confirms that tourist locations are largely fueled by international attractiveness.

62 In short, foreign visitors alone possess a considerable populating power. Compared to the general map designed in the
63 same way (Fig. 2), the map of foreign visitors overcolors France's spatial contrasts. Lots of people converge to the big
64 cities and tourist places, while, conversely, a large part of the country remains empty.

65 **A Global France**

66 Where do these foreigners come from? Once again, the data surprise us. The Table 1 shows a relationship between
67 France and the rest of the world that is not exactly what we might have expected. The visitors' origins are sorted in
68 descending order of the top 175 countries that send visitors, in proportion to their population and classified by
69 continental block.

70
71 The 2022-3 context in which these data were collected includes two powerful features. On the one hand, the last phase
72 of the CoviD-19 pandemic that kept Asian tourists, especially Chinese, away from Europe. In 2019, before the
73 Pandemic, Chinese tourists were more than two million in France, which means about 30 000 IYs. They disappeared
74 in 2020 and had not yet returned to Europe in early 2023. On the other hand, the war in Ukraine has certainly
75 strengthened in a multidimensional way the links between Eastern and Western Europe, including France. For the same
76 reason, Russia was almost cut off from Europe, hence its degraded rank beyond 100th place.

77 Moreover, the table shows the intense links between metropolitan France and its former colonial empire. Overseas
78 France (particularly Guadeloupe, Martinique, Réunion, and Mayotte) and the former French colonies occupy a
79 prominent place in this ranking.

80 With this in mind, an original configuration of French globality can be observed.

81 The most notable point in this table is the compact score of all European countries. The emergence of the Europe as a
82 consistent space, viewed from France, does not come under the same rationale as for long-term immigration. Some
83 countries very clearly dominate among the origins of foreigners who have settled more permanently in France (15).
84 These locations refer to past (southern Europe, mid and late 20th century) and present (Maghreb and Sub-Saharan
85 Africa, late 20th and early 21st centuries) development differentials between these countries and France. This pattern is
86 not found here. Nor is there any evidence of a tourist 'sunbelt'. Northern or continental Europe is not more attracted to
87 France than Mediterranean Europe.

88 Lastly, there is no clear 'visa effect'. In addition to Europeans, nationals of most of the Americas and developed
89 countries in the Asia-Pacific region are exempt from visa requirements to enter the Schengen area, and therefore France.
90 This does not seem to bring them any additional proximity.

91 The spatial configuration of foreign visitors' locations leads to the assumption that these inhabitants are not so different
92 from French residents. Their motivations appear to be diverse (work, leisure, personal relations), as if Europeans were
93 circulating in their own single country. As a result, a hypothesis can be formulated: Europe operates as an interactive,
94 intertwined space in which each region (in this case the national areas) is of interest to the others for different reasons.
95 In the absence of significant differentiation based on access time between European countries, we can speak of Europe
96 as a place, a space for which internal distances are of little relevance (16).

97 In brief, these data draw a global geography of French visitors' attractiveness. They provide an image of different levels
98 of attractivity of the French territory. They suggest new ways to define a world-scale nearness.

Table 1. Foreign visitors in France: Ranking of the 150 top origin countries, IYs per capita.

RANK REGION	1-25	26-50	51-75	76-100	101-125	126-150
Western Europe	Monaco, Luxembourg, Switzerland, Belgium, Andorra, Spain, Germany, UK, Portugal, Sweden, Malta, Ireland, Italy, Austria	Denmark, Norway, Iceland, Finland

Discussion

A revolution in progress

The results presented in this article are only the first phase of a research project that includes at least five phases. A mobility approach, the construction of a typology of spatial units, the redefinition of relevant urban areas, and the exploration of rhythms (day, week, year) are still in progress. A comparison of pre- and post-Pandemic situations thanks to the processing of two distinct datasets (2019-20 and 2022-3) will allow for the analysis of such a massive, disruptive event. Future data processes of the same dataset will take advantage of contingency tables that provide limited but

11 useful information on personal profiles. All of these ‘worksites’ will be based on the same simple principle: we can
12 know how to connect people and places and explore the richness of what being an inhabitant means.

13 The first results suggest that it is time for a paradigm shift. The quality of data provided by telephone operators can
14 certainly be further improved to reach the same level of reliability as the censuses. The available data already allow for
15 a thorough processing, and this would be even more the case if a dialogue between operators, statistical offices and
16 researchers were to take place.

17 The very principle of censuses – counting people at home as a sufficient proxy to give a reasonably accurate picture of
18 an inhabited space – deserves substantial enrichments. It is time to find out how and where the individuals spend their
19 days, their months, and their years, while obviously respecting their privacy. The use of high quality, comprehensive
20 data to explore effective realities of inhabiting is not only a complement for the classic censuses, but it could also (and
21 probably should) become a solid baseline for all those who are concerned with the spatial dimension of the social world.
22 This quest is no longer a utopia, it becomes a reachable horizon for statistical offices, for scholars, and for the public.

23 **Materials and Methods**

24 **A Fresh Approach to Emerging Data**

25 **A long Tradition: Censuses and an Increasingly Elusive Reality**

26
27 For a long time, knowledge of the relationship between humans and places was based on censuses that relied on the
28 postulate of immobile inhabitants, supposed to stay all the yearlong in their homes. What might have seemed an
29 acceptable approximation in the 19th century gradually became less and less relevant to describe people's actual
30 relationship to places. Statistical data gradually included studies on mobility, yet often restricted to a single, daily trip
31 to a fixed workplace (17). Statistical data are enriched by sample surveys on mobility, but they generally study daily
32 travel and tourism separately. Finally, when they are more comprehensive and include all travel motives, they lack
33 completeness by being reduced to one urban area and they lack precision by dividing the region studied into vast
34 heterogeneous zones.
35
36

37 **State of the art: Promising Answers and Missing Questions**

38
39 After probative initial results in the early 2010s, the use of phone data to approach human presence in a determined
40 area has shown its relevance. Today, the state of the art, to large extent, is about methodological issues, exploring two
41 major issues: I quality and sampling assessment: the reliability and representativeness of phone data in comparison of
42 baseline information of human presence or movement provided by censuses or by mobility surveys (18-25); and II
43 thematic issues at local scale: scholars and experts have used phone data in combination with other baseline datasets to
44 build up a more sophisticated approach to mobility and urban configurations: (26) on large Spanish cities; (27) on
45 Washington, DC; (28) on Seoul; (29) on Helsinki and (30) on Czech mobility) or to the spatial impact of exceptional
46 events, such as the 2020-22 Pandemic (31-32).

47 Data deriving from mobile phone use has become massively available, with rapid changes on their substance and their
48 quality. Phone operators provide ‘events’ (when a phone matches between an antenna), but originally these events were
49 defined by calls, while now any turned-on phone generates usable information. Turned-off phones and non-equipped
50 people are not forgotten anymore thanks to more efficient socio-demographic adjustments. Besides, the location
51 techniques coupling antennas and places are getting very accurate. An alternative method, the collection of GPS-traced
52 activities is another way, very promising too, to locate users.

53 These works are all stimulating. Several studies have focused on the relevance of the data by benchmarking them
54 against the usual statistical sources. The residential population provided by censuses or other pre-existing information
55 are taken as the ground truth. Phone data are then mobilized to measure daily or seasonal variations.

56 This step was undoubtedly necessary. It appears to be insufficient today, because if the aim is to verify that phone data
57 provide the same type of information as the censuses, it is not clear what added value they would have. Furthermore,
58 phone data that are now much more reliable as their providers have learned the various biases that could have
59 undermined research.

60 The current challenge is therefore to design a framework that will make the most of this novel information.

The Datasets

The datasets used in this project were provided by Orange FluxVision, an Orange Business product.

The set provides the number of presences in 48,789 spatial units (French statistical Iris which combine small municipalities and subdivisions of the most populated ones). They host an average of ≈ 1400 inhabitants. In these units, our data measure human presence in each of the 48 30-minute time slots, for 3 types of days in 4 different types of months (February, August, September, and November) in March 2022-February 2023 period for 2 types (French residents and roamers) of users, or 57.6 million elementary information items.

This dataset is totally anonymous. The absence of personal identifiers makes impossible any individual tracking.

Data Adjustment and Relevance

Two types of adjustments have been carried out by Orange Business before the data have been delivered to *La France habitée* taskforce.

1 Coupling antenna-data to spatial units. Matching the antenna network with the spatial units requires specific adjustment work. Orange Business acknowledges in a “*Note méthodologique*” (unpublished, issued on January 14, 2022) the significant probability of false positives and false negatives, especially in low density areas, where the antenna network is also the least dense. In response to this problem, the operator makes adjustments that take into account all the cell phone equipment and telephone traffic in the area concerned. In cooperation with Orange Business, the taskforce made a detailed adjustment to further refine the reliability at the hourly level.

Since these initial discrepancies are random, the distortions remain very limited after adjustment. By making various cross-checks with independent information on the same units (residential population, mobility, activities), we have estimated that significant residual errors could affect $\approx 2\%$ of the units. They confirm Orange Business own estimations. Above all, they do not affect the geographical configuration of IYs, even on a micro scale.

2 Weighting data to curb limits of the datasets. Market-share of the operator (Orange: 35.4% in mainland France), phones off, no-phone people, dual-phone people have been taken into account by the operator in the delivered data.

The potential error estimation is $\leq \pm 1\%$. There is no distortion on the distribution of values in spatial units.

Two complementary treatments have been carried out by *La France habitée* taskforce.

3 Weighting people presence. Using the distinction between the number of people entering a spatial unit and the overall number of those staying in the same unit, we were able to accurately measure the time spent by the persons than have stayed less than 30 minutes. The potential error estimation is $\leq \pm 0.01\%$. There is no distortion on the distribution of values in spatial units.

4 Estimating the actual all-year presence. The different types of days (working days, Saturdays, Sundays) and months have been taken into account to adjust the data. The potential error estimation is $\leq \pm 0.5\%$. There is no distortion on the distribution of values in spatial units.

5 Finally, for privacy reasons, Orange Business deleted information about presences of less than 20 people in a spatial unit in a given time slot. This operation may result in a slight underestimation of the effective population in the micro-units (<100 inhabitants) that host only 0.3% of the country’s population. This bias can therefore be considered negligible.

Asking Questions to the Data

The relative dissatisfaction with pioneer studies stems from the type of questions that have been asked of the data. For our part, we focused on fundamental questions for which these new data could constitute a relevant resource. These questions are the following: How many people *actually* live in the French territory? How are they spatially distributed? How does this new information modify the geography of population: settlement, density, urbanity? How can this study on France help us for comparable approaches applied carried out elsewhere?

A Novel Methodology: IY and A-index

A IY is a full year stay equivalent. The value of IY_i in a determined space is calculated as follows [1]:

[1]

$$IY_i = \sum_{i=1}^n \frac{S30_i}{17520}$$

where $S30_i$ is the number of people that stayed for any of the forty-eight 30-minute time lapses of a day of a determined year in the i spatial unit.

The principle is simple: we add up all the people present in a place of every single half-hour period of a year and we divide the result by the number of half-hours that a year comprises (17520). This allows us to define a population made up of people who, all together, have spent a certain number of years or fractions of a year in this place.

The relation between the number of primary-residents (PR) of a spatial unit i as measured by censuses (33) and their actual inhabitants (IY) can be considered a simple and powerful indicator of the attractiveness of a place. The attractivity index (A-index) is calculated as follows [2]:

$$A_i = 100 \left(\frac{IY_i}{PR_i} \right) \quad [2]$$

The A-index shows for any spatial unit i the propensity of a whole reference population (in our case, global) to be more present in a location than the residents would be if they stayed permanently in that location.

Cartograms

The base map of a Euclidean map is obtained through a homology of angles, lines, and surfaces between the referred reality and its cartographic transformation. In a cartogram, the base map is built up using a series of located data, such as population or any other continuous variable. In this project, the cartograms' base maps are drawn from information provided by the datasets (general population's IYs and foreign visitors' IYs). To create these base maps, the ScapeToad opensource application (<http://scapetoad.choros.place>) has been used. For Fig. 2 and 9, the base map data are the Iris spatial units (48,789). For Fig. 4, 6, and 8, the base map data are French municipalities, *arrondissements*, and *quartiers* (35,048).

61 **The Team**

62 This project is led by *La France Habitée* research taskforce, directed by Jean Coldefy and Jacques Lévy. The group
63 includes Sébastien Piantoni, Julien François, Jorge Cabrera, Marie-Emmanuelle Huilo, and Stéphane Gallardo.

64 The project benefited from the precious support of Boris Beaudé and Ogier Maitre (STS Lab, Lausanne University) for
65 the data preparation and processing.

66 Multiple and fruitful interactions with Kévin Grossetti, from Orange Business, were greatly beneficial to the
67 achievement of the project.
68

69 **Funding**

70 The project was funded by a consortium, created on March 16, 2022, including the following entities:

71 Transcité (NPO);

72 Chôros (non-profit research network);

73 Spatial Intelligence Chair, UPHF (academic research lab);

74 DGITM-MTECT (French ministerial department);

75 La Fabrique de la Cité (NPO).
76
