L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
Simulation of the 3D Radiative Transfer with Anisotropic Scattering for Convective Trails

Olivier Pironneau and Pierre-Henri Tournier

Abstract

In two earlier publications we have proposed a numerical algorithm to solve the RTE in 3D based on an integro-differential formulation and iterations using $\mathcal{H}$-matrices to speed-up the computation of the integrals. In this article we show how the method can be extended to handle an important class of non-isotropic scattering for the atmosphere. An application to the Earth atmosphere is given.

1 Introduction

Airplane combustion engines generate CO$_2$ (carbon dioxide), a gas which stays in the Earth atmosphere for $\sim$ 500 years before being partially absorbed by the oceans.

Currently used fuels and potential future substitutes like hydrogen, synthetic or agricultural fuel combustion generate also NO$_x$ (Nitrous oxides). Typically a nitrous oxide stays in the atmosphere $\sim$ 100 years.

Carbon dioxide, nitrous oxides, methane, ozone and water vapor are "green house gases", (GHG), in the sense that atmospheric and past climates measurements indicate that they are most likely responsible for the additional heat received by Earth (global warming).

Air travel – around 100,000 flights/day – produces 3% of CO$_2$ (or 12% of what is produced by all transport vehicles). It is still small, but the contribution of airplanes to global warming is expected to rise from today’s 0.024W/m$^2$ to 0.084W/m$^2$ by 2050 [13].

A cloud similar to a cirrus, called “contrail (short for condensation trail) may appear in the airplane wake if atmospheric pressure and temperature are on the left side of a threshold curve, and further left of that pressure versus temperature curve the contrail will persist [14]. Several studies claim that these clouds have a warming effect perhaps 3 times stronger than the one caused by the combustion gases [12].

In the past few years the authors have worked to see if these claims could be validated by a numerical simulation of the fundamental equations of physics for these problems [2], [8], [9], [10]. we approach the problem from an applied mathematics point of view, with convergence error estimation and computational efficiency in mind.

The formation of a contrail has been simulated by solving the Navier-Stokes equations (NSE) with chemistry for the engine exhaust and phase change for the ice formation in the airplane wake (see [14]); it is the right approach to understand the mechanisms of the formation of contrails. Once the cloud is sufficiently developed one may study its effect on the absorption and scattering coefficients of the Radiative Transfer Equations (RTE) in the Earth atmosphere (see the data in [6]) and then solve the RTE-NSE system. The numerical simulations of RTE in one dimension is the object of intense research [5], [6], but mostly without coupling with a temperature equation or NSE.

In [7] and [15] we have proposed a numerical algorithm to solve the RTE in 3D based on an integro-differential formulation and iterations using $H$-matrices to speed-up the computation of the integrals. In this article we show how the method can be extended to handle an important class of non-isotropic scattering for the atmosphere.

It is known that the preferred direction of scattering in clouds is the initial direction. It is modelled by an anisotropic probability of scattering (also called phase function) from $\omega$ to $\omega'$, $p_{\nu}(\omega, \omega')$ (see Figure 1).

2 The Radiative Transfer Equations

When molecular viscosity and wind convection are ignored, the temperature $T$ in a medium exposed to electromagnetic waves satisfies the RTE as explained in [16]. It involves a frequency dependent radiation intensity field
Simulation of the 3D Radiative Transfer

This polar plot shows the probability \( p(\theta) \) that a photon in the direction \( \omega \) scatters in the direction \( \omega' \):  

\[
p_{\nu}(\omega,\omega') = 1 + \frac{1}{2}\omega \cdot \omega' = 1 + \beta \cos(\theta)
\]

where \( \theta \) is the angle \((\omega, \omega')\). The solid curve is for \( \beta = \frac{1}{2} \), the dashed curve is for \( \beta = 0.75 \) and the dotted circle is the isotropic case is \( \beta = 0 \).

\[
I_{\nu}(x, \omega) \text{ at position } x \text{ in the physical domain } \Omega \text{ and in each direction } \omega.
\]

For all \( \{x, \omega, \nu\} \in \Omega \times S_2 \times \mathbb{R}^+ \),

\[
\omega \cdot \nabla_x I_{\nu} + \rho\kappa_{\nu} I_{\nu} + \frac{1}{4\pi} \int_{S^2} p_{\nu}(\omega,\omega')I_{\nu}(\omega')d\omega'
= \rho\kappa_{\nu}(1 - a_{\nu})[B_{\nu}(T) - I_{\nu}],
\]

\[
\int_0^{\infty} \int_{S^2} \rho\kappa_{\nu}(1 - a_{\nu})[B_{\nu}(T) - I_{\nu}]d\omega d\nu = 0,
\]

where \( S^2 \) is the unit sphere, \( B_{\nu}(T) = \frac{2\hbar \nu^3}{c^2 [e^{\frac{\hbar \nu}{kT}} - 1]} \) is the Planck function, \( h, c, k \) are the Planck constant, the speed of light in the medium and the Boltzmann constant. The absorption coefficient \( \kappa_{\nu} := \rho\tilde{\kappa}_{\nu} \), where \( \rho \) is the medium density, comes from nuclear physics, but for our purpose it is seen as the percentage of radiation absorbed per unit length. The scattering albedo is \( a_{\nu} \in (0,1) \) and \( p_{\nu}(\omega, \omega') \) is the probability that a ray in direction \( \omega \) scatters in direction \( \omega' \).

With appropriate boundary conditions, existence of solution has been established by [17] and [8]. In the latter, convergence of the following scheme was proved:

\[
\omega \cdot \nabla I_{\nu}^{n+1} + \kappa_{\nu} I_{\nu}^{n+1} = \frac{\kappa_{\nu}}{4\pi} \int_{S^2} p_{\nu}(\omega, \omega')I_{\nu}^{n}(\omega')d\omega' + \kappa_{\nu}(1 - a_{\nu})B_{\nu}(T^n),
\]

\[
\int_0^{\infty} \int_{S^2} \kappa_{\nu}(1 - a_{\nu})[B_{\nu}(T^{n+1}) - I_{\nu}^{n+1}]d\omega d\nu = 0.
\]
By the maximum principle for the first equation and the monotony of $T \mapsto B_\nu(T)$,
\[ I^n < I^{n-1}, \quad T^n < T^{n-1} \implies I^{n+1} < I^n, \quad T^{n+1} < T^n, \]
where $a < b$ means $a(x) \leq b(x)$, for all $x$ but not $a(x) = b(x)$ everywhere. Hence by choosing $T^0 = 0$ and $I^0 = 0$, the positivity of $T^1$ and $I^1$ implies that $T^1 < T^0$, $I^1 < I^0$ so that, by induction, a strictly increasing sequence is obtained. Similarly a decreasing sequence is obtained if we manage $T^1 > T^0$, $I^1 > I^0$. As it was observed in [10] that the increasing sequences converge faster we will focus on that one only.

### 3 Integral Formulation

Consider an anisotropic scattering density
\[ p_\nu(\omega, \omega') = 1 + \beta_\nu \omega \cdot \omega'. \]

Denote by $\Gamma$ the boundary of $\Omega$. One must find the radiation intensity $I_\nu(x, \omega)$ at all points $x \in \Omega$, for all directions $\omega \in S^2$ and all radiation frequencies $\nu \in \mathbb{R}_+$, by solving the radiative transfer equations (RTE):
\begin{align*}
\omega \cdot \nabla_x I_\nu + \kappa_\nu I_\nu &= \kappa_\nu (1 - a_\nu) (B_\nu(T) + \beta_\nu \omega \cdot K_\nu) + \kappa_\nu a_\nu J_\nu, \quad (3) \\
J_\nu(x) &= \frac{1}{4\pi} \int_{S^2} I_\nu d\omega, \quad K_\nu(x) := \frac{1}{4\pi} \int_{S^2} \omega I_\nu(x, \omega) d\omega, \quad (4) \\
\int_0^\infty \kappa_\nu (1 - a_\nu) (J_\nu - B_\nu(T)) d\nu &= 0, \quad (5) \\
I_\nu(x, \omega) &= R_\nu(x, \omega) I_\nu(x, \omega - 2(\text{n} \cdot \omega) \text{n}) + Q_\nu(x, \omega), \\
& \quad \text{on } \Sigma := \{(x, \omega) \in \Gamma \times S^2 : \omega \cdot n(x) < 0\}. \quad (6)
\end{align*}

In (6), $Q_\nu$ is the radiation source and $R_\nu$ is the portion of radiation which is reflected by the boundary; $n(x)$ is the outer normal of $\Gamma$ at $x$, $\kappa_\nu > 0$ and $a_\nu \in [0, 1]$ are the absorption and scattering coefficients; in general they depend on $\nu$ and $x$.

The general solution of (3) is
\[ I(x, \omega) = I(x \in \Sigma(x, \omega), \omega) e^{-\int_0^{\tau_{x, \omega}} \kappa(x - \omega s) ds} + \int_0^{\tau_{x, \omega}} e^{-\int_0^s \kappa(x - \omega t) dt} S_\nu(x - \omega s, \omega) ds, \]

where $\tau_{x, \omega}$ is the length $|x - x \in \Sigma(x, \omega)|$, and $S_\nu$ denotes its right-hand side,
\[ S_\nu(x, \omega) = \kappa_\nu(x)(1 - a_\nu(x)) (B_\nu(T(x)) + \beta_\nu(x) \omega \cdot K_\nu(x)) + \kappa_\nu(x) a_\nu(x) J_\nu(x). \quad (7) \]
3.1 Solution in Absence of Reflective Boundaries

Let us denote \( f_{[x,y]}^\kappa := \int_0^{|y-x|} \kappa(x+s(y-x))ds \). When \( R_\nu = 0 \), the following holds:

**Proposition 1**

\[
J_\nu(x) = S_\nu^E(x) + J[S_\nu](x),
\]

\[
S_\nu^E(x) = \frac{1}{4\pi} \int Q_\nu(y, \frac{y-x}{|y-x|}) \frac{[(y-x) \cdot n(y)]}{|y-x|^3} e^{-f_{[x,y]}^\kappa} d\Gamma(y),
\]

\[
J[S_\nu](x) = \frac{1}{4\pi} \int_\Omega \frac{e^{-f_{[x,y]}^\kappa}}{|y-x|^2} S_\nu(y, \frac{y-x}{|y-x|}) dy.
\]

Averaging (7) on \( S^2 \) after multiplication by \( \omega \) leads to

\[
K_\nu(x) := \frac{1}{4\pi} \int_{S^2} \omega I(x, \omega) d\omega = K_\nu^E(x) + \mathcal{K}[S_\nu](x) \quad \text{with}
\]

\[
K_\nu^E(x) := \frac{1}{4\pi} \int_{S^2} \omega I(x, \omega, \omega) e^{-f_{0}^\kappa \omega \cdot (x-\omega s)} ds d\omega
\]

\[
= \frac{1}{4\pi} \int_\Omega (y-x)Q_\nu(y, \frac{y-x}{|y-x|}) \frac{[(y-x) \cdot n(y)]}{|y-x|^3} e^{-f_{[x,y]}^\kappa} d\Gamma(y),
\]

\[
\mathcal{K}[S_\nu](x) := \frac{1}{4\pi} \int_{S^2} \int_0^{f_{0}^\kappa \omega \cdot (x-\omega s')} ds' S_\nu(x-\omega s, \omega) ds d\omega
\]

\[
= \frac{1}{4\pi} \int_\Omega (y-x)S_\nu(y, \frac{y-x}{|y-x|}) e^{-f_{[x,y]}^\kappa} dy.
\]

3.2 Iterative Method

In [7] it was shown that, in absence of \( K_\nu \), i.e. \( \beta_\nu = 0 \), the following is monotone and convergent. Its extension to \( \beta_\nu > 0 \) is:

**Algorithm**

1. Initialize \( J_\nu, K_\nu \) and \( T \) (by zero, for instance).
2. Compute \( S_\nu \) by (7).
3. Update \( J_\nu \) by (11), (9), (10) and \( K_\nu \) by (11).
4. Update \( T \) by solving (5).
4 Extension to Reflective Conditions (RC)

As in [15], consider boundary condition (6). Proposition 1 can be extended to case with RC and in the case of non-multiple reflection, it becomes:

**Proposition 2** The same iterations are proposed with

\[
J_{\nu}(x) = S_{\nu,1}^{E}(x) + S_{\nu,2}^{E}(x) + \bar{J}[S_{\nu}](x), \quad K_{\nu}(x) = K_{\nu,1}^{E}(x) + K_{\nu,2}^{E}(x) + \bar{K}[S_{\nu}](x),
\]

\[
S_{\nu,1}^{E}(x) = \frac{1}{4\pi} \int_{\Gamma} Q_{\nu}(y, \frac{y-x}{|y-x|}) \left( \frac{(y-x) \cdot n(y)}{|y-x|^3} - e^{-J_{[x,y]}} \right) d\Gamma(y),
\]

\[
S_{\nu,2}^{E}(x) = \sum_{n=1}^{M} \frac{1}{4\pi} \int_{\Gamma} R_{\nu}(x''_{n}, \frac{x''_{n}-x}{|x''_{n}-x|}) Q_{\nu}(y, \frac{x''_{n}-y}{|x''_{n}-y|})
\]

\[
\times \left( \frac{(x''_{n}-y) \cdot n(y)}{|x''_{n}-y|} - e^{-J_{[x,y]}} \right) d\Gamma(y),
\]

\[
\bar{J}[S_{\nu}](x) = \frac{1}{4\pi} \int_{\Omega} \left[ \frac{e^{-J_{[x,y]}}}{|y-x|^2} R_{\nu}(x''_{n}, \frac{x''_{n}-x}{|x''_{n}-x|}) \right] S_{\nu}(y, \frac{y-x}{|y-x|}) dy.
\]

\[
K_{\nu,1}^{E}(x) = \frac{1}{4\pi} \int_{\Gamma} (y-x) Q_{\nu}(y, \frac{y-x}{|y-x|}) \left( \frac{(y-x) \cdot n(y)}{|y-x|^3} - e^{-J_{[x,y]}} \right) d\Gamma(y),
\]

\[
K_{\nu,2}^{E}(x) = \sum_{n=1}^{M} \frac{1}{4\pi} \int_{\Gamma} (x-x'_{n}) R_{\nu}(x'', \frac{x''_{n}-x}{|x''_{n}-x|}) Q_{\nu}(y, \frac{x''_{n}-y}{|x''_{n}-y|})
\]

\[
\times \left( \frac{(x''_{n}-y) \cdot n(y)}{|x''_{n}-y|} - e^{-J_{[x,y]}} \right) d\Gamma(y),
\]

\[
\bar{K}[S_{\nu}](x) = \frac{1}{4\pi} \int_{\Omega} \left[ \frac{y-x}{|y-x|^3} e^{-J_{[x,y]}} \right]
\]

\[
+ \sum_{n=1}^{M} (x-x'_{n}) R_{\nu}(x'', \frac{x''_{n}-x}{|x''_{n}-x|}) S_{\nu}(y, \frac{y-x}{|y-x|}) dy.
\]

where \( M \) is the number of RC boundaries and \( x''_{n} \) is the point of reflection on the boundary of the ray going from \( x \) to \( y \) via \( x'_{n} \).

All equations are discretized using a \( P^1 \) finite element framework. Some integrals have a singular kernel, so a careful quadrature should be used.

In [7], [15] a strategy is explained to compute all the integrals as a matrix vector product where the matrices are hierarchical compressed \( \mathcal{H} \)-matrices [3],[4],[11].
In the grey case ($\kappa_\nu$ independent of $\nu$) we need $5+M$ matrices. This could be taxing in computer memory, but not in computing time because the core of the method is $N \ln N$ where $N$ is the number of finite element vertices.

In the non grey case we need $P(5+M)$ matrices where $P$ is the number of values taken by the numerical approximation of $\kappa_\nu$.

5 The Stratified One Dimensional Approximation

Let us consider the Earth’s atmosphere submitted to black body radiations from the sun at temperature $T_S$ and earth at $T_E$. The atmosphere is thin and the Sun is far. As a first approximation the ground is locally flat and has a negligible relief. Then all quantities are only function of the altitude $z$ and independent of $x$ and $y$. This, so called, stratified approximation of the RTE is (see [2])

\[
(\mu \partial_{\tau} + \kappa_\nu)I_\nu(\tau, \mu) = \kappa_\nu(1 - a_\nu)B_\nu(T(\tau)) + \frac{1}{2}\kappa_\nu a_\nu \int_{-1}^{1} p_\nu(\mu, \mu')I_\nu(\tau, \mu')d\mu',
\]

\[
I_\nu(0, \mu) = r_\nu I(0, -\mu) + \mu Q^+_\nu, \quad I_\nu(Z, -\mu) = \mu Q^-_\nu, \quad 0 < \mu < 1,
\]

\[
\int_{0}^{\infty} \kappa_\nu(1 - a_\nu)B_\nu(T(\tau))d\nu = \int_{0}^{\infty} \kappa_\nu(1 - a_\nu)J_\nu(\tau)d\nu,
\]
with

\[ Q^+_\nu = Q^E B_\nu (T_E), \quad Q^-_\nu = Q^S B_\nu (T_S), \quad J_\nu (\tau) := \frac{1}{2} \int_{-1}^{1} I_\nu (\tau, \mu) d\mu, \quad (18) \]

where \( \mu \) is the cosine of \( \omega \) with the vertical direction and \( \tau \) is the optical thickness:

\[ \tau = \int_{0}^{z} \rho(z') dz'. \]

5.1 RTE with Non-Isotropic and Rayleigh Phase Function

The scattering function is \( p_\nu (\mu, \mu') = 1 + \beta_\nu \mu' \) in a cloud between altitude \( Z_m \) and \( Z_M \) and at high altitude \( z > Z_M \) it is the Rayleigh phase function \( p_\nu (\mu, \mu') = \frac{3}{16} (3 - \mu^2) + \frac{3}{16} (3 \mu^2 - 1) \mu'^2 \). It is combined into one formula with two given altitudes and possibly frequency dependent functions \( b_\nu (\tau) \) and \( \beta_\nu (\tau) \) in \([0, 1]\),

\[ p_\nu (\mu, \mu') = b_\nu + \beta_\nu \mu' + \frac{3}{16} (1 - b_\nu) (3 - \mu^2 + (3 \mu^2 - 1) \mu'^2). \quad (19) \]

Observe that \( p_\nu (\mu, \mu') \geq 0 \) and \( \frac{1}{2} \int_{-1}^{1} p_\nu (\mu, \mu') d\mu' = 1 \). Keeping (17) as the defining equation for \( T_\nu \), given \( I_\nu \), the problem becomes

\[
\begin{cases}
(\mu \partial_\tau + \kappa_\nu) I_\nu (\tau, \mu) = S_\nu (\tau) := R_\nu (\tau) + P_\nu (\tau) \mu^2, \\
I_\nu (0, \mu) = r_\nu I (0, -\mu) + \mu Q^+_\nu, \quad I_\nu (Z, -\mu) = \mu Q^-_\nu, \quad 0 < \mu < 1,
\end{cases}
\quad (20)
\]

with

\[ K_\nu (\tau) := \frac{1}{2} \int_{-1}^{1} \mu I_\nu (\tau, \mu) d\mu, \quad L_\nu (\tau) = \frac{1}{2} \int_{-1}^{1} \mu^2 I_\nu d\mu, \]

\[ R_\nu (\tau) := \kappa_\nu a_\nu (\frac{7}{16} b + \frac{9}{16}) J_\nu (\tau) + \beta K_\nu (\tau) - \frac{3}{16} (1 - b) L_\nu (\tau) + \kappa_\nu (1 - a_\nu) B_\nu (T(\tau)) + \kappa_\nu (1 - a_\nu) B_\nu (T(\tau)), \]

\[ P_\nu (\tau) := \frac{3}{16} (1 - b) (-J_\nu (\tau) + 3 L_\nu (\tau)) \quad (21) \]

and (17).

Algorithm

1. Initialize \( J^n_\nu (\tau, \mu) = 0, \quad K^n_\nu (\tau, \mu) = 0, \quad L^n_\nu (\tau, \mu) = 0 \) and \( T^0 (\tau) = 0 \).
2. Compute \( T^{n+1} \) by (20) with \( S^n_\nu \).
3. Update \( J^{n+1}_\nu (\tau, \mu), \quad K^{n+1}_\nu (\tau, \mu), \quad L^{n+1}_\nu (\tau, \mu) \) by (21), then \( R_\nu (\tau) \) and \( P_\nu (\tau) \).
4. Then, compute \( T^{n+1} \) by solving (17).
5.2 Implementation

Recall the definition of the exponential integrals

\[ E_p(X) := \int_0^1 e^{-X/\mu} \mu^{p-2} d\mu, \quad X > 0. \] (22)

For \( i = 3, 4, 5 \), let

\[ S_i(\nu, \tau) := \frac{1}{2} E_i(\kappa_\nu \tau) Q^+(\tau) + \left( \frac{-1}{2} \right)^{i-1} (E_i(\kappa_\nu (Z - \tau)) + r_\nu E_i(\kappa_\nu (Z + \tau))) Q^-(\tau), \]
\[ F_i(\tau, t) := \frac{1}{2} E_3(\kappa_\nu |\tau - t|) + \frac{1}{2} E_3(\kappa_\nu |\tau + t|). \] (23)

**Proposition 3** With (21) and (23) the quantities needed by the algorithm above are given by

\[ J_{\nu}^{n+1}(\tau) = S_3(\nu, \tau) + \frac{1}{2} \int_0^Z F_3(\tau, t) P_{\nu}^n(t) dt + \frac{1}{2} \int_0^Z F_3(\tau, t) P_{\nu}^n(t) dt, \]
\[ K_{\nu}^{n+1}(\tau) = S_4(\nu, \tau) + \frac{1}{2} \int_0^Z F_2(\tau, t) R_{\nu}^n(t) dt + \frac{1}{2} \int_0^Z F_4(\tau, t) P_{\nu}^n(t) dt \]
\[ - \frac{1}{2} \int_\tau^Z F_2(\tau, t) R_{\nu}^n(t) dt - \frac{1}{2} \int_\tau^Z F_4(\tau, t) P_{\nu}^n(t) dt, \] (24)
\[ L_{\nu}^{n+1}(\tau) = S_5(\nu, \tau) + \frac{1}{2} \int_0^Z F_3(\tau, t) R_{\nu}^n(t) dt + \frac{1}{2} \int_0^Z F_5(\tau, t) P_{\nu}^n(t) dt. \]

**Proof** For clarity let us assume that \( r_\nu = 0 \). For the general case see [9]. Applying the method of characteristics shows that

\[ I_{\nu}(\tau, \mu) = \mu e^{-\frac{\nu_\tau}{\mu} Q^+(\mu > 0) + |\mu| e^{-\frac{\nu_{(Z - \tau)}}{|\mu|}} Q^-(\mu < 0)} + 1_{\mu > 0} \int_0^\tau e^{-\frac{\nu_{(\tau - t)}}{\mu}} \frac{\nu_\tau}{\mu} S_{\nu}(t) dt + 1_{\mu < 0} \int_\tau^Z e^{-\frac{\nu_{(t - \tau)}}{|\mu|}} \frac{\nu_\tau}{|\mu|} S_{\nu}(t) dt. \] (25)

Therefore with \( k = 0 \) or \( k = 2 \),
\[
\int_{-1}^{1} \mu^k I_{\nu}(\tau, \mu) \, d\mu = \int_{-1}^{1} |\mu|^{k+1} \left( e^{-\frac{\nu_\tau \mu}{\nu} Q_\nu^+ 1_{\mu>0}} + e^{-\frac{\nu_\tau (\tau-\tau)}{\nu} Q_\nu^- 1_{\mu<0}} \right) d\mu \\
+ \int_{-1}^{1} |\mu|^{k-1} \left( 1_{\mu>0} \int_0^\tau e^{-\frac{\nu_\tau (\tau-t)}{\nu} \kappa_\nu S_\nu(t) \, dt} + 1_{\mu<0} \int_\tau^Z e^{-\frac{\nu_\tau (\tau-t)}{\nu} \kappa_\nu S_\nu(t) \, dt} \right) d\mu \\
= \int_{0}^{1} |\mu|^{k+1} e^{-\frac{\nu_\tau \mu}{\nu} Q_\nu^+} d\mu + \int_{-1}^{0} |\mu|^{k+1} e^{-\frac{\nu_\tau (\tau-\tau)}{\nu} Q_\nu^-} d\mu \\
+ \int_{0}^{\tau} \int_{0}^{1} \left( e^{-\frac{\nu_\tau (\tau-t)}{\nu} \kappa_\nu S_\nu(t) \, dt} + \int_{-1}^{0} |\mu|^{k-1} \left( e^{-\frac{\nu_\tau (\tau-t)}{\nu} \kappa_\nu S_\nu(t) \, dt} \right) d\mu \\
= \int_{0}^{1} \left( e^{-\frac{\nu_\tau \mu}{\nu} Q_\nu^+} + e^{-\frac{\nu_\tau (\tau-\tau)}{\nu} Q_\nu^-} \right) d\mu \\
+ \int_{0}^{\tau} \int_{0}^{1} e^{-\frac{\nu_\tau (\tau-t)}{\nu} \kappa_\nu S_\nu(t) \, dt} + \int_{-1}^{0} \left( e^{-\frac{\nu_\tau (\tau-t)}{\nu} \kappa_\nu S_\nu(t) \, dt} \right) d\mu \\
= E_{k+3}(\kappa_\nu \tau) Q_\nu^+ + E_{k+3}(\kappa_\nu (Z-\tau)) Q^- \\
+ \int_{0}^{\tau} E_{k+1}(\kappa_\nu (\tau - t)) R_\nu(t) \, dt + \int_{\tau}^{Z} E_{k+1}(\kappa_\nu (t - \tau)) R_\nu(t) \, dt \\
+ \int_{0}^{\tau} E_{k+3}(\kappa_\nu (\tau - t)) P_\nu(t) \, dt + \int_{\tau}^{Z} E_{k+3}(\kappa_\nu (t - \tau)) P_\nu(t) \, dt.
\]

(26)

For \( k = 1 \), the same computation gives

\[
\int_{-1}^{1} \mu I_{\nu}(\tau, \mu) \, d\mu = \int_{-1}^{1} \mu^2 \left( e^{-\frac{\nu_\tau \mu}{\nu} Q_\nu^+ 1_{\mu>0}} - e^{-\frac{\nu_\tau (\tau-\tau)}{\nu} Q_\nu^- 1_{\mu<0}} \right) d\mu \\
+ \int_{-1}^{1} \left( 1_{\mu>0} \int_0^\tau e^{-\frac{\nu_\tau (\tau-t)}{\nu} \kappa_\nu S_\nu(t) \, dt} - 1_{\mu<0} \int_\tau^Z e^{-\frac{\nu_\tau (\tau-t)}{\nu} \kappa_\nu S_\nu(t) \, dt} \right) d\mu \\
= \int_{0}^{1} \mu^2 e^{-\frac{\nu_\tau \mu}{\nu} Q_\nu^+} d\mu - \int_{-1}^{0} \mu^2 e^{-\frac{\nu_\tau (\tau-\tau)}{\nu} Q_\nu^-} d\mu \\
+ \int_{0}^{\tau} \int_{0}^{1} e^{-\frac{\nu_\tau (\tau-t)}{\nu} \kappa_\nu S_\nu(t) \, dt} - \int_{-1}^{0} \int_{\tau}^{Z} e^{-\frac{\nu_\tau (\tau-t)}{\nu} \kappa_\nu S_\nu(t) \, dt} d\mu \\
(27)
\]
\[\begin{align*}

\end{align*}\]

\[\square\]

5.3 Numerical Simulations

At the top of the atmosphere, we are told, the solar radiation intensity is 340W/m² but the atmosphere reflects 30% of it and our RTE does not handle volumic reflection. At 10 or 12km the sunlight is diffused, so we apply an intensity proportional to \( \omega^3 \). Paris being at latitude 45°, the radiation is divided by \( \sqrt{2} \). Hence an effective number is \( Q_{\text{sun}} = 162 \text{W/m}^2 \). And yet a good portion is spent for the evaporation of water and into convection. Arbitrarily we keep only half \( 80 \text{W/m}^2 \).

Recall the scalings defined in [10]. The frequencies and the temperatures are scaled as follows (primes label scaled variables),

\[\nu' = 10^{-14} \nu, \quad T' = 10^{-14} \frac{k}{h} T = 10^{-14} \frac{1.381 \cdot 10^{-23}}{6.626 \cdot 10^{-34}} T = \frac{T}{4798}.\]

Planck’s function is written as

\[B_0 \frac{\nu'^3}{e^{\nu'/T'} - 1}, \quad \text{with } B_0 = \frac{2h}{e^2} 10^{42} = \frac{2 \times 6.626 \cdot 10^{-34}}{2.998^2 \cdot 10^{16}} 10^{42} = 1.4744 \cdot 10^{-8}.\]

Consequently the computed intensity, \( I'_{\nu'}, \) is the physical intensity divided by \( B_0 \). The scaled Sun temperature is \( T'_S = 5800/4798 = 1.209 \). According to (18),

\[\int_0^\infty Q^+_{\nu'} = 80 = Q^S \int_0^\infty B_0 \frac{\nu'^3}{e^{\nu'/T'} - 1} (10^{14} d\nu') = Q^S 1.4744 \cdot 10^6 \frac{\pi^4}{15} 1.209^4.\]
This leads to $Q^S = 4 \cdot 10^{-6}$.

Similarly Earth is at $T'_E = 288/4798 = 0.06$ and emits about 350W/m$^2$, but some is used for the evaporation of water so we have kept only 300W/m$^2$:

$$300 = Q^E \int_0^{\infty} B_0 \frac{\nu^3}{e^{T'_E} - 1} (10^{14} d\nu') = Q^E 1.4744 \cdot 10^6 \frac{\pi^4}{15} 0.06^4 = Q^E 124.3.$$ 

This leads to $Q^E = 2.41$.

The air density is $1 - \frac{3}{4}z$. The earth reflective albedo is set at $r_\nu = 0.3$. Isotropic scattering is set at $a_\nu = 0.3$.

$\kappa_\nu$ is given by the Gemini experimental program. To measure the temperature perturbation due to an increase of $CO_2$ (resp $NO_x$)in the atmosphere, we set $\kappa_\nu = 1$ in the range $(3/16, 3/14)$ (resp. $(3/7, 3/5)$).

### 5.3.1 Isotropic Scattering

Two tests were performed with the stratified 1D approximation, isotropic scattering, no cloud and Gemini $\kappa_\nu +$ Rayleigh scattering equal to 0.3 for $\nu > 3$ and $\tau > 0.7$. One computation is with an infrared source $Q^E$ at $\tau = 0$ only (similar to the situation at night) and another with a sunlight source $Q^S$ at $\tau = Z$ only.

Results are on Figures 3, 4. Computations are done with 3 different atmospheres. One is conform to the Gemini measurements, the other two imitate an addition of $CO_2$ or methane.

One can observe a small additional greenhouse effect due to addition of $CO_2$ but a cooling effect at high altitude. The opposite is observed for addition of $NO_x$.

*Fig. 3* Temperature $T$ versus altitude $z$ for 3 values of $\nu \mapsto \kappa_\nu$. Only the earth radiation is taken as a source. (night time).

![Fig. 4](image2.png)  
*Fig. 4* $T$ vs $z$ for 3 values of $\nu \mapsto \kappa_\nu$. Only the Sun radiation is taken as a source.
5.3.2 Anisotropic Scattering in a Cloud

Next, still with the stratified approximation, a cloud is added between altitude \( Z_m = 7000 \text{m} \) and \( Z_M = 9000 \text{m} \) with anisotropic scattering coefficient \( \beta = \frac{a_\nu}{2}, \ b = 1, \ a_\nu = 0.3 \left( \frac{Z_M - Z_m}{Z_M - Z_m + (Z_M - z)^+ (Z_M - z)^+} \right) \). Above \( Z_M \) Rayleigh scattering \( 0.31_{\nu > 3} \), replaces the anisotropic scattering.

Results are shown on Figure 5, 6 and 7. The strong effect of the cloud is shown on Figure 6. Figure 7 shows how important it is to take all the details of \( \kappa_\nu \) into account.

---

**Fig. 5** \( T \) versus \( z \) computed with a cloud

**Fig. 6** Difference \( T_{\text{no cloud}} - T_{\text{cloud}} \)

**Fig. 7** Radiative intensity \( J_\nu(Z) \) versus \( \nu \) for the 3 \( \nu \to \kappa_\nu \) cases.
Finally, in Table 1 total radiative intensities $\int_0^\infty J_\nu(\tau)$ are shown at $\tau = 0$ and $\tau = Z$ in a variety of situations to see the effect of clouds, scattering, earth albedo.

**Table 1** Radiative intensities for the Earth radiations + Sunlight (first 2 rows) and the Sunlight only (last 2 rows) when all terms are present and when one of the terms is removed.

In the presence of CO$_2$ the total radiative energy at ground level (resp. $\tau = Z$), is 9.91316 (resp. 5.72292). With NO$_x$ it is 9.55564 (resp. 5.8434). These numbers must be compared with the first number on the left in the first (resp 2nd) row in Table 1.

**Fig. 8** $T$ versus $z$ computed with a cloud with anisotropic scattering of coefficient $\beta$.

6 A 3D formulation with a Stratified Part

To implement in 3D the Earth albedo (reflective condition by the ground) in all generality is quite complicated. To simplify the computation we consider the reflection of the sunlight only and we use the linearity, with respect to the sources, of the equation for $I_\nu$, for a fixed temperature field.
For a portion \( \Omega \) of atmosphere between the ground \( g = (x_1, x_2, x_3 = g(x_1, x_2)) \), \( g \geq 0 \), and the lower stratosphere \( x_3 = Z \), consider

\[
\omega \cdot \nabla I_\nu + \rho \kappa \alpha I_\nu \left[ I_\nu - \frac{1}{4\pi} \int_{S^2} \rho_\nu(\omega, \omega') I_\nu(\omega')d\omega' \right] = \rho \kappa (1 - \alpha) [B_\nu(T) - I_\nu],
\]

\( I_\nu|_{g, \omega \cdot n < 0} = Q^E(\omega \cdot n) - B_\nu(T_E), \quad I_\nu|_{Z, \omega Z < 0} = Q^S \omega^3 B_\nu(T_S). \)

The solution is \( I_\nu = I^E_\nu + I^S_\nu \) with \( I^E_\nu \) computed with the condition \( I^E_\nu|_{g} \) only and the source term in \( T \), and \( I^S_\nu \) computed with \( I^S_\nu|_{Z} \) only and \( T = 0 \):

\[
\left\{ \begin{array}{l}
\omega \cdot \nabla I^S_\nu + \rho \kappa \alpha I^S_\nu \left[ I^S_\nu - \frac{1}{4\pi} \int_{S^2} \rho_\nu(\omega, \omega') I^S_\nu(\omega')d\omega' \right] + \rho \kappa (1 - \alpha) I^S_\nu = 0, \\
I^S_\nu|_{Z, \omega Z < 0} = Q^S \omega^3 B_\nu(T_S), \\
I^S_\nu|_{0, \omega Z > 0} = 0,
\end{array} \right.
\]

\[
\left\{ \begin{array}{l}
\omega \cdot \nabla I^E_\nu + \rho \kappa \alpha I^E_\nu \left[ I^E_\nu - \frac{1}{4\pi} \int_{S^2} \rho_\nu(\omega, \omega') I^E_\nu(\omega')d\omega' \right] = \rho \kappa (1 - \alpha) [B_\nu(T) - I^E_\nu], \\
I^E_\nu|_{g, \omega \cdot n < 0} = Q^E(\omega \cdot n) - B_\nu(T_E) - I^E_\nu|_{g, \omega \cdot n < 0} = 0.
\end{array} \right.
\]

For \( I^S_\nu \) the stratified approximation is justified. Furthermore, it can be precomputed beforehand.

To account for the fact that a fraction \( r_\nu(x) \) of the sunlight is reflected by the Earth surface, we consider a partial reflective condition

\( I^E_\nu|_{g, \omega \cdot n < 0} = -I^S_\nu|_{g, \omega + Q^E(\omega \cdot n) - B_\nu(T_E) + r_\nu(g) I^S_\nu|_{g, \omega - 2(\omega \cdot n)n} \),

but \( I^S_\nu|_{g, \omega} \approx 0 \) when \( \omega \cdot n < 0 \), so, neglecting scattering, \( a_\nu = 0 \) (see also [1])

\[
I^S_\nu(x, \omega) = \omega^3 Q^S B_\nu(T_S) e^{-\frac{x - r(\nu) \beta \omega Z}{\omega^3}}.
\]

Therefore, with \( \omega \cdot n < 0 \) and \( x \) on the ground,

\[
-I^S_\nu|_{g, \omega} + r_\nu(x) I^S_\nu|_{g, \omega - 2(\omega \cdot n)n} = (\omega^3 - 2(\omega \cdot n)n_3) Q^S B_\nu(T_S) r_\nu(g) e^{-\frac{x + \beta \omega Z}{\omega^3 - 2(\omega \cdot n)n_3}},
\]

\( \beta = 0 \).
All 4 vertical boundaries which limit the domain $\Omega$ are reflective. Results are shown on Figures 9 and 10.

![Graph](image)

**Fig. 9** Temperature above the city of Chamonix versus altitude in a grey case. The growth of $T$ from the ground up is partially due to quadrature errors, partially to the parabolic effect of mountains.

**Conclusion**

The integro-differential formulation of the RTE and its solution by iterations on the source has been extended here to handle anisotropic scattering.

The iterative part of the method is $O(N \ln N)$, thanks to an efficient use of $H$-matrices.

The precision is good enough to evaluate the effect of sensitive parameters for the study of contrails. Most of the time the stratified 1D approximation should suffice, but in complex cases with high relief the 3D formulation is needed.
