Abstract

In this paper, we report a simple, facile, and efficient method to obtain LiNbO₃/Au and LiNbO₃/Pt nanoparticles composed of LiNbO₃ NPs (LN NPs) (30 nm) and ultras-small nanoparticles (< 5 nm, seeds) of Au and Pt, respectively. The synthesis of the nanocomposites followed a simple layer-by-layer method introducing branched polyethyleneimine (BPEI) as a linker. By varying the volume of metal seeds dispersion added to the LN coated with BPEI, the loading of metal on the surface of the LN is controlled. The morphology of the as-prepared composite is characterized by TEM, EDS and DLS. Its applicability as peroxidase-mimics is investigated and compared to the separated counterparts (LN NPs, LN@BPEI, AuSeeds, PtSeeds and a simple mixture of LN NPs and metal seeds). The synthesized nanoparticles follow the Michaelis-Menten kinetic model with enhanced catalytic activity compared to the metal seeds alone. This intrinsic peroxidase activity

1

1 Introduction

The ability of certain inorganic nanoparticles to catalyze reactions that are typically driven by natural enzymes has seen the emergence of a new field called nanozymes.¹ To date, a range of nanoparticles with different compositions including metals, metal oxides, metal sulfides etc. have been reported for their potential to catalyze reactions that mimic the activity of peroxidase, oxidase, catalase, superoxide dismutase, glycosidase, protease, phosphatase, phosphodiesterase, and laccase.² Further, tunability of the nanozyme activity has also been achieved by modifying the properties of the nanoparticles (size, shape, composition), reaction conditions (pH, temperature, concentration of nanoparticles and/or substrates), and use of external stimuli (light or magnetism). Although the field of nanozymes is relatively new, most reports, until recently, focused on employing monometallic nanoparticles as nanozymes.^{3,4} Recent studies have outlined the importance of combining two nanoparticles to create bimetallic nanozymes that show unique properties due to the synergetic effect that is otherwise not observed in the monometallic nanozymes.⁵ For instance, hybrids of Cu-Pt and Cu-Pd showed the ability to drive the oxidation of 3,3',5,5'-tetramethylbenzidine (TMB), a common peroxidase enzyme substrate, to form a yellow colored diimine derivative product.⁶ This was interesting as nanozymes are typically only

1
2
3 capable of oxidizing TMB to form a blue charge transfer complex product. Other examples have
4
5
6 also reported increased H_2O_2 reduction current when employing Au- Fe_3O_4 heterodimers compared
7
8
9 to Au or Fe_3O_4 .⁷ Similarly, PtPd- Fe_3O_4 hybrids show superior catalytic activity when compared to
10
11
12 horseradish peroxidase (HRP).⁵ Based on these studies, it is clear that to obtain interesting
13
14
15 properties and achieve superior catalytic activities, it is critical to choose the right combination of
16
17
18 materials.
19
20
21
22

23 To this end, LiNbO_3 (LN) is an interesting material as it has a non-centrosymmetric structure
24
25
26 that confers outstanding nonlinear optics, pyroelectric and piezoelectric properties, making it ideal
27
28
29 for numerous applications in optics, batteries and optical communications.⁸⁻¹⁰ At the nanoscale,
30
31
32 LN NPs present low toxicity and lack phase-matching conditions, making them an excellent
33
34
35 candidates for bio-imaging and photo-triggered drug delivery.^{11,12} Other features include its
36
37
38 semiconducting and ferroelectric properties that enhance catalysis and photocatalysis, especially
39
40
41 in redox reactions. These properties favour charge separation and polarization-induced facile
42
43
44 adsorption.¹³ For instance, illuminating LN with UV light ($\lambda < 333$ nm) produces electrons and
45
46
47 holes favouring the production of hydroxyl and superoxide anion radicals, leading to the oxidation
48
49
50 of organic compounds.¹⁴ Although the presence of oxygen vacancies is anecdotic, preferential
51
52
53
54
55
56
57
58
59
60

1
2
3 oxygen fixation occurs in positively polarized regions on the LN surface.^{15,16} To date, LN has been
4
5
6
7 combined with natural enzymes such as glucose oxidase to develop sensors.¹⁷ To our best
8
9
10 knowledge, there are no studies that have combined LN with nanozymes to create a hybrid system.

11
12
13 In the current work, we focus our effort to create LN NPs coated with AuSeeds (< 5 nm) and
14
15
16
17 PtSeeds (< 5 nm) with fine control over the surface coverage of the metal seeds by exploiting
18
19
20 electrostatic forces. The addition of noble metal seeds on LN using a simple layer-by-layer
21
22
23 approach to create LN/Au and LN/Pt hybrid nanoparticles would allow for improving the weak
24
25
26
27 electronic mobility in LN thereby making redox reactions favourable, which is otherwise not
28
29
30 favoured.¹⁷ The hybrids showed the ability to oxidize common peroxidase substrates in the
31
32
33 presence of H₂O₂ as a co-substrate suggesting that both nanozymes show peroxidase-mimic
34
35
36
37 catalytic activity. In depth analysis of the peroxidase mimics showed that the interface formed as
38
39
40 a result of the chemical link created by BPEI between the LN NPs and the AuSeeds or PtSeeds is
41
42
43
44 critical to enhance the catalytic activity. The scope of this study is to investigate the synergetic
45
46
47
48 enhancement in the peroxidase-mimic activity due to the metal/metal oxide interface. Although
49
50
51 this paper is not focused on a specific application, we believe that these hybrid nanoparticles may
52
53
54 be suitable for a variety of biological functions, including biosensing, antimicrobial and cancer

1
2
3
4 therapy, protection against cell damage or reduction of inflammation for which peroxidase-mimic
5
6
7 nanozymes have been found useful.³ Some potential applications are thus detailed at the end of the
8
9
10 paper.

14 2 Experimental Section

27 **Scheme 1.** Layer-by-layer synthesis method for LN/Au and LN/Pt hybrid NPs.

31
32 A detailed list of materials and methods is given in the Supplementary Material (SI). LiNbO₃
33
34
35 NPs (LN NPs) were synthesized by non-aqueous solvothermal alkoxide process, as previously
36
37
38 described.¹⁸ The obtained LN NPs were dried and redispersed in water. Subsequently, the hybrid
39
40
41 nanoparticles of LN NPs and metal seeds were assembled through electrostatic interactions, as we
42
43
44 previously described (**Scheme 1**).¹⁹ In brief, branched polyethylenimine (BPEI) was attached to
45
46
47 the LN NPs, obtaining LN@BPEI NPs with positive surface charge. We synthesized separately
48
49
50 negatively charged metal seeds of Au and Pt (ultrasmall nanoparticles, < 5 nm) through a salt-
51
52
53 reduction method using tetrakis-(hydroxymethyl)-phosphonium chloride (THPC) as the surfactant
54

2
3 and reductor in the dark.²⁰ The negatively charged metal seeds and the positively charged
4
5
6
7 LN@BPEI NPs were mixed for 30 min and aged for 72 h. In addition, different loadings of metal
8
9
10 seeds onto LN@BPEI NPs were obtained by varying the volume ratio between metal seeds
11
12
13 dispersion to LN@BPEI dispersion. The hybrid nanoparticles were washed several times through
14
15
16 centrifugation to remove any unbounded metal seeds and unreacted species and then studied using
17
18
19 a suite of colloidal and material characterisation methods.
20
21
22

23
24 The peroxidase mimics of the hybrid nanoparticles of LN/Au and LN/Pt were assessed by
25
26 exposing a fixed amount of LN/Au and LN/Pt to TMB substrate in the presence of H₂O₂. The
27
28
29 change in absorbance was measured over time. We optimized the pH and temperature and obtained
30
31
32 the Michaelis-Menten steady-kinetic parameters while independently varying TMB and H₂O₂
33
34
35 substrates.

37
38
39
40

41 **3 Results and Discussion**

42 43 *3.1 Characterization of the NP constructs (LN, LN@BPEI, AuSeeds and PtSeeds)*

44
45
46 The diameter of LN NPs synthesized by a non-aqueous solvothermal method was determined
47
48
49 by TEM (**Figure 1A-1A1, Table 1**) and DLS. The average TEM diameter calculated from 200 LN
50
51
52 NPs was 30.4 ± 8.6 nm and the corresponding hydrodynamic diameter from DLS measurements
53
54
55
56
57
58
59
60

1
2
3 was 114.2 ± 1.7 nm (**Table 1**). The broad distribution of the TEM diameter could be attributed to
4
5
6
7 the platelet-like morphology of LN NPs which makes its estimation difficult due to the possible
8
9
10 inclinations on the TEM grid and a given size distribution along each crystallographic direction.¹⁸

11
12
13 The zeta potential was around -40 mV in water leading to a stable LN NPs dispersion. This
14
15
16 negative zeta potential can be attributed to the uncoordinated $-OH$ groups on the LN surface, which
17
18
19 are commonly observed on the surface of oxide nanoparticles.¹⁹ With X-Ray Diffraction, it was
20
21
22 previously evidenced that the LN NPs were monocrystalline with the expected trigonal $R3c$
23
24
25 structure of bulk $LiNbO_3$.^{18,19} The Li/Nb atomic ratio was determined by ICP-AES, leading to a
26
27
28 ratio of 1.02, which is close to the theoretical expected value in $LiNbO_3$.²¹ Following BPEI
29
30
31 adsorption on LN NPs, the LN@BPEI NPs showed blurred edges, which may be attributed to the
32
33
34 presence of BPEI polymer on their surface (**Figure 1B-1B1**). The hydrodynamic diameter of
35
36
37 LN@BPEI NPs was 147.6 ± 2.8 nm (**Table 1**), an increase of $\sim 29\%$ compared to the native LN
38
39
40 NPs which suggests the successful adsorption of BPEI. This was supported by the zeta potential
41
42
43 of $+39.4 \pm 3.6$ mV where the presence of protonated $-NH_2$ groups from the BPEI reversed the
44
45
46 charge from negative to positive.²²
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4 AuSeeds and PtSeeds were synthesized by the salt reduction method using THPC as a reducer
5
6
7 (Figure 1C-1C1 and Figure 1D-1D1). The average diameter of the AuSeeds calculated from 200
8
9
10 NPs observed by TEM was 2.0 ± 0.8 nm (Table 1). The diameter in the case of PtSeeds was slightly
11
12
13 higher, with an average value of 3.1 ± 0.6 nm. UV-Vis absorption spectroscopy did not reveal any
14
15
16 plasmon band further confirming that the average diameter of the metal seeds was below 5 nm.²⁰
17
18
19
20 The hydrodynamic diameter for AuSeeds and PtSeeds were 36.0 ± 8.5 nm and 135.7 ± 6.6 nm,
21
22
23 respectively (Table 1). The THPC coating and the solvating layer of nanoparticles associated with
24
25
26 the presence of some aggregates may explain the difference in TEM-determined diameter and DLS
27
28
29 hydrodynamic diameter in the case of AuSeeds. For PtSeeds, the presence of aggregates (as seen
30
31
32 in the TEM image, Figure 1D-1D1) may be responsible for a considerable increase in the
33
34
35 hydrodynamic diameter measured by DLS.²³ Both metal seeds showed a negative zeta potential in
36
37
38 water due to the presence of THPC on their surface.²⁰
39
40
41
42
43
44
45
46

48
49
50 NPs, AuSeeds and PtSeeds.
51
52
53
54
55
56
57
58
59
60

Sample name	TEM diameter (nm) \pm SD	Hydrodynamic diameter (nm) \pm SD	Zeta potential (mV) \pm SD
LN	30.4 \pm 8.6	114 \pm 2	-43 \pm 1
LN@BPEI	29.6 \pm 8.4	148 \pm 3	+39 \pm 4
AuSeeds	2.0 \pm 0.8	36 \pm 9	-12 \pm 6
PtSeeds	3.1 \pm 0.6	136 \pm 7	-15 \pm 2

3.2 Characterization of LN/Au and LN/Pt hybrid NPs

Au and Pt-coated LN NPs were prepared by an electrostatic assembly of the individual constructs while employing oppositely surface charged LN@BPEI particles and noble metal seeds.

TEM images of LN/Au and LN/Pt NPs prepared with different noble metal seeds to LN ratios are shown in **Figure S1 (Supporting information)** and the corresponding hydrodynamic diameters and zeta potential values are presented in **Table 2**.

Table 2. TEM diameter of metal seeds onto LN@BPEI, hydrodynamic diameter and zeta potential values of LN/Au and LN/Pt NPs measured in water.

Sample name	TEM diameter of metal seeds onto the LN@BPEI (nm) \pm SD	Hydrodynamic diameter of hybrid NPs (nm) \pm SD	Zeta potential of hybrid NPs (mV) \pm SD
LN/Au1	2.4 \pm 0.8	234 \pm 9	+25 \pm 1
LN/Au2	2.5 \pm 0.7	164 \pm 1	-29 \pm 0
LN/Au3	3.1 \pm 0.8	161 \pm 2	-32 \pm 0
LN/Pt1	2.5 \pm 0.6	176 \pm 3	+23 \pm 2
LN/Pt2	2.5 \pm 0.5	367 \pm 2	-13 \pm 1

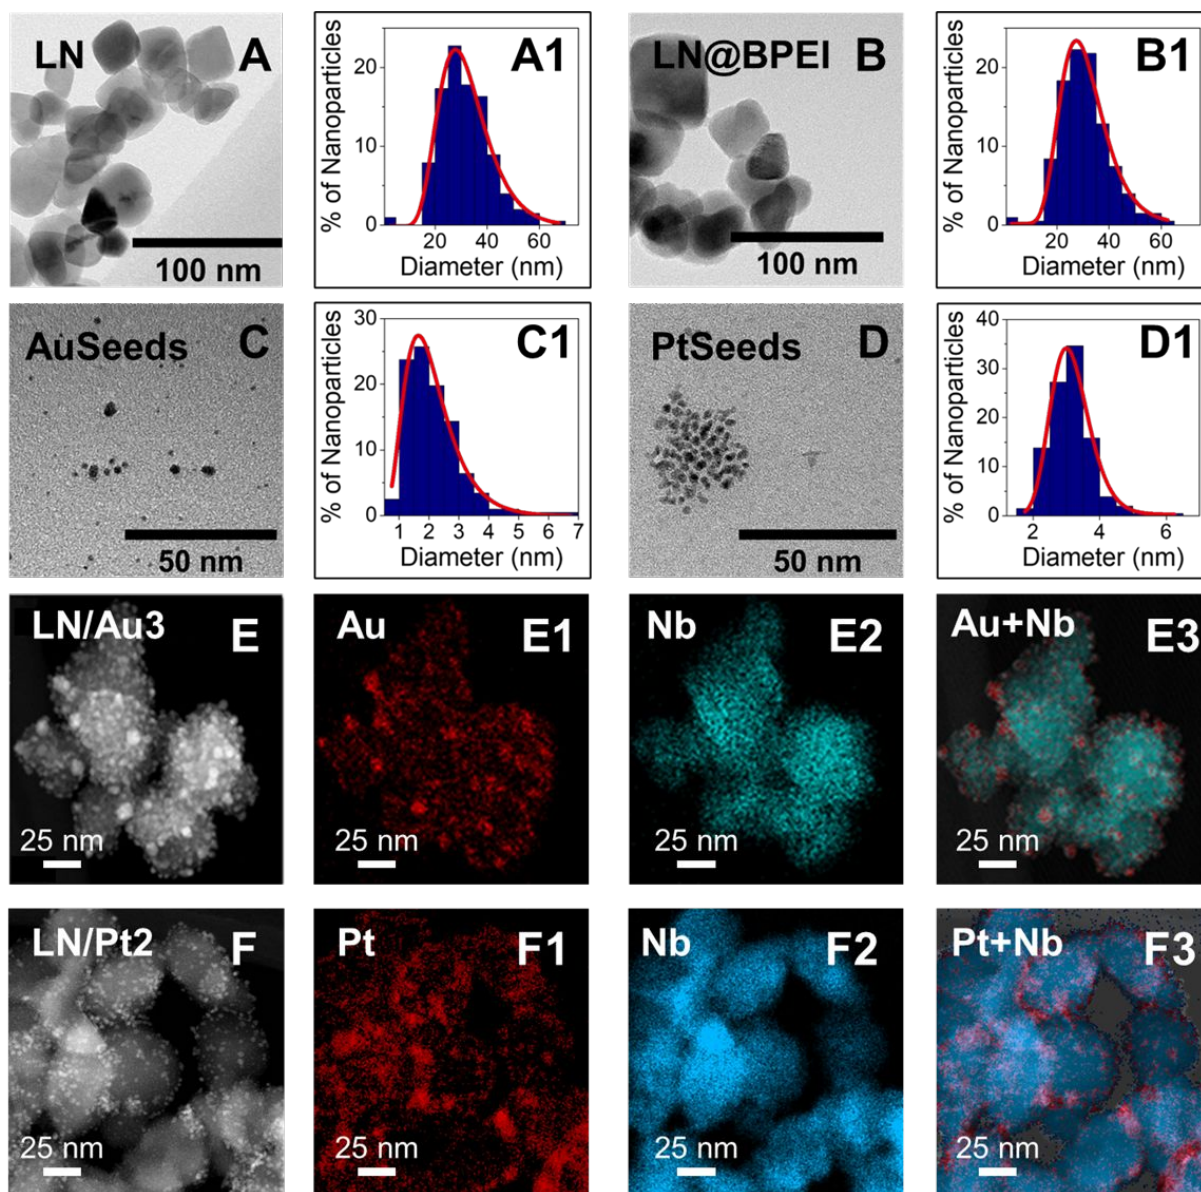

The deposition of AuSeeds on LN@BPEI NPs does not significantly increase the diameter in TEM when compared to the initial AuSeeds (see **Table 1**). However, a brownish supernatant, corresponding to free AuSeeds was observed for LN/Au3 after the first centrifugation step, indicating the saturation of LN@BPEI surface with the AuSeeds. Moreover, a slight increase in the TEM diameter is observed for AuSeeds in LN/Au3. This diameter increase may come from

1
2
3
4 the reduction and coalescence of the AuSeeds on the surface of LN@BPEI as the NH_3^+ of the
5
6
7 polymer can act as a reducing agent.²⁴ This may reduce any previously unreduced chloroaurate
8
9
10 ions present in the gold seed solution, especially when an excess of this solution is added to
11
12
13 LN@BPEI. The hydrodynamic diameter of LN/Au NPs tends to decrease with the increasing
14
15
16 amount of gold on the surface of LN, which is consistent with the increase in the absolute value of
17
18
19 their zeta potential from positive in the case of LN@BPEI to highly negative for LN/Au3. This
20
21
22 could be attributed to a higher degree of surface coverage by Au seeds for LN/Au3 compared to
23
24
25 LN/Au1 and LN/Au2. In fact, the zeta potential value of LN/Au1 is still positive, perhaps due to
26
27
28 the predominance of positive charges from BPEI, which negative AuSeeds are unable to screen.
29
30
31
32
33 As reflected from **Figure S1A**, the coating of LN@BPEI NPs with AuSeeds at the lowest
34
35
36 concentration is uneven. However, when the AuSeeds surface density increases, zeta potential
37
38
39 becomes negative. This suggests that the AuSeeds negative charge screened the amine groups'
40
41
42 positive charge. The gold loading on LN NPs was also verified by EDS (**Figure S2A**), which
43
44
45 confirmed increasing gold loading by varying the volume of AuSeeds suspension added to
46
47
48 LN@BPEI (**Figure S2A, insert**). This was also supported by previously published XPS analysis.²⁵
49
50
51
52
53
54 This work showed that upon BPEI coating followed by gold decoration, the presence of Au is
55
56
57
58
59
60

observed in addition to an increase of C and N percentages, while Nb and O percentages decreased.

It was also noticed that the Au to Nb atomic ratio increased when the gold seeds to LN ratio increased, as expected. We further confirmed the presence of AuSeeds onto LN@BPEI NPs by

STEM and EDS chemical mappings (**Figure 1E3**).

1
2
3 **Figure 1.** TEM image and TEM size lognormal distribution of (A, A1) LN NPs, (B, B1)
4 LN@BPEI, (C, C1) AuSeeds and (D, D1) PtSeeds. (E) STEM image of LN/Au₃ with

9
10 and (F3) Pt and Nb merged on the same image.
11
12
13
14
15
16
17
18
19
20

21 A similar strategy was used to control the surface density of PtSeeds to LN NPs to synthesize
22
23 LN/Pt. In this case, the particle size calculated from TEM images indicated a slight decrease in the
24
25 diameter of the PtSeeds. However, changing the concentration does not significantly increase the
26
27 diameter. In contrast to that observed for LN/Au, the hydrodynamic diameter increased with an
28
29 diameter. In contrast to that observed for LN/Au, the hydrodynamic diameter increased with an
30
31 increasing amount of Pt on the surface of LN. As shown in **Figure S1E**, the addition of a higher
32
33 PtSeeds to LN ratio leads to a higher surface density associated with a more homogeneous spatial
34
35 distribution of PtSeeds onto LN. The zeta potential of LN/Pt NPs decreases with the Pt coverage,
36
37 starting from a positive value for the lowest Pt amount. For the highest Pt loading, the zeta potential
38
39 around -12 mV can be associated with low repulsive electrical charges between NPs. This also
40
41 explains the increase in the hydrodynamic diameter. EDS results show an increasing content of Pt
42
43 as the ratio of PtSeeds volume to LN@BPEI volume is increased (**Figure S2B, insert**). This was

also confirmed using STEM and EDS chemical mappings (**Figure 1F3**). The batch-to-batch variability in the synthesis and the long-term storage (more than one year) stability of LN/Au and LN/Pt NPs were also assessed. The results are detailed in **Supporting Information (Table S2, Figures S3 and S4)**.

Based on these characterization techniques, we believe that the optimal surface coverage of AuSeeds and PtSeeds could be achieved at the highest concentration *i.e.*, LN/Au₃ and LN/Pt₂. Additional characterization using HRTEM was performed to gain some understanding of which crystalline facets from AuSeeds and PtSeeds bind to LN and ICP-AES to calculate the concentration of Au, Pt and Nb in each sample. HRTEM images of LN/Au₃ (**Figure S6A, Supporting Information**) and PtSeeds in LN/Pt₂ (**Figure S6B, Supporting Information**) showed that the same facets of Au and Pt from the cubic fcc crystal structure are on the LN surface, which suggests that similar mode of interactions are likely to be involved during the construction of LN/Au and LN/Pt hybrid materials. ICP-AES measurements revealed that for LN/Au, the Au content of 12.9 % was observed, which corresponds to 40 AuSeeds per LN NP, while for LN/Pt, a Pt content of 16.1 % was observed, which corresponds to 73 PtSeeds per LN NP (detailed calculation is provided in Supporting Information). For further nanozyme experiments, LN/Au₃

and LN/Pt2 were selected as they show similar characteristics in terms of an even distribution of the metal seeds on the surface of LN@BPEI.

3.3 Optimization of peroxidase-mimic nanozyme activity of LN/Au NPs and LN/Pt NPs

The catalytic activity optimization was then carried out through absorbance measurements at 650 nm (for ease of understanding, LN/Au₃ will be labelled as LN/Au and LN/Pt₂ will be labelled as LN/Pt).

Figure 2. (A) Time-dependent kinetics of the LN/Au nanozyme mediated oxidation of TMB. TMB

+ LN/Au allowed to test the oxidase activity, TMB + H₂O₂ and LN/Au were negative controls. (B)

Time-dependent kinetics of the LN/Pt nanozyme mediated oxidation of TMB. TMB + LN/Pt

allowed to test the oxidase activity, TMB + H₂O₂ and LN/Pt were negative controls. TMB and

1

7 at pH 4 and 37 °C. Y-axis, A is the abbreviation of absorbance.
8
9

10
11 The first step was to establish the inherent peroxidase-mimic catalytic nanozyme activity of
12
13
14 LN/Au. For this, we carried out a time-dependent kinetic study with a fixed amount of LN/Au
15
16
17 ([Au] = 27 μM; [LiNbO₃] = 182 μM). As seen in **Figure 2A**, the LN/Au nanozyme promotes the
18
19
20 oxidation of peroxidase substrate TMB (167 μM) in the presence of H₂O₂ (29.7 mM) as a co-
21
22
23 substrate. This is evident from the increase in the absorbance at 650 nm which is due to the
24
25
26 oxidation of TMB to its blue-coloured charge transfer product (**Figure S7**). Another important
27
28
29 observation was that the LN/Au nanozyme could also promote the catalytic reaction to form the
30
31
32 double oxidized yellow coloured diimine product (**Figure S7**). At the 38 min time point, the
33
34
35 absorbance corresponding to diimine is less than 10% compared to the one corresponding to the
36
37
38 blue complex, which is in agreement with previous works (**Figure S5A**).^{5,26} The oxidation of TMB
39
40
41 proceeds almost linearly until the saturation point of absorbance, which is obtained after 38 min.
42
43
44
45 However, the reaction does not occur in the absence of H₂O₂, which excludes the oxidase mimic
46
47
48 characteristic of these nanozymes.^{27–30} We notice negative absorbance values for LN/Au + TMB
49
50
51 (green curve) in **Figure 2A**. A possible explanation for this would be the potential aggregation of
52
53
54
55
56
57
58
59
60

1
2
3 LN/Au in the presence of TMB. In the absence of TMB, LN/Au does not seem to aggregate (grey
4
5
6
7 curve) as reflected by the almost constant absorbance. We note that while the y-axis is typically
8
9
10 denoted as 'absorbance' in these assays, it is in fact 'extinction' that contains some degree of
11
12
13 'scattering' from the particles (Extinction = Absorption + Scattering). The aggregated particles at
14
15
16
17 higher time points perhaps undergo a lesser degree of scattering than the original well-dispersed
18
19
20 particles, or due to aggregation, the effective nanoparticle concentration in the solution reduces.
21
22
23
24 These factors may lead to negative absorbance observed in the green curve. Control experiments
25
26
27 performed in the absence of the nanozyme showed insignificant oxidation. This suggests that the
28
29
30 peroxidase-mimic activity is an inherent property of LN/Au.
31
32

33
34 To ascertain that TMB is the optimal substrate for the nanozymes, we exposed the LN/Au
35
36
37 nanozyme ($[Au] = 27 \mu\text{M}$; $[\text{LiNbO}_3] = 182 \mu\text{M}$ from LN/Au) to a fixed concentration of other
38
39
40 commonly used peroxidase substrates ($167 \mu\text{M}$ of ABTS, OPD and TMB) in the presence of H_2O_2
41
42
43 (29.7 mM). As seen in **Figure S8B**, the LN/Au nanozyme promotes the oxidation of all substrates
44
45
46 to produce yellow ($\lambda_{\text{max}} = 415 \text{ nm}$ for OPD), green ($\lambda_{\text{max}} = 450 \text{ nm}$ for ABTS) and blue ($\lambda_{\text{max}} = 650$
47
48
49 nm for TMB). Based on the result, TMB was the most optimal substrate, which could be due to
50
51
52
53 favorable interaction between the negatively-charged nanozyme and the positively-charged TMB
54
55
56
57
58
59
60

1
2
3
4 ³¹ and/or the better capability of the nanozyme to detach the oxidized product.³² Due to its better
5
6
7 activity, further studies were performed with TMB as the colorimetric substrate.
8
9

10 We then performed similar experiments to determine the peroxidase-mimic activity of LN/Pt.
11
12
13 Considering that Pt is catalytically more active than Au for TMB oxidation as outlined in previous
14 reports ^{33,34}, we optimized the quantity of LN/Pt. For this, we measured the peroxidase mimic
15
16 activity of LN/Pt at two independent concentrations *viz.*, the same concentration as used for LN/Au
17
18 (27 μM of Au and 182 μM of LN - 3.9×10^{11} hybrid NPs/mL) and a concentration with ~ 10 times
19
20 lower metal content (2.8 μM of Pt and 14.5 μM of LN - 2.8×10^{10} hybrid NPs/mL). Keeping all
21
22 other reaction conditions consistent ($[\text{TMB}] = 167 \mu\text{M}$, $[\text{H}_2\text{O}_2] = 29.7 \mu\text{M}$, pH 4 and 37 $^\circ\text{C}$), both
23
24 tested concentrations result in TMB oxidation within 5 min (**Figure S9A**). We, therefore, chose
25
26 the lower concentration of LN/Pt for further experiments. As shown in **Figure 2B**, the time-
27
28 dependent kinetic study performed using a fixed concentration of LN/Pt ($[\text{Pt}] = 2.8 \mu\text{M}$; $[\text{LiNbO}_3]$
29
30 = 14.5 μM), TMB (167 μM) and H_2O_2 (29.7 mM) showed that the reaction proceeds almost linearly
31
32 and achieves saturation in less than 5 min (4 min 20s). This means that compared to LN/Au, LN/Pt
33
34 can complete the reaction 8 times faster using 10 times less metal concentration. This corroborates
35
36 well with previous reports where Pt is catalytically more active than Au for TMB oxidation for
37
38
39
40
41
42
43
44
45
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4 non-supported Au NPs and Pt NPs and NPs supported on oxides.^{33,34} In contrast to LN/Au, LN/Pt
5
6
7 was able to promote the oxidation of TMB in the absence of H₂O₂, albeit much more slowly. This
8
9
10 suggests that LN/Pt also has some level of oxidase activity. Similar to LN/Au control experiment,
11
12
13 the reaction does not proceed in the absence of the nanozyme, confirming that the nanozyme
14
15
16 activity is an inherent property of the LN/Pt NPs. Additionally, some level of subsequent oxidation
17
18
19 of TMB to yellow diimine product was also observed, similar to LN/Au nanozyme (**Figure S9B**).
20
21
22
23 Based on these results, LN/Pt exhibited higher peroxidase nanozyme activity than LN/Au. The
24
25
26 batch-to-batch variability and the long-term storage (more than one year) effect on peroxidase
27
28
29 activity were also assessed. The results are detailed in **Supporting Information (Figure S5)**.
30
31
32

33
34 We then optimized the reaction conditions for the peroxidase mimic activity of both nanozymes
35
36
37 as a function of pH and temperature (**Figure S10**). Both nanozymes showed activity across a wide
38
39
40 temperature range (**Figures S10A and S10C**). In the case of LN/Au nanozyme, optimum
41
42
43 peroxidase activity was obtained at 37 °C. The catalytic activity was nearly similar at 20 °C, while
44
45
46 higher temperature of 45 °C substantially decreased the activity (~45%). In contrast, the LN/Pt
47
48
49 nanozyme showed minimal difference in the activity at all temperatures with 37 °C showing
50
51
52 optimal performance. For instance, unlike the LN/Au nanozyme, the catalytic activity of the LN/Pt
53
54
55
56
57
58
59
60

1
2
3 nanozyme at higher temperature of 45 °C only decreased the activity by 13%. Optimization of the
4
5
6
7 reaction pH showed that both nanozymes were highly active at pH 4. This is possibly because, at
8
9
10 this pH one of the amino groups of TMB will be protonated, favouring the electrostatic interaction
11
12
13 between the positively-charged TMB and the negatively-charged nanoparticles.³⁵ In both cases,
14
15
16 the absorbance at 650 nm appears to reduce at lower pH of 3 and 2 (**Figures S10B and S10D**). This
17
18
19 may not necessarily reflect poor catalytic performance. At highly acidic pH, the blue product tends
20
21
22 to rapidly convert to a yellow product,³⁶ as reflected from the spectra and the photos of the reaction
23
24
25 products at different pH provided in **Figure S11**. It should also be noted that the activity of LN/Pt
26
27
28 is relatively better than that observed for LN/Au at pH 3 and 2. This suggests that at lower pH,
29
30
31 LN/Pt is able to drive a higher conversion of blue TMB product to the yellow product, compared
32
33
34 to that driven by LN/Au (**Figure S11B**). These results corroborate well with previous studies.^{36–38}
35
36
37
38
39

40 Finally, the possibility of the potential leaching of gold and platinum ions from LN/Au and
41
42
43 LN/Pt, respectively, and their role in catalyzing the reaction were studied by incubating the
44
45
46 nanozymes for one hour in pH 4 buffer and exposing the supernatant of the reaction after
47
48
49 centrifugation to H₂O₂ (29.7 μM) and TMB (167 μM), while keeping all the other parameters
50
51
52 constant (Au, Pt, LN, H₂O₂ and TMB concentrations, pH 4 and 37 °C). The results in **Figure S12**
53
54
55
56
57
58
59
60

1
2
3
4 (Supporting Information) provide evidence of minimal catalytic activity of potentially leached
5
6
7 metal ions and confirm that the presence of the nanoparticles is crucial for the reaction to proceed
8
9
10 in both systems. From these studies, we can conclude that LN/Au and LN/Pt have peroxidase-
11
12
13 mimicking activity and they can readily catalyze the reaction between TMB and H₂O₂ to produce
14
15
16 a predominantly blue product ($\lambda_{\text{max}} = 650 \text{ nm}$, one electron complex diimine-diamine.³⁹ Both
17
18
19 systems produce residual oxidation to diimine ($\lambda_{\text{max}} = 450 \text{ nm}$), which can be neglected when the
20
21
22
23 pH is higher than 3. The catalytic activity of LN/Pt hybrid was better than LN/Au hybrid as the
24
25
26
27 former required 10 times lower metal quantity.
28
29

30 *3.4 Synergetic effect of AuSeeds and PtSeeds on the surface of LN.*

31

32
33 To understand if the potential synergetic effect created by the interface of LN with the catalytic
34
35
36 metal seeds in the hybrid nanoparticles, we compared the ability of LN/Au and LN/Pt to oxidize
37
38
39 TMB in the presence of H₂O₂ with the individual components of these hybrids (LN, LN@BPEI,
40
41
42 AuSeeds and PtSeeds) and a simple physical mixture of these without BPEI (LN + AuSeeds and
43
44
45 LN + PtSeeds) (**Figure 3**). During the oxidation of TMB, it can produce two coloured products: a
46
47
48
49 blue charge transfer complex that results from the combination of TMB and a radical cation
50
51
52
53 initially produced from TMB oxidation and a yellow diimine that results from subsequent
54
55
56
57
58
59
60

oxidation of radical cation and gives an absorbance maximum at 450 nm (Figure S7, Supporting Information).³⁹ To obtain a more detailed understanding of catalytic performance, the absorbance of the blue oxidized TMB product was measured, and its concentration was calculated using the value of its extinction molar coefficient, i.e. $39000 \text{ L}\cdot\text{mol}^{-1}\cdot\text{cm}^{-1}$ at 650 nm.²⁹

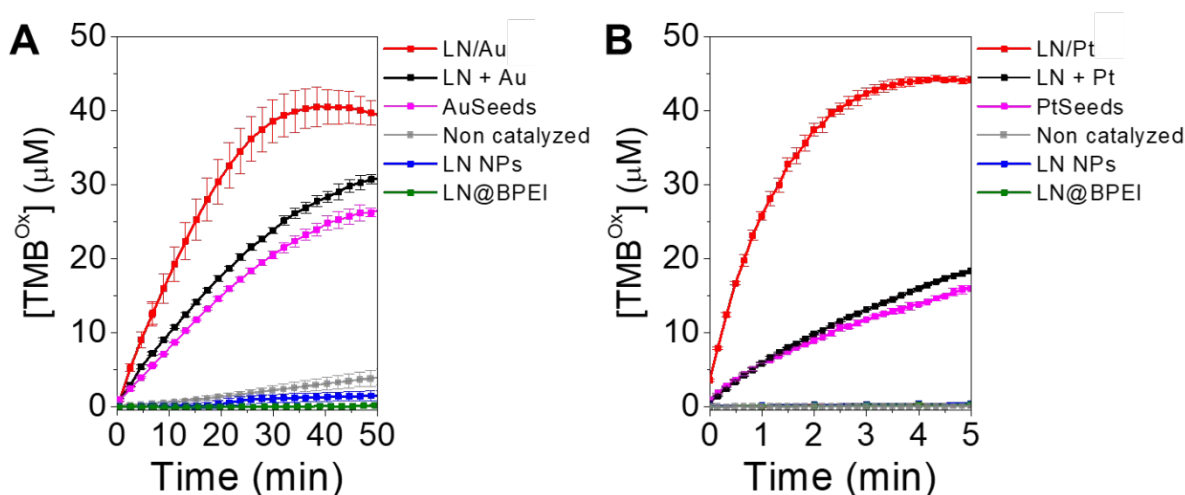

Figure 3. (A) The peroxidase-mimic activity of LN/Au (red) compared to its individual constituents. The concentration of the nanozymes is: $[\text{Au}] = 27 \mu\text{M}$; $[\text{LiNbO}_3] = 182 \mu\text{M}$, corresponding to 3.9×10^{11} NPs/mL and 40 AuSeeds per LN. (B) The peroxidase-mimic activity of LN/Pt (red) compared to its individual constituents. The concentration of the nanozymes are: $[\text{Pt}] = 2.8 \mu\text{M}$; $[\text{LiNbO}_3] = 14.5 \mu\text{M}$, corresponding to 2.8×10^{10} hybrid NPs/mL and 73 PtSeeds per LN in the reaction well. For both LN/Au and LN/Pt, the measurements were performed in the presence of TMB ($167 \mu\text{M}$) and H_2O_2 (29.7 mM) at pH 4 and 37°C .

1
2
3
4 It is clear that the catalytic activities of LN/Au and LN/Pt are significantly higher than for any
5
6
7 other tested component. LN NPs alone do not present any intrinsic peroxidase-like activity, and it
8
9
10 may even be the case that they perhaps inhibit the spontaneous basal level oxidation of TMB in
11
12
13 the presence of H₂O₂. This observation is even more pronounced for LN@BPEI NPs. To our
14
15
16
17 knowledge, LN has never been reported as a peroxidase-mimic material, although it is well known
18
19
20 that LN nanoparticles have photocatalytic and pyro-electrocatalytic applications due to surface
21
22
23 charge carrier separation under light excitation or heating.⁴⁰ As expected, AuSeeds and PtSeeds
24
25
26
27 have peroxidase-mimicking activities. Noble metal nanoparticles have been extensively studied
28
29
30 over the past decade for their peroxidase-like activity,³ which is affected by several parameters,
31
32
33 including their size and surface charge. In particular, ultra-small nanoparticles (diameter below 5
34
35
36
37 nm) present higher peroxidase activity due to increased surface atoms and therefore an increase of
38
39
40 active catalytic sites, which justifies our choice to use 2 nm AuSeeds and PtSeeds. Only a slight
41
42
43
44 increase in their activity is observed when LN NPs are also present in the reaction as a physical
45
46
47
48 mixture. But the overall activity of these physical mixtures remains significantly lower in
49
50
51 comparison to LN/Au and LN/Pt hybrid NPs. This suggests that the chemical link created by BPEI
52
53
54 between LN NPs and AuSeeds or PtSeeds is necessary to increase the catalytic activity. It has been
55
56
57
58
59
60

1
2
3 reported that metal NPs supported oxides show enhanced catalytic activity.⁴¹⁻⁴⁴ A possible
4
5
6
7 mechanism is a charge transfer between the oxide and the metal, increasing the electron density
8
9
10 around the junction and thus favouring the electron transfer in redox-type reactions.^{45,46} Moreover,
11
12
13 the inclusion of the metal onto the oxide surface causes the partial reduction of the latter at the
14
15
16 interface, which may potentially create oxygen vacancies. These oxygen-deficient locations within
17
18
19 the oxide can help oxygen-containing species (like H₂O₂) to bind and cleave more efficiently and
20
21
22 thus enhance the catalytic activity of the hybrid systems.^{47,48} The effect of BPEI on peroxidase
23
24
25 activity was also investigated using mixtures of metal Seeds with BPEI (Supporting Information).
26
27
28 It showed that BPEI plays a significant role when combined with metal Seeds. Indeed, AuSeeds
29
30
31 with BPEI presented a slightly higher activity than AuSeeds while PtSeeds with BPEI had a
32
33
34 significantly lower activity than PtSeeds. Nevertheless, as shown in **Figures S14C** and **S14D**,
35
36
37 respectively, the peroxidase activities of LN/Au and LN/Pt hybrid NPs were still significantly
38
39
40 higher than the one metal Seeds and metal Seeds with BPEI, which confirms the synergetic
41
42
43 catalytic effect provided by the combination of metal Seeds to LN core. Finally, the dispersion of
44
45
46 AuSeeds onto the LN@BPEI surface can also hinder their aggregation during catalysis compared
47
48
49
50
51 to the pristine form of metal seeds, enhancing the accessibility to the catalytically-active metal
52
53
54
55
56
57
58
59
60

1
2
3 surface, which is key to obtaining better catalytic performance.⁴⁹ The combination of these
4
5
6
7 processes is expected to lead to the observed synergetic effect of the enhanced peroxidase-mimic
8
9
10 activity of LN/Au and LN/Pt hybrids.

11 12 13 *3.5 Calculation of the enzymatic kinetic parameters*

14
15
16 As the nanoparticles mimic the activity of natural enzymes, their catalytic parameters can be
17
18
19 calculated using the Michaelis-Menten model (**Equation 1**).^{3,50} This model allows us to obtain the
20
21
22 steady-state kinetics such as maximum velocity (V_{\max}), Michaelis constant (K_m), catalytic constant
23
24
25 or turnover number (K_{cat}) and catalytic efficiency (K_{eff}). V_{\max} is the maximum velocity of catalysis
26
27
28 achieved by the system at saturated substrate concentration, and it is directly proportional to the
29
30
31 reaction speed. Substrate concentration ($[S]$) at which the reaction speed is half of the V_{\max} is
32
33
34 defined by K_m and is inversely proportional to the affinity of the nanozyme towards the substrate
35
36
37 (TMB or H_2O_2), i.e., lower the K_m , higher the affinity of the substrate to the nanozyme. K_{cat}
38
39
40 indicates the number of molecules converted per unit of time per unit of an enzyme, which can be
41
42
43 calculated by dividing V_{\max} by the concentration of the enzyme. Although this value permits us to
44
45
46 address many mechanism questions, to standardize our data, we need to calculate the K_{eff} , which
47
48
49
50 results from the ratio K_{cat}/K_m . As TMB and H_2O_2 are both substrates for the hybrids, to calculate
51
52
53
54
55
56
57
58
59
60

1
2
3 these parameters, we varied the concentration of one substrate while keeping the concentration of
4
5
6 the other constant.⁵¹ The rest of the parameters were kept constant (pH 4, 37 °C) and nanozyme
7
8
9 concentration was fixed for LN/Au ([Au]= 27 μM, [LiNbO₃]=182 μM) and LN/Pt ([Pt]=2.8 μM,
10
11 [LiNbO₃]=14.5 μM) (**Figure S15**). We also calculated the steady state kinetic parameters for
12
13 AuSeeds and PtSeeds and compared them to the hybrid nanozymes (**Table S4**). It has to be pointed
14
15
16 out that to calculate K_{cat} , V_{max} is divided by the concentration of enzyme, which in this case is
17
18
19 nanozyme. We considered that AuSeeds and PtSeeds were the catalytic hot points in LN/Au and
20
21
22 LN/Pt and that each surface metal atom works as a single enzyme (detailed calculation is provided
23
24
25 in **Supporting Information**).⁵² LN NPs were not considered in this calculation as they did not show
26
27
28 any peroxidase mimics (**Figure 3**). We note that the calculated values of kinetic parameters, in
29
30
31 particular K_{cat} will depend upon the consideration of whether a single metal atom or a single metal
32
33
34 nanoparticle is considered equivalent to a single nanozyme. Since the surface atoms of metal NPs
35
36
37 are expected to predominantly participate in the catalysis reaction, it can be safely presumed that
38
39
40 a single metal NP will offer more than one catalytic site, while at the same time, all atoms
41
42
43 (particularly those not on the NP surface) will not participate in catalysis. Since it is highly
44
45
46 challenging to determine the absolute number of catalytic sites on a particle, we employed the
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4 number of surface metal atoms available during the reaction, as this will underestimate the catalytic
5
6
7 efficiency, rather than reporting an overestimated efficiency. Overall, irrespective of the calculated
8
9
10 values, the relative values among the different samples are still valid and can be confidently
11
12
13 compared.
14
15

16
17 **Equation 1.** Michaelis-Menten natural enzyme model.
18

$$V = \frac{V_{\max}[S]}{K_M + [S]}$$

19
20
21
22
23
24 From the data presented in **Table S4**, it is clear that all the nanozymes show a higher affinity for
25
26
27 TMB over H₂O₂. This suggests a preference of these nanozymes towards TMB adsorption over
28
29
30 H₂O₂. If we compare the K_m of the hybrid with the respective metal seed, the affinity towards H₂O₂
31
32
33 improves while the affinity towards TMB decreases in the hybrids. The higher affinity to H₂O₂
34
35
36 could be attributed to the creation of oxygen vacancies at the LN/metal interface.^{50,53} On the other
37
38
39 hand, the decrease in the affinity for TMB can be due to the steric hindrance caused by BPEI on
40
41
42 their surface and the larger size of TMB that may impede its interaction with the hybrid.³⁵ Further,
43
44
45 while Au-containing nanozymes have a higher affinity to TMB, the Pt-containing nanozymes have
46
47
48 a higher affinity to H₂O₂. This is consistent with previous observations in the literature.^{3,33} In the
49
50
51 context of V_{max}, the LN/metal hybrids can drive the reaction faster than their corresponding metal
52
53
54
55
56
57
58
59
60

seeds, particularly in the case of Pt system, where ~15-20 times increase in the reaction velocity is observed.

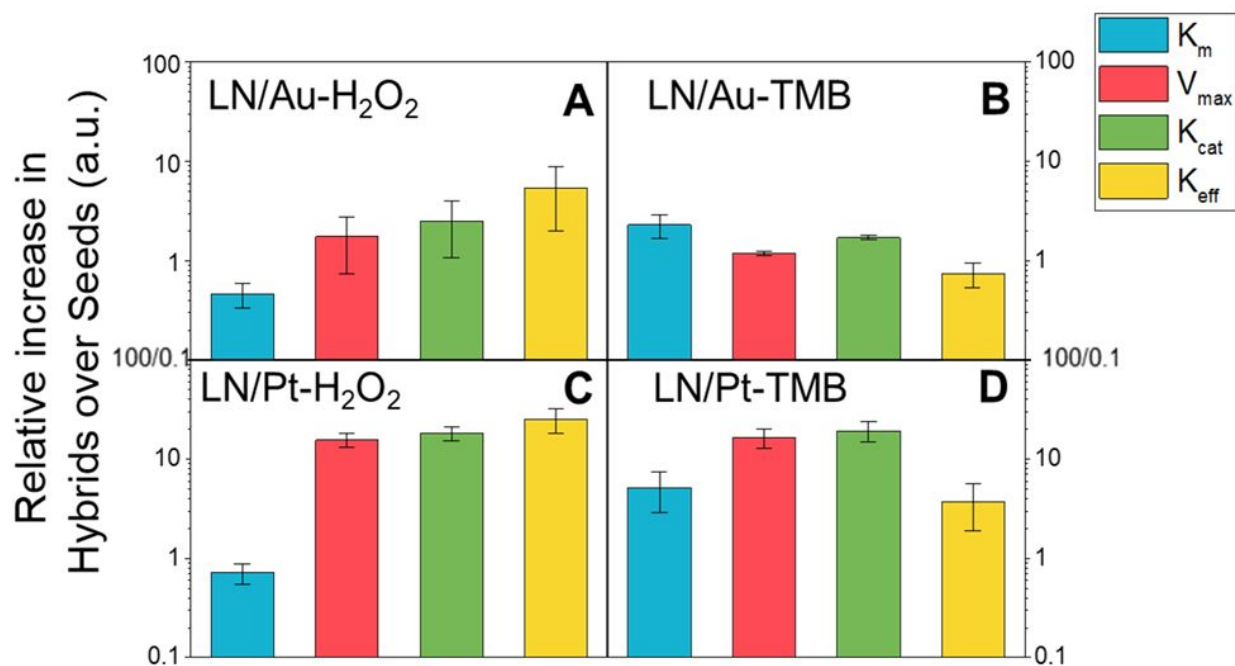

Figure 4. Relative increase of steady kinetic parameters calculated from the number of surface metal atoms of hybrids over seeds. LN/Au increase over AuSeeds with H₂O₂ as a substrate (A). LN/Au₃ increase over AuSeeds with TMB as a substrate (B). LN/Pt increase over PtSeeds with H₂O₂ as a substrate (C). LN/Pt increase over PtSeeds with TMB as a substrate (D).

The relative increase in the K_{cat} and K_{eff} of the hybrid nanozymes for H₂O₂ was much more pronounced than that observed for the metal seeds (**Figure 4**). This increase was 18-25 times higher in the case of the LN/Pt hybrids (**Figure 4C**) and 2.5-5 times higher in LN/Au hybrids (**Figure 4A**)

1
2
3 supporting the synergetic effect provided by the interface between LN and metal NPs. A
4
5
6
7 comparison between the hybrids showed that the K_{cat} and K_{eff} for LN/Pt hybrids were more
8
9
10 noticeable than LN/Au hybrids. This increase in the K_{cat} and K_{eff} for LN/Pt hybrids may be due to
11
12
13 the stronger affinity of H_2O_2 to Pt NPs (lower K_{m} for H_2O_2), which will allow for efficient cleavage
14
15
16 of H_2O_2 to produce $\bullet\text{OH}$ radicals. When we compared the K_{cat} and K_{eff} of the hybrid nanozymes
17
18
19 for TMB, the increase was not as pronounced as that observed for H_2O_2 . This suggests that the
20
21
22 catalytic efficiency for TMB oxidation is lower than that for H_2O_2 .
23
24
25

26
27 A combination of a favourable K_{m} and V_{max} obtained for the hybrid nanozymes translates into a
28
29
30 higher K_{cat} and K_{eff} for the hybrids over pristine metal seeds, specifically for H_2O_2 . In the case of
31
32
33 TMB, the K_{cat} for both hybrids is higher than the metal seeds (**Figure 4B and 4D**). This is not
34
35
36 surprising as this parameter depends on the surface atoms, which remains consistent over the
37
38
39 reaction. However, the K_{eff} for TMB decreases unlike the observation in the case of H_2O_2 . This is
40
41
42 due to the higher affinity of the AuSeeds and PtSeeds for TMB than the hybrids (**Table S4**). Even
43
44
45 though the relative increase in the K_{eff} is lower for the hybrids over the respective seeds, the
46
47
48 catalytic reaction is considerably faster for LN/Au and LN/Pt.
49
50
51
52
53
54
55

We can state that the hybrid nanozymes present the best performance compared to the pristine metal seeds for the H_2O_2 substrate. This improvement has exciting potential applications in biomedicine. For instance, both LN/Au and LN/Pt nanozymes show low K_m and high V_{\max} values for H_2O_2 (**Table S4, Supporting Information**), which are required for sensing applications.⁵⁴ This would allow us to detect H_2O_2 in biological samples in the mM range. The antimicrobial effect of nanozymes would also benefit from these improved enzymatic properties for H_2O_2 . It is commonly admitted that peroxidase mimics in metal and metal oxide nanozymes produce reactive oxygen species (ROS), specially $\text{HO}\cdot$.³ These extremely oxidative species are widely used as antimicrobial agents.⁵⁵ Indeed, the higher affinity towards H_2O_2 implies a lower H_2O_2 concentration needed to produce $\text{HO}\cdot$. In addition, the higher V_{\max} values (for H_2O_2 substrate) obtained for LN/Au and LN/Pt (**Table S4, Supporting Information**) suggest that the production of $\text{HO}\cdot$ radicals would be over around 1.5-fold and 11-fold faster than for the pristine nanoparticles, respectively. This would enhance the antimicrobial effect for LN/Au and moreover for LN/Pt.

Many other studies report the kinetic parameters of hybrid nanozymes combining metal and metal oxide.^{56–58} However, the calculation of K_{cat} and K_{eff} , which gives a better comprehension of the nanozyme's performance, is either missing or calculated considering that each nanoparticle is

a catalytic site, thus overestimating the performance of the nanozyme. Here we used the calculation method provided by Zandieh et al in which each surface metal atom is a catalytic site.⁵⁹ **Table 3** presents K_{cat} and K_{eff} values for LN/Au and LN/Pt compared to the values obtained for 300 nm Fe_3O_4 nanozymes, which were calculated based on the number of surface Fe atoms, and for the natural enzyme, horseradish peroxidase (HRP).⁶⁰

Table 3. Comparison of LN/Au and LN/Pt efficiency constants for TMB and H_2O_2 with Fe_3O_4 nanozyme (300 nm) and horseradish peroxidase.

Nanozyme	H_2O_2 K_{eff} ($\text{M}^{-1}\cdot\text{s}^{-1}$)	TMB K_{eff} ($\text{M}^{-1}\cdot\text{s}^{-1}$)	Reference
LN/Au	0.26	128.8	This work
LN/Pt	64	5.0×10^3	This work
Fe_3O_4 (300 nm)	0.38	210	60
HRP	9.5×10^5	9.2×10^6	60

The above results (**Table 3**) show that LN/Au and Fe_3O_4 nanozymes present similar levels of efficiency. However, LN/Pt nanozymes overcome the efficiency of Fe_3O_4 by 2 and 1 orders of magnitude for H_2O_2 and TMB substrates, respectively. The presence of oxygen vacancies created

1
2
3 on the surface of LiNbO_3 due to the presence of PtSeeds may increase the affinity towards H_2O_2 .
4
5

6
7 However, the nanozymes presented in **Table 3** do not overcome the performance of natural enzyme
8
9

10 HRP that surpasses by 4 and 3 orders of magnitude the performance of LN/Pt for H_2O_2 and TMB
11
12

13 substrates, respectively, suggesting that there is still room for improving the efficiency of
14
15

16 nanozymes. Nevertheless, nanozymes present other advantages, for instance, stability over time,
17
18

19 resistance towards harsh conditions or easiness of fabrication, which make them interesting for
20
21

22 biomedical applications.¹
23
24

25 26 27 **4 Conclusions**

28
29 In summary, we have created hybrid nanoparticles combining LiNbO_3 NPs with AuSeeds and
30
31

32 PtSeeds using layer-by-layer synthesis introducing BPEI as a linker. The metal loading in the
33
34

35 hybrid LN/Au and LN/Pt nanoparticles was controlled by varying the ratio of the volume ratio
36
37

38 between metal seeds dispersion to LN@BPEI dispersion. The hybrids with the optimal surface
39
40

41 coverage of the metal seeds showed that ~40 AuSeeds were associated per LN, while ~70 PtSeeds
42
43

44 were associated per LN. These hybrids showed catalytic activity similar to natural peroxidase
45
46

47 enzymes. The nanozyme activity of the LN/Pt hybrid was 8 times faster than LN/Au hybrids even
48
49

50 with 10 times lower Pt concentration suggesting that LN/Pt is a faster and more powerful
51
52
53

1
2
3 nanozyme than LN/Au. We also observed that the catalytic activity of the hybrid nanozymes was
4
5
6
7 higher than the individual counterparts or a simple mixture containing a similar concentration of
8
9
10 the individual counterparts. The affinity of the hybrids to H₂O₂ improved while decreasing for
11
12
13 TMB when compared to the respective metal seeds. However, the V_{max} for both TMB and H₂O₂
14
15
16 showed improvement when compared to the respective metal seeds. Based on this study, the
17
18
19 interface between the LN NPs and the Au or PtSeeds is critical to achieve superior catalytic
20
21
22 activity. This ability to achieve superior nanozyme activity can be employed in a variety of
23
24
25 applications such as sensing, biomedicine or environmental treatment. Their low K_m and high V_{max}
26
27
28 values would thus make them appropriate for H₂O₂ sensing or antimicrobial agents.

Author Contributions

A.M.P.S.E. carried out the experiments. A.M.P.S.E. wrote the manuscript with support from V.M., Y.C., V.B.R.R., F.R., Y.M. and R.D. fabricated the LN NPs sample. P.R.D.M helped A.M.P.S.E. implementing the peroxidase-mimics experiments. Correction and review were performed by all authors. All authors have given approval to the final version of the manuscript.

Funding Sources

This research was primarily funded by the ECLAUSion program. The ECLAUSion project has received funding from the European Union's Horizon 2020 research and innovation programme under the Marie Skłodowska-Curie grant agreement No 801512. We acknowledge the support of the International Associated Laboratory in Photonics between France and Australia (LIA ALPhFA). V. Bansal and R. Ramanathan acknowledge the Australian Research Council (ARC) for funding support through the Discovery Grant No. DP230101650.
